A note on warped product almost quasi-Yamabe solitons

Adara M. Blaga

Abstract

We consider almost quasi-Yamabe solitons in Riemannian manifolds, derive a Bochner-type formula in the gradient case and prove that under certain assumptions, the manifold is of constant scalar curvature. We also provide necessary and sufficient conditions for a gradient almost quasi-Yamabe soliton on the base manifold to induce a gradient almost quasi-Yamabe soliton on the warped product manifold.

1 Introduction

The notion of Yamabe solitons, which generate self-similar solutions to Yamabe flow [20]:

\[ \frac{\partial}{\partial t} g(t) = -\text{scal}(t) \cdot g(t), \]

firstly appeared to L. F. di Cerbo and M. N. Disconzi in [18]. In [16], B.-Y. Chen introduced the notion of quasi-Yamabe soliton which we shall consider in the present paper for a more general case, when the constants are let to be functions.

Let \((M, g)\) be an \(n\)-dimensional Riemannian manifold \((n > 2)\), \(\xi\) a vector field and \(\eta\) a 1-form on \(M\).

**Definition 1.1.** An almost quasi-Yamabe soliton on \(M\) is a data \((g, \xi, \lambda, \mu)\) which satisfy the equation:

\[ \frac{1}{2} \mathcal{L}_\xi g + (\lambda - \text{scal})g + \mu \eta \otimes \eta = 0, \]

where \(\mathcal{L}_\xi\) is the Lie derivative operator along the vector field \(\xi\) and \(\lambda\) and \(\mu\) are smooth functions on \(M\).

2010 Mathematics Subject Classification. 53C21, 53C44.

Key words and phrases. almost quasi-Yamabe solitons.
When the potential vector field of (2) is of gradient type, i.e. \( \xi = \text{grad}(f) \), then \((g, \xi, \lambda, \mu)\) is said to be a gradient almost quasi-Yamabe soliton (or a generalized quasi-Yamabe gradient soliton) \([21]\) and the equation satisfied by it becomes:

\[
\text{Hess}(f) + (\lambda - \text{scal})g + \mu df \otimes df = 0.
\]

In the next section, we shall derive a Bochner-type formula for the gradient almost quasi-Yamabe soliton case and prove that under certain assumptions, the manifold is of constant scalar curvature. In the last section we construct an almost quasi-Yamabe soliton on a warped product manifold. Remark that results on warped product gradient Yamabe solitons for certain types of warping functions \( f \) have been obtained by W. I. Tokura, L. R. Adriano and R. S. Pina in \([22]\).

## 2 Gradient almost quasi-Yamabe solitons

Remark that in the gradient case, from (3) we get:

\[
\nabla \xi = -(\lambda - \text{scal})I - \mu df \otimes \xi.
\]

Therefore, \( \nabla \xi \xi = [\Delta(f) + (n - 1)(\lambda - \text{scal})] \xi \), i.e. \( \xi \) is a generalized geodesic vector field with the potential function \( \Delta(f) + (n - 1)(\lambda - \text{scal}) \) \([17]\).

Also, if \((\lambda, \mu) = (\text{scal} - 1, 1)\), then \( \xi \) is torse-forming and if \( \mu = 0 \), then \( \xi \) is concircular.

Now we shall get a condition that \( \mu \) should satisfy in a gradient almost quasi-Yamabe soliton \((g, \xi, \lambda, \mu)\). Taking the scalar product with \( \text{Hess}(f) \), from (3) we get:

\[
|\text{Hess}(f)|^2 + (\lambda - \text{scal})\Delta(f) + \frac{\mu}{2} \xi(\xi^2) = 0
\]

and tracing (3) we obtain:

\[
\Delta(f) + n(\lambda - \text{scal}) + \mu |\xi|^2 = 0.
\]

From the above relations we deduce the equation:

\[
n\lambda^2 + (2n \cdot \text{scal} + \mu |\xi|^2)\lambda + n \cdot \text{scal}^2 + \mu |\xi|^2 \cdot \text{scal} - \frac{\mu}{2} \xi(\xi^2) - |\text{Hess}(f)|^2 = 0
\]

which has solution (in \( \lambda \)) if and only if

\[
\mu^2 |\xi|^4 + 2n\mu \xi(\xi^2) + 4n|\text{Hess}(f)|^2 \geq 0
\]

(that is always true for \( \xi \) of constant length).

