Abstract

Gao’s quantum union bound is a generalization of the union bound from probability theory and finds a range of applications in quantum communication theory, quantum algorithms, and quantum complexity theory [Phys. Rev. A, 92(5):052331, 2015]. It is relevant when performing a sequence of binary-outcome quantum measurements on a quantum state, giving the same bound that the classical union bound would, except with a scaling factor of four. In this paper, we improve upon Gao’s quantum union bound, by proving a quantum union bound that involves a tunable parameter that can be optimized. This tunable parameter plays a similar role to a parameter involved in the Hayashi-Nagaoka inequality [IEEE Trans. Inf. Theory, 49(7):1753 (2003)], used often in quantum information theory when analyzing the error probability of a square-root measurement. An advantage of the proof delivered here is that it is elementary, relying only on basic properties of projectors, the Pythagorean theorem, and the Cauchy–Schwarz inequality. As a non-trivial application of our quantum union bound, we prove that a sequential decoding strategy for classical communication over a quantum channel achieves a lower bound on the channel’s second-order coding rate. This demonstrates the advantage of our quantum union bound in the non-asymptotic regime, in which a communication channel is called a finite number of times.

1 Introduction

The union bound, alternatively known as Boole’s inequality, represents one of the simplest yet non-trivial methods for bounding the probability that either one event or another occurs, in terms of the probabilities of the individual events (see, e.g., [Roz77]). By induction, the bound applies to the union of multiple events, and it often provides a good enough bound in a variety of applications whenever the probabilities of the individual events are small compared to the number of events. Concretely, given a finite set \( \{A_i\}_{i=1}^L \) of events, the union bound is the following inequality:

\[
\Pr\left(\bigcup_{i=1}^L A_i\right) \leq \sum_{i=1}^L \Pr\{A_i\}.
\]  

(1.1)
By applying DeMorgan’s law and basic rules of probability theory, we can rewrite the union bound such that it applies to the probability that an intersection of events does not occur

\[
1 - \Pr \left\{ \bigcap_{i=1}^{L} A_i \right\} \leq \sum_{i=1}^{L} \Pr\{A_i^c\},
\]

and this is the form in which it is typically employed in applications. Recently, the union bound has been listed as the second step to try when attempting to “upper-bound the probability of something bad,” with the first step being to determine if the trivial bound of one is reasonable in a given application [Aar18].

Generalizing the union bound to a quantum-mechanical setup is non-trivial. A natural setting in which we would consider this generalization is when the goal is to bound the probability that two or more successive measurement outcomes do not occur. Concretely, suppose that the state of a quantum system is given by a density operator \( \rho \). Suppose that there are \( L \) projective quantum measurements \( \{P_i, I - P_i\} \) for \( i \in \{1, \ldots, L\} \), where \( P_i \) is a projector, thus satisfying \( P_i = P_i^\dagger \) and \( P_i = P_i^2 \) by definition. Suppose that the first measurement is performed, followed by the second measurement, and so on. If the projectors \( P_1, \ldots, P_L \) commute, then the probability that the outcomes \( P_1, \ldots, P_L \) do not occur is calculated by applying the Born rule and can be bounded as

\[
1 - \text{Tr}\{P_L P_{L-1} \cdots P_1 \rho P_1 \cdots P_L\} \leq \sum_{i=1}^{L} \text{Tr}\{(I - P_i)\rho\},
\]

with the bound following essentially from an application of the union bound. However, if the projectors \( P_1, \ldots, P_L \) do not commute, then classical reasoning does not apply and alternative methods are required.

Recently, Gao proved a quantum union bound [Gao15] that has been useful in a variety of applications, including quantum communication theory [Gao15, Hir15, BCN16, Ren17, YSM17], quantum algorithms [MW16, Aar16, HLM17], quantum complexity theory [Aar16, WHKN18], and Hamiltonian complexity theory [AAV16, KL18]. Given an arbitrary set of projectors \( \{P_i\}_{i=1}^{L} \), each corresponding to one outcome of a binary-valued measurement, Gao’s quantum union bound is the following inequality [Gao15, Theorem 1]:

\[
1 - \text{Tr}\{P_L P_{L-1} \cdots P_1 \rho P_1 \cdots P_L\} \leq 4 \sum_{i=1}^{L} \text{Tr}\{(I - P_i)\rho\}.
\]

By comparing (1.4) with (1.3), we notice that the only difference is the factor of four in (1.4). The factor of four is inconsequential for many applications, but nevertheless, it is natural to wonder whether this bound can be improved. Furthermore, at least one application in which improving the factor of four does make a difference is in the context of whether a sequential decoding strategy can be used to achieve the second-order coding rate for classical communication—we discuss this application in more detail later.

### 2 Summary of results

In this paper, we prove the following quantum union bound:
Theorem 1 (Quantum union bound) Let $\rho$ be a density operator acting on a separable Hilbert space $\mathcal{H}$, let $\{P_i\}_{i=1}^L$ be an arbitrary set of projectors, each acting on $\mathcal{H}$, and let $c > 0$ be an arbitrary positive constant. Then
\[
1 - \text{Tr}\{P_L P_{L-1} \cdots P_1 \rho P_1 \cdots P_{L-1}\} \leq (1 + c) \text{Tr}\{(I - P_L) \rho\} + (2 + c + c^{-1}) \sum_{i=2}^{L-1} \text{Tr}\{(I - P_i) \rho\} + (2 + c^{-1}) \text{Tr}\{(I - P_1) \rho\}. \tag{2.1}
\]

Our proof of the above theorem is elementary, relying only on basic properties of projectors, the Pythagorean theorem, and the Cauchy–Schwarz inequality. Furthermore, the theorem directly applies to states of infinite-dimensional quantum systems and can thus be employed to analyze practical situations involving not only qubits but also bosonic quantum systems [Ser17]. The tunable parameter $c > 0$ is an advantage of our quantum union bound, and it is essential in the application mentioned above, in which it really is necessary for $c > 0$ to be decreasing with the number of channel uses so that the prefactor in front of the term $\text{Tr}\{(I - P_L) \rho\}$ is as close to one as possible. More generally, one could certainly take an infimum over the parameter $c > 0$ in any given application in order to have the upper bound be as tight as possible.

Our quantum union bound represents a strict improvement over that of Gao’s in (1.4). Indeed, by setting $c = 1$ and then loosening the above bound further, we recover Gao’s. Our quantum union bound can also be compared with the Hayashi–Nagaoka (HN) inequality from [HN03, Lemma 2], which is often used to analyze the error probability of the square-root measurement. The HN inequality also features a tunable parameter $c > 0$, and this is one of the main reasons why quantum information theory has recently advanced in the direction of characterizing second-order asymptotics for communication tasks [TH13, TT15, DL15, DTW16, WRG16, TBR16, Led16, WTB17, Wil17]. Our quantum union bound provides essentially the same trade-off given by the HN inequality, but just slightly improved, in the sense that the prefactor for the term $\text{Tr}\{(I - P_L) \rho\}$ is $1 + c$, while the prefactor for $L - 2$ other terms is $2 + c + c^{-1}$ and the prefactor for the term $\text{Tr}\{(I - P_1) \rho\}$ is $2 + c^{-1}$, the last prefactor representing the improvement.

