ON GEOMETRY OF THE RING OF ALGEBRAIC INTEGERS

IGOR NIKOLAEV

Abstract. We study geometry of the ring of algebraic integers $O_K$ of a number field $K$. Namely, it is proved that the inclusion $\mathbb{Z} \subset O_K$ defines a covering of the Riemann sphere $\mathbb{C}P^1$ ramified over three points \{0, 1, $\infty$\}. Our approach is based on the notion of a Serre $C^*$-algebra. As an application, a new short proof of the Belyi Theorem is given.

1. Introduction

An interplay between arithmetic and geometry is an established and active area, see e.g. [Weil 1949] [11]. The proof of Weil’s Conjectures was a motivation for the notion of a scheme [Grothendieck 1960] [3]. Recall that $Spec R$ of a commutative ring $R$ is the set of all prime ideals of $R$ endowed with the Zariski topology. The topology of $Spec R$ is not Hausdorff, yet it admits a cohomology theory and an analog of the Lefschetz Fixed-Point Theorem [Grothendieck 1960] [3]. It appears to be enough to prove Weil’s Conjectures.

Let $\mathbb{Z}$ be the ring of integers. It was observed, that $Spec \mathbb{Z}$ “looks like” the Riemann sphere $\mathbb{C}P^1$ [Eisenbud & Harris 1999] [2, p. 83]. Such an analogy extends to the inclusions $\mathbb{Z} \subset O_K$, where $O_K$ is the ring of integers of a number field $K$. In this case, one gets a ramified covering $\mathcal{R} \to \mathbb{C}P^1$, where $\mathcal{R}$ is a Riemann surface. The theory of schemes alone cannot explain this analogy, see e.g. [Manin 2006] [6, Section 2.2].

The aim of our note is a proof of the relation between $\mathbb{Z}$ and $\mathbb{C}P^1$. It shown that the inclusion $\mathbb{Z} \subset O_K$ defines a covering $\mathcal{R} \to \mathbb{C}P^1$ ramified over three points \{0, 1, $\infty$\} (theorem 1.3). Our approach is based on the notion of a Serre $C^*$-algebra [7, Section 5.3.1]. To formalize our results, we shall need the following definitions.

Let $V$ be a complex projective variety. Denote by $B(V, \mathcal{L}, \sigma)$ a twisted homogeneous coordinate ring of $V$, where $\mathcal{L}$ is an invertible sheaf and $\sigma$ is an automorphism of $V$ [Stafford & van den Bergh 2001] [10, p. 173]. Recall that a Serre $C^*$-algebra $\mathcal{A}_V$ is the norm closure of a self-adjoint representation of the ring $B(V, \mathcal{L}, \sigma)$ by the bounded linear operators on a Hilbert space $\mathcal{H}$; such an algebra depends on $V$ alone, since the values of $\mathcal{L}$ and $\sigma$ are fixed by the *-involution of algebra $B(V, \mathcal{L}, \sigma)$ [7, Section 5.3.1]. The map $V \mapsto \mathcal{A}_V$ is a functor. Namely, if $V$ and $V'$ are defined over a number field $K \subset \mathbb{C}$, then $V$ is $K$-isomorphic to $V'$ if and only if the algebra $\mathcal{A}_V$ is isomorphic to $\mathcal{A}_{V'}$. In contrast, the variety $V$ is $\mathbb{C}$-isomorphic to $V'$ if and only if $\mathcal{A}_V$ is Morita equivalent to $\mathcal{A}_{V'}$, i.e. $\mathcal{A}_V \otimes \mathcal{H} \cong \mathcal{A}_{V'} \otimes \mathcal{H}$, where $\mathcal{H}$ is the $C^*$-algebra of compact operators [9, Corollary 1.2]. Thus, the tensor product $\mathcal{A}_V \otimes \mathcal{H}$ can be viewed as an analog of the base change $K \subset \mathbb{C}$.

