

\mathbb{C}^N -Smorodinsky-Winternitz system in a constant magnetic field

Hovhannes Shmavonyan^{1,*}

¹Yerevan Physics Institute, 2 Alikhanian Brothers St., Yerevan 0036 Armenia

We propose the superintegrable generalization of Smorodinsky-Winternitz system on the N -dimensional complex Euclidian space which is specified by the presence of constant magnetic field. We find out that in addition to $2N$ Liouville integrals the system has additional functionally independent constants of motion, and compute their symmetry algebra. We perform the Kustaanheimo-Stiefel transformation of \mathbb{C}^2 - Smorodinsky-Winternitz system to the (three-dimensional) generalized MICZ-Kepler problem and find the symmetry algebra of the latter one. We observe that constant magnetic field appearing in the initial system has no qualitative impact on the resulting system.

I. INTRODUCTION

N -dimensional mechanical system will be called *integrable* if it has N mutually commuting and functionally independent constants of motion. In addition to these constants of motion the system can have additional ones. In that case we will say that the system is *superintegrable*. Particularly if N -dimensional mechanical system has $2N - 1$ functionally independent constants of motion it will be called *maximally superintegrable*. The one-dimensional singular oscillator is a textbook example of a system which is exactly solvable both on classical and quantum levels. The sum of its N copies, i.e. N -dimensional singular isotropic oscillator is, obviously, exactly solvable as well. It is given by the Hamiltonian

$$H = \sum_{i=1}^N I_i, \quad \text{with} \quad I_i = \frac{p_i^2}{2} + \frac{g_i^2}{2x_i^2} + \frac{\omega^2 x_i^2}{2}, \quad \{p_i, x_j\} = \delta_{ij}, \quad \{p_i, p_j\} = \{x_i, x_j\} = 0 \quad (1)$$

It is not obvious that in addition to Liouville Integrals I_i this system possesses supplementary series of constants of motion, and is respectively, *maximally superintegrable*, i.e. possesses $2N - 1$ functionally independent constants of motion. All these constants of motion are of the second order on momenta, which guarantee the separability of variables in few coordinate systems and cause degeneracy of the energy spectrum in quantum level. It seems that this was first noticed by Smorodinsky and Winternitz, who then investigated superintegrability properties of this system in great detail [1–3]. For this reason this model is sometimes called Smorodinsky-Winternitz system and we will use this name as well. For sure, such a simple and internally rich system would attract wide attention in the community of mathematical and theoretical physics, and that is one of the main reasons why there are so many publications devoted to its study and further generalizations. Besides the above-mentioned publications, we should as well mention the references [4–12] (see the recent PhD thesis on this subject with expanded list of references [13]). Notice also that Smorodinsky-Winternitz system is a simplest case of the generalized Calogero model (with oscillator potential) associated with an arbitrary Coxeter root system [14]. Thus, one hopes that observations done in this simple model could be somehow extended to the Calogero models. There is a well-known superintegrable generalization of the oscillator to sphere, which is known as Higgs oscillator [15, 16]. Smorodinsky-Winternitz model admits superintegrable generalization of the sphere as well [17]. Though it was first suggested by Rosochatius in XIX century (without noticing its superintegrability) [20], it was later rediscovered by many other authors as well (e.g. [18, 19]). Superintegrable generalization of Calogero model on the sphere also exists [21–23].

In this paper we consider simple generalization of the Smorodinsky-Winternitz system *interacting with constant magnetic field*. It is defined on the N -dimensional complex Euclidian space parameterized by the coordinates z^a by the Hamiltonian

$$\mathcal{H} = \sum_{a=1}^N \left(\pi_a \bar{\pi}_a + \frac{g_a^2}{z^a \bar{z}^a} + \omega^2 z^a \bar{z}^a \right), \quad \text{with} \quad \{\pi_a, z^b\} = \delta_{ab}, \quad \{\pi_a, \bar{\pi}_b\} = \imath B \delta_{ab} \quad (2)$$

The (complex) momenta π_a have nonzero Poisson brackets due to the presence of magnetic field with magnitude B [24, 25]. We will refer this model as \mathbb{C}^N -Smorodinsky-Winternitz system. For sure, in the absence of magnetic field

*Electronic address: hovhannes.shmavonyan@mail.yerphi.am

this model could be easily reduced to the conventional Smorodinsky-Winternitz model, but the presence of magnetic field could have nontrivial impact which will be studied in this paper. So, *our main goal is to investigate the whole symmetry algebra of this system*. Notice that this is not only for academic interest: the matter is that \mathbb{C}^1 -Smorodinsky-Winternitz system is a popular model for the qualitative study of the so-called quantum ring [26–28], and the study of its behaviour in external magnetic field is quite a natural task. Respectively, \mathbb{C}^N -Smorodinsky-Winternitz could be viewed as an ensemble of N quantum rings interacting with external magnetic field. So investigation of its symmetry algebra is of the physical importance.

