COMPATIBLE FILTERS FOR ISOMORPHISM TESTING

JOSHUA MAGLIONE

Abstract. Like the lower central series of a nilpotent group, filters generalize the connection between nilpotent groups and graded Lie rings. However, unlike the case with the lower central series, the associated graded Lie ring may share few features with the original group: e.g. the associated Lie ring may be trivial or arbitrarily large. We determine properties of filters such that the Lie ring and group are in bijection. We prove that, under such conditions, every isomorphism between groups is induced by an isomorphism between graded Lie rings.

1. Introduction

There are several progressively more general methods to associate a Lie ring to a nilpotent group, see [H2, K2]. While the applications vary, a common theme is to make group-theoretic problems easier by employing linear algebra in the context of the Lie ring. In particular, this helps in the study of isomorphism and automorphism problems for groups [ELGO, H1, K1, M1, M3]. A recent development, described in [W], generalizes approaches from Magnus [M5, M6] and Lazard [L]. J.B. Wilson defined filters as a means to allow refinements of the well-studied upper and lower central series associated to nilpotent groups, while still connected to a graded Lie ring. We describe a process of lifting isomorphisms between the associated Lie rings to (potential) isomorphisms between the groups, which has application to isomorphism testing of finite $p$-groups, i.e. groups of order $p^n$ for a prime $p$.

Throughout, we assume that $G$ is a finitely generated nilpotent group.

Definition 1.1. For a finitely generated, commutative, pre-ordered monoid, with minimal element 0, $M = (M, +, 0, \preceq)$ and a group $G$, an $(M, G)$-filter is a function from $M$ into the set of normal subgroups of $G$ such that for all $s, t \in M$,

$$[\phi_s, \phi_t] \leq \phi_{s+t} \quad s \preceq t \implies \phi_s \geq \phi_t.$$ 

An $(M, G)$-filter $\phi$ is finite if $\operatorname{im}(\phi)$ is a finite set, and $\phi$ is non-degenerate if $\langle \phi_s \mid s \neq 0 \rangle = G$ and $\bigcap_{s \in M} \phi_s = 1$. We abbreviate “finitely generated, commutative, pre-ordered monoid, with minimal element 0,” by fgc$p_0$. The boundary filter of an $(M, G)$-filter $\phi$, denoted $\partial \phi$, is the $(M, G)$-filter such that for all $s \in M$, $\partial \phi_s = \langle \phi_{s+t} \mid t \neq 0 \rangle$. The abelian group

$$L(\phi) = \bigoplus_{s \in M \setminus \{0\}} \phi_s/\partial \phi_s$$

is an $M$-graded Lie ring under the following product on homogeneous components, $[\partial \phi_s x, \partial \phi_t y] = \partial \phi_{s+t} x^{-1} y^{-1} x y$, see [M4, W] for details.

Date: August 28, 2019.

This research was supported in part by NSF grant DMS 1620454.
Theorem A. If $\phi$ is a finite, non-degenerate $(M, G)$-filter, with partial order $\leq$, then there exists a fgp monoid $M'$, an $(M', G)$-filter $\theta$, a graded generating set $Y$ for the abelian group $L(\theta)$, and a surjection of sets $\pi_Y : L(\theta) \to G$ such that $\text{im}(\phi) \subseteq \text{im}(\theta)$ and $\pi_Y(Y)$ generates $G$.

The requirement that $\leq$ be a partial order can be replaced with additional conditions on $\phi$. In Section 4 a strong statement is proved, and the concept of an inertia-free filter is introduced. The filter $\theta$ defined in Theorem A is inertia-free, and it is this property that guarantees $\pi_Y$ is a surjection. In the subsequent section we discuss what further properties of an inertia-free filter are required to ensure that $\pi_Y$ is injective. Then generating sets for $G$ that are compatible with the lattice structure of $\phi$ are introduced.

The closure of $\text{im}(\phi)$ under intersections and products will be denoted by $\text{Lat}(\phi)$.

Definition 1.2. An $(M, G)$-filter $\phi$ is faithful if $\phi$ is non-degenerate and there exists $X \subseteq G$ such that

(i) for all $H \in \text{Lat}(\phi)$, \( H \cap X = H \),

(ii) the map $H \mapsto H \cap X$ is a lattice embedding from $\text{Lat}(\phi)$ into the subset lattice of $X$, and

(iii) for each $x \in X$, there exists a unique $s \in M$ such that $x \in \phi_s \setminus \partial \phi_s$.

As $G$ is a finitely generated nilpotent group, it is a polycyclic group. Every polycyclic group $G$ has a polycyclic generating sequence (pcgs) $(a_1, \ldots, a_n)$ such that for $G_i = \langle a_i, \ldots, a_n \rangle$, the factors $G_i/G_{i+1}$ are cyclic for all $i \in \{1, \ldots, n-1\}$, see for example [S2, Chapter 9]. Along with the map given in Theorem A, we use properties of pcgs to prove the next theorem.

Theorem B. If $\phi$ is a finite, faithful, and inertia-free $(M, G)$-filter, then there exists a bijection between $L(\phi)$ and $G$ that maps a pcgs of $L(\phi)$, as an abelian group, to a pcgs of $G$.

In particular, if the filter $\theta$ from Theorem A is faithful, then the map $\pi_Y$ is a bijection. When the monoid $M$ is cyclic, like in the $(\mathbb{N}, G)$-filter $\gamma$ given by the lower central series with $\gamma_0 = \gamma_1 = G$, every non-degenerate filter is faithful and inertia-free. The structure of cyclic commutative monoids is known, see Proposition 2.1. Also, when the monoid $M$ is totally ordered, one can construct faithful, inertia-free filters in a simpler way, see [M1]. Therefore, we are interested in pre-orders that are not total orders, but we do not require this.

We are interested in lifting isomorphisms between graded Lie rings to isomorphisms between groups and Theorem B is critical to that objective. For an $(M, G)$-filter $\phi$, denote its minimal subgroup by $m_\phi = \bigcap_{s \in M} \phi_s$. We define the border set of $\phi$ to be

\[ \mathcal{I}_\phi = \{ s \in M : \partial \phi_s \neq \phi_s \text{ or } \phi_s = m_\phi \}. \]

Note that if $\phi$ is non-degenerate, then $L(\phi) \cong \bigoplus_{s \in \mathcal{I}_\phi} \phi_s / \partial \phi_s$ as abelian groups because $\phi_0 = \partial \phi_0$.

Suppose for each $i \in \{1, 2\}$, $\phi^{(i)}$ is a characteristic $(M, G_i)$-filter: for $s \in M$, each $\phi_s^{(i)}$ is characteristic (i.e. fixed by every automorphism) in $G_i$. For each $s \in M \setminus \{0\}$ choose a transversal $r_s^{(i)} : \phi_s^{(i)} / \partial \phi_s^{(i)} \to \phi_s^{(i)}$. Suppose $\alpha : L(\phi^{(1)}) \to L(\phi^{(2)})$ is an $M$-graded Lie ring isomorphism. That is, $\alpha$ is an isomorphism of Lie rings and for each $s \in M$, $L_s(\phi^{(1)}) \alpha = L_s(\phi^{(2)})$. For each $s \in M$, let $\mathcal{X}_s$ be the image of a
generating set for $L_s(\phi^{(1)})$ under $r_s^{(1)}$. Define a partial lift of $\alpha$ to be the function $\beta : \bigcup_{s \in I_{\phi^{(1)}}} X_s^s \to G_2$ such that if $x \in X_s^s$, then

$$x \mapsto (\partial \phi^{(1)}_s x) \alpha r_s^{(2)}.$$ 

If $\beta$ induces a well-defined group homomorphism, then such a homomorphism is called a lift of $\alpha$. Not every graded Lie ring isomorphism has a lift.

We have two main obstructions that we describe with examples in Section 2.3. Suppose, for the moment, $G = G_1 = G_2$. There exist $(M,G)$-filters $\phi$ such that $L(\phi) = 0$. In such a case $I_\phi = \emptyset$, so there is not even a partial lift function; Theorem A addresses this issue. On the other hand, if for example $G$ is finite, then there exist $(M,G)$-filters $\phi$ where the order of $L(\phi)$ can be made arbitrarily large. In this case, a partial lift may not even induce a well-defined function, and this is addressed by Theorem B. In fact these two examples illustrate the major issues to constructing potential lifts from $M$-graded Lie ring isomorphisms.

Because we consider $M$-graded isomorphisms between Lie rings, we require a compatibility condition on our filters.

**Definition 1.3.** Suppose $\phi^{(i)}$ are characteristic $(M,G_i)$-filters, for $i \in \{1,2\}$. We say the pair of filters $\phi^{(i)}$ are $M$-determined if the existence of an isomorphism $\beta : G_1 \to G_2$ implies that for all $s \in M$, $\phi^{(1)}_s = \phi^{(2)}_s$.

The existence of one such isomorphism $\beta$ implies that every isomorphism between $G_1$ and $G_2$ satisfies the $M$-determined condition since the filters are characteristic. Every pair of characteristic filters constructed by a recipe is $M$-determined. For example, pairs of filters constructed via the lower central series or lower $p$-central series are $N$-determined filters, and pairs of filters from [M2] and from the examples in [M1] are $N^d$-determined, for some integer $d$. We state, at last, the main result concerning lifts of $M$-graded Lie ring isomorphisms, whose proof follows from Theorem B.

**Theorem C.** Suppose $G_1 \cong G_2$, and let $\phi^{(i)}$ be a finite and characteristic $(M,G_i)$-filter for $i \in \{1,2\}$. In addition, for each $i$ suppose $\phi^{(i)}$ is faithful and inertia-free. If $\phi^{(1)}$ and $\phi^{(2)}$ are $M$-determined, then every isomorphism $\beta : G_1 \to G_2$ is a lift of some $\alpha : L(\phi^{(1)}) \to L(\phi^{(2)})$.

One of the driving motivations for Theorem C comes from the isomorphism problem of groups\(^1\), see for example [BCQ,BCGQ,GQ]. Algorithms to decide isomorphism or compute automorphism groups of finite nilpotent groups rely on induction and the ability to construct characteristic subgroups [CH,ELGO,O]. The algorithms for finite nilpotent groups reduce to finite $p$-groups. The difficult case is when $G$ has precisely three known characteristic subgroups, namely $G$, $G'$, and $\langle 1 \rangle$.

Because of Theorem B, we can leverage the structure of the Lie algebra $L(\phi)$ to constrain the possible automorphisms of $G$. For example, if each $\phi_s$ is characteristic in $G$, then each automorphism of $G$ induces an $M$-graded automorphism of $L(\phi)$. If it is more efficient to calculate graded Lie automorphisms of $L(\phi)$ than to construct $\text{Aut}(G)$ recursively by going down the lower $p$-central series, this may be a starting point to construct automorphisms of $G$. For example, there is a large family of

\(^1\)Filters naturally apply to rings and algebras as well, but our focus is on groups.
graded algebras \( L \) such that the graded Lie automorphisms can be constructed in time polynomial in \( |L| \), see [BOW] for details.

Filters—in particular, their associated \( M \)-graded Lie rings—are a significant resource for constructing characteristic subgroups efficiently, see the examples in Section 7 and [M1, M2, W]. The main benefit is that the inclusion of one new subgroup in a filter can drastically change the filter and the associated graded Lie algebra. More work is needed to understand how to best refine filters, but this opens the door to efficient recursive methods, uncovering characteristic subgroups. The characteristic features of the associated \( M \)-graded Lie rings offer exponential speedups in the realm of isomorphism testing for finite \( p \)-groups.