The next step is to deduce a Bochner-type formula for the gradient almost quasi-Yamabe soliton case.
Theorem 2.1. If (3) defines a gradient almost quasi-Yamabe soliton on the n-dimensional Riemannian manifold $(M, g)$ and $\eta = df$ is the $g$-dual of the gradient vector field $\xi := \text{grad}(f)$, then:

\begin{equation}
\frac{1}{2} \Delta(|\xi|^2) = |\nabla \xi|^2 - \frac{1}{n-1} S(\xi, \xi) - \frac{n-2}{2(n-1)} \mu \nabla_\xi(|\xi|^2) - |\xi|^2 \mu - \frac{n}{n-1} \mu^2 |\xi|^2 - \frac{n^2}{n-1} \lambda \mu + \frac{n^2}{n-1} \mu \cdot \text{scal}.
\end{equation}

Proof. First remark that:

\[ \text{trace}(\mu \eta \otimes \eta) = \mu |\xi|^2 \]

and

\[ \text{div}(\mu \eta \otimes \eta) = \frac{\mu}{2} d(|\xi|^2) + \mu \Delta(f) df + d\mu(\xi) df. \]

Taking the trace of the equation (3), we obtain:

\begin{equation}
\Delta(f) + n(\lambda - \text{scal}) + \mu |\xi|^2 = 0
\end{equation}

and differentiating it:

\begin{equation}
d(\Delta(f)) + n d\lambda - n d(\text{scal}) + \mu d(|\xi|^2) + |\xi|^2 d\mu = 0.
\end{equation}

Now taking the divergence of the same equation, we get:

\begin{equation}
\text{div}(\text{Hess}(f)) + d\lambda - d(\text{scal}) + \frac{\mu}{2} d(|\xi|^2) + \mu \Delta(f) df + d\mu(\xi) df = 0.
\end{equation}

Subtracting the relations (8) and (7) computed in $\xi$ and using (9):

\[ \text{div}(\text{Hess}(f)) = d(\Delta(f)) + i_Q g, \]

\[ (\text{div}(\text{Hess}(f)))(\xi) = \frac{1}{2} \Delta(|\xi|^2) - |\nabla \xi|^2, \]

we obtain (5).

Remark 2.2. For the case $\mu = 0$, under the assumptions $S(\xi, \xi) \leq (n-1)|\nabla \xi|^2$ we get $\Delta(|\xi|^2) \geq 0$ and from the maximum principle follows that $|\xi|^2$ is constant in a neighborhood of any local maximum. If $|\xi|$ achieve its maximum, then $S(\xi, \xi) = (n-1)|\nabla \xi|^2$. \qed
Let us make some remarks on the scalar curvature of $M$.

From (4) we get:
\[ R(\cdot, \cdot)\xi = -[d(\lambda - \text{scal}) \otimes I - I \otimes d(\lambda - \text{scal})] - \mu(\lambda - \text{scal})(df \otimes I - I \otimes df) - (d\mu \otimes df - df \otimes d\mu) \]
and
\[(9)\quad R(\cdot, \xi) = d(\lambda - \text{scal}) \otimes I - g \otimes [\text{grad}(\lambda - \text{scal}) - \mu(\lambda - \text{scal})\xi] + \mu(\lambda - \text{scal})df \otimes I +
\]
\[+ d\mu \otimes df \otimes \xi - df \otimes df \otimes \text{grad}(\mu) \]

which for $\lambda$ and $\mu$ constant become:
\[ R(\cdot, \cdot)\xi = [d(\text{scal}) \otimes I - I \otimes d(\text{scal})] - \mu(\lambda - \text{scal})(df \otimes I - I \otimes df) \]
and
\[(10)\quad R(\cdot, \xi) = -d(\text{scal}) \otimes I + g \otimes [\text{grad}(\text{scal}) + \mu(\lambda - \text{scal})\xi] + \mu(\lambda - \text{scal})df \otimes I. \]