2010 Mathematics Subject Classification. Primary 11R04, 14H55; Secondary 46L85.
Key words and phrases. arithmetic geometry, Serre $C^*$-algebra.
The last remark allows to define “geometry” of the ring $O_K$ as follows. We can always assume, that $B(V, L, \sigma) \cong M_2(R)$, where $R$ is the homogeneous coordinate ring of a variety $V$ [Stafford & van den Bergh 2001] [10, Section 8]. If $R \cong O_K$, one still gets a $C^*$-algebra, $A_R$, defined by the norm closure of a self-adjoint representation of the ring $M_2(R)$. Of course, the $A_R$ is no longer a Serre $C^*$-algebra. However due to the analogy with a base change, the tensor product $A_R \otimes \mathcal{K}$ can be isomorphic to such an algebra. Thus, one gets the following

**Definition 1.1.** The complex projective variety $V$ is called a *karma* of the ring $R$, if there exists a homomorphism

$$h : A_V \to A_R \otimes \mathcal{K}. \quad (1.1)$$

**Example 1.2.** If $R$ is the homogeneous coordinate ring of a complex projective variety $V$, then $V$ is a karma of $R$. In this case, $A_R \otimes \mathcal{K} \cong A_V$, i.e. the map $h$ is an isomorphism.

Our main result can be formulated as follows.

**Theorem 1.3.** Let $Z$ be the ring of rational integers and let $O_K$ be the ring of algebraic integers of a number field $K$. Then:

(i) the Riemann sphere $\mathbb{CP}^1$ is a karma of the ring $Z$;

(ii) there exists a Riemann surface $\mathcal{R} = \mathcal{R}(K)$, such that $\mathcal{R}$ is a karma of the ring $O_K$;

(iii) the inclusion $Z \subset O_K$ defines a covering $\mathcal{R} \to \mathbb{CP}^1$ ramified over three points $\{0, 1, \infty\}$.

The article is organized as follows. In Section 2 we briefly review noncommutative algebraic geometry and arithmetic groups. Theorem 1.3 is proved in Section 3. As an application of theorem 1.3, we give a new short proof of the Belyi Theorem [Belyi 1979] [1, Theorem 4].

2. Preliminaries

We review some facts of noncommutative algebraic geometry and arithmetic groups. The reader is referred to [Humphreys 1980] [4] and [Stafford & van den Bergh 2001] [10] for a detailed account.

2.1. **Noncommutative algebraic geometry.** Let $V$ be a projective variety over the field $k$. Denote by $\mathcal{L}$ an invertible sheaf of the linear forms on $V$. If $\sigma$ is an automorphism of $V$, then the pullback of $\mathcal{L}$ along $\sigma$ will be denoted by $\mathcal{L}^\sigma$, i.e. $\mathcal{L}^\sigma(U) := \mathcal{L}(\sigma U)$ for every $U \subset V$. The graded $k$-algebra

$$B(V, \mathcal{L}, \sigma) = \bigoplus_{i \geq 0} H^0 \left( V, \mathcal{L} \otimes \mathcal{L}^\sigma \otimes \cdots \otimes \mathcal{L}^{\sigma^{i-1}} \right) \quad (2.1)$$

is called a *twisted homogeneous coordinate ring* of $V$. Such a ring is always noncommutative, unless the automorphism $\sigma$ is trivial. A multiplication of sections of $B(V, \mathcal{L}, \sigma)$ is defined by the rule $ab = a \otimes b^{\sigma}$, where $a \in B_m$ and $b \in B_n$. An invertible sheaf $\mathcal{L}$ on $V$ is called $\sigma$-ample, if for every coherent sheaf $\mathcal{F}$ on $V$, the