In the previous paragraphs, we focused exclusively on the comparison of Theorem 1 with Gao’s bound in (1.4). However, there were many works that preceded Gao’s, which we recall now. [Aar06] established a quantum union bound, with applications in quantum complexity theory. [GLM12] analyzed the error probability of a sequential decoding strategy and proved that it can achieve the Holevo information of a quantum channel for classical communication. The work of [GLM12] then inspired [Sen11], who established another quantum union bound (also called “non-commutative union bound”) of the following form:
\[
1 - \text{Tr}\{P_L P_{L-1} \cdots P_1 \rho P_1 \cdots P_{L-1}\} \leq 2 \sqrt{\sum_{i=1}^L \text{Tr}\{(I - P_i) \rho\}}. \tag{2.2}
\]

[Wil13] subsequently generalized the result of [Sen11] beyond projectors, such that it would hold for a set of operators $\{\Lambda_i\}_{i=1}^L$, each of which satisfies $0 \leq \Lambda_i \leq I$. Then Gao’s bound in (1.4) appeared after [Wil13]. Clearly, Gao’s bound was a significant improvement over (2.2), eliminating the square root at the cost of a doubling of the prefactor.

To demonstrate an application in which Theorem 1 is useful, we show how a sequential decoding strategy achieves a lower bound on the second-order coding rate for classical communication over
a quantum channel. We consider the cases in which there is entanglement assistance as well as no assistance, and our result here also covers the important case when the channel takes input density operators acting on a separable Hilbert space to output density operators acting on a separable Hilbert space. An advantage of our proof is that it is arguably simpler than other approaches that could be taken to solve this problem, relying on a method called position-based coding [AJW17], as well as sequential decoding [GLM12, Sen11, Wil13], and an error analysis that uses Theorem 1. Our proof can be compared with the proof from [Hol03, Hol04], in which it was shown how to achieve the capacity for energy-constrained classical communication (i.e., the first-order coding rate), and we advocate here that our proof is considerably simpler.

We organize the rest of our paper as follows. In Section 3, we provide a proof of Theorem 1. Section 4 briefly discusses the results of numerical investigations that compare the performance of the bound in Theorem 1 and Gao’s bound in (1.4). In Section 5, we consider the generalization of Theorem 1 to positive operator-valued measures (POVMs). Section 6 discusses the application to obtaining a lower bound on the second-order coding rate for classical communication. In Section 7, we conclude with a summary and discuss some open directions for future research.

3 Proof of Theorem 1

We prove our main result, Theorem 1, by establishing the following more general result:

**Theorem 2** Let $H$ be a separable Hilbert space, let $|\psi\rangle \in H$, let $\{P_i\}_{i=1}^L$ be a finite set of projectors acting on $H$, and let $c > 0$. Then

$$\|\psi\|^2 - \|P_L P_{L-1} \cdots P_1 |\psi\|^2 \leq (1 + c) \|(I - P_L) |\psi\|\|^2 \tag{3.1}$$

$$+ (2 + c + c^{-1}) \sum_{i=2}^{L-1} \|(I - P_i) |\psi\|\|^2 + (2 + c^{-1}) \|(I - P_1) |\psi\|\|^2.$$  

Theorem 1 is a direct consequence of Theorem 2. Indeed, a density operator $\rho$ acting on a separable Hilbert space has a spectral decomposition as follows:

$$\rho = \sum_{j \in J} p_j |\psi_j\rangle\langle \psi_j|,$$  

(3.2)

where the index set $J$ is countable, $\{p_j\}_{j \in J}$ is a probability distribution, and $\{|\psi_j\rangle\}_{j \in J}$ is an orthonormal set of eigenvectors [Hol11]. Applying Theorem 2, we find that

$$1 - \text{Tr}\{P_L P_{L-1} \cdots P_1 |\psi_j\rangle\langle \psi_j| P_L P_{L-1} \cdots P_1 \}$$

$$= \| |\psi_j\rangle\|^2 - \| P_L P_{L-1} \cdots P_1 |\psi_j\rangle\|^2 \tag{3.3}$$

$$\leq (1 + c) \|(I - P_L) |\psi_j\|\|^2 + (2 + c + c^{-1}) \sum_{i=2}^{L-1} \|(I - P_i) |\psi_j\|\|^2$$

$$+ (2 + c^{-1}) \|(I - P_1) |\psi_j\|\|^2 \tag{3.4}$$

$$= (1 + c) \text{Tr}\{(I - P_L) |\psi_j\rangle\langle \psi_j| \} + (2 + c + c^{-1}) \sum_{i=2}^{L-1} \text{Tr}\{(I - P_i) |\psi_j\rangle\langle \psi_j| \}$$

$$(2 + c^{-1}) + \text{Tr}\{(I - P_1) |\psi_j\rangle\langle \psi_j| \}.$$  

(3.5)
The reduction from Theorem 1 to Theorem 2 follows by averaging over the distribution \( \{ p_j \}_{j \in J} \).

So now we shift our focus to proving Theorem 2, and we do so with the aid of several lemmas. To simplify the notation, hereafter we employ the following shorthand:

\[
\begin{align*}
\| \cdots \| & \equiv \| \cdots | \psi \rangle \|_2, \\
\langle \cdots \rangle & \equiv \langle \psi | \cdots | \psi \rangle, \\
Q_i & \equiv I - P_i.
\end{align*}
\] (3.6)

Furthermore, we also assume without loss of generality that the vector \( | \psi \rangle \) in Theorem 2 is a unit vector. Clearly, this assumption can be easily released by scaling the resulting inequality by an arbitrary positive number.

First recall that, due to the idempotence of projectors, we have the following identities holding for all \( i \in \{ 1, 2, \ldots, L \} \):

\[
\begin{align*}
\langle Q_i P_{i-1} \cdots P_1 \rangle &= \langle Q_i Q_i P_{i-1} \cdots P_1 \rangle, \\
\langle P_1 \cdots P_i \rangle &= \langle P_1 \cdots P_i P_i \rangle,
\end{align*}
\] (3.9)

under the convention that \( P_{i-1} \cdots P_1 = P_1 \cdots P_{i-1} = I \) for \( i = 1 \).

**Lemma 3** For a set \( \{ P_i \}_{i=1}^L \) of projectors acting on a separable Hilbert space \( \mathcal{H} \), a unit vector \( | \psi \rangle \in \mathcal{H} \), and employing the shorthand in (3.6)–(3.8), we have the following identities:

\[
\begin{align*}
\sum_{i=1}^L \langle Q_i P_{i-1} \cdots P_1 \rangle &= 1 - \langle P_L \cdots P_1 \rangle, \\
\sum_{i=1}^L \langle P_1 \cdots P_{i-1} Q_i \rangle &= 1 - \langle P_1 \cdots P_L \rangle, \\
\sum_{i=1}^L \langle P_1 \cdots P_{i-1} Q_i P_{i-1} \cdots P_1 \rangle &= 1 - \langle P_1 \cdots P_L \cdots P_1 \rangle, \\
1 - \sqrt{\langle P_L \rangle} \sqrt{\langle P_1 \cdots P_L \cdots P_1 \rangle} &\leq \sum_{i=1}^L \sqrt{\langle Q_i \rangle} \sqrt{\langle P_1 \cdots P_i Q_i P_{i-1} \cdots P_1 \rangle},
\end{align*}
\] (3.10–3.13)

under the convention that \( P_{i-1} \cdots P_1 = P_1 \cdots P_{i-1} = I \) for \( i = 1 \).