Using (9), $R(\xi, \xi)X = 0$ implies:
\[ [d(\lambda - \text{scal}) + |\xi|^2d\mu] \otimes \xi = df \otimes [\text{grad}(\lambda - \text{scal}) + |\xi|^2\text{grad}(\mu)] \]
which for $\lambda$ and $\mu$ constant becomes:
\[ d(\text{scal}) \otimes \xi = df \otimes \text{grad}(\text{scal}). \]

Assume further that $\lambda$ and $\mu$ are constant. Computing the previous relation in $\xi$ and choosing an open subset where $\xi \neq 0$, we deduce:
\[(11)\quad \text{grad}(\text{scal}) = \frac{\xi(\text{scal})}{|\xi|^2} \xi. \]

Denoting by $h =: \frac{\xi(\text{scal})}{|\xi|^2}$, from the symmetry of $\text{Hess}(\text{scal})$ we obtain:
\[ dh \otimes df = df \otimes dh \]
which implies:
\[ |\xi|^2 dh = \xi(h)df \quad \text{and} \quad |\xi|^2 \text{grad}(h) = \xi(h)\xi. \]

A similar result like the one obtained by B.-Y. Chen, S. Deshmukh in [17] for Yamabe solitons can be obtained for quasi-Yamabe solitons, following the same ideas in proving it.
Theorem 2.3. Let \( \xi \) define a gradient quasi-Yamabe soliton on the connected \( n \)-dimensional Riemannian manifold \( (M,g) \) \( (n > 1) \) for \( \eta = df \) the \( g \)-dual of the unitary vector field \( \xi := \text{grad}(f) \). If \( \xi(scal) \) is constant along the integral curves of \( \xi \) and \( \text{Hess}(scal) \) is degenerate in the direction of \( \xi \), then \( M \) is of constant scalar curvature.

Proof. Under these hypotheses, applying divergence to (1) we obtain:

\[
\Delta(scal) = \xi(scal)\Delta(f) = -[n(\lambda - scal) + \mu]\xi(scal).
\]

Computing the Ricci operator in \( \xi \), \( Q\xi = -\sum_{i=1}^{n} R(E_i,\xi)E_i \), for \( \{E_i\}_{1 \leq i \leq n} \) a local orthonormal frame field on \( M \), and using (10) we get:

\[
Q\xi = -(n-1)\text{grad}(scal) + (n-1)\mu(\lambda - scal)\xi
\]

and

\[
S(\xi,\xi) = g(Q\xi,\xi) = -(n-1)\xi(scal) + (n-1)\mu(\lambda - scal).
\]

Applying the divergence to (13) we have:

\[
div(Q\xi) = -(n-1)\Delta(scal) + (n-1)\mu(\lambda - scal)\xi(scal).
\]

Computing the same divergence like:

\[
div(Q\xi) = div(S)(\xi) + \langle S, \text{Hess}(f) \rangle,
\]

taking into account the gradient quasi-Yamabe soliton equation, the fact that

\[
div(S)(\xi) = \frac{\xi(scal)}{2},
\]

the expression of \( S(\xi,\xi) \) from (14) and replacing \( \Delta(scal) \) from (12), we obtain:

\[
\left[ \frac{1}{2} - n(n-1)(\lambda - scal) + (n-1)\mu \right] \xi(scal) =
\]

\[
= (\lambda - scal)[(1 + n(n-1)\mu)scal - n(n-1)\lambda \mu].
\]

Differentiating the previous expression along \( \xi \) and taking into account the degeneracy of \( \text{Hess}(scal)(\xi,\xi) = \xi(\xi(scal)) - (\nabla_\xi\xi)(scal) \) in the direction of \( \xi \), after a long computation, we get:

\[
\xi(scal) \left[ \xi(scal) + scal^2 + k_1scal + k_2 \right] = 0,
\]
where the constants $k_1$ and $k_2$ are respectively given by:

$$k_1 = \frac{n+1}{n} \mu + \frac{5}{2n(n-1)}, \quad k_2 = \frac{\lambda^2 - \frac{1}{n} \mu^2 - \frac{n+1}{n} \lambda \mu - \frac{3\lambda + \mu}{2n(n-1)}}{2n(n-1)}.$$