1.1. Overview. Section 2 details preliminary definitions and theorems needed for the rest of the paper. We include examples of filters referenced in the introduction. In Section 3 we prove statements about \( \mathbb{g} \mathbb{c} \mathbb{p} \mathbb{d} \) monoids that are used in Section 4 and in Section 4, we provide a general construction for filters for which there exists a surjection from the Lie ring to the group, thereby proving Theorem A. In Sections 5 and 6 we turn to desirable combinatorial properties from lattices. We investigate structural properties of faithful and inertia-free filters, and we prove Theorems B and C. We close with some examples in Section 7.

2. Preliminaries

2.1. Notation. For a set \( \mathcal{X} \), we let \( 2^\mathcal{X} \) denote the power set of \( \mathcal{X} \). For a group \( G \), let \( \text{Nor}(G) \) denote the set of normal subgroups of \( G \). We denote the set of nonnegative integers by \( \mathbb{N} \).

For \( x, y \in G \), set \( [x] = x \) and \( [x, y] = x^{-1}y^{-1}xy \). For \( x_1, \ldots, x_n \in G \), we recursively define \( [x_1, \ldots, x_n] = [[x_1, \ldots, x_{n-1}], x_n] \). We say the commutator \([x_1, \ldots, x_n]\) has \textit{weight} \( n \). For \( X, Y \subseteq G \), set \([X, Y] = \{[x, y] : x \in X, y \in Y\} \); we apply the same recursive formula for commutators of subsets of weight \( n \). Let \( \gamma_1 = G \) and for \( i \geq 1 \), set \( \gamma_{i+1} = [\gamma_i, G] \). A nilpotent group has class \( c \) if \( \gamma_c > \gamma_{c+1} = 1 \).

A commutative monoid \( \langle M, +, 0 \rangle \) is pre-ordered by a pre-order \( \preceq \) if \( s \preceq t \) and \( s' \preceq t' \) imply that \( s + s' \preceq t + t' \). Throughout, we will use \( \preceq \) by default for the pre-order on \( M \). For \( s, t \in M \), we let \( s \prec t \) denote \( s \preceq t \) and \( s \neq t \) (in general \( \prec \) is not transitive). An element \( s \in M \) is a \textit{unit} if there exists \( t \in M \) such that \( s + t = 0 \). For \( s, t \in M \), we let \( s \parallel t \) denote the case when \( s \) and \( t \) are incomparable under \( \preceq \), i.e. \( s \not\preceq t \) and \( t \not\preceq s \). A subset \( S \subseteq M \) is a \( \preceq \)-\textit{chain} if \( S \) is totally ordered with respect to \( \preceq \). Similarly, \( S \subseteq M \) is an \( \preceq \)-\textit{antichain} if every distinct pair of elements of \( S \) is incomparable.

A partially ordered set \( L \) is a \textit{lattice} if for all \( x, y \in L \) both \( x \cap y \in L \) and \( x \cup y \in L \). A partially ordered set \( L \) is a \textit{complete lattice} if for all \( X \subseteq L \) both \( \bigcap_{x \in X} x \in L \) and \( \bigcup_{x \in X} x \in L \). All of our lattices are sublattices of either \( 2^\mathcal{X} \) or \( \text{Nor}(G) \). Therefore, \( \cap \) and \( \cup \) are understood to be either set or subgroup intersection and union (join), respectively.

2.2. Monoids and pre-orders. An important pre-order on monoids is the \textit{algebraic pre-order} denoted \( \preceq^+ \) where for \( s, t \in M \),

\[
 s \preceq^+ t \iff \exists u \in M, s + u = t.
\]

Every commutative monoid is pre-ordered by \( \preceq^+ \). Another pre-order that we will use in examples later is the lexicographical (abbreviated lex) pre-order. Suppose
(\(M, \leq\)) and (\(N, \preceq\)) are two pre-ordered commutative monoids. The lex order of \(M \times N\), denoted \(\leq_{\ell}\), is defined as follows. For all \((m, n), (m', n') \in M \times N\),
\[(m, n) \leq_{\ell} (m', n') \iff (m < m') \text{ or } (m = m' \text{ and } n \preceq n').\]

It is possible to describe all cyclic monoids up to isomorphism. Let \(r, s \in \mathbb{N}\), \(s \geq 1\) (these are the index and period, respectively). Define a congruence \(\sim\) on \(\mathbb{N}\) where \(i, j \in \mathbb{N}\),
\[i \sim j \iff \begin{cases} i \equiv j \pmod{s} & \text{if } i, j \geq r, \\ i = j & \text{otherwise.} \end{cases}\]
Define \(C_{r,s} = \mathbb{N}/\sim\) with addition induced from \(\mathbb{N}\), and note that \(|C_{r,s}| = r + s\).

**Figure 1.** The Cayley graph of the cyclic monoid \(C_{r,s}\), with generating set \(\{1\}\).

**Proposition 2.1** ([G, Proposition 5.8]). If \(M\) is a cyclic monoid, then either \(M \cong \mathbb{N}\) or there exist \(r, s \in \mathbb{N}\) such that \(M \cong C_{r,s}\).

**2.3. Examples of filters.** We provide some explicit examples of properties we want to avoid. To emphasize that these properties are inherently concerned with the monoid, we use a similar group in all these examples. For a ring \(R\), we denote the Heisenberg group over \(R\) by
\[H(R) = \left\{ \begin{pmatrix} 1 & a & c \\ 1 & b & 1 \\ & & 1 \end{pmatrix} \mid a, b, c \in R \right\}.\]

**Example 2.2.** Here we construct a filter such that the associated Lie ring is trivial. Let \(G = H(\mathbb{Z})\), and let \(M = (\mathbb{N}^2, \leq_{\ell})\), ordered by the lex ordering. For \(s \in M\),
\[\phi_s = \begin{cases} G & s \prec_{\ell} (2, 0), \\ G' & (2, 0) \preceq_{\ell} s \prec_{\ell} (3, 0), \\ 1 & (3, 0) \preceq_{\ell} s. \end{cases}\]
For all \(s \in M\), \(\phi_s = \phi_{s+(0,1)}\). Therefore, for all \(s \in M\), \(\partial \phi_s = \phi_s\), so \(L(\phi) = 0\). In fact, \(\phi\) is the resulting filter when applied to the generation formula in [W], with \(X = \{s \in M \mid s \prec_{\ell} (2, 0)\}\) and \(\pi : X \to \{G\}\) the constant function.

**Example 2.3.** We construct a family of filters for a fixed finite group \(G\) whose associated Lie algebras are of arbitrarily large dimension. Let \(K\) be a finite field, \(G = H(K)\) and \(M = (\mathbb{N}^2, \preceq_{\times})\). Fix \(n \geq 2\). For \(s = (i, j) \in M\) define
\[\phi_s = \begin{cases} G & i + j \leq 1, \\ G' & 2 \leq i + j \leq n, \\ 1 & \text{otherwise.} \end{cases}\]
The boundary filter is given by
\[
\partial \phi_s = \begin{cases} 
G & i = j = 0, \\
G' & 1 \leq i + j \leq n - 1, \\
1 & \text{otherwise},
\end{cases}
\]
where \( s = (i, j) \in M \). It follows that \( L(\phi) \) is a \( K \)-algebra, and the dimension of \( L(\phi) \) over \( K \) is \( n + 5 \).

**Example 2.4.** We combine aspects of the Examples 2.2 and 2.3 and construct a filter where the Lie ring and group are in bijection as sets. However, no pre-image of a pcgs for the Lie ring induces a pcgs for the group.

Let \( G = H(K) \) for a finite field \( K \) and \( M = (\mathbb{N}^2, \preceq_+) \). For \( s = (i, j) \in \mathbb{N}^2 \), define
\[
\phi_s = \begin{cases} 
G & i = 0, \\
G' & i = 1 \text{ or } i + j \leq 4, \\
1 & \text{otherwise}.
\end{cases}
\]
The border set is \( I_\phi = \{(4, 0), (3, 1), (2, 2)\} \), so as \( K \)-vector spaces \( L(\phi) \cong K^3 \). Therefore, \( G \) and \( L(\phi) \) are in bijection, but \( L(\phi) = (G')^3 \) is an abelian Lie algebra.

In particular, every pre-image of a pcgs for \( L(\phi) \) will be contained in the center of \( G \).

**Example 2.5.** We construct an example that conspicuously hides subgroups. Let \( M = C_{3,1} \times C_{1,1} \) be the monoid with pre-order given by the algebraic order \( \preceq + \). Let \( G = H(\mathbb{Z}) \), and suppose \( K \triangleleft G' \) has index 2 in \( G' \). Define an \((M, G)\)-filter \( \phi \) such that, for \( s = (i, j) \in M \),
\[
\phi_s = \begin{cases} 
G & i = j = 0, \\
\gamma_i(G) & i > j = 0, \\
K & i \leq 2, j = 1, \\
1 & i = 3, j = 1.
\end{cases}
\]
The boundary filter is then
\[
\partial \phi_s = \begin{cases} 
G & i = j = 0, \\
G' & (i, j) = (1, 0), \\
1 & i = 3, \\
K & \text{otherwise}.
\end{cases}
\]
Therefore, as abelian groups \( L(\phi) \cong \mathbb{Z}^2 \oplus \mathbb{Z}/2\mathbb{Z} \). This filter also serves as an example of a filter for which our construction in Section 4 cannot be applied. Since the order on \( M \) is a partial order, Theorem A can still be applied to this filter, but we need to change the monoid.

### 3. Monoids associated to filters

The assumption that 0 is minimal is important for filters. It also restricts the possible monoids we consider as well. Recall, \( s \in M \) is a unit of \( M \) if there exists \( t \in M \) such that \( s + t = 0 \). A commutative monoid \( M \) is conical if \( s + t = 0 \) implies \( s = t = 0 \), for all \( s, t \in M \).

**Lemma 3.1.** Suppose \( M \) is a commutative, pre-ordered monoid. If 0 is the minimal element of \( M \), then

(i) \( M \) is conical,
The filter from Example 2.2.

(A) The filter from Example 2.3, for $n = 3$.

(B) The filter from Example 2.4.

(C) The filter from Example 2.5.

\begin{align*}
0 & \ 1 & \ 2 & \ 3 & \ 4 \\
3 & G & G & G' & 1 \\
2 & G' & G & 1 \\
1 & G & G' & 1 \\
0 & G & G' & 1 \\
0 & 1 & 2 & 3 & 4 \\
4 & G' & 1 & 1 & 1 \\
3 & G' & 1 & 1 & 1 \\
2 & G' & 1 & 1 & 1 \\
1 & G' & 1 & 1 & 1 \\
0 & G' & 1 & 1 & 1 \\
0 & 1 & 2 & 3 & 4 \\
\end{align*}

(\begin{figure}
\centering
\begin{tabular}{|c|c|c|c|c|}
\hline
0 & 1 & 2 & 3 & 4 \\
G & G & G' & 1 & 1 \\
G' & G & 1 & 1 & 1 \\
G & G' & 1 & 1 & 1 \\
0 & G & G' & 1 & 1 \\
0 & 1 & 2 & 3 & 4 \\
\hline
\end{tabular}
\caption{The plots of every filter in Section 2.3.}
\end{figure}\

(ii) the only unit of $M$ is 0, and
(iii) for all $s,t \in M$, if $s \preceq t$, then $s \preceq t$.

Proof. All three statements follow from the formula: $s = s + 0 \preceq s + u = t$. □

By Proposition 2.1, every pre-order $\preceq$ is equal to $\preceq_+$ in cyclic fgcp\textsubscript{0} monoids. We will need to show that in a fgcp\textsubscript{0} monoid $M$, there is no infinite set of $\preceq_+$-antichains. To do this, we will reduce the statement to the following lemma, which follows from the pigeonhole principle.

Lemma 3.2. Let $m \in \mathbb{N}$. If $S \subseteq \mathbb{N}^m$ such that $S$ is an $\preceq_+$-antichain, then $|S| < \infty$.