---

1For the lack of a better word meaning the “correspondence” or “relationship”.
cohomology group $H^k(V, \mathcal{L} \otimes \mathcal{L}^\sigma \otimes \cdots \otimes \mathcal{L}^{\sigma^{n-1}} \otimes \mathcal{F})$ vanishes for $k > 0$ and $n >> 0$. If $\mathcal{L}$ is a $\sigma$-ample invertible sheaf on $V$, then

$$Mod \left( B(V, \mathcal{L}, \sigma) \right) / Tors \cong Coh \left( V \right),$$

where $Mod$ is the category of graded left modules over the ring $B(V, \mathcal{L}, \sigma)$, $Tors$ is the full subcategory of $Mod$ of the torsion modules and $Coh$ is the category of quasi-coherent sheaves on a scheme $V$. In other words, the $B(V, \mathcal{L}, \sigma)$ is a coordinate ring of the variety $V$.

**Example 2.1.** ([Stafford & van den Bergh 2001] [10, p.173]) Denote by $P^1(k)$ a projective line over the field $k$. Consider an automorphism $\sigma$ of the $P^1(k)$ given by the formula $\sigma(u) = qu$, where $u \in P^1(k)$ and $q \in k^\times$. Then $B(P^1(k), \mathcal{L}, \sigma) \cong U_q$, where $U_q$ is the $k$-algebra of polynomials in variables $x_1$ and $x_2$ satisfying a commutation relation:

$$x_2 x_1 = q x_1 x_2.$$

**Example 2.2.** ([Stafford & van den Bergh 2001] [10, p.197]) Denote by $E(k) = \{ (u, v, w, z) \in P^3(k) \mid u^2 + v^2 + w^2 + z^2 = \frac{1}{1-\beta} v^2 + \frac{1}{1-\beta} w^2 + z^2 = 0 \}$ an elliptic curve over the field $k$, where $\alpha, \beta, \gamma \in k$ are constants, such that $\beta \neq -1$ and $\gamma \neq 1$. Let $\sigma$ be a shift automorphism of the $E(k)$. Then $B(E(k), \mathcal{L}, \sigma) \cong S(\alpha, \beta, \gamma)$, where $S(\alpha, \beta, \gamma)$ is the Sklyanin algebra on four generators $x_i$ satisfying the commutation relations:

$$
\begin{align*}
  x_1 x_2 - x_2 x_1 &= \alpha (x_3 x_4 + x_4 x_3), \\
  x_1 x_2 + x_2 x_1 &= x_3 x_4 - x_4 x_3, \\
  x_1 x_3 - x_3 x_1 &= \beta (x_4 x_2 + x_2 x_4), \\
  x_1 x_3 + x_3 x_1 &= x_4 x_2 - x_2 x_4, \\
  x_1 x_4 - x_4 x_1 &= \gamma (x_2 x_3 + x_3 x_2), \\
  x_1 x_4 + x_4 x_1 &= x_2 x_3 - x_3 x_2,
\end{align*}
$$

where $\alpha + \beta + \gamma + \alpha \beta \gamma = 0$.

**Example 2.3.** ([8, Lemma 3.1]) Let $\mathcal{R}$ be an arithmetic Riemann surface, i.e. given by the AF-algebra of stationary type [7, Section 5.2]. In inner terms, such Riemann surfaces can be identified with the complex algebraic curves defined over a number field. Let $\mathcal{L}$ be a link in the three-sphere $S^3$. Then $B(\mathcal{R}, \mathcal{L}, \sigma) \cong R[\pi_1(S^3, \mathcal{L})]$, where $\sigma$ is an automorphism of $\mathcal{R}$ and $R[\pi_1(S^3, \mathcal{L})]$ is the group ring of the fundamental group $\pi_1(S^3, \mathcal{L})$ of a complement of the link $\mathcal{L}$ in $S^3$.