It is well-known for many years that the energy surface of two-/three-/five-dimensional Coulomb system could be transformed to those of two-/four-/eight-dimensional oscillator by the use of so-called Levi-Civita-Bohlin/Kustaanheimo-Stiefel/Hurwitz transformation [29–31]. More generally, reducing the two-/four-/eight-dimensional oscillator (-like) models by the action of $\mathbb{Z}_2/U(1)/SU(2)$ group action, we can get the two-/three-/five-dimensional Coulomb-like systems specified by the presence of $(\mathbb{Z}_2/\text{Dirac}/\text{Yang})$ monopole [32]. Since \mathbb{C}^2 -Smorodinsky-Winternitz system is manifestly invariant with respect to $U(1)$ group action, we can perform its Kustaanheimo-Stiefel transformation, in order to obtain three-dimensional Coulomb-like system. It was done about ten years ago [39], but in the absence of magnetic field in initial system. Repeating this transformation for the system with constant magnetic field we get unexpected result: it has no qualitative impact in the resulting system, which was referred in [40] as "generalized MICZ-Kepler system" [36–38]. In addition, we obtain, in this way, the explicit expression of its symmetry generators and their symmetry algebra, which as far as we know was not constructed before.

We already mentioned that both oscillator and Smorodinsky-Winternitz system admit superintegrable generalizations to the spheres. On the other hand the isotropic oscillator on \mathbb{C}^N admits the superintegrable generalization on the complex projective space, moreover, the inclusion of constant magnetic field preserves all symmetries of that system [42, 43]. It will be shown that introduction of a constant magnetic field doesn't change these properties of the \mathbb{C}^N -Smorodinsky-Winternitz system. Thus, presented model could be viewed as a first step towards the construction of the analog of Smorodinsky-Winternitz system on \mathbb{CP}^N .

The paper is organized as follows.

In the *Section 2* we review the main properties of the conventional (\mathbb{R}^N) -Smorodinsky-Winternitz system, presenting explicit expressions of its symmetry generators, as well as wavefunctions and Energy spectrum. We also present symmetry algebra in a very simple, and seemingly new form via redefinition of symmetry generators.

In the *Section 3* we present \mathbb{C}^N -Smorodinsky-Winternitz system in a constant magnetic field, find the explicit expressions of its constants of motion. We compute their algebra and find that it is independent from the magnitude of constant magnetic field. Then we quantize a system and obtain wavefunctions and energy spectrum. We notice that the \mathbb{C}^N -Smorodinsky-Winternitz system has the same degree of degeneracy as \mathbb{R}^N - one, due to the lost part of additional symmetry.

In the *Section 4* we perform Kustaanheimo-Stieffel transformation of the \mathbb{C}^2 -Smorodinsky-Winternitz system in constant magnetic field and obtain, in this way, the so-called "generalized MICZ-Kepler system". We find that constant magnetic field appearing in the initial system, does not lead to any changes in the resulting one.

In the *Section 5* we discuss the obtained results and possibilities of further generalizations. Possible extensions of discussed system include supersymmetrization and quaternionic generalization as well as generalization of these systems in curved background.

II. SMORODINSKY-WINTERNITZ SYSTEM ON \mathbb{R}^N

Smorodinsky-Winternitz system is defined as a sum of N copies of one-dimensional singular oscillators (1), each of them defined by generators I_i which obviously form its Liouville integrals $\{I_i, I_j\} = 0$. About fifty years ago it was noticed that this system possesses additional set of constants of motion given by the expressions [1]

$$I_{ij} = L_{ij}L_{ji} - \frac{g_i^2 x_j^2}{x_i^2} - \frac{g_j^2 x_i^2}{x_j^2}, \quad \{I_{ij}, H\} = 0, \quad (3)$$

where L_{ij} are the generators of $SO(N)$ algebra,

$$L_{ij} = p_i x_j - p_j x_i : \quad \{L_{ij}, L_{kl}\} = \delta_{ik}L_{jl} + \delta_{jl}L_{ik} - \delta_{il}L_{jk} - \delta_{jk}L_{il}. \quad (4)$$