Proof. The statement follows if $m = 1$, so we assume $m \geq 2$. If $s = (s_1, \ldots, s_m) \in S$, then for each $k$, define $R_k(s) = \{(t_1, \ldots, t_m) \in \mathbb{N}^m \mid t_k < s_k\}$. Because $S$ is an $\preceq_+$-antichain, $S \setminus \{s\} \subseteq \bigcup_{k=1}^{m} R_k(s)$. If for each $k$, the intersection $I_k = (S \setminus \{s\}) \cap R_k(s)$ is finite, then $S$ is finite and we are done. Otherwise, there exists $k$ such that $I_k$ is infinite. Again, by the pigeonhole principle, there exists $r_k < s_k$ such that $\{(t_1, \ldots, t_m) \in I_k \mid t_k = r_k\}$ is infinite. This implies the existence of an infinite $\preceq_+$-antichain in $\mathbb{N}^{m-1}$. Since this does not hold for $m = 1$, $S$ is finite. □

Definition 3.3. Suppose $M$ is a commutative monoid. An element $s \in M$ is unit-cancellative if $s + t = s$ implies that $t$ is a unit. We say $s \in M$ is a sink if it is not unit-cancellative.

Definition 3.4. In a commutative monoid $M$, an element $s \in M$ is an atom if $s = t + u$ implies that either $t = 0$ or $u = 0$. The next proposition is critical to a number of statements about the structure of $(M,G)$-filters. We prove a special finiteness property on the set of unit-cancellative elements of a fgcp\textsubscript{0} monoid $M$. The property is well-studied in the context of non-unique factorization in rings of integers of number fields, see [GHK, Sections 1.1 & 1.5].
Proposition 3.5. If \( M \) is a \( \text{fgcp}_0 \) monoid, then there exists a finite set of unit-cancellative atoms \( \mathcal{U} \subseteq M \) that generates every unit-cancellative element of \( M \).

Proof. First, we prove that if \( s \in M \) is unit-cancellative and \( s = t + u \) for \( t, u \in M \), then \( t \) and \( u \) are unit-cancellative. Suppose \( t + t' = t \) and \( u + u' = u \). Then, \( s = t + u = t + t' + u + u' = s + t' + u' \).

Since the only unit of \( M \) is 0 by Lemma 3.1, it follows that \( t' + u' = 0 \). Moreover, since \( M \) is conical, \( t' = u' = 0 \). Thus, the unit-cancellative elements of \( M \) decompose as a (possibly trivial) sum of unit-cancellative elements.

Since \( M \) is finitely generated, let \( S \) be a minimal generating set for \( M \), and suppose \( \mathcal{U} \subseteq S \) is the subset of unit-cancellative elements of \( S \). From the argument above, if \( s \in M \) is unit-cancellative, then \( s \) is contained in the monoid generated by \( \mathcal{U} \).

Now we show that for a fixed \( u \in \mathcal{U} \), if \( s + t = u \), then either \( s = 0 \) or \( t = 0 \). By above, if \( s + t = u \), then both \( s \) and \( t \) are unit-cancellative. Since the only unit of \( M \) is 0, by Lemma 3.1, there exist \( (a_v)_{v \in \mathcal{U}}, (b_v)_{v \in \mathcal{U}} \in \mathbb{N}^{(\mathcal{U})} \) such that

\[
s = \sum_{v \in \mathcal{U}} a_v \cdot v, \quad t = \sum_{v \in \mathcal{U}} b_v \cdot v.
\]

By minimality of \( S \) and \( \mathcal{U} \), either \( s \) or \( t \) is not generated by \( \mathcal{U} \setminus \{u\} \), so in particular either \( a_u \) or \( b_u \) is nonzero. Suppose \( b_u \neq 0 \). Therefore, \( b_u - 1 \in \mathbb{N} \), and

\[
u = s + t = \sum_{v \in \mathcal{U}} (a_v + b_v)v = \sum_{v \in \mathcal{U} \setminus \{u\}} (a_v + b_v)v + (a_u + b_u - 1)u + u,
\]

this implies that \( a_v + b_v = 0 \) for all \( v \in \mathcal{U} \setminus \{u\} \) and \( a_u + b_u - 1 = 0 \). Hence, \( s = 0 \).

We extend Proposition 3.5 a little further. Because there exists a set of unit-cancellative atoms, there are only finitely many distinct ways to express a unit-cancellative element as a sum of non-zero elements.

Corollary 3.6. If \( M \) is a \( \text{fgcp}_0 \) monoid and \( s \in M \) is unit-cancellative, then the following set is finite:

\[
\mathcal{Z}(s) = \left\{ (t_1, \ldots, t_k) \in (M \setminus 0)^k \left| \begin{array}{l} k \in \mathbb{N}, \sum_{i=1}^{k} t_i = s \end{array} \right. \right\}.
\]

Proof. By Proposition 3.5, it follows that \( \mathcal{Z}(s) \) is finite if, and only if,

\[
\mathcal{N}(s) = \left\{ (n_u)_{u \in \mathcal{U}} \in \mathbb{N}^{(\mathcal{U})} \left| \begin{array}{l} \sum_{u \in \mathcal{U}} n_u \cdot u = s \end{array} \right. \right\}
\]

is finite. Suppose \( \mathcal{N}(s) \) is infinite. By Lemma 3.2, since \( \mathcal{U} \) is finite, there exist distinct \( (n_u)_{u \in \mathcal{U}}, (n'_u)_{u \in \mathcal{U}} \in \mathcal{N}(s) \) such that \( n_u \leq n'_u \), for all \( u \in \mathcal{U} \). This implies that \( d_u = n'_u - n_u \in \mathbb{N} \) and for some \( u \in \mathcal{U} \), \( d_u \geq 1 \). But since \( s \) is unit-cancellative,

\[
\sum_{u \in \mathcal{U}} n_u \cdot u = s + \sum_{u \in \mathcal{U}} d_u \cdot u = \sum_{u \in \mathcal{U}} n'_u \cdot u
\]

Thus, for all \( u \in \mathcal{U} \), \( d_u = 0 \), a contradiction. Hence, \( \mathcal{N}(s) \) and \( \mathcal{Z}(s) \) are finite.

We are in a position to prove a critical statement about sequences of unit-cancellative elements in \( \text{fgcp}_0 \) monoids that will be used in the next section.
Corollary 3.7. If $M$ is a fgc$\pi_0$ monoid, then

(i) every descending $\preceq_+\cdot$-chain of unit-cancellative elements stabilizes, and

(ii) every $\preceq_+\cdot$-antichain of unit-cancellative elements is finite.

Proof. For (i), if $s_0 \geq_+ s_1 \geq_+ \cdots$, then there exists $t_i \in \mathbb{N}$ such that $s_{i-1} = s_i + t_i$ for $i \geq 1$. Therefore, $s_0 = s_k + \sum_{j=1}^{k} t_j$, for every $k \geq 1$. By Corollary 3.6, all but finitely many $t_i = 0$.

For (ii), suppose $\{s_i\}_{i \geq 1} \subseteq M$ is an $\preceq_+\cdot$-antichain. Let $\mathcal{U} \subseteq M$ be the unit-cancellative atoms of $M$. An infinite $\preceq_+\cdot$-antichain of unit-cancellative elements in $M$ is equivalent to an infinite $\preceq_+\cdot$-antichain in $\mathbb{N}^{\mathcal{U}}$. Since $\mathcal{U}$ is finite, this is impossible by Lemma 3.2.

Remark 3.8. The Infinite Ramsey Theorem along with Corollary 3.7 imply the following statement about $(M,G)$-filters $\phi$. The set $\text{im}(\phi)$ is finite if, and only if, $\text{im}(\phi)$ satisfies the descending chain condition.

4. INERT SUBGROUPS OF FILTERS

In Example 2.2, the filter $\phi$ has the property that $L(\phi) = 0$. This is an extreme example, but this illustrates a property we want to repair. Throughout, we fix an $(M,G)$-filter $\phi$. Recall, the minimal subgroup of $\phi$ is denoted by $m_\phi$. Define a collection of ascending subsets of $\text{im}(\phi) \cup \{m_\phi\}$ as follows. Set $\mathcal{B}_0 = \{m_\phi\}$, and for $i \geq 0$, define

$$\mathcal{B}_{i+1} = \mathcal{B}_0 \cup \{\phi_s | (\exists B \subseteq \mathcal{B}_i, \partial_\phi s = (B))\}.$$

If $H \in \mathcal{B}_i \setminus \mathcal{B}_{i-1}$, then $i$ is a measure of how far away $H$ is from $m_\phi$ by taking boundaries. Set

$$\mathcal{B} = \bigcup_{i \geq 0} \mathcal{B}_i.$$

With this, we are able to define inert subgroups precisely.

Definition 4.1. A subgroup $H$ is an inert subgroup of $\phi$ if $H \in \text{im}(\phi) \setminus \mathcal{B}$. A filter $\phi$ is inertia-free if $\mathcal{B} = \text{im}(\phi)$.

Problems can arise, for example, when a subset $S \subseteq M \setminus \{0\}$ forms a group under $+$ (with identity different from $0$). Recall that $s \in M$ is unit-cancellative if $s + t = s$ implies $t = 0$, cf. Lemma 3.1 and Definition 3.3.

Definition 4.2. An $(M,G)$-filter $\phi$ is progressive if $\phi_s \neq m_\phi$ implies that $s$ is unit-cancellative.

From Section 2.3, Examples 2.2, 2.3, and 2.4 are progressive filters, but Example 2.5 is not progressive. By definition, $m_\phi$ is not an inert subgroup of $\phi$. We now state our main theorems for this section; the combination of which implies Theorem A.

Theorem 4.3. Suppose $\phi$ is a finite $(M,G)$-filter. If either $\phi$ is progressive or $\preceq$ is a partial order on $M$, then there exists a fgc$\pi_0$ monoid $M'$ and an inertia-free $(M',G)$-filter $\theta$ such that $\text{im}(\phi) \subseteq \text{im}(\theta)$.

Theorem 4.4. Suppose $\phi$ is a finite, non-degenerate $(M,G)$-filter. If $\phi$ is inertia-free, then there exists a graded generating set $\mathcal{Y}$ for the abelian group $L(\phi)$ and a surjection $\pi_\mathcal{Y} : L(\phi) \rightarrow G$ of sets such that $\pi_\mathcal{Y}(\mathcal{Y})$ generates $G$. 
The next proposition is critical to working with inertia in filters. In this section, it gives us a useful characterization of inert subgroups. And in the coming sections, it gives us a foothold to apply Noetherian induction on the subgroups in $\im(\phi)$.

Recall the border set of an $(M,G)$-filter $\phi$, given in (1), is denoted by $\mathcal{I}_\phi$. We characterize the inertia-free filters by showing that $\phi_s \in \mathcal{B}_n$, with $\partial \phi_s \neq \mathfrak{m}_\phi$, implies that there exists a subset $B \subseteq \mathcal{B}_{n-1}$ and $I \subseteq \mathcal{I}_\phi$ such that $B = \{ \phi_t \mid t \in I_s \}$. We do this constructively. If this property does not hold for a particular $H \in B$, then we choose a better subset $C$ where $H$ is replaced by a subset of subgroups that generate $H$. If no such choice is available, then $\phi_s$ must be an inert subgroup of $\phi$. We prove this by induction, moving up the $\mathcal{B}$-chain.

**Proposition 4.5.** Suppose $\phi$ is a finite $(M,G)$-filter. The following are equivalent.

(i) For all $s \in M$, there exists $I_s \subseteq \mathcal{I}_\phi$ such that $\partial \phi_s = \langle \phi_t \mid t \in I_s \rangle$.

(ii) $\im(\phi) = \mathcal{B}$.