2.2. Arithmetic groups. Let $G$ be a linear algebraic group defined over the field $\mathbb{Q}$. Denote by $G_{\mathbb{Z}}$ the group of integer points of $G$. A subgroup $\Gamma \subset G$ is called *arithmetic* if $\Gamma$ is commensurable with the $G_{\mathbb{Z}}$, i.e. $\Gamma \cap G_{\mathbb{Z}}$ has a finite index both in $\Gamma$ and $G_{\mathbb{Z}}$. Informally, the arithmetic group is a discrete subgroup of the group $GL_n(\mathbb{C})$ defined by some arithmetic properties. For instance, $\mathbb{Z} \subset \mathbb{R}$, $GL_n(\mathbb{Z}) \subset GL_n(\mathbb{R})$ and $SL_n(\mathbb{Z}) \subset SL_n(\mathbb{R})$ are examples of the arithmetic groups.

Denote by $\mathcal{O}$ the ring of algebraic integers of all finite extensions of the number field $\mathbb{Q}$. Let $\mathbb{H}^3$ be the hyperbolic 3-dimensional space. The following remarkable result establishes a deep link between arithmetic groups and topology.

**Theorem 2.4.** ([Maclachlan & Reid 2003] [5, p. 169]) Let $M = \mathbb{H}^3/\Gamma$ be a finite volume hyperbolic 3-manifold. Then $\Gamma$ is conjugate to a subgroup of the group $PSL_2(\mathcal{O})$. 
Example 2.5. Let $\mathcal{L}$ be a hyperbolic link, i.e. $S^3 \setminus \mathcal{L} \cong \mathbb{H}^3 / \Gamma$ for an arithmetic group $\Gamma$. Then

$$\pi_1(S^3 \setminus \mathcal{L}) \cong \Gamma.$$  \hfill (2.5)

Remark 2.6. By Thurston’s classification, every link $\mathcal{L}$ is hyperbolic, unless $\mathcal{L}$ is a torus or a satellite knot. Moreover a “majority” of the links are hyperbolic, i.e. the probability of a prime link to be hyperbolic is close to 1. In view of Theorem 2.4 and Example 2.5, one gets a family of number fields $K$ corresponding to the hyperbolic links. In what follows, we assume that $K$ comes from a hyperbolic link $\mathcal{L}$ and $K$ is a Galois extension of $\mathbb{Q}$.

3. Proof of theorem 1.3

(i) Let us show that the $\mathbb{C}P^1$ is a karma of $\mathbb{Z}$. Indeed, in this case $R \cong \mathbb{Z}$ and $\mathcal{A}_\mathbb{Z}$ is the closure of a self-adjoint representation of the ring $M_2(\mathbb{Z})$. Consider the group $PSL_2(\mathbb{Z}) = SL_2(\mathbb{Z})/ \pm I$, where $SL_2(\mathbb{Z})$ is the group of invertible elements of $M_2(\mathbb{Z})$. Recall that the such a group is generated by the matrices:

$$u = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \quad \text{and} \quad v = \begin{pmatrix} 0 & -1 \\ 1 & 1 \end{pmatrix} \hfill (3.1)$$

which satisfy the relations:

$$u^2 = v^3 = 1.$$  \hfill (3.2)

On the other hand, consider Example 2.1 with $k \cong \mathbb{Q}$ and assume that $q = -1$ in relation (2.3). In other words, one gets a relation:

$$x_2x_1 = -x_1x_2.$$  \hfill (3.3)

Consider a substitution:

$$\begin{cases} 
  u &= x_2x_1^{-1}x_2^{-1} \\
  v &= x_2.
\end{cases} \hfill (3.4)$$

The reader can verify, that substitution (3.4) and relation (3.3) reduces relations (3.2) to the form:

$$x_2^3 = 1.$$  \hfill (3.5)

Let $\mathcal{J}$ be a two-sided ideal in the algebra $B(P^1(\mathbb{Q}), \mathcal{L}, \sigma)$ of Example 2.1 generated by relation (3.5). In view of (3.2)-(3.5), one gets an isomorphism:

$$B(P^1(\mathbb{Q}), \mathcal{L}, \sigma)/\mathcal{J} \cong M_2(\mathbb{Z}).$$  \hfill (3.6)