Differentiating again the term in the parentheses along $\xi$ we get:

$$\xi(\text{scal}) \left[ 3 \text{scal} - \lambda + \frac{1}{n} \mu + \frac{5}{2n(n-1)} \right] = 0$$

which completes the proof.

\[\square\]

3 Warped product almost quasi-Yamabe solitons

3.1 Warped product manifolds

Consider $(B, g_B)$ and $(F, g_F)$ two Riemannian manifolds of dimensions $n$ and $m$, respectively. Denote by $\pi$ and $\sigma$ the projection maps from the product manifold $B \times F$ to $B$ and $F$ and by $\tilde{\varphi} := \varphi \circ \pi$ the lift to $B \times F$ of a smooth function $\varphi$ on $B$. In this context, we shall call $B$ the base and $F$ the fiber of $B \times F$, the unique element $\tilde{X}$ of $\chi(B \times F)$ that is $\pi$-related to $X \in \chi(B)$ and to the zero vector field on $F$, the horizontal lift of $X$, and the unique element $\tilde{V}$ of $\chi(B \times F)$ that is $\sigma$-related to $V \in \chi(F)$ and to the zero vector field on $B$, the vertical lift of $V$. Also denote by $\mathcal{L}(B)$ the set of all horizontal lifts of vector fields on $B$, by $\mathcal{L}(F)$ the set of all vertical lifts of vector fields on $F$, by $\mathcal{H}$ the orthogonal projection of $T_{(p,q)}(B \times F)$ onto its horizontal subspace $T_{(p,q)}(B \times \{q\})$ and by $\mathcal{V}$ the orthogonal projection of $T_{(p,q)}(B \times F)$ onto its vertical subspace $T_{(p,q)}(\{p\} \times F)$.

Let $\varphi > 0$ be a smooth function on $B$ and

$$g := \pi^* g_B + (\varphi \circ \pi)^2 \sigma^* g_F$$

be a Riemannian metric on $B \times F$.

**Definition 3.1.** The product manifold of $B$ and $F$ together with the Riemannian metric $g$ defined by (17) is called the warped product of $B$ and $F$ by the warping function $\varphi$ (and is denoted by $(M := B \times F, g)$).

In particular, if $\varphi = 1$, then the warped product becomes the usual product of the Riemannian manifolds.

For simplification, in the rest of the paper we shall simply denote by $X$ the horizontal lift of $X \in \chi(B)$ and by $V$ the vertical lift of $V \in \chi(F)$.  
Notice that the lift on \( M \) of the gradient and the Hessian satisfy:

\[
\nabla(\tilde{f}) = \nabla(f),
\]
\[
\text{Hess}(\tilde{f})(X, Y) = \text{Hess}(f)(X, Y), \quad \text{for any } X, Y \in \mathcal{L}(B),
\]

for any smooth function \( f \) on \( B \).

Also, the scalar curvatures are connected by the relation [19]:

\[
\text{scal} = \text{scal}_B + \frac{\text{scal}_F}{\varphi^2} - \pi^* \left( 2m \frac{\Delta(\varphi)}{\varphi} + m(m-1) \frac{|\nabla(\varphi)|^2}{\varphi^2} \right).
\]

### 3.2 Warped product almost quasi-Yamabe solitons

We shall construct a gradient almost quasi-Yamabe soliton on a warped product manifold.

Let \((B, g_B)\) be an \( n \)-dimensional Riemannian manifold, \( \varphi > 0 \) a smooth function on \( B \) and \( f, \mu \) smooth functions on \( B \) such that:

\[
\Delta(f) + \mu |\nabla(f)|^2 = n \frac{(\nabla(f))(\varphi)}{\varphi}.
\]

In this case, any gradient almost quasi-Yamabe soliton \((g_B, \nabla(f), \lambda_B, \mu_B)\) on \((B, g_B)\) is given by \( \lambda_B = \text{scal}_B - \frac{(\nabla(f))(\varphi)}{\varphi} \) and \( \mu_B = \mu \).