**Proof.** (i) $\implies$ (ii): Suppose, via contradiction, $\phi_s \notin \mathcal{B}$. Since $\phi$ is finite, we assume $\phi_s$ is minimal. By the assumption, there exists $I_s \subseteq \mathcal{I}_\phi$ such that $\partial \phi_s = \langle \phi_t \mid t \in I_s \rangle$. If for every $t \in I_s$, $\phi_t \in \mathcal{B}$, then $\phi_s \in \mathcal{B}$. Therefore, since $\phi_s \notin \mathcal{B}$, we choose $t \in I_s$ such that $\phi_t \notin \mathcal{B}$. Since $t \in \mathcal{I}_\phi$, $\phi_t > \partial \phi_t$, so

$$\phi_s \geq \partial \phi_s \geq \phi_t > \partial \phi_t.$$ 

By (i), there exists $I_t \subseteq \mathcal{I}_\phi$ such that $\partial \phi_t = \langle \phi_u \mid u \in I_t \rangle$. By minimality of $\phi_s$, for each $u \in I_t$, $\phi_u \in \mathcal{B}$. This implies that $\phi_t \in \mathcal{B}$, which is a contradiction. Therefore, $\phi_s \in \mathcal{B}$ for all $s \in M$.

(ii) $\implies$ (i): Conversely, suppose $\im(\phi) = \mathcal{B}$. If there exists $s \in M$ such that $\phi_s$ does not satisfy (i), then there exists a minimal $\phi_s$ that does not that satisfy (i) because $\phi$ is finite. Since $\phi_s \in \mathcal{B}$, it follows that there exists $B \subseteq \bigcup_{i \geq 0} \mathcal{B}_i$ such that $\partial \phi_s = \langle B \rangle$, and without loss of generality, we assume that $B$ is minimal. Therefore, we have two cases. Because $B$ is minimal, either $B = \{ \phi_s \}$ or $\phi_s \notin B$.

First, suppose $B = \{ \phi_s \}$, and suppose that $B \subseteq \mathcal{B}_m$, where $m$ is minimal. Therefore, there exists $C \subseteq \mathcal{B}_{m-1}$ such that $\partial \phi_s = \langle C \rangle$. By the minimality of $m$, $\phi_s \notin C$. Hence, without loss of generality, we may assume $\phi_s \notin B$. By minimality of $\phi_s$, every $\phi_t \in B$ satisfies (i). Therefore, there exists $I_t \subseteq \mathcal{I}_\phi$ such that $\partial \phi_t = \langle \phi_u \mid u \in I_t \rangle$. If $t \notin \mathcal{I}_\phi$, then $\partial \phi_t = \phi_t$. Therefore, we can replace $B$ with $C = (B \setminus \{ \phi_t \}) \cup \{ \phi_u \mid u \in I_t \}$ and $\partial \phi_s = \langle C \rangle$. Applying this to every $\phi_t \in B$ such that $t \notin \mathcal{I}_\phi$ yields a new set that satisfies (i). Therefore, this holds for all $s \in M$.

4.1. **Refreshing filters.** In this subsection we show how to remove the inertia from finite progressive $(M,G)$-filters $\phi$. To do this, we attempt to make every subgroup different from $\mathfrak{m}_\phi$ have finite support on $M$. There is a two-step process to accomplish this: first, apply a new version of the generation formula in [W], then apply a closure operation to force the order-reversing property for filters, i.e. for all $s,t \in M$, if $s \leq t$, then $\phi_s \geq \phi_t$.

Throughout the remainder of this subsection, we fix a minimal set of generators for $M$, denoted by $S$. For a fixed $E \subseteq M$, define a set of restricted partitions of $M$ as follows. If $s \in M$, then define the set of $E$-excluded partitions of $M$ to be

$$R_E(s) = \{ (r_1, \ldots, r_k) \mid k \in \mathbb{N}, r_i \in (M \setminus E) \cup S, r_1 + \cdots + r_k = s \}.$$
\[ \nu_s = \prod_{r \in R_E(s)} [\phi_r], \]

where \([\phi_r] = [\phi_{r_1}, \ldots, \phi_{r_k}]\). Observe that for every \(s \in M\), the set \(R_E(s) \neq \emptyset\) because \(M = \langle S \rangle\). As this definition depends on the sets \(S\) and \(E\), we are careful to explicitly define \(E\) whenever we use the definition in (2), but we do not explicitly mention \(S\) as it is assumed to be fixed. We refer to \(E\) as the \(\nu\)-exclusion set. The next lemma shows that \(\nu\) and \(\phi\) are equal on \((M \setminus E) \cup S\).

**Lemma 4.6.** Suppose \(\phi\) is an \((M,G)\)-filter. If \(E \subseteq M\) and \(\nu\) is defined as in (2), with \(\nu\)-exclusion set \(E\), then for all \(s \in M\), \(\nu_s \leq \phi_s\). If \(s \in (M \setminus E) \cup S\), then equality holds.

**Proof.** For \(s \in M\), let \(r \in R_E(s)\). Since \(\phi\) is an \((M,G)\)-filter, \([\phi_r] \leq \phi_s\). Therefore, \(\nu_s \leq \phi_s\), for all \(s \in M\). If \(s \in (M \setminus E) \cup S\), then \(r = (s) \in R_E(s)\). Hence, \(\nu_s \geq [\phi_r] = \phi_s\). Thus, the lemma follows. \(\square\)

Lemma 4.6 hints at the reason why \(\nu\) might fail to be an \((M,G)\)-filter: we cannot guarantee that \(\nu\) is order-reversing. We include another layer to our construction to get an \((M,G)\)-filter. Define a function \(\tilde{\nu}\) from \(M\) into \(\text{Nor}(G)\), such that

\[ \tilde{\nu}_s = \prod_{s \leq t} \nu_t = \prod_{s \leq t} \left( \prod_{r \in R_E(t)} [\phi_r] \right). \]

At this point, we pause to give a map of the remainder of the subsection. The first major destination is Proposition 4.10, which proves that \(\tilde{\nu}\) is an \((M,G)\)-filter with the properties we want. The coming four lemmas work towards this goal. After Proposition 4.10, we journey towards inertia-free. Here, we leverage Section 3 to show that, with a small change to \(\tilde{\nu}\), we get an inertia-free filter. This involves investigating sequences in \(M\).

The next lemma is a useful extension of Lemma 4.6.

**Lemma 4.7.** Suppose \(\phi\) is an \((M,G)\)-filter, \(E \subseteq M\), and \(\nu\) and \(\tilde{\nu}\) are defined with \(\nu\)-exclusion set \(E\). For \(s \in (M \setminus E) \cup S\), \(\tilde{\nu}_s = \phi_s\).

**Proof.** By Lemma 4.6, \(\nu_s = \phi_s\) for \(s \in (M \setminus E) \cup S\). Since \(\phi\) is an \((M,G)\)-filter, \(s \leq t\) implies \(\phi_s \leq \phi_t\). Since \(\nu_t \leq \phi_t\) for all \(t \in M\),

\[ \phi_s \leq \nu_s \prod_{s \leq t} \nu_t = \prod_{s \leq t} \nu_t \leq \prod_{s \leq t} \phi_t \leq \phi_s. \]

By (3), \(\phi_s \leq \tilde{\nu}_s = \prod_{s \leq t} \nu_t \leq \phi_s\). \(\square\)

The difficult part of showing \([\tilde{\nu}_s, \tilde{\nu}_t] \leq \tilde{\nu}_{s+t}\), for \(s, t \in M\), is showing this identity holds for \(\nu\), which is what we do first. The next lemma accomplishes this by applying the Three Subgroups Lemma, cf. [R, 5.1.10].

**Lemma 4.8.** Suppose \(\phi\) is an \((M,G)\)-filter. Let \(E \subseteq M\), and define \(\nu\) with \(\nu\)-exclusion set \(E\). If \(s, t \in M\), then \([\nu_s, \nu_t] \leq \nu_{s+t}\).

**Proof.** If \(s + t \notin E\), then by Lemma 4.6, \(\nu_s \leq \phi_s, \nu_t \leq \phi_t\), and \(\nu_{s+t} = \phi_{s+t}\). Since \(\phi\) is an \((M,G)\)-filter, it follows that

\[ [\nu_s, \nu_t] \leq [\phi_s, \phi_t] \leq \phi_{s+t} = \nu_{s+t}. \]
Now consider the case when \( s + t \in E \). For \( s \in R_E(s) \) and \( t \in R_E(t) \), we prove
\[
[[\phi_s], [\phi_t]] \leq \nu_{s+t}
\]
which proves the lemma. We prove the inequality in (4) by induction on the size of the partition of \( s \). If \( s = (s) \), then \( s \in (M \setminus E) \cup S \), so \( \nu_s = \phi_s \) by Lemma 4.6. If \( t = (t_1, \ldots, t_\ell) \in R_E(t) \), then \( (s, t) \in R_E(s + t) \) and \( r = (t, s) = (t_1, \ldots, t_\ell, s) \in R_E(s + t) \). It follows that
\[
[[\phi_s], [\phi_t]] = [[\phi_t], [\phi_s]] = [\phi_t] \leq \nu_{s+t}.
\]
Therefore, \([\nu_t, \phi_s] \leq \nu_{s+t}\), and since \( \phi_s = \nu_s \),
\[
[\nu_s, \nu_t] = [\nu_t, \phi_s] \leq \nu_{s+t}.
\]
Now we proceed by induction on \( k \geq 2 \), the size of the partition \( s = (s_1, \ldots, s_k) \in R_E(s) \). Let \( s' = (s_1, \ldots, s_{k-1}) \), and let \( A = [\phi_{s'}], B = \phi_{s_k}, \) and \( C = [\phi_t] \). Then
\[
[[\phi_s], [\phi_t]] = [A, B, C].
\]
Since \((s, t) \in R_E(s + t)\), all permutations of \((s, t)\) are also contained in \(R_E(s + t)\). Hence, \((t_1, \ldots, t_\ell, s_k, s_1, \ldots, s_{k-1}) \in R_E(s + t)\). If \( t' = (t_1, \ldots, t_\ell, s_k) \), then by the induction hypothesis
\[
[B, C, A] = [C, B, A] = [[\phi_t], [\phi_{s'}]] \leq \nu_{s+t}.
\]
Although \(-s_k\) may not be contained \( M \), we let \( s - s_k \) denote \( s_1 + \cdots + s_{k-1} \). Again, by the induction hypothesis
\[
[C, A, B] \leq [\nu_{s-s_k+t}, \phi_{s_k}] \leq \nu_{s+t}.
\]
By the Three Subgroups Lemma,
\[
[[\phi_s], [\phi_t]] = [A, B, C] \leq [B, C, A][C, A, B] \leq \nu_{s+t}.
\]
Therefore, in this case, \([\nu_s, \nu_t] \leq \nu_{s+t}\). \( \square \)

We fix the following notation. For \( H \in \text{im}(\phi) \), define
\[
\text{supp}_\phi(H) = \{ s \in M \mid \phi_s = H \},
\]
\[
\text{supp}^+_\phi(H) = \{ s + t \mid s \in \text{supp}_\phi(H), t \neq 0 \} \cap \text{supp}_\phi(H).
\]
We generalize this to subsets \( \mathcal{H} \subseteq \text{im}(\phi) \), where \( \text{supp}_\phi(\mathcal{H}) \) is the disjoint union of \( \text{supp}_\phi(H) \), for \( H \in \mathcal{H} \) and similarly for \( \text{supp}^+_\phi(\mathcal{H}) \). Our plan is to define the \( \nu \)-exclusion set, \( E \), to be \( \text{supp}^+_\phi(\mathcal{H}) \) for some subset of \( \text{im}(\phi) \). We use the next lemma to show that \( \text{im}(\phi) \subseteq \text{im}(\bar{r}) \).