The generators I_{ij} provides additional $N - 1$ functionally independent constants of motions and so this system is maximally superintegrable. These generators define highly nonlinear symmetry algebra,

$$\{I_i, I_{jk}\} = \delta_{ij}S_{ik} - \delta_{ik}S_{ij}, \quad \{I_{ij}, I_{kl}\} = \delta_{jk}T_{ijl} + \delta_{ik}T_{jkl} - \delta_{jl}T_{ikl} - \delta_{il}T_{ijk} \quad (5)$$

where

$$S_{ij}^2 = -16(I_i I_j I_{ij} + I_i^2 g_j^2 - I_j^2 g_i^2 + \frac{\omega^2}{4} I_{ij}^2 - g_i^2 g_j^2 \omega^2), \quad T_{ijk}^2 = -16(I_{ij} I_{jk} I_{ik} + g_k^2 I_{ij}^2 + g_j^2 I_{ik}^2 + g_i^2 I_{jk}^2 - 4g_i^2 g_j^2 g_k^2). \quad (6)$$

The generators S_{ij}^2 and T_{ijk}^2 are of the sixth-order in momenta and antisymmetric over i, j, k indices. The above symmetry algebra could be written in a compact form if we introduce the notation

$$M_{ij} = I_{ij}, \quad M_{0i} = I_i, \quad M_{ii} = g_i^2, \quad M_{00} = \frac{\omega^2}{4}, \quad R_{ijk} = T_{ijk}, \quad R_{ij0} = S_{ij}. \quad (7)$$

Then one can introduce capital letters which will take values from 0 to N . It is worth to mention that M_{IJ} is symmetric, whereas R_{IJK} is antisymmetric with respect to all indices. In this terms the whole symmetry algebra of Smorodinsky-Winternitz system reads

$$\{M_{IJ}, M_{KL}\} = \delta_{JK} R_{IJL} + \delta_{IK} R_{JKL} - \delta_{JL} R_{IKL} - \delta_{IL} R_{IJK} \quad (8)$$

where

$$R_{IJK}^2 = -16(M_{IJ} M_{JK} M_{IK} + M_{IJ}^2 M_{KK} + M_{IK}^2 M_{JJ} + M_{KL}^2 M_{II} - 4M_{II} M_{JJ} M_{KK}) \quad (9)$$

One important fact should be mentioned, although in this algebra on the right side we have sum of many terms (square roots), only one term always survives, since in case of three indices are equal, the result is automatically 0. Consequently in this algebra we always have one square root on the right hand side. Quantum-mechanically the maximal superintegrability is reflected in the dependence of its energy spectrum on the single, ‘‘principal’’ quantum number only. Having in mind that in Cartesian coordinates the system decouples to the set of one-dimensional singular oscillators, we can immediately extract the expressions for its wavefunctions and spectrum from the standard textbooks on quantum mechanics, e.g. [44],

$$E_{n|\omega} = \hbar \omega \left(2n + 1 + \sum_{i=1}^N \sqrt{\frac{1}{4} + \frac{g_i^2}{\hbar^2}} \right), \quad \Psi = \prod_{i=1}^N \psi(x_i, n_i), \quad n = \sum_{i=1}^N n_i \quad (10)$$

where

$$\psi(x_i, n_i) = F\left(-n_i, 1 + \sqrt{\frac{1}{4} + \frac{g_i^2}{\hbar^2}}, \frac{\omega x_i^2}{\hbar}\right) \left(\frac{\omega x_i^2}{\hbar}\right)^{\frac{1 + \sqrt{1 + 4g_i^2/\hbar^2}}{4}} e^{-\frac{\omega x_i^2}{2\hbar}} \quad (11)$$

Here F is the hypergeometric function. With these expressions at hands we are ready to study Smorodinsky-Winternitz system on complex Euclidean space in the presence of constant magnetic field.

III. \mathbb{C}^N -SMORODINSKY-WINTERITZ SYSTEM

Now let us study $2N$ -dimensional analog of Smorodinsky-Winternitz system interacting with constant magnetic field. It is defined by (2) and could be viewed as an analog of Smorodinsky-Winternitz system on complex Euclidean space $(\mathbb{C}^N, ds^2 = \sum_{a=1}^N dz^a d\bar{z}^a)$. Thus, we will refer it as \mathbb{C}^N -Smorodinsky-Winternitz system. The analog of SW-system which respects the inclusion of constant magnetic field is defined as follows,

$$\mathcal{H} = \sum_a I_a, \quad I_a = \pi_a \bar{\pi}_a + \frac{g_a^2}{z^a \bar{z}^a} + \omega^2 z^a \bar{z}^a, \quad (12)$$

where z^a, π_a are complex (phase space) variables with the following non-zero Poisson bracket relations

$$\{\pi_a, z^b\} = \delta_{ab}, \quad \{\bar{\pi}_a, \bar{z}^b\} = \delta_{ab}, \quad \{\pi_a, \bar{\pi}_b\} = \imath B \delta_{ab}. \quad (13)$$