**Proof.** The following identities are straightforward:

\[
\begin{align*}
1 &= \langle Q_1 \rangle + \langle Q_2 P_1 \rangle + \cdots + \langle Q_{L-1} P_L \cdots P_1 \rangle + \langle Q_L P_{L-1} \cdots P_1 \rangle + \langle P_L P_{L-1} \cdots P_1 \rangle, \\
1 &= \langle Q_1 \rangle + \langle P_1 Q_2 \rangle + \cdots + \langle P_1 \cdots P_{L-1} Q_L \rangle + \langle P_1 \cdots P_{L-1} P_L \rangle, \\
1 &= \langle Q_1 \rangle + \langle P_1 Q_2 P_1 \rangle + \cdots + \langle P_1 \cdots P_{L-1} Q_L \cdots P_1 \rangle \\
&\quad + \langle P_1 \cdots P_{L-1} Q_L P_{L-1} \cdots P_1 \rangle + \langle P_1 \cdots P_{L-1} P_L P_{L-1} \cdots P_1 \rangle.
\end{align*}
\] (3.14–3.16)

Consequently, from the equalities in (3.14), (3.15), and (3.16), we obtain (3.10), (3.11), and (3.12), respectively. The following equality is a direct consequence of (3.14) and (3.9):

\[
1 = \langle Q_1 \rangle + \langle Q_2 Q_2 P_1 \rangle + \cdots + \langle Q_{L-1} Q_{L-1} P_L \cdots P_1 \rangle + \langle Q_L Q_L P_{L-1} \cdots P_1 \rangle \\
&\quad + \langle P_L P_L P_{L-1} \cdots P_1 \rangle. \quad (3.17)
\]
By applying the Cauchy-Schwarz inequality to (3.17), we find that

$$1 \leq \langle Q_1 \rangle + \sqrt{\langle Q_2 \rangle} \sqrt{\langle P_1 Q_2 P_1 \rangle} + \cdots + \sum_{j=1}^{L} \sqrt{\langle Q_{L} \rangle} \sqrt{\langle P_{1} \cdots P_{L-1} Q_{L} P_{L-1} \cdots P_{1} \rangle}$$

from which (3.13) immediately follows.

**Lemma 4** For a set \( \{ P_i \}_{i=1}^{L} \) of projectors acting on a separable Hilbert space \( \mathcal{H} \), a unit vector \( \psi \) \( \in \mathcal{H} \), and employing the shorthand in (3.6)–(3.8), the following inequality holds for all \( i \in \{ 1, \ldots, L \} \):

$$\sqrt{\langle P_1 \cdots P_{i-1} Q_i P_{i-1} \cdots P_1 \rangle} \leq \| Q_i (I - P_{i-1} \cdots P_1) \| + \| Q_i \|, \quad (3.19)$$

under the convention that \( P_{i-1} \cdots P_1 = P_1 \cdots P_{i-1} = I \) for \( i = 1 \).

**Proof.** Fix \( i \in \{ 1, \ldots, L \} \). Consider that

$$\| I - Q_i P_{i-1} \cdots P_1 \|^2 = \langle (I - P_1 \cdots P_{i-1} Q_i)(I - Q_i P_{i-1} \cdots P_1) \rangle$$

$$= 1 - \langle Q_i P_{i-1} \cdots P_1 \rangle - \langle P_1 \cdots P_{i-1} Q_i \rangle + \langle P_1 \cdots P_{i-1} Q_i P_{i-1} \cdots P_1 \rangle. \quad (3.20)$$

Now using the above equality, the Cauchy–Schwarz inequality, and the identities in (3.9), we find that

$$1 + \langle P_1 \cdots P_{i-1} Q_i P_{i-1} \cdots P_1 \rangle - \| I - Q_i P_{i-1} \cdots P_1 \|^2$$

$$= \langle Q_i Q_i P_{i-1} \cdots P_1 \rangle + \langle P_1 \cdots P_{i-1} Q_i Q_i \rangle$$

$$\leq 2 \sqrt{\langle Q_i \rangle} \sqrt{\langle P_1 \cdots P_{i-1} Q_i P_{i-1} \cdots P_1 \rangle}. \quad (3.22)$$

By rearranging terms, we find that

$$1 - 2 \sqrt{\langle Q_i \rangle} \sqrt{\langle P_1 \cdots P_{i-1} Q_i P_{i-1} \cdots P_1 \rangle} + \langle P_1 \cdots P_{i-1} Q_i P_{i-1} \cdots P_1 \rangle$$

$$\leq \| I - Q_i P_{i-1} \cdots P_1 \|^2 \quad (3.24)$$

$$= \| P_i + Q_i (I - P_{i-1} \cdots P_1) \|^2 \quad (3.25)$$

$$= \| P_i \|^2 + \| Q_i (I - P_{i-1} \cdots P_1) \|^2 \quad (3.26)$$

$$= 1 - \| Q_i \|^2 + \| Q_i (I - P_{i-1} \cdots P_1) \|^2. \quad (3.27)$$

The first equality follows because \( I = P_i + Q_i \). The second equality follows from the Pythagorean theorem, because \( P_i \) is orthogonal to \( Q_i (I - P_{i-1} \cdots P_1) \). The third equality follows because \( \| P_i \|^2 = 1 - \| Q_i \|^2 \). Thus

$$\| Q_i \|^2 - 2 \sqrt{\langle Q_i \rangle} \sqrt{\langle P_1 \cdots P_{i-1} Q_i P_{i-1} \cdots P_1 \rangle} + \langle P_1 \cdots P_{i-1} Q_i P_{i-1} \cdots P_1 \rangle$$

$$\leq \| Q_i (I - P_{i-1} \cdots P_1) \|^2, \quad (3.28)$$

or equivalently,

$$\left( \sqrt{\langle P_1 \cdots P_{i-1} Q_i P_{i-1} \cdots P_1 \rangle} - \| Q_i \| \right)^2 \leq \| Q_i (I - P_{i-1} \cdots P_1) \|^2. \quad (3.29)$$
Finally, by taking a square root and invoking the inequality \(|y| - |x| \leq |y - x|\), with
\[
y = \sqrt{\langle P_1 \cdots P_{i-1} Q_i P_{i-1} \cdots P_1 \rangle}, \quad x = \|Q_i\|,
\]
we find that
\[
\sqrt{\langle P_1 \cdots P_{i-1} Q_i P_{i-1} \cdots P_1 \rangle} \leq \|Q_i(I - P_{i-1} \cdots P_1)\| + \|Q_i\|.
\]
This concludes the proof. ■

**Lemma 5** For a set \(\{P_i\}_{i=1}^L\) of projectors acting on a separable Hilbert space \(\mathcal{H}\), a unit vector \(|\psi\rangle \in \mathcal{H}\), and employing the shorthand in (3.6)-(3.8), the following inequality holds for \(L \geq 2\):
\[
\sum_{i=1}^L \|Q_i(I - P_{i-1} \cdots P_1)\|^2 \leq \sum_{i=1}^{L-1} \|Q_i\|^2,
\]
under the convention that \(P_{i-1} \cdots P_1 = P_{i-1} \cdots P_{i-1} = I\) for \(i = 1\). Equivalently,
\[
\sum_{i=2}^L \|Q_i(I - P_{i-1} \cdots P_1)\|^2 \leq \sum_{i=1}^{L-1} \|Q_i\|^2,
\]
due to the aforementioned convention.