**Lemma 4.9.** If \( \phi \) is a progressive \((M, G)\)-filter, then for all \( H \in \text{im}(\phi) \setminus \{ m_\phi \} \), the set \( \text{supp}_\phi(H) \setminus \text{supp}^+_\phi(H) \) is finite and nonempty.

**Proof.** Suppose \( \text{supp}_\phi(H) = \text{supp}^+_\phi(H) \), and let \( s_0 \in \text{supp}_\phi(H) \). As \( s_0 \in \text{supp}^+_\phi(H) \), there exists \( s_1 \in \text{supp}_\phi(H) \) and \( t_1 \neq 0 \) such that \( s_0 = s_1 + t_1 \). By induction, there exists \( s_{i+1} \in \text{supp}_\phi(H) \) and \( t_{i+1} \neq 0 \) such that \( s_i = s_{i+1} + t_{i+1} \), for \( i \geq 1 \). Since \( \phi \) is progressive and \( H \neq m_\phi \), each \( s_i \) is unit-cancellative. Therefore, \( s_i \neq s_{i+1} \).
Because \( t_i \neq 0 \) for all \( i \geq 1 \), it follows that \( s_0 \succ_+ s_1 \succ_+ \cdots \) is an infinite descending chain in \( M \) (and \( \prec_+ \) is transitive on the subset of unit-cancellative elements). By Corollary 3.7, this is a contradiction. Therefore, \( \text{supp}_\phi(H) \neq \text{supp}^+_\phi(H) \). By definition, \( \text{supp}_\phi(H) \setminus \text{supp}^+_\phi(H) \) is an \( \preceq_+ \)-antichain. By Corollary 3.7, \( \text{supp}_\phi(H) \setminus \text{supp}^+_\phi(H) \) must be finite. \( \square \)
Now we can put everything together to prove the next proposition: that \( \tilde{\nu} \) is an \((M, G)\)-filter.

**Proposition 4.10.** Suppose \( \phi \) is a finite progressive \((M, G)\)-filter. If \( \mathcal{H} \subseteq \text{im}(\phi) \setminus \{m_\phi\} \) and \( \tilde{\nu} \) as defined above with \( \nu\)-exclusion set \( E = \text{supp}_\nu^+ (\mathcal{H}) \), then \( \tilde{\nu} \) is a finite \((M, G)\)-filter such that \( \text{im}(\phi) \subseteq \text{im}(\tilde{\nu}) \).

**Proof.** By Lemma 4.8, for all \( s, t \in M \),

\[
[\tilde{\nu}_s, \tilde{\nu}_t] = \prod_{s \leq u \leq t} \prod_{w \leq u + w} [\nu_u, \nu_w] \leq \prod_{s \leq u \leq t} \prod_{w \leq u + w} \nu_{u+w} \leq \tilde{\nu}_{s+t}.
\]

If \( s \leq t \), then

\[
\tilde{\nu}_s = \prod_{s \leq u \leq w} \nu_u \geq \prod_{s \leq u \leq t} \nu_u = \tilde{\nu}_t.
\]

Therefore, \( \tilde{\nu} \) is an \((M, G)\)-filter. By Lemma 4.7, \( \tilde{\nu}_s = \phi_s \) for each \( s \in (M \setminus E) \cup S \).

By Lemma 4.9, since \( m_\phi \notin \mathcal{H} \) and \( \phi \) is progressive, for each \( H \in \mathcal{H} \) there exists \( t_H \in \text{supp}_\phi^+(H) \setminus \text{supp}_\nu^+(\mathcal{H}) \). Since \( \text{supp}_\phi^+(\mathcal{H}) \) is the disjoint union of sets \( \text{supp}_\nu^+(\mathcal{H}) \), it follows for all \( H \in \mathcal{H} \), \( t_H \in \text{supp}_\phi^+(H) \setminus \text{supp}_\nu^+(\mathcal{H}) \). Thus, \( \phi_{t_H} = H = \tilde{\nu}_{t_H} \), so \( \text{im}(\phi) \subseteq \text{im}(\tilde{\nu}) \). Since \( \phi \) is finite, \( \tilde{\nu} \) is also finite.

Now we need some lemmas toward inertia. Recall, \( \phi_s \) is not an inert subgroup of \( \phi \) if there exists \( B \subseteq \mathcal{B} \) such that \( \partial \phi_s = \langle B \rangle \). The way we show a subgroup \( \phi_s \) is not an inert subgroup of \( \phi \) is to prove that \( \partial \phi_s \) is generated by subgroups strictly contained in \( \phi_s \). Proving this for all \( s \in M \), together with the finiteness of \( \phi \), yields our desired result: \( \phi \) is inertia-free.

We define some length functions that we only use for the proof of the next lemma. For \( r \in R_E(x) \), let \( \ell(r) \in \mathbb{N} \) denote the number of terms in \( r \). Define

\[
\ell(R_E(x)) = \min_{r \in R_E(x)} \ell(r).
\]

**Lemma 4.11.** Suppose \( \phi \) is a finite progressive \((M, G)\)-filter. Let \( \mathcal{H} = \text{im}(\phi) \setminus \{m_\phi\} \), and define \( \nu \) with \( \nu\)-exclusion set \( E = \text{supp}_\nu^+(\mathcal{H}) \). For all \( H \in \text{im}(\nu) \) with \( H > m_\phi \), the set \( \text{supp}_\nu(H) \) is finite.

**Proof.** By Lemma 4.9, \( \text{supp}_\phi^+(H) \setminus \text{supp}_\nu^+(\mathcal{H}) \) is finite and possibly empty if \( H \notin \text{im}(\phi) \). So if \( |\text{supp}_\nu(H)| \) is infinite, then there exists an infinite set \( T \subseteq \text{supp}_\nu(H) \) such that \( T \subseteq E = \text{supp}_\nu^+(\mathcal{H}) \). Since \( \phi \) is progressive, \( T \) only contains unit-cancellative elements. Therefore, for all \( t \in T \) and every \( s = (s_1, \ldots, s_k) \in R_E(t) \), each \( s_i \) is unit-cancellative by Proposition 3.5. Since \( \phi \) is finite and \( M \) is finitely generated, the set \( M \setminus (E \cup \text{supp}_\nu^+(m_\phi)) \cup S \) is finite by Lemma 4.9 and generates every element of the infinite set \( T \). Thus, for all \( N \geq 1 \) there exists only finitely many \( t \in T \) such that \( \ell(R_E(t)) \leq N \). Since \( G \) is nilpotent, there exists \( c \geq 1 \) such that all commutators of weight \( c + 1 \) are trivial. Therefore, there are only finitely many \( t \in T \) such that

\[
H = \prod_{s \in R_E(t)} |\phi_s|,
\]

which is a contradiction. Hence, no such \( T \) exists.

**Lemma 4.12.** Let \( \phi \) be a progressive \((M, G)\)-filter and \( H \in \text{im}(\phi) \) such that \( H \neq m_\phi \). If \( |\text{supp}_\phi(H)| \) is finite, then there exists \( s \in \text{supp}_\phi(H) \) and \( I_s \subseteq M \) such that for all \( t \in I_s \), \( \phi_t \subset H \) and \( \partial \phi_s = \langle \phi_t \mid t \in I_s \rangle \).
Proof. Let \( s \in \supp_{\partial}(H) \) be maximal with respect to \( \preceq \). We claim that \( I_s = \{ s + t \mid t \neq 0 \} \) suffices. Since \( \phi \) is progressive and \( H \neq m_\phi \), the element \( s \) is not a sink. In particular, \( s \notin I_s \). By the maximality of \( s \), for all \( t \in I_s \), it follows that \( \phi_t < H \), and by definition \( \partial \phi_s = \langle \phi_t \mid t \in I_s \rangle \).

Now we are ready to prove that we can refresh inert subgroups and construct more vigorous filters. To do this, we first show that all minimal subgroups strictly containing \( m_\phi \) are not inert subgroups of \( \theta \). Then we show that if \( \theta_s \) has the property that every \( \theta_{s+t} < \theta_s \) is not an inert subgroup of \( \theta \), then \( \theta_s \) is not an inert subgroup of \( \theta \).

**Theorem 4.13.** If \( \phi \) is a finite progressive \((M,G)\)-filter, then there exists a finite progressive, inertia-free \((M,G)\)-filter \( \theta \) such that \( \im(\phi) \subseteq \im(\theta) \).

Proof. Let \( \mathcal{H} = \im(\phi) \setminus \{m_\phi\} \). Define \( \nu \) with \( \nu \)-exclusion set \( \mathcal{E} = \supp^+_\phi(\mathcal{H}) \). Let \( \tilde{\nu} \) denote the \((M,G)\)-filter from Proposition 4.10, see also (3). By Proposition 4.10, \( \tilde{\nu} \) is finite and \( \im(\phi) \subseteq \im(\tilde{\nu}) \). Define a new \((M,G)\)-filter \( \tilde{\theta} \), such that for all \( s \in M \), \( \theta_s = \tilde{\nu}_s m_\phi \). It follows that \( \theta \) is finite and \( \im(\phi) \subseteq \im(\theta) \). Because \( m_\phi \notin \mathcal{H} \), all sinks \( s \in M \) are contained in \( M \setminus \mathcal{E} \). From Lemma 4.7, since \( s \) is a sink, \( \tilde{\nu}_s = \phi_s = m_\phi \). Since \( m_\theta = m_\phi, \theta \) is progressive. It remains to prove that \( \theta \) is inertia-free.

We show that \( \theta \) is inertia-free by induction. By definition, the base case, \( m_\theta \), is not an inert subgroups of \( \theta \). Suppose \( n \geq 0 \), and let \( H \in \im(\theta) \setminus \mathfrak{B}_n \) be minimal. We show that \( H \in \mathfrak{B}_{n+1} \). This implies that \( \theta \) is inertia-free since \( \theta \) is finite.

By the minimality of \( H \), it is enough to show that there exists \( s \in \supp_{\partial}(H) \) such that \( \partial \theta_s \) is generated by subgroups \( \theta_{s+t} < H \). If \( |\supp_{\partial}(H)| \) is finite, then apply Lemma 4.12, and if there exists \( s \in \supp_{\partial}(H) \) such that \( \partial \theta_s \neq \theta_s \), then every \( \theta_{s+t} < H \) for \( t \neq 0 \). In both cases, we conclude \( H \in \mathfrak{B}_{n+1} \). Therefore, we assume that \( |\supp_{\partial}(H)| \) has infinite cardinality and for all \( s \in \supp_{\partial}(H) \), \( \partial \theta_s = H \).

By Lemma 4.11 every \( K \in \im(\nu) \) strictly containing \( m_\phi = m_\theta \) has finite support. Since for all \( s \in \supp_{\partial}(H) \),

\[
H = m_\phi \prod_{s \preceq t} \nu_t,
\]

all but finitely many \( t \) from (5) satisfy \( \nu_t > m_\phi \). Thus, there exists a finite (and hence minimal) set \( T \subseteq \mathcal{M} \) such that for all \( s \in \supp_{\partial}(H) \) and for all \( t \in T \), either \( s \preceq t \) or \( s \) and \( t \) are incomparable and \( H = \prod_{t \in T} \nu_t \). By definition,

\[
H = m_\phi \prod_{t \in T} \nu_t = m_\theta \prod_{t \in T} \tilde{\nu} = \prod_{t \in T} \partial_t.
\]

If for all \( t \in T \), \( \theta_t < H \), then we are done. On the other hand, if there exists \( t \in T \) such that \( \theta_t = H \), then \( t \) is a maximal element of \( \supp_{\partial}(H) \). In particular, for all \( u \in M \) with \( u \neq 0, \theta_{t+u} < H \). Thus, \( H \in \mathfrak{B}_{n+1} \subseteq \mathfrak{B} \).