Let $\rho$ be a self-adjoint representation of the ring $B(P^1(\mathbb{Q}), \mathcal{L}, \sigma)$ by the linear operators on a Hilbert space $\mathcal{H}$. Notice that such a representation exists, because relation (3.3) is invariant under the involution $x_1^* = x_2$ and $x_2^* = x_1$. Since $\rho(B(P^1(\mathbb{Q}), \mathcal{L}, \sigma)) = \mathcal{A}_{P^1(\mathbb{Q})}$ and $\rho(M_2(\mathbb{Z})) = \mathcal{A}_{\mathbb{Z}}$, it follows from (3.6) that there exists a homomorphism

$$h : \mathcal{A}_{P^1(\mathbb{Q})} \rightarrow \mathcal{A}_{\mathbb{Z}},$$  \hfill (3.7)

where $\text{Ker} \ h = \rho(\mathcal{J})$. The homomorphism $h$ extends to a homomorphism between the products

$$h : \mathcal{A}_{P^1(\mathbb{Q})} \otimes \mathcal{H} \rightarrow \mathcal{A}_{\mathbb{Z}} \otimes \mathcal{H}.$$  \hfill (3.8)

But $\mathcal{A}_{P^1(\mathbb{Q})} \otimes \mathcal{H} \cong \mathcal{A}_{\mathbb{C}P^1}$ and, therefore, one gets a homomorphism

$$h : \mathcal{A}_{\mathbb{C}P^1} \rightarrow \mathcal{A}_{\mathbb{Z}} \otimes \mathcal{H}.$$  \hfill (3.9)

In other words, the Riemann sphere $\mathbb{C}P^1$ is a karma of the ring $\mathbb{Z}$.
Let us show that if $K$ is a number field, then there exists a Riemann surface $\mathcal{R}$, such that $\mathcal{R}$ is a karma of the ring $O_K$. Let $K$ be a number field specified in remark 2.6. Since $K$ is a Galois extension of $\mathbb{Q}$, the field $K$ is either a totally imaginary or a totally real number field. We shall always assume that $K$ is a totally imaginary number field; for otherwise, we replace $K$ by a CM-field of $K$, i.e. a totally imaginary quadratic extension of the totally real field $K$.

For simplicity, let $\Gamma \sim \text{PSL}_2(\mathbb{O}_K)$. In view of (2.5) and remark 2.6, there exists a link $L$, such that:

$$\text{PSL}_2(\mathbb{O}_K) \cong \pi_1(S^3 \setminus L).$$

(3.10)

On the other hand, it is known that $R[\pi_1(S^3 \setminus L)] \cong B(\mathcal{R}, \mathcal{L}, \sigma)$,

$$R[\pi_1(S^3 \setminus L)] \cong B(\mathcal{R}, \mathcal{L}, \sigma),$$

(3.11)

where $R[\pi_1(S^3 \setminus L)]$ is the group ring of $\pi_1(S^3 \setminus L)$ and $\mathcal{R}$ is a Riemann surface, see example 2.3. In particular, it follows from (3.10) that

$$B(\mathcal{R}, \mathcal{L}, \sigma) \cong R[\text{PSL}_2(\mathbb{O}_K)].$$

(3.12)

Let $\rho$ be a self-adjoint representation of the ring $B(\mathcal{R}, \mathcal{L}, \sigma)$ by the linear operators on a Hilbert space $\mathcal{H}$. The norm closure of $\rho(B(\mathcal{R}, \mathcal{L}, \sigma))$ is the Serre $C^*$-algebra $\mathcal{A}_\mathcal{R}$.

On the other hand, it follows from (3.12) that taking the norm closure of $\rho(R[\text{PSL}_2(\mathbb{O}_K)])$, one gets a $C^*$-algebra $\mathcal{A}_{\mathbb{O}_K}$, such that

$$\mathcal{A}_{\mathbb{O}_K} \otimes \mathcal{K} \cong \mathcal{A}_\mathcal{R}.$$

(3.13)

In other words, there exists an isomorphism:

$$h : \mathcal{A}_\mathcal{R} \rightarrow \mathcal{A}_{\mathbb{O}_K} \otimes \mathcal{K}.$$

(3.14)

It follows from (3.14) that the Riemann surface $\mathcal{R}$ is a karma of the ring $\mathbb{O}_K$.