For sure, it can be interpreted as a sum of N two-dimensional singular oscillators interacting with constant magnetic field perpendicular to the plane. It is obvious that in addition to N commuting constants of motion I_a this system has another set of N constants of motion defining manifest $(U(1))^N$ symmetries of the system

$$L_{a\bar{a}} = \imath(\pi_a z^a - \bar{\pi}_a \bar{z}^a) - B z^a \bar{z}^a : \{L_{a\bar{a}}, \mathcal{H}\} = 0 \quad (14)$$

and supplementary, non-obvious, set of constants of motion defined in complete analogy with those of conventional Smorodinsky-Winternitz system:

$$I_{ab} = L_{a\bar{b}}L_{b\bar{a}} + \left(\frac{g_a^2 z^b \bar{z}^b}{z^a \bar{z}^a} + \frac{g_b^2 z^a \bar{z}^a}{z^b \bar{z}^b} \right), \quad \{I_{ab}, \mathcal{H}\} = 0, \quad a \neq b \quad (15)$$

with $L_{a\bar{b}}$ being generators of $SU(N)$ algebra

$$L_{a\bar{b}} = i(\pi_a z^b - \bar{\pi}_b \bar{z}^a) - B \bar{z}^a z^b : \quad \{L_{a\bar{b}}, L_{c\bar{d}}\} = i\delta_{a\bar{d}}L_{c\bar{b}} - i\delta_{c\bar{b}}L_{a\bar{d}}. \quad (16)$$

These symmetry generators, and I_a obviously commute with $L_{a\bar{a}}$ due to manifest $U(1)^N$ symmetry

$$\{L_{a\bar{a}}, I_b\} = \{L_{a\bar{a}}, I_{bc}\} = \{L_{a\bar{a}}, L_{b\bar{b}}\} = \{I_a, I_b\} = 0 \quad (17)$$

The rest Poisson brackets between them are highly nontrivial

$$\{I_a, I_{bc}\} = \delta_{ab}S_{ac} - \delta_{ac}S_{ab}, \quad \{I_{ab}, I_{cd}\} = \delta_{bc}T_{abd} + \delta_{ac}T_{bcd} - \delta_{bd}T_{acd} - \delta_{ad}T_{abc}, \quad (18)$$

where

$$\begin{aligned} S_{ab}^2 = & 4I_{ab}I_aI_b - (L_{a\bar{a}}I_b + L_{b\bar{b}}I_a)^2 - 4g_a^2I_b^2 - 4g_b^2I_a^2 - 4\omega^2I_{ab}(I_{ab} - L_{a\bar{a}}L_{b\bar{b}}) + 4\omega^2g_b^2L_{a\bar{a}}^2 + 4g_a^2\omega^2L_{b\bar{b}}^2 + 16g_a^2g_b^2\omega^2 \\ & - 2B(I_{ab} - L_{a\bar{a}}L_{b\bar{b}})(L_{a\bar{a}}I_b + L_{b\bar{b}}I_a) - B^2(I_{ab} - L_{a\bar{a}}L_{b\bar{b}})^2 + 4B(g_b^2I_aL_{a\bar{a}} + g_a^2I_bL_{b\bar{b}}) + 4B^2g_a^2g_b^2 \end{aligned} \quad (19)$$

$$T_{abc}^2 = 2(I_{ab} - L_{a\bar{a}}L_{b\bar{b}})(I_{bc} - L_{b\bar{b}}L_{c\bar{c}})(I_{ac} - L_{a\bar{a}}L_{c\bar{c}}) + 2I_{ab}I_{ac}I_{bc} + L_{a\bar{a}}^2L_{b\bar{b}}^2L_{c\bar{c}}^2 - (I_{bc}^2L_{a\bar{a}}^2 + I_{ab}^2L_{c\bar{c}}^2 + I_{ac}^2L_{b\bar{b}}^2)$$

$$- 4(g_c^2I_{ab}(I_{ab} - L_{a\bar{a}}L_{b\bar{b}}) + g_a^2I_{bc}(I_{bc} - L_{b\bar{b}}L_{c\bar{c}}) + g_b^2I_{ac}(I_{ac} - L_{a\bar{a}}L_{c\bar{c}})) + 4g_b^2g_c^2L_{a\bar{a}}^2 + 4g_a^2g_c^2L_{b\bar{b}}^2 + 4g_a^2g_b^2L_{c\bar{c}}^2 + 16g_a^2g_b^2g_c^2 \quad (20)$$

To write the symmetry algebra in a simpler form we can redefine the generators

$$M_{aa} = L_{a\bar{a}}^2 + 4g_a^2, \quad M_{ab} = I_{ab} - \frac{1}{2}L_{a\bar{a}}L_{b\bar{b}}, \quad M_{a0} = I_a - \frac{B}{2}L_{a\bar{a}}, \quad M_{00} = 4\omega^2 + B^2. \quad (21)$$