**Remark 4.14.** It is unknown what conditions are sufficient for \( \phi \) to guarantee that \( \theta \) from Theorem 4.13 is faithful. Example 4.16 shows that \( \theta \) need not be faithful. In the context of algorithms for isomorphism testing, an algorithm that refines filters and always returns a faithful filter would be sufficient. However, it may not be possible for such an algorithm to always refine; it may have to remove some subgroups from the image.
4.2. **Some examples.** In Section 2.3, there are three examples of filters with inert subgroups, two of which are progressive. We illustrate the construction of $\tilde{\nu}$ with these progressive filters.

**Example 4.15.** First we consider Example 2.2. Suppose $G = H(\mathbb{Z})$ and $M = (\mathbb{N}^2, \preceq_\ell)$, ordered by the lex ordering. A generating set for $M$ is $\mathcal{S} = \{(1,0), (0,1)\}$. The following function is an $(M,G)$-filter given by

$$
\phi_s = \begin{cases} 
  G & s \preceq_\ell (2,0), \\
  G' & (2,0) \preceq_\ell s \preceq_\ell (3,0), \\
  1 & (3,0) \preceq_\ell s,
\end{cases}
$$

and every subgroup in $\text{im}(\phi)$ has infinite support. Set $\mathcal{H} = \{G,G'\}$, so

$$
\text{supp}^+_\phi(\mathcal{H}) = \{s \in M \mid (0,0) \preceq_\ell s \preceq_\ell (2,0)\} \cup \{s \in M \mid (2,0) \preceq_\ell s \preceq_\ell (3,0)\}.
$$

We plot both $\nu$ and $\tilde{\nu}$ with $\nu$-exclusion set $E = \text{supp}^+_\phi(\mathcal{H})$. In light of [M1], the $(\mathbb{N}^2, G)$-filter is exactly what we expect.

![Figure 3](image)

**Figure 3.** We refresh the $(M,G)$-filter $\phi$, defined in Example 2.2. First, we construct the function $\nu$ in Figure 3(B). We circle the elements in $(M \setminus E) \cup \mathcal{S}$ that do not evaluate to the trivial group. Then we construct the $(M,G)$-filter $\tilde{\nu}$, as seen in Figure 3(C).

**Example 4.16.** Now we consider Example 2.4. Recall, $G = H(K)$, for some finite field $K$, $M = (\mathbb{N}^2, \preceq_+)$, and for all $s \in M$,

$$
\phi_s = \begin{cases} 
  G & i = 0, \\
  G' & i = 1 \text{ or } i + j \leq 4, \\
  1 & \text{otherwise}.
\end{cases}
$$

Again, we set $\mathcal{H} = \{G,G'\}$, so

$$
\text{supp}^+_\phi(\mathcal{H}) = \{(0,j) \in M \mid j \geq 1\} \cup \{(i,j) \in M \mid 2 \leq i + j \leq 4 \text{ or } j \geq i = 1\}.
$$

All the functions are plotted in Figure 4. In particular, $\tilde{\nu}$ is not a faithful filter as

$$
\tilde{\nu}_{(1,0)} \setminus \partial\tilde{\nu}_{(1,0)} = \tilde{\nu}_{(0,2)} \setminus \partial\tilde{\nu}_{(0,2)} = G' \setminus \{1\}.
$$

Indeed, $L(\tilde{\nu}) \cong G/G' \oplus G' \oplus G'$, which is not in bijection with $G$. 

4.3. Proof of Theorem 4.3. From the previous section, we required the monoid structure of $M$ to be nice enough so our construction would remove inertness. If we change the monoid the filter is defined over, then we require fewer assumptions on $M$, only that $\leq$ be a partial order instead of just a pre-order. We move to the free commutative monoid $\mathbb{N}^d$, which eliminates sinks. Care is needed when constructing a partial order that is compatible with the partial order on $M$, and that is the objective of the next lemma.

Lemma 4.17. If $M$ is a fgcp$_0$ monoid with $\leq$ a partial order, then there exists an integer $d \in \mathbb{N}$, a partial order $\leq'$ for $\mathbb{N}^d$, and a surjection $\pi : \mathbb{N}^d \to M$ such that

(i) $(\mathbb{N}^d, \leq')$ is a fgcp$_0$ monoid and

(ii) if $s \leq' t$, then $\pi(s) \leq \pi(t)$.

Proof. Since $M$ is finitely generated, there exists $d \in \mathbb{Z}$ and a congruence $\sim$ of $\mathbb{N}^d$ such that $\mathbb{N}^d/\sim \cong M$. Let $\pi : \mathbb{N}^d \to M$ be the induced surjection. Define a partial order $\leq'$ on $\mathbb{N}^d$ as follows. For $s, t \in \mathbb{N}^d$,

$$s \leq' t \iff (\pi(s) < \pi(t)) \text{ or } (\pi(s) = \pi(t) \text{ and } s \leq_+ t).$$

Because $\leq$ is a partial order on $M$, $<$ is transitive. Since $\pi$ is a monoid homomorphism, $\leq$ a partial order on $M$, and $\leq_+$ a partial order of $\mathbb{N}^d$, it follows that $\leq'$ is a partial order for $\mathbb{N}^d$. As 0 is $\leq'$-minimal in $\mathbb{N}^d$, $(\mathbb{N}^d, \leq')$ is a fgcp$_0$ monoid. \qed

Proof of Theorem 4.3. If $\phi$ is a progressive $(M, G)$-filter, then apply Theorem 4.13. Otherwise, $\leq$ is a partial order. By Lemma 4.17, there exists a fgcp$_0$ monoid $(\mathbb{N}^d, \leq')$ and a surjection $\pi : \mathbb{N}^d \to M$. Define a function $\rho$ from $\mathbb{N}^d$ into $\text{Nor}(G)$ such that $\rho_s = \phi_{\pi(s)}$. For $s, t \in \mathbb{N}^d$,

$$[\rho_s, \rho_t] = [\phi_{\pi(s)}, \phi_{\pi(t)}] \leq \phi_{\pi(s)+t} = \rho_{s+t}.$$ 

In addition, if $s \leq' t$, then $\pi(s) \leq \pi(t)$. Thus, $\rho_s = \phi_{\pi(s)} \geq \phi_{\pi(t)} = \rho_t$. Therefore, $\rho$ is an $(\mathbb{N}^d, G)$-filter. Since $\pi$ is surjective, $\text{im}(\rho) = \text{im}(\phi)$. Since every element of $\mathbb{N}^d$ is unit-cancellative, $\rho$ is progressive. Apply Theorem 4.13 to $\rho$. \qed

Example 4.18. We want to fix the last filter in Section 2.3 that has inert subgroups: Example 2.5. Recall, $G = H(\mathbb{Z})$, $M = (C_{3,1} \times C_{1,1, \leq_+})$, and for all
Because \((0,1)\) is not unit-cancellative and \(\phi(0,1) = K \neq m_\phi\), \(\phi\) is not progressive. Since \(\preceq\) is a partial order on \(M\), we can fix this by applying Theorem 4.3.

A generating set for \(M\) is \(S = \{(1,0),(0,1)\}\), so by Lemma 4.17, there exists a surjection \(\pi: \mathbb{N}^2 \to M\) and a partial order \(\preceq'\) on \(\mathbb{N}^2\). Using this, we define an \((\mathbb{N}^2,G)\)-filter \(\rho\) such that, for \(s = (i,j) \in M\),

\[
\rho_s = \begin{cases} 
G & i = j = 0, \\
\gamma_i(G) & i > j = 0, \\
K & i \leq 2, j = 1, \\
1 & i = 3, j = 1.
\end{cases}
\]

Now \(\rho\) is progressive, and we can construct an inertia-free \((\mathbb{N}^2,G)\)-filter \(\tilde{\nu}\). We plot these four functions in Figure 5.

4.4. Proof of Theorem A. Theorems 4.3 and 4.4 imply Theorem A, so we finish off the proof of Theorem 4.4 now.

Definition 4.19. A sequence \(Y\) of elements of an abelian group \(\bigoplus_{s \in M} L_s\) is a graded pcgs if

(i) for all \(y \in Y\), there exists \(s \in M\) such that \(y \in L_s\), and

(ii) for all \(s \in M\), the subsequence \(Y \cap L_s\) is a pcgs for \(L_s\).

Throughout the remainder of this section we denote the graded pcgs for the abelian group \(L(\phi)\) by \(\mathcal{Y}\). Because \(\phi\) is inertia-free, we use the \(\mathfrak{B}\)-sequence as a method of Noetherian induction to prove the next lemma.

Lemma 4.20. Suppose \(\phi\) is a finite, non-degenerate, inertia-free \((M,G)\)-filter, and \(\mathcal{Y}\) is a graded pcgs for \(L(\phi)\). If \(X\) is a pre-image of \(\mathcal{Y}\) in \(G\), then for all \(s \in M\), \(\langle \phi_s \cap X \rangle = \phi_s\) and \(X\) contains a pcgs for \(G\).
Proof. Since $\phi$ is finite and non-degenerate, $\langle 1 \rangle \in \text{im}(\phi)$, so $\mathcal{B}_0 = \{\langle 1 \rangle \}$. For all $\phi_s \in \mathcal{B}_0$, it follows that $\langle \phi_s \cap X \rangle = \phi_s$ and $X$ contains a pcgs for $\phi_s$. We assume this holds for all subgroups in $\mathcal{B}_n$, for $n \geq 0$.

Suppose $\phi_s \in \mathcal{B}_{n+1}$ for $n \geq 0$. By definition, there exists $B \subseteq \mathcal{B}_n$ such that $\partial \phi_s = (B)$. By induction, for all $\phi_i \in B$, $\langle \phi_i \cap X \rangle = \phi_i$ and $X$ contains a subsequence that is a pcgs for $\phi_i$. Since $\mathcal{Y}$ is a graded pcgs for $L(\phi)$, the subsequence $\mathcal{Y}_s = L_s(\phi) \cap \mathcal{Y}$ is a pcgs for $L_s(\phi)$. Let $X_s$ be the subsequence of $X$ corresponding to $\mathcal{Y}_s$ in $G$. Therefore by induction,

$$\langle \phi_s \cap X \rangle = \langle X_s \cup (\partial \phi_s \cap X) \rangle = \phi_s.$$

Since $\phi$ is finite and inertia-free, for every $s \in M$, there exists $n \geq 0$ such that $\phi_s \in \mathcal{B}_n$. Since $\phi$ is non-degenerate, $X$ contains a pcgs for $G$. \hfill \Box

By Lemma 4.20, there is little work left to do to prove Theorem A. We define a map $\pi : L(\phi) \to G$, since the image of a graded pcgs for $L(\phi)$ contains a pcgs for $G$, the map is surjective.

Proof of Theorem 4.4. Let $\mathcal{Y} = (y_1, \ldots, y_r)$ be a graded pcgs for $L(\phi)$ such that, for $L^{(i)} = \langle y_i, \ldots, y_r \rangle$, the quotients $L^{(i)}/L^{(i+1)}$ are isomorphic to either $\mathbb{Z}$ or $\mathbb{Z}/n$ for $n \in \mathbb{N}$. It follows that $L^{(i)} = \langle y_i, L^{(i+1)} \rangle$, so let $o(y_i)$ be either $\infty$ or $n$, depending on the order of the $L^{(i)}/L^{(i+1)}$. For each $a \in L(\phi)$ and $i \in \{1, \ldots, r\}$, there exists integers $0 \leq k_i(a) < o(y_i)$ such that

$$a = k_1(a) \cdot y_1 + \cdots + k_r(a) \cdot y_r. \tag{6}$$

We call the expression for $a$ in (6) its normal word with respect to $\mathcal{Y}$, which is uniquely determined by $\mathcal{Y}$.