(iii) Finally, let us show that the inclusion $\mathbb{Z} \subset \mathbb{O}_K$ defines a covering $\mathcal{R} \rightarrow \mathbb{C}P^1$ ramified over three points $\{0, 1, \infty\}$.

In the lemma below we shall prove a stronger result. Namely, let $\mathfrak{K}$ be a category of the Galois extensions of the field $\mathbb{Q}$, such that the morphisms in $\mathfrak{K}$ are inclusions $K \subseteq K'$, where $K, K' \in \mathfrak{K}$. Likewise, let $\mathfrak{R}$ be a category of the Riemann surfaces, such that the morphisms in $\mathfrak{R}$ are holomorphic maps $\mathcal{R} \rightarrow \mathcal{R}'$, where $\mathcal{R}, \mathcal{R}' \in \mathfrak{R}$.

Let $F : \mathfrak{K} \rightarrow \mathfrak{R}$ be a map acting by the formula $O_K \mapsto \mathcal{R}$, where $\mathcal{R}$ is the Riemann surface defined by the isomorphism (3.12).

Remark 3.1. The category $\mathfrak{R}$ consists of the Riemann surfaces, which are algebraic curves defined over a number field. In particular, the morphisms in $\mathfrak{R}$ can be defined over the number field. Both facts follow from the property of the AF-algebra $\mathcal{A}_\mathcal{R}$ being of a stationary type [7, Section 5.2]. We refer the reader to Example 2.3 and [8, Lemma 3.1].

Lemma 3.2. The map $F : \mathfrak{K} \rightarrow \mathfrak{R}$ is a covariant functor, i.e. $F$ transforms inclusions in the category $\mathfrak{K}$ to holomorphic maps in the category $\mathfrak{R}$.

Proof. Let $K \in \mathfrak{K}$ be a number field and let $\mathcal{R} = F(K)$ be the corresponding Riemann surface $\mathcal{R} \in \mathfrak{R}$. Let $K \subseteq K'$ be an inclusion, where $K' \in \mathfrak{K}$.
Using isomorphism (3.13), one gets an inclusion of the corresponding Serre $C^*$-algebras:

$$\mathcal{A}_R \subseteq \mathcal{A}_R' \tag{3.15}$$

On the other hand, it is known the algebra $\mathcal{A}_R$ is a coordinate ring of the Riemann surface $\mathcal{R}$ [7, Theorem 5.2.1]. In particular, if $h : \mathcal{A}_R' \to \mathcal{A}_R$ is a homomorphism, one gets a holomorphic map $w : \mathcal{R}' \to \mathcal{R}$ defined by a commutative diagram in Figure 1.

![Figure 1. Holomorphic map $w$.](image)

Thus $F$ is a functor, which maps the inclusion $K \subseteq K'$ into a holomorphic map $w : \mathcal{R}' \to \mathcal{R}$. The reader can verify that $F$ is a covariant functor. Lemma 3.2 is proved.

**Lemma 3.3.** The inclusion $\mathbf{Z} \subset O_K$ defines a covering $\mathcal{R} \to \mathbb{C}P^1$ ramified over three points $\{0, 1, \infty\}$.

**Proof.** Let $\mathcal{U}$ be the Riemann sphere $\mathbb{C}P^1$ without three points, which we always assume to be $\{0, 1, \infty\}$ after a proper Möbius transformation. It is easy to see, that the fundamental group $\pi_1(\mathcal{U}) \cong \mathbb{F}_2$, where $\mathbb{F}_2$ is a free group on two generators $u$ and $v$.