Since $L_{a\bar{a}}$ commute with all other generators Poisson brackets of M will exactly coincide with the Poisson brackets of I_{ab} and I_a . Similarly the R tensor is defined as in the real case. So the algebra will have the following form

$$\{M_{ab}, M_{cd}\} = \delta_{bc}T_{abd} + \delta_{ac}T_{bcd} - \delta_{bd}T_{acd} - \delta_{ad}T_{abc}, \quad \{M_{a0}, M_{ab}\} = \delta_{ab}S_{ac} - \delta_{ac}S_{ab}. \quad (22)$$

where

$$S_{ab}^2 = 4M_{ab}M_{a0}M_{b0} + \left(\omega^2 + \frac{B^2}{4} \right) (M_{aa}M_{bb} - 4M_{ab}^2) - M_{b0}^2M_{aa} - M_{a0}^2M_{bb} \quad (23)$$

$$T_{abc}^2 = 4M_{ab}M_{bc}M_{ac} - M_{ab}^2M_{cc} - M_{ac}^2M_{bb} - M_{bc}^2M_{aa} + \frac{1}{4}M_{aa}M_{bb}M_{cc} \quad (24)$$

Needless to say that $L_{a\bar{a}}$ commute with all the other constants of motion. Finally the full symmetry algebra then reads

$$\{M_{AB}, M_{CD}\} = \delta_{BC}R_{ABD} + \delta_{AC}R_{BCD} - \delta_{BD}R_{ACD} - \delta_{AD}R_{ABC} \quad (25)$$

where

$$R_{ABC}^2 = 4M_{AB}M_{BC}M_{AC} - M_{AB}^2M_{CC} - M_{AC}^2M_{BB} - M_{BC}^2M_{AA} + \frac{1}{4}M_{AA}M_{BB}M_{CC} \quad (26)$$

Again capital letters take values from 0 to N . In the complex case R_{ABC} and M_{AB} are again respectively antisymmetric and symmetric as in the real case. Up to multiplication by a constant this has the same form as the symmetry algebra for the real case.

Let us briefly discuss the number of conserved quantities. We have N real functionally independent constants of motion (I_a). Moreover let us mention that I_{ab} is also real, and although it has $N(N-1)/2$ components, the number of functionally independent constants of motion is $N-1$. In addition to this, the complex system has N real conserved quantities ($L_{a\bar{a}}$). So the total number of constants of motion is $3N-1$ and it is superintegrable (but not maximally superintegrable). Especially if $N=1$ the system is integrable. For $N=2$ the system is superintegrable, but it has only one additional constant of motion. In this case the system is called *minimally superintegrable*.

Quantization

Quantization will be done using the fact that \mathbb{C}^N -Smorodinsky-Winternitz system is a sum of two dimensional singular oscillators. This allows to write the wave function as a product of N wave functions and total energy of the system as a sum of the energies of its subsystems. So the initial problem reduces to two-dimensional one.

$$\hat{I}_a \Psi_a(z_a, \bar{z}_a) = E_a \Psi_a(z_a, \bar{z}_a), \quad \hat{H} \Psi_{tot} = E_{tot} \Psi_{tot}, \quad \Psi_{tot} = \prod_{a=1}^N \Psi_a(z_a, \bar{z}_a), \quad E_{tot} = \sum_a^N E_a. \quad (27)$$

After this reduction, complex indices can be temporarily dropped. Now it is obvious to introduce the momenta operators and commutation relations, which will have the following form in the presence of constant magnetic field.

$$\hat{\pi} = -i(\hbar \partial + \frac{B}{2} \bar{z}), \quad \hat{\bar{\pi}} = -i(\hbar \bar{\partial} - \frac{B}{2} z) \quad [\pi, \bar{\pi}] = \hbar B, \quad [\pi, z] = -i\hbar \quad (28)$$

Schrödinger equation can be written down

$$\left[-\hbar^2 \partial \bar{\partial} + \left(\omega^2 + \frac{B^2}{4} \right) z \bar{z} - \hbar \frac{B}{2} (\bar{z} \bar{\partial} - \partial z) + \frac{g^2}{z \bar{z}} \right] \Psi(z, \bar{z}) = E \Psi(z, \bar{z}). \quad (29)$$

Even in this two-dimensional system additional separation of variables can be done if one writes this system in a polar coordinates using the fact that $z = \frac{r}{\sqrt{2}} e^{i\phi}$.

$$\left[\frac{\partial^2}{\partial r^2} + \frac{1}{r} \frac{\partial}{\partial r} + \frac{2}{\hbar^2} \left(E + \frac{\hbar^2}{2r^2} \frac{\partial^2}{\partial \phi^2} - \frac{2g^2}{r^2} - \frac{1}{2} \left(\omega^2 + \frac{B^2}{4} \right) r^2 + \frac{iB\hbar}{2} \frac{\partial}{\partial \phi} \right) \right] \Psi(r, \phi) = 0. \quad (30)$$