Let $\mathcal{X} = (x_1, \ldots, x_r)$ be a sequence of pre-images of $\mathcal{Y}$ in $G$ such that $y_i \in L_s(\phi)$ implies that $y_i x_i^{-1} \in \partial \phi_s$. Define a function of sets $\pi_\mathcal{Y} : L(\phi) \to G$ such that

$$a \mapsto x_1^{k_1(a)} \cdots x_r^{k_r(a)}. \tag{7}$$

Because normal words are unique, $\pi_\mathcal{Y}$ is well-defined. By Lemma 4.20, $\mathcal{X}$ contains a pcgs for $G$, so $\pi$ is surjective. \hfill \Box

5. Filtered generating sets and lattices

Our main objective in this section is to develop a generating set that interacts nicely with filters. A common theme for using groups effectively in computational settings is to have a structured generating set for the group. Some examples include bases and strong generating sets for permutation groups [S1, Chapter 4], (special) polycyclic generating sequences for solvable groups [CELG, EW] and [S2, Chapter 9], and power-commutator presentations for $p$-groups [HN, NO]. These generating sets are all based on a series in the group. Influenced by these generating sets, we define an appropriate generating set in the context of filters.

Throughout this section, we fix an $(M,G)$-filter $\phi$. For now, we say a generating set $\mathcal{X} \subseteq G$ is filtered by $\phi$ if $\mathcal{X}$ contains a generating set for each $\phi_s$ and is compatible with the induced complete lattice of im($\phi$), Lat($\phi$), see Definition 5.4 below. In this section we prove the following theorem.

**Theorem 5.1.** For a group $G$ and a fgcp$_0$ monoid $M$, let $\phi$ be an $(M,G)$-filter. If the generating set $\mathcal{X} \subseteq G$ is filtered by $\phi$, then

(i) the complete lattice induced by im($\phi$) is distributive, and
(ii) $\mathcal{X}$ is filtered by the boundary filter $\partial \phi$.

Since the lattice of normal subgroups is not in general distributive, Theorem 5.1 shows that not all filters have such a generating set. We begin with a natural condition on generating sets, akin to strong generating sets from the context of permutation groups.

**Definition 5.2.** A set $\mathcal{X} \subseteq G$ is weakly-filtered by $\phi$ if for all $s \in M$, $\langle \phi_s \cap \mathcal{X} \rangle = \phi_s$.

The property of a generating set $\mathcal{X}$ being weakly-filtered can be rephrased in the context of partially-ordered sets. Suppose $\mathcal{X} \subseteq G$ is weakly-filtered by $\phi$. Define functions on partially-ordered sets $\text{Nor}(G)$ and $2^X$; namely, $\cap : \text{Nor}(G) \to 2^X$ where $H \mapsto H \cap X$ and $\langle \cdot \rangle : 2^X \to \text{Nor}(G)$ where $Y \mapsto \langle Y \rangle$. These functions are isotone because $H,K \in \text{Nor}(G)$ with $H \leq K$ implies $H \cap X \subseteq K \cap X$, and if $Y,Z \in 2^X$ with $Y \leq Z$, then $\langle Y \rangle \leq \langle Z \rangle$. This proves the following lemma.

**Lemma 5.3.** If $\mathcal{X} \subseteq G$ is weakly-filtered by $\phi$, then the restriction of $\cap \mathcal{X}$ on $\text{im}(\phi)$ is an (order) isomorphism with inverse $\langle \cdot \rangle : \text{im}(\phi) \cap \mathcal{X} \to \text{im}(\phi)$.

We need a stronger definition for our purposes. The set $\text{im}(\phi)$ is, in general, not a lattice. Let $\text{Lat}(\phi)$ denote the image of $\text{Lat}(\phi)$ in $2^X$ under $\cap \mathcal{X}$. The surjection $\cap : \text{Lat}(\phi) \to \text{Lat}(\phi) \cap \mathcal{X}$ is isotone; however, if $H,K \in \text{Lat}(\phi)$ and $H \cap \mathcal{X} \subseteq K \cap \mathcal{X}$, then $H$ need not be a subgroup of $K$. Even as partially-ordered sets $\text{Lat}(\phi)$ need not be isomorphic to $\text{Lat}(\phi) \cap \mathcal{X}$. The strength of the following definition comes when $\cap \mathcal{X}$ and $\langle \cdot \rangle$ are complete lattice homomorphisms.

**Definition 5.4.** A set $\mathcal{X} \subseteq G$ is filtered by $\phi$ if it is weakly-filtered and for all $S \subseteq M$,

$$\bigcap_{s \in S} \phi_s = \left( \bigcap_{s \in S} (\phi_s \cap \mathcal{X}) \right) \quad \text{and} \quad \left( \prod_{s \in S} \phi_s \right) \cap \mathcal{X} = \bigcup_{s \in S} (\phi_s \cap \mathcal{X}).$$

This definition is not just a weakly-filtered analogue for the complete lattice $\text{Lat}(\phi)$. If $\mathcal{X}$ satisfies the property that for all $H \in \text{Lat}(\phi)$, $\langle H \cap X \rangle = H$, then $\mathcal{X}$ may still not be filtered by $\phi$. Some subtleties of this definition are revealed in Example 5.5. It is worth pointing out that the generating set that is filtered by $\phi$ in Example 5.5 induces a pcgs for the associated Lie ring $L(\phi)$.

**Example 5.5.** Let $G = Z/60$, and $M = (\mathbb{N}^2, \leq^+ )$. Define an $(M,G)$-filter $\phi$ where $\phi_0 = G$,

$$\phi_s = \begin{cases} \langle 2 \rangle & \text{if } s = e_1, \\ \langle 3 \rangle & \text{if } s = e_2, \\ \langle 10 \rangle & \text{if } s = 2e_1, \\ \langle 15 \rangle & \text{if } s = 2e_2, \end{cases}$$

and $\phi_s = 0$ otherwise. Set $\mathcal{X} = \{2,3,10,15\}$, and observe that $\mathcal{X}$ is weakly-filtered by $\phi$. In Figure 6, we plot the Hasse diagram of $\text{im}(\phi)$ and $\text{Lat}(\phi)$. Set $H = \langle 6 \rangle$ and $K = \langle 30 \rangle$. Then $H \cap \mathcal{X} = \emptyset = K \cap \mathcal{X}$, but $\langle 6 \rangle = H \not\leq K = \langle 30 \rangle$. Thus, $\cap \mathcal{X} : \text{Lat}(\phi) \to \text{Lat}(\phi) \cap \mathcal{X}$ is not isotone and, hence, is not an isomorphism. By Proposition 5.6, $\mathcal{X}$ is not filtered by $\phi$.

If, instead, we set $\mathcal{X} = \{2,3,5,6,10,15,30\}$, then for all $H \in \text{Lat}(\phi)$, $\langle H \cap X \rangle = H$. However, $\mathcal{X}$ is not filtered by $\phi$: for example,

$$(\phi_{2e_1},\phi_{2e_2}) \cap \mathcal{X} = \langle 5 \rangle \cap \mathcal{X} = \{5,10,15,30\}$$
and

$$(\phi_{2e_1} \cap \mathcal{X}) \cup (\phi_{2e_2} \cap \mathcal{X}) = \langle (10) \cap \mathcal{X} \rangle \cup \langle (15) \cap \mathcal{X} \rangle = \{10, 15, 30\}.$$ 

If, for example, $\mathcal{X} = \{6, 10, 15, 30\}$, then $\mathcal{X}$ is filtered by $\phi$. □

\[
\begin{array}{ccc}
G & & G \\
\langle 2 \rangle & | & \langle 2 \rangle \\
\langle 3 \rangle & | & \langle 3 \rangle \\
\langle 10 \rangle & | & \langle 6 \rangle \\
\langle 15 \rangle & | & \langle 10 \rangle \\
\langle 30 \rangle & | & \langle 15 \rangle \\
0 & | & 0 \\
\end{array}
\]

(A) The Hasse diagram of $\text{im}(\phi)$. 

(B) The lattice $\text{Lat}(\phi)$.

**Figure 6.** Hasse diagrams related to $(M, G)$-filter $\phi$ from Example 5.5.

If $\mathcal{X}$ is filtered by $\phi$, then $\cap \mathcal{X}$ is not just a lattice homomorphism but an isomorphism, and therefore, the lattice $\text{Lat}(\phi)$ inherits properties of the subset lattice $\text{Lat}(\phi) \cap \mathcal{X}$. The next proposition proves Theorem 5.1 (i).

**Proposition 5.6.** Let $\phi$ be an $(M, G)$-filter. The set $\mathcal{X} \subseteq G$ is filtered by $\phi$ if, and only if, $\cap \mathcal{X} : \text{Lat}(\phi) \to \text{Lat}(\phi) \cap \mathcal{X}$ and $\langle \cdot \rangle_{\mathcal{X}} : \text{Lat}(\phi) \cap \mathcal{X} \to \text{Lat}(\phi)$ are complete lattice isomorphisms. In such a case, $\text{Lat}(\phi)$ is a distributive lattice.

**Proof.** Suppose $\mathcal{X}$ is filtered by $\phi$ and $S \subseteq M$. Since $\cap$ is associative and $\mathcal{X}$ is filtered by $\phi$,

$$\left( \bigcap_{s \in S} \phi_s \right) \cap \mathcal{X} = \bigcap_{s \in S} (\phi_s \cap \mathcal{X}), \quad \left( \biglcap_{s \in S} \phi_s \bigr) \cap \mathcal{X} = \bigcup_{s \in S} (\phi_s \cap \mathcal{X}).$$

Hence $\cap \mathcal{X} : \text{Lat}(\phi) \to \text{Lat}(\phi) \cap \mathcal{X}$ is a lattice homomorphism. Since $\mathcal{X}$ is filtered by $\phi$ it is also weakly-filtered. Therefore,

$$\left( \bigcup_{s \in S} (\phi_s \cap \mathcal{X}) \right) = \bigl( \bigcup_{s \in S} (\phi_s \cap \mathcal{X}) \bigr) = \bigl( \bigcup_{s \in S} (\phi_s \cap \mathcal{X}) \bigr) = \bigcup_{s \in S} (\phi_s \cap \mathcal{X}).$$

Therefore, $\langle \cdot \rangle_{\mathcal{X}} : \text{Lat}(\phi) \cap \mathcal{X} \to \text{Lat}(\phi)$ is a lattice homomorphism. Both homomorphisms $\cap \mathcal{X}$ and $\langle \cdot \rangle_{\mathcal{X}}$ are isotone. Since $\mathcal{X}$ is weakly-filtered, $\langle \cdot \rangle_{\mathcal{X}}$ is the inverse of $\cap \mathcal{X}$, and hence, $\text{Lat}(\phi) \cong \text{Lat}(\phi) \cap \mathcal{X}$.

Conversely, suppose $\cap \mathcal{X}$ and $\langle \cdot \rangle_{\mathcal{X}}$ are complete lattice isomorphisms. It follows then that $\mathcal{X}$ is weakly-filtered by $\phi$. Let $S \subseteq M$, so $\bigcap_{s \in S} \phi_s \in \text{Lat}(\phi)$. Since $\langle \cdot \rangle_{\mathcal{X}}$ is a complete lattice homomorphism,

$$\bigcap_{s \in S} \phi_s = \left( \bigcap_{s \in S} \phi_s \right) \cap \mathcal{X} = \left( \bigcup_{s \in S} (\phi_s \cap \mathcal{X}) \right).$$
Furthermore, since $\cap X$ is a complete lattice homomorphism,
\[
\left( \prod_{s \in S} \phi_s \right) \cap X = \bigcup_{s \in S} (\phi_s \cap X).
\]
\[\square\]

Now we can prove the second part of Theorem 5.1 by employing Proposition 5.6. The key to the next proof is to use the fact that $\cap X$ and $\langle \cdot \rangle_X$ are complete lattice homomorphisms when $X$ is filtered by $\phi$.