Since the the Riemann surface $\mathcal{U}$ corresponds to an unlink $\mathcal{L} \cong S^1 \cup S^1$, one gets an isomorphism:

$$B(P^1(\mathcal{U}, \mathcal{L}, \sigma)) \cong R[\mathbb{F}_2]. \tag{3.16}$$

Consider a two-sided ideal $\mathcal{I} \subset B(P^1(\mathcal{U}, \mathcal{L}, \sigma))$ generated by relations (3.2). In view of (3.16), we have:

$$B(P^1(\mathcal{U}, \mathcal{L}, \sigma))/\mathcal{I} \cong R[PSL_2(\mathbf{Z})]. \tag{3.17}$$

In other words, one gets a homomorphism between the $C^*$-algebras:

$$\mathcal{A}_\mathcal{U} \to \mathcal{A}_{\mathbb{C}P^1}. \tag{3.18}$$

Using the commutative diagram in Figure 1, we get a holomorphic map between the corresponding Riemann surfaces:

$$\mathcal{U} \to \mathbb{C}P^1. \tag{3.19}$$

Let now $\mathbf{Z} \subset O_K$ be an inclusion, where $K$ is a number field. By item (ii) of theorem 1.3 there exists a Riemann surface $\mathcal{R} \in \mathcal{R}$ corresponding to $O_K$. By lemma 3.2, there exists a holomorphic map:

$$\mathcal{R} \to \mathbb{C}P^1. \tag{3.20}$$
Using (3.19) and (3.20), one gets a commutative diagram in Figure 2.

\[ \mathcal{R} \rightarrow CP^1 \]

\[ \mathcal{U} \]

\[ \mathcal{U} \rightarrow \mathcal{R} \]

**Figure 2.** The map $\mathcal{R} \rightarrow \mathcal{U}$.

We use the diagram in Figure 2 to define a holomorphic map:

\[ \mathcal{R} \rightarrow \mathcal{U}. \]  \hspace{1cm} (3.21)

Since $\mathcal{U} = CP^1 \setminus \{0, 1, \infty\}$, one gets the conclusion of lemma 3.3. \hfill \Box

Item (iii) of theorem 1.3 follows from lemmas 3.2 and 3.3.

Theorem 1.3 is proved.

4. Belyi’s Theorem

Such a theorem says that the algebraic curve $\mathcal{R}$ can be defined over a number field $K$ if and only if there exist a covering $\mathcal{R} \rightarrow CP^1$ ramified over three points of the Riemann sphere $CP^1$. This remarkable result was proved by [Belyi 1979] [1, Theorem 4]. In this section we show that Belyi’s Theorem follows from theorem 1.3 and remark 3.1.

**Theorem 4.1.** (Belyi’s Theorem) A complete non-singular algebraic curve over the field of characteristic zero can be defined over an algebraic number field if and only if such a curve is a covering of the Riemann sphere $CP^1$ ramified over three points.

**Proof.** We identify the Riemann surface $\mathcal{R} \in \mathfrak{R}$ with a complete non-singular algebraic curve over the field of characteristic zero (Chow’s Theorem).

In view of the remark 3.1, each $\mathcal{R} \in \mathfrak{R}$ is the algebraic curve defined over a finite extension of the field $\mathbb{Q}$. On the other hand, item (iii) of theorem 1.3 says that each Riemann surface $\mathcal{R} \in \mathfrak{R}$ is a covering of the $CP^1$ ramified over the points $\{0, 1, \infty\}$. The “only if” part of Belyi’s Theorem follows.

Let $\mathcal{R}$ be a covering of the $CP^1$ ramified over the points $\{0, 1, \infty\}$. Using lemma 3.2, one can construct a ring $O_K$ corresponding to the Riemann surface $\mathcal{R}$. By item (ii) of theorem 1.3 and remark 3.1 we have $\mathcal{R} \in \mathfrak{R}$. In other words, $\mathcal{R}$ is an algebraic curve defined over an algebraic number field. The “if” part of Belyi’s Theorem is proved. \hfill \Box