Take \((F, g_F)\) an \( m \)-dimensional manifold with

\[
\text{scal}_F = \pi^* \left( (\lambda - \lambda_B)\varphi^2 + 2m\varphi \Delta(\varphi) + m(m-1)|\nabla(\varphi)|^2 \right)|_F,
\]

where \( \pi \) and \( \sigma \) are the projection maps from the product manifold \( B \times F \) to \( B \) and \( F \), respectively, \( g := \pi^* g_B + (\varphi \circ \pi)^2 \sigma^* g_F \) is a Riemannian metric on \( B \times F \), \( \lambda_B = \text{scal}_B - \frac{(\nabla(f))(\varphi)}{\varphi} \) and \( \lambda \) is a smooth function on \( B \).

With the above notations, we prove:

**Theorem 3.2.** Let \((B, g_B)\) be an \( n \)-dimensional Riemannian manifold, \( \varphi > 0 \), \( f, \mu \) smooth functions on \( B \) satisfying (21) and \((F, g_F)\) an \( m \)-dimensional Riemannian manifold with the scalar curvature given by (22). Then \((g, \xi, \pi^* (\lambda), \pi^* (\mu))\), where \( \xi = \nabla(\tilde{f}) \), is a gradient almost quasi-Yamabe soliton on the warped product manifold \((B \times \varphi F, g)\) if and only if \((g_B, \nabla(f), \lambda_B = \text{scal}_B - \frac{(\nabla(f))(\varphi)}{\varphi}, \mu)\) is a gradient almost quasi-Yamabe soliton on \((B, g_B)\).
Proof. The gradient almost quasi-Yamabe soliton \((g, \xi, \pi^*(\lambda), \pi^*(\mu))\) on \((B \times_\varphi F, g)\) is given by:

\[ \text{Hess}(\tilde{f}) + (\pi^*(\lambda) - \text{scal})g + \pi^*(\mu)d\tilde{f} \otimes d\tilde{f} = 0. \]

Notice that from (20), (21) and (22) we deduce that
\[ \pi^*(\lambda) - \text{scal} = \pi^*(\lambda_B) - \tilde{\text{scal}}_B, \]

hence for any \(X, Y \in \mathcal{L}(B)\) we get:

\[ H^f(X, Y) + (\lambda_B - \tilde{\text{scal}}_B)g_B(X, Y) + \mu df(X)df(Y) = 0 \]

i.e. \((g_B, \text{grad}(f), \lambda_B, \mu)\) is a gradient almost quasi-Yamabe soliton on \((B, g_B)\), where \(H^f\) denotes the lift of \(\text{Hess}(f)\).

Conversely, notice that the left-hand side term in (23) computed in \((X, V)\), for \(X \in \mathcal{L}(B)\) and \(V \in \mathcal{L}(F)\) vanishes identically and for each situation \((X, Y)\) and \((V, W)\), we can recover the equation (23) from (21) and the fact that \((g_B, \text{grad}(f), \lambda_B, \mu)\) is a gradient almost quasi-Yamabe soliton on \((B, g_B)\). Indeed, taking the trace of (24) we get

\[ \Delta(f) + n(\lambda_B - \tilde{\text{scal}}_B) + \mu|\text{grad}(f)|^2 = 0 \]

and using (21) we obtain

\[ \pi^*(\lambda_B) - \tilde{\text{scal}}_B = -\left(\frac{\text{grad}(f)}{\varphi}\right). \]

We know that for any \(V, W \in \mathcal{L}(F)\):

\[ H^f(V, W) = (\text{Hess}(\tilde{f}))(V, W) = g(\nabla_V(\text{grad}(\tilde{f})), W) = \pi^*\left[\left(\frac{\text{grad}(f)}{\varphi}\right)\right]|_F \tilde{\varphi}^2|_F g_F(V, W) \]

and we deduce that

\[ H^f(V, W) + (\pi^*(\lambda_B) - \tilde{\text{scal}}_B)|_F g(V, W) = 0. \]

\[ \Box \]