Further separation of variables can be done and one can use the fact that L is a constant of motion.

$$\Psi(r, \phi) = R(r) \Phi(\phi), \quad \hat{L} \Phi = \hbar m \Phi. \quad (31)$$

Using the explicit form of the $U(1)$ generator, normalized solution can be written

$$\hat{L} = -i\hbar \frac{\partial}{\partial \phi}, \quad \Phi(\phi) = \frac{1}{\sqrt{2\pi}} e^{im\phi}. \quad (32)$$

This result allows to write the equation (30) in the following form

$$\left[\frac{d^2}{dr^2} + \frac{1}{r} \frac{d}{dr} + \frac{2}{\hbar^2} \left(E - \frac{\hbar^2 m^2}{2r^2} - \frac{2g^2}{r^2} - \frac{1}{2} \left(\omega^2 + \frac{B^2}{4} \right) r^2 - \frac{B\hbar m}{2} \right) \right] R(r) = 0. \quad (33)$$

Solution of this kind of Schrödinger equation can be written down. The final result for the wave functions of two-dimensional system and the energy spectrum are as follows

$$\psi(z, \bar{z}, n, m) = \frac{C_{n,m}}{\sqrt{2\pi}} (\sqrt{z/\bar{z}})^m F\left(-n, \sqrt{m^2 + \frac{4g^2}{\hbar^2}} + 1, \frac{2\sqrt{\omega^2 + \frac{B^2}{4}}}{\hbar} z \bar{z}\right) \left(\frac{2\sqrt{\omega^2 + \frac{B^2}{4}}}{\hbar} z \bar{z}\right)^{1/2 \sqrt{m^2 + \frac{4g^2}{\hbar^2}}} e^{-\frac{2\sqrt{\omega^2 + \frac{B^2}{4}}}{\hbar} z \bar{z}} \quad (34)$$

$$E = \hbar \sqrt{\omega^2 + \frac{B^2}{4}} \left(2n + 1 + \sqrt{m^2 + \frac{4g^2}{\hbar^2}} \right) + \frac{B\hbar m}{2} \quad (35)$$

Finally the indices of \mathbb{C}^N can be recovered. The total wave function is a product of the wavefunctions and the total energy is the sum of the energies of two-dimensional subsystems

$$\Psi(z, \bar{z}) = \prod_{a=1}^N \psi(z_a, \bar{z}_a, n_a, m_a) \quad (36)$$

$$E_{tot} = \sum_{a=1}^N E_{n_a, m_a} = \hbar \sqrt{\omega^2 + \frac{B^2}{4}} \left(2n + N + \sum_{a=1}^N \sqrt{m_a^2 + \frac{4g_a^2}{\hbar^2}} \right) + \frac{B\hbar}{2} \sum_{a=1}^N m_a, \quad (37)$$

$$n = \sum_{a=1}^N n_a, \quad n = 0, 1, 2, \dots \quad m_a = 0, \pm 1, \pm 2, \dots \quad (38)$$

In contrast to the real case the energy spectrum of the \mathbb{C}^N -Smorodinsky-Winternitz system depends on $N+1$ quantum numbers, namely n and m_a .

IV. KUSTAAANHEIMO-STIEFEL TRANSFORMATION

There is a well-known procedure reducing two-/four-/eight-dimensional oscillator to the two-/three-/five-dimensional Coulomb system. It is related with the Hopf maps and assumes the reduction by $\mathbb{Z}_2 - /U(1) - /SU(2)$ -group action. In general case it results in the Coulomb like systems specified by the presence of \mathbb{Z}_2 -/Dirac-/Yang-monopole[32–35]. Since \mathbb{C}^N -Smorodinsky-Winternitz system has manifest $U(1)$ invariance, we could apply its respective reduction procedure related with first Hopf map $S^3/S^1 = S^2$, which is known as Kustaanheimo-Stiefel transformation, for the particular case of $N = 2$. Such a reduction was performed decade ago [39] and was found to be resulted in the so-called “generalized MICZ-Kepler problem” suggested by Mardoyan a bit earlier [40, 41]. However the initial system was considered, it was not specified by the presence of constant magnetic field, furthermore, the symmetry algebra of the reduced system was not obtained there. Hence, it is at least deductive to perform Kustaanheimo-Stiefel transformation to the \mathbb{C}^2 -Smorodinsky-Winternitz system with constant magnetic field in order to find its impact (appearing in the initial system) in the resulting one. Furthermore, it is natural way to find the constants of motion of the “generalized MICZ-Kepler system” and construct their algebra.