**Proof.** Consider the following chain of equalities:
\[
\sum_{i=1}^L \|Q_i(I - P_{i-1} \cdots P_1)\|^2
\]
\[
= \sum_{i=1}^L \|Q_i - Q_i P_{i-1} \cdots P_1\|^2
\]
\[
= \sum_{i=1}^L \left(\|Q_i\|^2 - \langle Q_i P_{i-1} \cdots P_1 \rangle - \langle P_1 \cdots P_{i-1} Q_i \rangle + \langle P_1 \cdots P_{i-1} Q_i P_{i-1} \cdots P_1 \rangle\right)
\]
\[
= \left(\sum_{i=1}^L \|Q_i\|^2\right) - 1 + \langle P_L \cdots P_1 \rangle - 1 - \langle P_1 \cdots P_L \rangle + 1 - \langle P_1 \cdots P_L \cdots P_1 \rangle
\]
\[
= \left(\sum_{i=1}^L \|Q_i\|^2\right) - 1 + \langle P_L P_L P_{L-1} \cdots P_1 \rangle + \langle P_1 \cdots P_{L-1} P_L P_L \rangle - \langle P_1 \cdots P_L \cdots P_1 \rangle.
\]
To obtain (3.35), we used the identities in (3.9). Next, to get (3.36), the identities in (3.10), (3.11), and (3.12) of Lemma 3 were used. Continuing, we have that
\[
\text{Eq. (3.37)} \leq \left(\sum_{i=1}^L \|Q_i\|^2\right) - 1 + \langle P_1 \cdots P_L \cdots P_1 \rangle + 2\sqrt{\langle P_L \rangle} \sqrt{\langle P_1 \cdots P_L \cdots P_1 \rangle}
\]
\[
= \left(\sum_{i=1}^L \|Q_i\|^2\right) - 1 + \langle P_L \rangle - \left(\sqrt{\langle P_L \rangle} - \sqrt{\langle P_1 \cdots P_L \cdots P_1 \rangle}\right)^2
\]
\[
\leq \left(\sum_{i=1}^L \|Q_i\|^2\right) - \|Q_L\|^2 = \sum_{i=1}^{L-1} \|Q_i\|^2.
\]
To obtain (3.38), the Cauchy-Schwarz inequality was employed.

We are now in a position to prove Theorem 2.

**Proof of Theorem 2.** Consider that

$$1 - ||P_L \cdots P_1||^2 = 1 - \langle P_1 \cdots P_L \cdots P_1 \rangle + 2 \left(1 - \sqrt{\langle P_L \rangle \langle P_1 \cdots P_L \cdots P_1 \rangle}\right)$$

$$- 2 \left(1 - \sqrt{\langle P_L \rangle \langle P_1 \cdots P_L \cdots P_1 \rangle}\right)$$

$$= 2 \left(1 - \sqrt{\langle P_L \rangle \langle P_1 \cdots P_L \cdots P_1 \rangle}\right)$$

$$- \left(\sqrt{\langle P_L \rangle} - \sqrt{\langle P_1 \cdots P_L \cdots P_1 \rangle}\right)^2 - 1 + \langle P_L \rangle.$$  (3.42)

Continuing, we have that

Eq. (3.42) \leq - ||Q_L||^2 + 2 \left(1 - \sqrt{\langle P_L \rangle \langle P_1 \cdots P_L \cdots P_1 \rangle}\right) \leq - ||Q_L||^2 + 2 \sum_{i=1}^{L} \sqrt{\langle Q_i \rangle} \sqrt{\langle P_1 \cdots P_{i-1} \rangle Q_i Q_{i-1} \cdots P_1} \leq - ||Q_L||^2 + 2 \sum_{i=1}^{L} \sqrt{\langle Q_i \rangle} (||Q_i|| + ||Q_i(I - P_{i-1} \cdots P_1)||).  (3.45)

First, (3.43) is obtained by observing that

$$- \left(\sqrt{\langle P_L \rangle} - \sqrt{\langle P_1 \cdots P_L \cdots P_1 \rangle}\right)^2 - 1 + \langle P_L \rangle \leq -1 + \langle P_L \rangle = - ||Q_L||^2.$$  (3.46)

Next, (3.44) follows from (3.13) of Lemma 3. Then, (3.45) is a consequence of Lemma 4. Continuing, we have that

Eq. (3.45) = - ||Q_L||^2 + 2 \sum_{i=1}^{L} ||Q_i||^2 + 2 \sum_{i=2}^{L} (||Q_i|| ||Q_i(I - P_{i-1} \cdots P_1)||) \leq - ||Q_L||^2 + 2 \sum_{i=1}^{L} ||Q_i||^2 + 2 \sum_{i=2}^{L} (||Q_i|| ||Q_i(I - P_{i-1} \cdots P_1)||) \leq - ||Q_L||^2 + 2 \sum_{i=1}^{L} ||Q_i||^2 + \sum_{i=2}^{L} \left(c ||Q_i||^2 + c^{-1} ||Q_i(I - P_{i-1} \cdots P_1)||^2\right) \leq - ||Q_L||^2 + 2 \sum_{i=1}^{L} ||Q_i||^2 + c \sum_{i=2}^{L} ||Q_i||^2 + c^{-1} \sum_{i=1}^{L-1} ||Q_i||^2 \leq (1 + c) ||Q_L||^2 + (2 + c^{-1}) ||Q_1||^2 + (2 + c + c^{-1}) \sum_{i=2}^{L-1} ||Q_i||^2.  (3.51)

Eq. (3.48) follows from the convention that $P_{i-1} \cdots P_1 = I$ for $i = 1$. Eq. (3.49) is a consequence of the inequality $2xy \leq cx^2 + c^{-1} y^2$, holding for $x, y \in \mathbb{R}$ and $c > 0$. Finally, (3.50) is obtained by using Lemma 5. ■
4 Numerical investigations

In this section, we discuss the results of numerical investigations in order to compare the newly derived bound with Gao’s bound.

First, notice that Theorem 2 has been derived under the assumption $L \geq 2$ (in order to use Lemma 5). For $L = 1$, it is trivially $1 - \|P_1\|^2 = \|Q_1\|^2$. For $L = 2$, note that the term $(2 + c + c^{-1}) \sum_{i=2}^{L-1} \|Q_i\|^2$ should not be considered.

Then, by a calculus argument, the optimal value of $c$ is given by

$$c_{opt} = \sqrt{\frac{\sum_{i=1}^{L-1} \|Q_i\|^2}{\sum_{i=2}^{L} \|Q_i\|^2}}, \quad \text{for} \quad L \geq 2. \quad (4.1)$$

Next let us define

$$F(L) \equiv 1 - \|P_L P_{L-1} \ldots P_1\|^2 \quad (4.2)$$

$$G(L) \equiv 4 \sum_{i=1}^{L} \|Q_i\|^2 \quad (4.3)$$

$$H(L) \equiv \begin{cases} 
\|Q_1\|^2, & L = 1 \\
(1 + c_{opt}) \|Q_L\|^2 + (2 + c_{opt}) \|Q_1\|^2, & L = 2 \\
(1 + c_{opt}) \|Q_L\|^2 + (2 + c_{opt} + c_{opt}^{-1}) \sum_{i=2}^{L-1} \|Q_i\|^2 + (2 + c_{opt}^{-1}) \|Q_1\|^2, & L > 2 
\end{cases} \quad (4.4)$$

which are, respectively, the quantity that we are trying to bound, Gao’s bound in (1.4), and our bound from Theorem 2.

We now consider the qubit case. For fixed $L$, we randomly select projectors $P_i$ for $i \in \{1, \ldots, L\}$ independently and identically. This is done by considering the seed projector $|0\rangle \langle 0|$ and then applying a unitary $U|0\rangle \langle 0|U^\dagger$ selected randomly according to the Haar measure on SU(2). Furthermore,
given that the sequence of projectors is chosen randomly, the state \( |\psi\rangle \) for which we evaluate the norms can be taken as fixed, e.g., \( |\psi\rangle = |0\rangle \).

A sufficiently large number of sequences of projectors \( \{P_L, P_{L-1}, \ldots, P_2, P_1\} \) is generated in order to have \( G(L) < 1 \) for approximately \( 10^2 \) trials. Averaging over such trials the values of \( F(L) \), \( G(L) \), and \( H(L) \) allows us to have sufficient statistics for reliable results. The larger \( L \) is, the larger must be the number of projector sequences generated; e.g., for \( L = 10 \), approximately \( 10^8 \) sequences are needed.