Example 3.3. Consider \(M = \{(x, y, z) \in \mathbb{R}^3, z > 0\}\), where \((x, y, z)\) are the standard coordinates in \(\mathbb{R}^3\),

\[ g_M := \frac{1}{z^2}(dx \otimes dx + dy \otimes dy + dz \otimes dz) \quad \text{and} \quad \xi_M := -z \frac{\partial}{\partial z}. \]

Let \((g_M, \xi_M, -8, 2)\) be the gradient quasi-Yamabe soliton on the Riemannian manifold \((M, g_M)\) and let \(S^3\) be the 3-sphere with the round metric \(g_S\) (which is Einstein with the Ricci tensor equals to \(2g_S\)). Thus we obtain the gradient quasi-Yamabe soliton \((g, \xi, -2, 2)\) on the "generalized cylinder" \(M \times S^3\), where \(g = g_M + g_S\) and \(\xi\) is the lift on \(M \times S^3\) of the gradient vector field \(\xi_M = \text{grad}(f)\), where \(f(x, y, z) := -\ln z\).
3.3 Some consequences of condition (21)

Let us make some remarks on the class of manifolds that satisfy the condition:

\[
\Delta(f) + \mu |\xi|^2 = n \frac{d\varphi(\xi)}{\varphi},
\]

for \( \varphi > 0 \), \( f \) and \( \mu \) smooth functions on the oriented and compact Riemannian manifold \((B, g_B)\) and \( \xi := \text{grad}(f) \).

Remark that if

\[
Hess(f) - \frac{n}{2\varphi}(df \otimes d\varphi + d\varphi \otimes df) + \mu df \otimes df = 0,
\]

then (25) is satisfied. Computing \( Hess(f)(X, Y) := g_B(\nabla_X \xi, Y) \) we get

\[
\nabla \xi = \frac{n}{2\varphi}(df \otimes \text{grad}(\varphi) + d\varphi \otimes \xi) - \mu df \otimes \xi.
\]

Also notice that in this case, if \((g_B, \xi, \lambda_B, \mu)\) is a gradient almost quasi-Yamabe soliton on \((B, g_B)\), then the metric \(g_B\) is precisely

\[
g_B = -\frac{n}{2\varphi(\lambda_B - \text{scal}_B)} (df \otimes d\varphi + d\varphi \otimes df)
\]

and \( \text{scal}_B = \lambda_B + \frac{d\varphi(\xi)}{\varphi} \).

In what follows, we shall focus on condition (26). We’ve checked that [9]:

\[
|Hess(f) - \frac{\Delta(f)}{n} g_B|^2 = |Hess(f)|^2 - \frac{(\Delta(f))^2}{n},
\]

\[
(\text{div}(Hess(f)))(\xi) = \text{div}(Hess(f)(\xi)) - |Hess(f)|^2,
\]

therefore:

\[
(\text{div}(Hess(f)))(\xi) = \text{div}(Hess(f)(\xi)) - |Hess(f)|^2 - \frac{(\Delta(f))^2}{n}.
\]

Applying the divergence to (26), computing it in \( \xi \) and taking into account that

\[
\text{div} \left( \frac{1}{\varphi} df \otimes d\varphi \right) = \left( \frac{\Delta(f)}{\varphi} - \frac{d\varphi(\xi)}{\varphi^2} \right) d\varphi + \frac{1}{\varphi} i_{\nabla_{\xi \text{grad}(\varphi)}} g_B
\]

and

\[
\text{div}(\mu df \otimes df) = \frac{\mu}{2} d(|\xi|^2) + \mu \Delta(f) df + d\mu(\xi) df,
\]
we get:

\[
(28) \quad (\text{div}(\text{Hess}(f)))(\xi) = n \left( \frac{\Delta(f)}{\varphi} - \frac{d\varphi(\xi)}{\varphi^2} \right) d\varphi(\xi) + \frac{n}{\varphi} g_B(\nabla_{\xi} \text{grad}(\varphi), \xi) - \frac{\mu}{2} d(|\xi|^2) - \mu \Delta(f) |\xi|^2 - d\mu(\xi)|\xi|^2
\]