So, let us perform the reduction of \mathbb{C}^2 -Smorodinsky-Winternitz system by the $U(1)$ -group action given by the generator

$$J_0 = L_{11} + L_{22} = i(z\pi - \bar{z}\bar{\pi}) - Bz\bar{z} \quad (39)$$

For this purpose we have to choose six independent functions of initial phase space variables which commute with that generators,

$$q_k = z\sigma_k\bar{z}, \quad p_k = \frac{z\sigma_k\pi + \bar{\pi}\sigma_k\bar{z}}{2z\bar{z}}, \quad k = 1, 2, 3 \quad (40)$$

where σ_k are standard 2×2 Pauli matrices. Matrix indices are dropped here. This transformation is called Kustaanheimo-Stiefel transformation. Then we calculate their Poisson brackets and fix the value of $U(1)$ - generator $J_0 = 2s$. As a result, we get the reduced Poisson brackets

$$\{q_k, q_l\} = 0, \quad \{p_k, q_l\} = \delta_{kl}, \quad \{p_k, p_l\} = s\epsilon_{klm} \frac{q_m}{|q|^3} \quad (41)$$

Expressing the Hamiltonian via q_i, p_i, J_0 and fixing the value of the latter one, we get

$$H_{SW} = 2|q| \left[\frac{p^2}{2} + \frac{s^2}{2|q|^2} + \frac{Bs}{2|q|} + \frac{1}{2} \left(\frac{B^2}{4} + \omega^2 \right) + \frac{g_1^2}{|q|(|q| + q_3)} + \frac{g_2^2}{|q|(|q| - q_3)} \right] \quad (42)$$

So, we reduced the \mathbb{C}^2 -Smorodinsky-Winternitz Hamiltonian to the three-dimensional system. To get the Coulomb-like system we fix the energy surface or reduced Hamiltonian, $H_{SW} - E_{SW} = 0$ and divide it on $2|q|$. This yields the equation

$$\mathcal{H}_{gMICZ} - \mathcal{E} = 0, \quad \text{with} \quad \mathcal{E} \equiv -\frac{\omega^2 + B^2/4}{2} \quad (43)$$

and

$$\mathcal{H}_{gMICZ} = \frac{p^2}{2} + \frac{s^2}{2|q|^2} + \frac{g_1^2}{|q|(|q| + q_3)} + \frac{g_2^2}{|q|(|q| - q_3)} - \frac{\gamma}{|q|} \quad \text{with} \quad \gamma \equiv \frac{E_{SW} - Bs}{2}. \quad (44)$$

The latter expression defines the Hamiltonian of “generalized MICZ-Kepler problem”. Hence, we transformed the energy surface of the reduced \mathbb{C}^2 -Smorodinsky-Winternitz Hamiltonian to those of (three-dimensional) “Generalized MICZ-Kepler system”. Additionally it has an inverse square potential and this system has an interaction with a Dirac monopole magnetic field which affects the symplectic structure.

Surprisingly, the reduced system contains interaction with Dirac monopole field only, i.e. the constant magnetic field in the original system does not contribute in the reduced one. All dependence on B is hidden in s and γ , which are fixed, so the reduced system does not depend on B explicitly.

Now this reduction can be done for constants of motion. Before doing that it is convenient to present the initial generators of $u(2)$ algebra given by (16) in the form

$$J_0 = i(z\pi - \bar{z}\bar{\pi}) - Bz\bar{z}, \quad J_k = \frac{i}{2}(z\sigma_k\pi - \bar{\pi}\sigma_k\bar{z}) - \frac{Bz\sigma_k\bar{z}}{2} : \{J_0, J_i\} = 0, \quad \{J_i, J_j\} = \epsilon_{ijk}J_k. \quad (45)$$

After reduction we get $J_0 = 2s$. After the reduction, the rest $su(2)$ generators result in the generators of the $so(3)$ rotations of three-dimensional Euclidian space with the Dirac monopole placed in the beginning of Cartesian coordinate frame,

$$J_k = \epsilon_{klm} p_l q_m - s \frac{q_k}{|q|} \quad (46)$$

Then the symmetry generators for the “generalized MICZ-Kepler system” can be written down,

$$\mathcal{I} = \frac{I_1 - I_2}{2} + \frac{B}{4}(L_{22} - L_{11}) = p_1 J_2 - p_2 J_1 + \frac{x_3 \gamma}{r} + \frac{g_1^2(r - x_3)}{r(r + x_3)} - \frac{g_2^2(r + x_3)}{r(r - x_3)} \quad (47)$$

$$\mathcal{L} = \frac{1}{2}(L_{22} - L_{11}) = J_3 = p_1 q_2 - q_1 p_2 - \frac{s q_3}{|q|}, \quad \mathcal{J} = I_{12} = J_1^2 + J_2^2 + \frac{g_1^2(r - q_3)}{r + q_3} + \frac{g_2^2(r + q_3)}{r - q_3}. \quad (48)$$

It is important to notice that \mathcal{I} is a generalization of the z -component of the Runge-Lenz vector.