Figure [4] depicts the behavior of the quantities \( E(F) \), \( E(G) \), \( E(H) \) versus \( L \). It is clear that our bound tends to Gao’s bound in [1] when \( L \) becomes large. However, in such a regime the probability that \( G(L) < 1 \) (i.e., the bounds are meaningful), becomes negligibly small. Thus, for all practical purposes, our bound improves upon Gao’s. Nevertheless, it is far from being tight in this particular set of numerical investigations.

It is worth noticing that \( E(F) \) does not saturate to one as would be expected for increasing \( L \). This is due to the fact that only realizations with \( G(L) < 1 \) are considered overall.

We conclude this section by stating that by considering systems of dimension \( d \) larger than two (qubits), the probability of having \( G(L) < 1 \) decreases further. In fact, on a single instance, we have \( \mathbb{E} \text{Tr}(U|0\rangle\langle 0|U^\dagger|0\rangle) = 1/d \). This is a regime in which we would not expect the union bound to give a good bound, motivating the need for finding alternate bounds in this regime.

5 Generalization to POVMs

Just as the bound from [Sen11] was generalized in [Wil13] Section 3] from projectors to positive semi-definite operators having eigenvalues between zero and one, we can do the same here. This generalization is useful for applications, and we discuss one such application in the next section.

We now give an extension of the quantum union bound in Theorem [1] that applies for general measurements. The main idea behind it is the well known Naimark extension theorem, following the approach from [Wil13] Section 3.

**Lemma 6** Let \( \rho \) be a positive semi-definite operator acting on a separable Hilbert space \( \mathcal{H}_S \), let \( \{\Lambda_i\}_{i=1}^L \) denote a set of positive semi-definite operators such that \( 0 \leq \Lambda_i \leq I \) for all \( i \in \{1, \ldots, L\} \), and let \( c > 0 \). Then the following quantum union bound holds

\[
\text{Tr}\{\rho\} - \text{Tr}\{\Pi_{\Lambda_L} \cdots \Pi_{\Lambda_1} (\rho \otimes |0\rangle\langle 0\|_{PL}) \Pi_{\Lambda_1} \cdots \Pi_{\Lambda_L}\} \leq (1 + c) \text{Tr}\{(I - \Lambda_L)\rho\}
+ (2 + c + c^{-1}) \sum_{i=2}^{L-1} \text{Tr}\{(I - \Lambda_i)\sigma\} + (2 + c^{-1}) \text{Tr}\{(I - \Lambda_1)\rho\}, \tag{5.1}
\]

where \( |0\|_{PL} \equiv |0\rangle_{P_1} \otimes \cdots \otimes |0\rangle_{P_L} \) is an auxiliary state of \( L \) qubit probe systems and \( \Pi_{\Lambda_i} \) is a projector defined as \( \Pi_{\Lambda_i} \equiv U_i^\dagger P_i U_i, \) for some unitary \( U_i \) and projector \( P_i \) such that

\[
\text{Tr}\{\Pi_{\Lambda_i} (\rho \otimes |0\rangle\langle 0\|_{PL})\} = \text{Tr}\{\Lambda_i\rho\}. \tag{5.2}
\]

**Proof.** This extension of Theorem [1] follows easily by employing the Naimark extension theorem. Concretely, to each operator \( \Lambda_i \), we associate the following unitary:

\[
U_{SP_i} \equiv \sqrt{I_S - (\Lambda_i)S} \otimes |0\rangle\langle 0|_{P_i} + |1\rangle\langle 1|_{P_i} + \sqrt{(\Lambda_i)S} \otimes |1\rangle\langle 1|_{P_i} - |0\rangle\langle 0|_{P_i}. \tag{5.3}
\]
Then defining the projectors
\[ \Pi_{\Lambda} \equiv U_{SP_i}^\dagger (I_S \otimes |1\rangle\langle 1|_{P_i}) U_{SP_i}, \]  
(5.4)
a straightforward calculation gives that
\[ \text{Tr}\{\Pi_{\Lambda} (\rho \otimes |0\rangle\langle 0|_{P_L})\} = \text{Tr}\{\Lambda_i \rho_S\}. \]  
(5.5)
Observe that the operator \( \Pi_{\Lambda} \) is an orthogonal projector (because it is Hermitian and idempotent), so that Theorem 1 applies to each of these operators. Then (5.1) follows. ■

6 Lower bound on the second-order coding rate for classical communication

One application of our main result, Theorem 1, is in achieving the second-order coding rate for classical communication. As we stated earlier, this area of quantum information theory has advanced in recent years [TH13, TT15, DL15, DTW16, WRG16, TBR16, Led16, WTB17, Wil17], with one of the main reasons being the availability of the tunable parameter \( c > 0 \) in the Hayashi–Nagaoka inequality [HN03, Lemma 2]. That is, one can let \( c > 0 \) vary, to become closer to zero, as the number of channel uses increases.

An advantage of our Theorem 1 is that it applies directly to the case of states and projectors that act on an infinite-dimensional, separable Hilbert space. Thus, the theorem can be applied directly in order to achieve a lower bound on the second-order coding rate for classical communication. To our knowledge, prior to our work here, [WRG16] presented the only case in which lower bounds on the second-order coding rates have been considered in this general case, and there, the analysis was limited to channels that accept a classical input and output a pure quantum state. The situation that we analyze here is thus more general.

6.1 Information quantities

Before we begin with the application, let us recall some information quantities that are essential in the analysis. Let \( \mathcal{H} \) denote a separable Hilbert space, and let \( \mathcal{D}(\mathcal{H}) \) denote the set of density operators acting on \( \mathcal{H} \) (positive, semi-definite operators with trace equal to one). Let spectral decompositions of \( \rho, \sigma \in \mathcal{D}(\mathcal{H}) \) be given as
\[ \rho = \sum_{x \in \mathcal{X}} p(x) |\psi_x\rangle\langle \psi_x|, \]  
(6.1)
\[ \sigma = \sum_{y \in \mathcal{Y}} q(y) |\phi_y\rangle\langle \phi_y|, \]  
(6.2)
where \( \mathcal{X} \) and \( \mathcal{Y} \) are countable index sets, \( \{p(x)\}_{x \in \mathcal{X}} \) and \( \{q(y)\}_{y \in \mathcal{Y}} \) are probability distributions, and \( \{|\psi_x\rangle\}_{x \in \mathcal{X}} \) and \( \{|\phi_y\rangle\}_{y \in \mathcal{Y}} \) are sets of orthonormal eigenvectors [Hol11]. The hypothesis testing relative entropy \( D_H^\varepsilon(\rho||\sigma) \) is defined for \( \varepsilon \in [0,1] \) as [BD10, WR12]
\[ D_H^\varepsilon(\rho||\sigma) \equiv -\log_2 \inf_{\Lambda} \{\text{Tr}\{\Lambda \sigma\} : \text{Tr}\{\Lambda \rho\} \geq 1 - \varepsilon \land 0 \leq \Lambda \leq I\}. \]  
(6.3)
The quantum relative entropy is defined as [Lin73]
\[ D(\rho||\sigma) \equiv \sum_{x \in \mathcal{X}, y \in \mathcal{Y}} |\langle \phi_y | \psi_x \rangle|^2 p(x) \log_2 [p(x)/q(x)], \]  
(6.4)
the quantum relative entropy variance is defined as \[ TH13, Li14, KW17 \]
\[
V(\rho\|\sigma) \equiv \sum_{x \in X, y \in Y} |\langle \phi_y | \psi_x \rangle|^2 p(x) \left( \log_2 \frac{p(x)}{q(x)} \right) - D(\rho\|\sigma)^2 ,
\]
(6.5)
and the following quantity is needed as well \[ TH13, Li14, KW17 \]:
\[
T(\rho\|\sigma) \equiv \sum_{x \in X, y \in Y} |\langle \phi_y | \psi_x \rangle|^2 p(x) \left| \log_2 \frac{p(x)}{q(x)} \right| - D(\rho\|\sigma)^3 .
\]
(6.6)
For states \( \rho \) and \( \sigma \) satisfying
\[
D(\rho\|\sigma), V(\rho\|\sigma), T(\rho\|\sigma) < \infty ,
\]
(6.7)
\[
V(\rho\|\sigma) > 0 ,
\]
(6.8)
the following expansion holds for the hypothesis testing relative entropy for \( \varepsilon \in (0, 1) \) and a sufficiently large positive integer \( n \):
\[
D_H^\varepsilon (\rho^\otimes n\|\sigma^\otimes n) = n D(\rho\|\sigma) + \sqrt{n V(\rho\|\sigma)} \Phi^{-1}(\varepsilon) + O(\log n),
\]
(6.9)
where
\[
\Phi(a) \equiv \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{a} dx \exp \left( -x^2/2 \right) ,
\]
(6.10)
\[
\Phi^{-1}(\varepsilon) \equiv \sup \{ a \in \mathbb{R} \mid \Phi(a) \leq \varepsilon \} .
\]
(6.11)
The equality in (6.9) was proven for finite-dimensional states \( \rho \) and \( \sigma \) in \[ TH13, Li14 \]. For the case of states acting on infinite-dimensional, separable Hilbert spaces, the inequality \( \leq \) in (6.9) was proven in \[ DPR16 \] and \[ KW17, Appendix C \]. The inequality \( \geq \) has not appeared in print, but it has been claimed in \[ DPR17 \]. The proof therein is based on that given in \[ Li14 \], along with a limiting argument. Regarding this latter inequality, one should observe that the explicit bound given in \[ Li14, Eq. (44) \] has no dimension dependence, and this is an underlying reason why the result extends transparently to the infinite-dimensional case via a limiting argument.