and we obtain:

\[
(29) \quad \text{div}(\text{Hess}(f)(\xi)) = |\text{Hess}(f) - \frac{\Delta(f)}{n} g_B|^2 + \frac{(\Delta(f))^2}{n} + n \left( \frac{\Delta(f)}{\varphi} - \frac{d\varphi(\xi)}{\varphi^2} \right) d\varphi(\xi) + \frac{n}{\varphi} g_B(\nabla_{\xi} \text{grad}(\varphi), \xi) - \frac{\mu}{2} d(|\xi|^2) - \mu \Delta(f) |\xi|^2 - d\mu(\xi)|\xi|^2.
\]

Integrating with respect to the canonical measure on \(B\), we have:

\[
\int_{B} d(|\xi|^2)(\xi) = \int_{B} \langle \text{grad}(|\xi|^2), \xi \rangle = - \int_{B} \langle ||\xi||^2, \text{div}(\xi) \rangle = - \int_{B} |\xi|^2 \cdot \Delta(f).
\]

Using:

\[
|\xi|^2 \cdot \Delta(f) = |\xi|^2 \cdot \text{div}(\xi) = \text{div}(|\xi|^2 \xi) - |\xi|^2
\]

taking \(\mu\) constant and integrating (29) on \(B\), from the above relations and the divergence theorem, we obtain:

\[
(30) \quad \int_{B} |\text{Hess}(f) - \frac{\Delta(f)}{n} g_B|^2 + (n + 1) \int_{B} \Delta(f) \cdot \frac{d\varphi(\xi)}{\varphi} + \frac{(2 - \mu)n + 2}{2n} \int_{B} |\xi|^2 - n \int_{B} \frac{(d\varphi(\xi))^2}{\varphi^2} + n \int_{B} g_B(\frac{1}{\varphi} \nabla_{\xi} \text{grad}(\varphi), \xi) = 0.
\]

Assume now that \(\mu\) is constant and consider the product manifold \(B \times F\), in which case (26) and (25) (for \(\varphi = 1\)) become:

\[
(31) \quad \text{Hess}(f) + \mu df \otimes df = 0 \quad \text{and} \quad \Delta(f) + \mu |\xi|^2 = 0.
\]

**Remark 3.4.** i) In the case of product manifold (for \(\varphi = 1\)), the chosen manifold \((F, g_F)\) is of scalar curvature \(\text{scal}_F = \pi^*(\lambda - \text{scal}_B)|_F\). In particular, for \(\lambda = \text{scal}_B\), \((F, g_F)\) is locally isometric to an Euclidean space. Moreover, \(\nabla_{\xi} \xi = -\mu |\xi|^2 \xi\), therefore, \(\xi\) is a generalized geodesic vector field with the potential function \(\Delta(f)\).

ii) For \(\varphi = 1\) and \(\mu\) constant, we obtain:

\[
\mu^2 \int_{B} |\xi|^4 = 0
\]
and we can state:

**Corollary 3.5.** Let $(B, g_B)$ be an oriented and compact $n$-dimensional Riemannian manifold, $f$ a smooth function on $B$ and $\mu$ a real constant satisfying (31). Then $\mu = 0$ hence, $f$ is harmonic and $\nabla \xi = 0$.

**Proposition 3.6.** Let $(B, g_B)$ be an oriented, compact and complete $n$-dimensional $(n > 1)$ Riemannian manifold, $f$ a smooth function on $B$ and $\mu$ a real constant satisfying (31). Then $B$ is conformal to a sphere in the $(n+1)$-dimensional Euclidean space.

**Proof.** From the above observations, we have:

\[
\int_B |\text{Hess}(f) - \frac{\Delta(f)}{n} g_B|^2 = \int_B |\text{Hess}(f)|^2 - \int_B \frac{\Delta(f)^2}{n} = \frac{n-1}{n} \mu^2 \int_B |\xi|^4 = 0,
\]

so $\text{Hess}(f) = \frac{\Delta(f)}{n} g_B$ which implies by [23] that $B$ is conformal to a sphere in the $(n+1)$-dimensional Euclidean space. \qed