The relation of the initial system and the reduced one will allow to find the symmetry algebra of the final system using the previously obtained result for the complex Smorodinsky-Winternitz system. First of all the constants of motion in the initial system will also commute with the reduced Hamiltonian.

$$\{\mathcal{H}_{gMICZ}, \mathcal{I}\} = \{\mathcal{H}_{gMICZ}, \mathcal{J}\} = \{\mathcal{H}_{gMICZ}, \mathcal{L}\} = 0 \quad (49)$$

Moreover, since in the initial system $L_{a\bar{a}}$ generators commute with all the other constants of motion one can write.

$$\{\mathcal{L}, \mathcal{J}\} = \{\mathcal{L}, \mathcal{I}\} = 0 \quad (50)$$

There is only one non-trivial commutator

$$\{\mathcal{I}, \mathcal{J}\} = S \quad (51)$$

S here coincides with S_{12} of \mathbb{C}^2 -Smorodinsky-Winternitz system and can be written using the generators of the reduced system.

$$\begin{aligned} S^2 = 2\mathcal{H}_{gMICZ} & \left[4\left(\mathcal{J} + \frac{1}{2}(\mathcal{L}^2 - s^2)\right)^2 - \left(4g_2^2 + (\mathcal{L} + s)^2\right)\left(4g_1^2 + (\mathcal{L} - s)^2\right) \right] - \left(4g_2^2 + (\mathcal{L} + s)^2\right)(\mathcal{I} + \gamma)^2 \\ & - \left(4g_1^2 + (\mathcal{L} - s)^2\right)(\mathcal{I} - \gamma)^2 - 4\left(\mathcal{J} + \frac{1}{2}(\mathcal{L}^2 - s^2)\right)(\mathcal{I} - \gamma)(\mathcal{I} + \gamma) \end{aligned} \quad (52)$$

There is a crucial fact that should be mentioned. Although the initial system had an interaction with magnetic field, after reduction we don't have any dependence on B both in symplectic structure and in generators of the symmetry algebra, at least in classical level. In other words, the reduced system does not feel the magnetic field of the initial system.

V. DISCUSSION AND OUTLOOK

In this paper we formulated the analog of the Smorodinsky-Winternitz system interacting with a constant magnetic field on the N -dimensional complex Euclidian space \mathbb{C}^N . We found out it has $3N - 1$ functionally independent constants of motion and derived the symmetry algebra of this system. Quantization of these systems is also discussed. While for the real Smorodinsky-Winternitz system energy spectrum is totally degenerate and depends on single (“principal”) quantum number, the \mathbb{C}^N -Smorodinsky-Winternitz energy spectrum depends on $N + 1$ quantum numbers. Then we performed Kustaanheimo-Stiefel transformation of the \mathbb{C}^2 -Smorodinsky-Winternitz system and reduced it to the so-called “generalized MICZ-Kepler problem”. We obtained the symmetry algebra of the latter system using the result obtained for the initial ones. Moreover, we have shown that the presence of constant magnetic field in the initial problem does not affect the reduced system.

There are several generalizations one can perform for this system. Straightforward task is the construction of a quaternionic (\mathbb{H}^N -) analog of this system. While complex structure allows to introduce constant magnetic field without violating the superintegrability, quaternionic structure should allow to introduce interaction with $SU(2)$ instanton. It seems that one can also introduce the superintegrable analogs of the $\mathbb{C}^N/\mathbb{H}^N$ -Smorodinsky-Winternitz systems on the complex/quaternionic projective space $\mathbb{CP}^N/\mathbb{HP}^N$, having in mind the existence of such generalization for the $\mathbb{C}^N/(\mathbb{H}^N)$ oscillator [42, 45]. We expect that the inclusion of a constant magnetic/instanton field does not cause any qualitative changes for this system. These generalizations will be discussed later on.

Acknowledgments

I am grateful to Armen Nersessian for his impact on this work, which includes suggestion of the problem and introduction to subject, numerous discussions and help in preparation of manuscript. Thanks to his great support and encouragement this work is finally completed. I am also thankful to Lusine Goroyan and Ruben Hasratyan for editing.

This work was done within ICTP Affiliated Center programs AF-04 and Regional Doctoral Program on Theoretical and Experimental Particle Physics sponsored by Volkswagen Foundation. I also acknowledge partial financial support within research grant from the ANSEF-Armenian National Science and Education Fund based in New York, USA.