6.2 Communication codes

We now recall what we mean by a code for classical communication and one for entanglement-assisted classical communication, starting with the former. Note that classical communication was considered for the asymptotic case in \[ Hol98, SW97 \]. Suppose that a channel \( \mathcal{N}_{A \rightarrow B} \) connects a sender Alice to a receiver Bob. For positive integers \( n \) and \( M \), and \( \varepsilon \in [0, 1] \), an \( (n, M, \varepsilon) \) code for classical communication consists of a set \( \{ \rho_{A^n}^m \}_{m \in M} \) of quantum states, which are called quantum codewords, and where \( |M| = M \). It also consists of a decoding POVM \( \{ \Lambda_{B^n}^m \}_{m \in M} \) and satisfies the following condition:
\[
\frac{1}{M} \sum_{m \in M} \text{Tr}\{(I_{B^n} - \Lambda_{B^n}^m) \mathcal{N}_{A \rightarrow B}^\otimes n(\rho_{A^n}^m)\} \leq \varepsilon ,
\]
(6.12)
which we interpret as saying that the average error probability is no larger than \( \varepsilon \), when using the quantum codewords and decoding POVM described above. The non-asymptotic classical capacity
of $N_{A\to B}$, denoted by $C(N_{A\to B}, n, \varepsilon)$ is equal to the largest value of $\frac{1}{n} \log_2 M$ (bits per channel use) for which there exists an $(n, M, \varepsilon)$ code as described above.

Entanglement-assisted classical communication is defined similarly, but one allows for Alice and Bob to share an arbitrary quantum state $\Psi_{A'B'}$ before communication begins. Note that entanglement-assisted classical communication was considered for the asymptotic case in [BSST99, BSST02, Hol02]. For positive integers $n$ and $M$, and $\varepsilon \in [0, 1]$, an $(n, M, \varepsilon)$ code for entanglement-assisted classical communication consists of the resource state $\Psi_{A'B'}$, a set $\{E^n_{A'\to A^n}\}_{m \in M}$ of encoding channels, where $|M| = M$. It also consists of a decoding POVM $\{A_{B^nB'}^m\}_{m \in M}$ and satisfies the following condition:

$$
\frac{1}{M} \sum_{m \in M} \text{Tr}\{(I_{B^nB'} - A_{B^nB'}^m)N^n_{A\to B}(E^n_{A'\to A^n}(\Psi_{A'B'}))\} \leq \varepsilon,
$$

(6.13)

which we interpret as saying that the average error probability is no larger than $\varepsilon$, when using the entanglement-assisted code described above. The non-asymptotic entanglement-assisted classical capacity of $N_{A\to B}$, denoted by $C_{EA}(N_{A\to B}, n, \varepsilon)$ is equal to the largest value of $\frac{1}{n} \log_2 M$ (bits per channel use) for which there exists an $(n, M, \varepsilon)$ entanglement-assisted code as described above.

### 6.3 Lower bound on second-order coding rate

Defining the $\varepsilon$-mutual information of a bipartite state $\tau_{CD}$ as

$$
I^\varepsilon_H(C; D)_{\tau} \equiv D_H(\tau_{CD} \| \tau_{C} \otimes \tau_D),
$$

(6.14)

the following inequality was proven recently in [QWW17, Theorem 8] for the finite-dimensional case, improving upon a prior result from [DTW16].

$$
C_{EA}(N_{A\to B}, 1, \varepsilon) \geq I_H^{\varepsilon-\eta}(R; B)_\zeta - \log_2(4\varepsilon/\eta^2),
$$

(6.15)

where $\varepsilon \in (0, 1)$, $\eta \in (0, \varepsilon)$, $\zeta_{RB} \equiv N_{A\to B}(\rho_{RA})$, and $\rho_{RA}$ is a bipartite state. The techniques employed in the proof of [QWW17, Theorem 8] were position-based coding [AJW17] and the Hayashi–Nagaoka inequality [HN03, Lemma 2]. Note that the position-based coding method can be understood as a variation of the well known and studied coding technique called pulse position modulation [Ver90, CE03]. We now generalize the inequality in (6.15) to the infinite-dimensional case by applying Theorem 1 along with position-based coding [AJW17] and the sequential decoding strategy from [Wil13].

**Theorem 7** Let $H_A$, $H_B$, and $H_R$ be separable Hilbert spaces. Let $N_{A\to B}$ be a quantum channel, taking $D(H_A)$ to $D(H_B)$. Then the following bound holds:

$$
C_{EA}(N_{A\to B}, 1, \varepsilon) \geq I_H^{\varepsilon-\eta}(R; B)_\zeta - \log_2(4\varepsilon/\eta^2),
$$

(6.16)

where $\varepsilon \in (0, 1)$, $\eta \in (0, \varepsilon)$, $\zeta_{RB} \equiv N_{A\to B}(\rho_{RA})$, and $\rho_{RA} \in D(H_R \otimes H_A)$ is a bipartite state.

**Proof.** Let $\Lambda_{RB}$ be a measurement operator (i.e., $0 \leq \Lambda_{RB} \leq I_{RB}$) satisfying

$$
\text{Tr}\{(I_{RB} - \Lambda_{RB})N_{A\to B}(\rho_{RA})\} \leq \varepsilon - \eta.
$$

(6.17)
To this operator $\Lambda_{RB}$ is associated a unitary $U_{RB}$, defined as
\[ U_{RB} \equiv \sqrt{I_{RB} - \Lambda_{RB}} \otimes |0\rangle\langle 0|_P + |1\rangle\langle 1|_P + \sqrt{\Lambda_{RB}} \otimes |1\rangle\langle 0|_P - |0\rangle\langle 1|_P. \] (6.18)

Then defining the projectors
\[ \Pi_{RB} \equiv U_{RB}^\dagger (I_{RB} \otimes |1\rangle\langle 1|_P) U_{RB}, \] (6.19)
\[ \hat{\Pi}_{RB} \equiv I_{RB} - \Pi_{RB} = U_{RB}^\dagger (I_{RB} \otimes |0\rangle\langle 0|_P) U_{RB}, \] (6.20)
the inequality in (6.17) and a simple calculation imply that
\[ \text{Tr}\{(I_{RB} - \Pi_{RB}) N_{A \rightarrow B}(\rho_{RA}) \otimes |0\rangle\langle 0|_P \} \leq \epsilon - \eta. \] (6.21)

This kind of construction and equality is known as the Naimark extension theorem.

The position-based coding strategy then proceeds as follows. We let Alice and Bob share $M$ copies of the resource state $\rho_{RA}$, where Bob has the $R$ systems and Alice the $A$ systems. If Alice would like to transmit message $m \in \mathcal{M}$, then she simply selects the $m$th $A$ system, and sends it through the channel $N_{A \rightarrow B}$. The marginal state of Bob’s systems is then as follows:

\[ \rho_{R_1} \otimes \cdots \otimes \rho_{R_{m-1}} \otimes N_{A_m \rightarrow B} (\rho_{R_m A_m}) \otimes \rho_{R_{m+1}} \otimes \cdots \otimes \rho_{R_M}. \] (6.22)

Bob then uses a sequential decoding strategy to determine which message Alice transmitted. He introduces $M$ auxiliary probe systems in the state $|0\rangle\langle 0|$, so that Bob’s overall state is now

\[ \omega_{RMBP}^m \equiv \rho_{R_1} \otimes \cdots \otimes \rho_{R_{m-1}} \otimes N_{A_m \rightarrow B} (\rho_{R_m A_m}) \otimes \rho_{R_{m+1}} \otimes \cdots \otimes \rho_{R_M} \otimes |0\rangle\langle 0| P_1 \otimes \cdots \otimes |0\rangle\langle 0| P_M. \] (6.23)

He then performs the binary measurements $\{\Pi_{R_iBP_i}, \hat{\Pi}_{R_iBP_i}\}$ sequentially, in the order $i = 1, 2, \ldots$, etc. With this strategy, the probability that he decodes the $m$th message correctly is given by

\[ \text{Tr}\{\Pi_{R_mB} \hat{\Pi}_{R_{m-1}BP_{m-1}} \cdots \hat{\Pi}_{R_1BP_1} \omega_{RMBP}^m \hat{\Pi}_{R_1BP_1} \cdots \hat{\Pi}_{R_{m-1}BP_{m-1}} \}. \] (6.24)

Applying Theorem [1] we can bound the complementary (error) probability as

\[ p_e(m) \equiv 1 - \text{Tr}\{\Pi_{R_mB} \hat{\Pi}_{R_{m-1}BP_{m-1}} \cdots \hat{\Pi}_{R_1BP_1} \omega_{RMBP}^m \hat{\Pi}_{R_1BP_1} \cdots \hat{\Pi}_{R_{m-1}BP_{m-1}} \} \]
\[ \leq (1 + c) \text{Tr}\{\hat{\Pi}_{R_mB} \omega_{RMBP}^m \hat{\Pi}_{R_1BP_1} \cdots \hat{\Pi}_{R_{m-1}BP_{m-1}} \} + (2 + c + c^{-1}) \sum_{i=1}^{m-1} \text{Tr}\{\Pi_{R_iBP_i} \omega_{RMBP}^m \hat{\Pi}_{R_iBP_i} \cdots \hat{\Pi}_{R_{m-1}BP_{m-1}} \} \]
\[ = (1 + c) \text{Tr}\{(I_{RB} - \Lambda_{RB}) N_{A \rightarrow B}(\rho_{RA})\}
\[ + (2 + c + c^{-1}) (m - 1) \text{Tr}\{\Lambda_{RB} [\rho_{R} \otimes N_{A \rightarrow B}(\rho_{A})]\} \]
\[ \leq (1 + c)(\epsilon - \eta) + (2 + c + c^{-1}) M \text{Tr}\{\Lambda_{RB} [\rho_{R} \otimes N_{A \rightarrow B}(\rho_{A})]\}, \]

where $c > 0$. Since the whole development above holds for all measurement operators $\Lambda_{RB}$ satisfying (6.17), we can take an infimum over all of them to obtain the following uniform bound on the error probability when sending an arbitrary message $m \in \mathcal{M}$:

\[ p_e(m) \leq (1 + c)(\epsilon - \eta) + (2 + c + c^{-1}) M 2^{-I_H^{\epsilon - \eta}(R;B)\zeta}. \] (6.29)

Picking $c = \eta/(2\epsilon - \eta)$ and taking $M$ such that

\[ \log_2 M = I_H^{\epsilon - \eta}(R;B)\zeta - \log_2(4\epsilon/\eta^2) \]

then implies that $p_e(m) \leq \epsilon$ for all $m \in \mathcal{M}$. Since we have shown the existence of a $(1, M, \epsilon)$ entanglement-assisted code, where $M$ satisfies (6.30), this concludes the proof. □
Remark 8 It is worthwhile to note that the code above has an error probability less than \( \varepsilon \) for every message \( m \in M \), and so the error criterion is maximal error probability and not just average error probability.

The above result also implies rates that are achievable for unassisted classical communication, by combining Theorem 7 with an analysis nearly identical to that given in [Wil17, Section 3.3]. In particular, we could allow Alice and Bob to share many copies of the following classical–quantum state before communication begins:

\[
\rho_{X A} \equiv \sum_{x \in X} p(x) |x\rangle \langle x| \otimes \rho^x_A,
\]

(6.31)

where \( \mathcal{H}_X \) and \( \mathcal{H}_A \) are separable Hilbert spaces, \( X \) is a countable index set, \( \{p(x)\}_{x \in X} \) is a probability distribution, \( \{|x\rangle\}_{x \in X} \) is a set of orthonormal states, and \( \{\rho^x_A\}_{x \in X} \) is a set of states. This state then plays the role of the resource state \( \rho_{RA} \) in the proof of Theorem 7. However, the above state is a classical–quantum state, and as such, the code can be derandomized. Specifically, to do so, we can employ the analysis given in [Wil17, Section 3.3], but replacing the square-root measurement there with the sequential decoding strategy. This leads to the following result, which generalizes one of the main results of [WR12] to the infinite-dimensional case:

Corollary 9 Let \( \mathcal{H}_A, \mathcal{H}_B, \) and \( \mathcal{H}_X \) be separable Hilbert spaces. Let \( \mathcal{N}_{A \rightarrow B} \) be a quantum channel, taking \( \mathcal{D}(\mathcal{H}_A) \) to \( \mathcal{D}(\mathcal{H}_B) \). Then the following bound holds:

\[
C(\mathcal{N}_{A \rightarrow B}, 1, \varepsilon) \geq I_{\mathcal{H}} - \eta(X; B) \zeta - \log_2(4\varepsilon/\eta^2),
\]

(6.32)

where \( \varepsilon \in (0, 1), \eta \in (0, \varepsilon), \zeta_{XB} \equiv \mathcal{N}_{A \rightarrow B}(\rho_{XA}), \) and \( \rho_{XA} \in \mathcal{D}(\mathcal{H}_X \otimes \mathcal{H}_A) \) is a bipartite, classical–quantum state of the form in (6.31).

6.4 Energy constraints

It is common in the theory of communication over infinite-dimensional channels [Hol03, Hol04, Hol12] to impose energy constraints on the space of inputs. If we do not so, then the capacities can be infinite. The definitions of these energy-constrained non-asymptotic capacities are the same as we discussed previously, except that we impose energy constraints on the channel input states.

Before defining them, let us first recall the notion of an energy observable [Hol12, HST13]:

Definition 10 (Energy Observable) For a Hilbert space \( \mathcal{H} \), let \( G \in \mathcal{L}_+(\mathcal{H}) \) denote a positive semi-definite operator, defined in terms of its action on a vector \( |\psi\rangle \) as

\[
G|\psi\rangle = \sum_{j=1}^{\infty} g_j |e_j\rangle \langle e_j|\psi\rangle,
\]

(6.33)

for \( |\psi\rangle \) such that \( \sum_{j=1}^{\infty} g_j |\langle e_j|\psi\rangle|^2 < \infty \). In the above, \( \{|e_j\rangle\}_{j} \) is an orthonormal basis and \( \{g_j\}_{j} \) is a sequence of non-negative, real numbers. Then \( \{|e_j\rangle\}_{j} \) is an eigenbasis for \( G \) with corresponding eigenvalues \( \{g_j\}_{j} \).
Definition 11 The \( n \)th extension \( \overline{G}_n \) of an energy observable \( G \) is defined as
\[
\overline{G}_n \equiv \frac{1}{n} [G \otimes I \otimes \cdots \otimes I + \cdots + I \otimes \cdots \otimes I \otimes G],
\]
where \( n \) is the number of factors in each tensor product above.

Then the non-asymptotic, energy-constrained classical capacity \( C(\mathcal{N}_{A\rightarrow B}, G, P, n, \varepsilon) \) is defined exactly as it was previously in Section 6.2, except that we demand that
\[
\frac{1}{M} \sum_{m \in M} \text{Tr}\{ \overline{G}_n \rho_{A^n}^m \} \leq P,
\]
(6.35)
for a real \( P \in [0, \infty) \). Similarly, the non-asymptotic, energy-constrained entanglement-assisted classical capacity \( C_{EA}(\mathcal{N}_{A\rightarrow B}, G, P, n, \varepsilon) \) is defined exactly as it was previously in Section 6.2, except that we demand that
\[
\frac{1}{M} \sum_{m \in M} \text{Tr}\{ (\overline{G}_n \otimes I_{B'}) \mathcal{E}_m^{A'\rightarrow A^n}(\Psi_{A'B'}) \} \leq P.
\]
(6.36)

One could alternatively demand that the energy constraint hold for every codeword, not just on average. Note that we recover the usual notion of capacity (unconstrained) by taking \( G = I \) and setting \( P = 1 \).

An advantage of the approach given in the proof of Theorem 7 is that we easily obtain a lower bound on the second-order coding rate for energy-constrained entanglement-assisted classical communication over a quantum channel:

Theorem 12 Let \( \mathcal{H}_A, \mathcal{H}_B, \) and \( \mathcal{H}_R \) be separable Hilbert spaces. Let \( \varepsilon \in (0, 1) \). Let \( G \) be an energy observable, and let \( P \in [0, \infty) \). Let \( \mathcal{N}_{A\rightarrow B} \) be a quantum channel, taking \( \mathcal{D}(\mathcal{H}_A) \) to \( \mathcal{D}(\mathcal{H}_B) \). Then the following bound holds:
\[
C_{EA}(\mathcal{N}_{A\rightarrow B}, G, P, n, \varepsilon) \geq I(R; B)_{\xi} + \sqrt{\frac{1}{n} V(R; B)_{\xi} \Phi^{-1}(\varepsilon)} + O\left(\frac{1}{n \log n}\right),
\]
(6.37)
where \( \xi_{RB} \equiv N_{A\rightarrow B}(\rho_{RA}) \) and \( \rho_{RA} \in \mathcal{D}(\mathcal{H}_R \otimes \mathcal{H}_A) \) is a bipartite state such that
\[
I(R; B)_{\xi}, \quad V(R; B)_{\xi}, \quad T(R; B)_{\xi} < \infty, \quad V(R; B)_{\xi} > 0,
\]
(6.38)
and
\[
\text{Tr}\{ G \rho_A \} \leq P.
\]
(6.39)
In the above, we have the mutual information, mutual information variance, and another quantity:
\[
I(R; B)_{\xi} \equiv D(\xi_{RB} || \xi_R \otimes \xi_B),
\]
(6.40)
\[
V(R; B)_{\xi} \equiv V(\xi_{RB} || \xi_R \otimes \xi_B),
\]
(6.41)
\[
T(R; B)_{\xi} \equiv T(\xi_{RB} || \xi_R \otimes \xi_B).
\]
(6.42)
Proof. Let $\zeta_{RA}$ be a state satisfying the conditions stated above. Then the claim follows by applying Theorem 7, picking $\eta = 1/\sqrt{n}$, and invoking the expansion in (6.9). \[\square\]

The proof given above is quite simple once all of the relevant components are in place (namely, the quantum union bound from Theorem 1, position-based coding [AJW17], and the expansion in (6.9)). This is to be contrasted with the approach taken in [Hol03, Hol04], in which the energy-constrained entanglement-assisted classical capacity was identified. Not only can we argue to have a simpler approach for the achievability part, but our method also delivers a lower bound on the second-order coding rate. An important open question remaining however is to determine whether this lower bound on the second-order coding rate is tight. To our knowledge, this tightness has only been shown for finite-dimensional channels that are covariant [DTW16].

We note here that the bound in Theorem 12 applies to the practically relevant case of bosonic Gaussian channels [Ser17]. The energy-constrained entanglement-assisted classical capacity of these channels was identified in [HW01, Hol03, GLMS03, Hol04]. The additive-noise, thermal, and amplifier channels are of major interest for applications, as stressed in [HGI12, Hol12]. It is known that the energy-constrained, entanglement-assisted capacity formula for these channels is achieved by a two-mode squeezed vacuum state, whose reduction to the channel input system has an average photon number meeting the desired photon number constraint. Thus, we could evaluate the lower bound in Theorem 12 by taking $\rho_{RA}$ therein to be the two-mode squeezed vacuum and then applying the formula from [WTLB17] to evaluate the mutual information variance $V(R; B)_\zeta$, while noting that the quantity $T(R; B)_\zeta$ is finite for any finite-energy state, as proven in [KW17, Appendix D].

We end this section on a different note, by remarking that the same argument as above gives a non-trivial lower bound on the second-order coding rate for energy-constrained classical communication with randomness assistance. However, it remains open to determine whether this rate is achievable without the assistance of randomness. It is also open to extend the result to a continuous (uncountable) index set $X$. We suspect that these extensions should be possible but leave it for future work.

7 Conclusion

In this paper, we proved Theorem 1, which improves Gao’s quantum union bound to include a tunable parameter $c > 0$ that plays a role similar to the tunable parameter available in the Hayashi–Nagaoka inequality from [HN03, Lemma 2]. An advantage of the proof of Theorem 1 is that it is elementary, relying only on basic properties of projectors, the Pythagorean theorem, and the Cauchy–Schwarz inequality. Due to our improvement, the quantum union bound can now be employed in a wider variety of scenarios. As an example application, we showed how to achieve a lower bound on the second-order coding rate for classical communication over a quantum channel by employing a sequential decoding strategy.

For future directions, we think it would be interesting to determine whether the improved bound in Theorem 1 would find application in any of the works in which Gao’s bound has been used, including quantum algorithms [MW16, Aar16, HLM17], quantum complexity theory [Aar16, WHKN18], and Hamiltonian complexity theory [AAV16, KL18]. We also wonder whether Theorem 1 could be useful outside of quantum information, for example in the analysis of projection algorithms.