**Proof of Theorem 5.1 (ii).** Suppose $X$ is filtered by $\phi$; we will prove that $X$ is also filtered by $\partial \phi$. First we show that for all $S \subseteq M$,
\[
\bigcap_{s \in S} \partial \phi_s = \left\langle \bigcap_{s \in S} (\partial \phi_s \cap X) \right\rangle.
\]
By Proposition 5.6, $\cap X$ and $\langle \cdot \rangle_X$ are complete lattice homomorphisms, so
\[
\left\langle \bigcap_{s \in S} (\partial \phi_s \cap X) \right\rangle = \left\langle \bigcap_{s \in S} \bigcup_{t \in M \setminus \{0\}} (\phi_{s+t} \cap X) \right\rangle = \bigcap_{s \in S} \prod_{t \in M \setminus \{0\}} (\phi_{s+t} \cap X) = \bigcap_{s \in S} \partial \phi_s.
\]
For the second part, we show that
\[
\left( \prod_{s \in S} \partial \phi_s \right) \cap X = \bigcup_{s \in S} (\partial \phi_s \cap X).
\]
Again, we use the fact that $\cap X$ is a complete lattice homomorphism:
\[
\left( \prod_{s \in S} \partial \phi_s \right) \cap X = \left( \prod_{s \in S} \prod_{t \in M \setminus \{0\}} \phi_{s+t} \right) \cap X = \bigcup_{s \in S} (\partial \phi_s \cap X).
\]
Therefore, $X$ is filtered by $\partial \phi$. \[\square\]

6. Faithful filters

In this section, we impose one more property on our filters so that the sets $L(\phi)$ and $G$ are in bijection. The main reason that the surjection $\pi : L(\phi) \rightarrow G$ from Theorem 4.4, cf. equation (7), might not be injective comes down to the fact that $(\phi_s \setminus \partial \phi_s) \cap (\phi_t \setminus \partial \phi_t)$ might be nonempty for distinct $s, t \in M$. Recall the definition of a faithful filter from Definition 1.2. Observe that the first property of faithful filters implies that $X$ is weakly-filtered by $\phi$, and the second property implies that $X$ is filtered by $\phi$. If $\phi$ is a faithful $(M, G)$-filter such that $X \subseteq G$ satisfies the three properties, then we say that $X$ is **faithfully filtered** by $\phi$.

We prove the following theorems in this section.

**Theorem 6.1.** Assume $\phi$ is a finite, inertia-free $(M, G)$-filter. If $\phi$ is faithful, then every pre-image of every graded pcgs for $L(\phi)$ is filtered by $\phi$.

**Theorem 6.2 (Theorem B).** If $\phi$ is a finite, faithful, and inertia-free $(M, G)$-filter, then there exists a bijection between $L(\phi)$ and $G$ that maps a pcgs of $L(\phi)$, as an abelian group, to a pcgs of $G$. 
The argument in the next lemma is fundamental to the proofs for the above theorems, and it illustrates a proof by descent for finite inertia-free filters. The essence of the argument is that if \( x \in \phi_s \cap \phi_t \), then \( x \) is contained in either \( \partial \phi_s \) or \( \partial \phi_t \) because \( \phi \) is faithful. Because \( \phi \) is finite and inertia-free, we apply Proposition 4.5 to both \( \partial \phi_s \) and \( \partial \phi_t \). The element \( x \) must be contained in one of these smaller subgroups, say \( x \in \phi_u \cap \phi_t \). So we continue descending until we reach a contradiction.

**Lemma 6.3.** Suppose \( \phi \) is a finite, faithful, and inertia-free \((M,G)\)-filter. If \( s,t \in M \) such that \( \phi_s < \phi_t \), then \( \phi_s \leq \partial \phi_t \).

**Proof.** If \( \partial \phi_t = \phi_t \), then we are done. Otherwise, \( L_t(\phi) \neq 0 \). Since \( \phi \) is faithful, there exists \( \mathcal{X} \subseteq G \) such that \( \mathcal{X} \) is faithfully filtered by \( \phi \). Without loss of generality, we assume that \( 1 \notin \mathcal{X} \). Let \( \mathcal{X}_t = (\phi_t \setminus \partial \phi_t) \cap \mathcal{X} \). Since \( \mathcal{X} \) is filtered by \( \phi \), by Theorem 5.1 \((\mathcal{X}_t) \partial \phi_t = \phi_t \). If \( \phi_s \cap \mathcal{X}_t = \emptyset \), then by Theorem 5.1 and Proposition 5.6,

\[
\phi_s = (\phi_s \cap \phi_t \cap \mathcal{X}) \leq (\phi_s \cap \mathcal{X}_t) \partial \phi_t = \partial \phi_s.
\]

Otherwise, \( \phi_s \cap \mathcal{X}_t \neq \emptyset \). Since \( \mathcal{X} \) is faithfully filtered by \( \phi \),

\[
\phi_s \cap \mathcal{X}_t = \partial \phi_s \cap \mathcal{X}_t \neq \emptyset.
\]

Let \( x \in \partial \phi_s \cap \mathcal{X}_t \). Since \( \phi \) is finite and inertia-free, there exists \( I_s \subseteq \mathcal{I}_\phi \) such that \( \partial \phi_s = (\phi_u | u \in I_s) \) by Proposition 4.5. Since \( \mathcal{X} \) is filtered by \( \phi \),

\[
\partial \phi_s \cap \mathcal{X} = \bigcup_{u \in I_s} (\phi_u \cap \mathcal{X}).
\]

For each \( u \in I_s \), \( \phi_u < \phi_s \), and since \( x \in \mathcal{X}_t \), there exists \( u \in I_s \) such that \( x \in \phi_u \). Now we are back to where we were earlier but with a new subgroup: \( \phi_u < \phi_t \) and \( x \in \phi_u \cap \mathcal{X}_t \). Because \( \phi \) is finite and inertia-free, \( x \in m_\phi \cap \mathcal{X} \). Since \( \phi \) is non-degenerate (since faithful), \( m_\phi = 1 \), so \( x = 1 \), which is a contradiction. Therefore, \( \phi_s \cap \mathcal{X}_t \neq \emptyset \) cannot happen, so the lemma follows. \( \square \)

Recall that \( \| \) denotes that two elements of a partially-ordered set are incomparable.

**Proposition 6.4.** Suppose \( \phi \) is a finite, faithful, and inertia-free \((M,G)\)-filter, and suppose \( S \subseteq M \) such that \( |S| \geq 2 \). If for every distinct pair \( s,t \in S \), \( \phi_s \| \phi_t \), then

\[
\bigcap_{s \in S} \phi_s = \bigcap_{s \in S} \partial \phi_s.
\]

**Proof.** Since \( \phi_s \geq \partial \phi_s \) for all \( s \in M \), we need only show one containment direction. If \( \bigcap_{s \in S} \phi_s = 1 \), then we are done, so suppose that \( \bigcap_{s \in S} \phi_s \neq 1 \). Since \( \phi \) is faithful, there exists \( \mathcal{X} \subseteq G \) faithfully filtered by \( \phi \). Thus, \( \bigcap_{s \in S} \phi_s = (\bigcap_{s \in S} \phi_s \cap \mathcal{X}) \). Since the intersection is nontrivial, it follows there exists an \( x \neq 1 \) such that

\[
x \in (\bigcap_{s \in S} \phi_s) \cap \mathcal{X} = (\bigcap_{s \in S} \phi_s \cap \mathcal{X}).
\]

(8)

Since \( \phi \) is faithful and \( x \in \mathcal{X} \), there exists a unique \( t \in M \) such that \( x \in \phi_t \setminus \partial \phi_t \). If \( t \notin S \), then \( x \in \bigcap_{s \in S} \partial \phi_s \). If this holds for all choices of \( x \) that satisfy (8), then

\[
\bigcap_{s \in S} \phi_s = \left( \bigcap_{s \in S} (\phi_s \cap \mathcal{X}) \right) \leq \bigcap_{s \in S} \partial \phi_s.
\]
Therefore, the lemma follows in this case.

Otherwise, assume \( t \in S \). Since \( \phi \) is faithful, for every \( s \in S \setminus \{ t \} \), \( x \in \partial \phi_s \cap (\phi_t \setminus \partial \phi_t) \). Because \( |S| \geq 2 \), there is at least one such \( s \). As \( \phi \) is finite and inertia-free, it follows that there exists \( \mathcal{I}_t \subseteq \mathcal{I}_\phi \) such that \( \partial \phi_s = \langle \phi_u \mid u \in \mathcal{I}_s \rangle \) by Proposition 4.5. For \( u \in \mathcal{I}_s \), we consider three cases: \( \phi_u \geq \phi_t \), \( \phi_u < \phi_t \), and \( \phi_u \parallel \phi_t \). We show that all cases lead to a contradiction. And therefore, \( t \notin S \).

Since \( \phi_s \parallel \phi_t \), there cannot be \( u \in \mathcal{I}_s \) such that \( \phi_u \geq \phi_t \). This would imply that \( \phi_s \geq \partial \phi_s \geq \phi_u \geq \phi_t \). By the same argument as used in the proof of Lemma 6.3 (using the fact that \( \mathcal{X} \) is filtered by \( \phi \)), there exists \( u \in \mathcal{I}_s \) such that \( x \in \phi_u \). If \( \phi_u < \phi_t \), then by Lemma 6.3, \( \phi_u \leq \partial \phi_t \), which would be a contradiction since \( x \notin \partial \phi_t \). Thus, we have shown that \( \phi_u \parallel \phi_t \). Since \( u \in \mathcal{I}_\phi \), \( \partial \phi_u \neq \phi_u \), and we can continue this descent down the \( \mathcal{B} \)-chain. Eventually, we reach a subgroup that must be contained in \( \phi_t \); in particular, \( \mathcal{B}_0 = \{ \langle 1 \rangle \} \). This is a contradiction, and so we cannot have \( t \in S \). \( \square \)

From the above statements, faithful filters are highly structured filters. Indeed, if \( \phi \) is a faithful filter and \( \mathcal{X} \) is filtered by \( \phi \), then \( \mathcal{X} \) is faithfully filtered by \( \phi \).

6.1. Proof of Theorem 6.1. Now we are ready to prove that every graded pcgs of \( L(\phi) \), for a finite, faithful, inertia-free filter \( \phi \), induces a faithfully filtered set of \( G \). The following proof uses Noetherian induction, going up the \( \mathcal{B} \)-sequence

\[
\{ \langle 1 \rangle \} = \mathcal{B}_0 \subseteq \mathcal{B}_1 \subseteq \cdots.
\]

**Definition 6.5.** For an \((M,G)\)-filter \( \phi \), a set \( \mathcal{X} \subseteq G \) is \( \mathcal{B}_n \)-filtered if \( \mathcal{X} \) is weakly-filtered by \( \phi \) and for all \( S \subseteq M \) such that \( \{ \phi_s \mid s \in S \} \subseteq \mathcal{B}_n \),

\[
\bigcap_{s \in S} \phi_s = \left( \bigcap_{s \in S} (\phi_s \cap \mathcal{X}) \right) = \left( \prod_{s \in S} \phi_s \right) \cap \mathcal{X} = \bigcup_{s \in S} (\phi_s \cap \mathcal{X}).
\]

The idea is to assume that a pre-image \( \mathcal{X} \) of an arbitrary graded pcgs \( \mathcal{Y} \) of \( L(\phi) \) is filtered by \( \phi \) up to some \( \mathcal{B}_n \). Because \( \langle 1 \rangle \in \text{im}(\phi) \), this holds for \( \mathcal{B}_0 \). Then for every group \( \phi_s \in \mathcal{B}_{n+1} \), there exists \( B \in \mathcal{B}_n \) such that \( \partial \phi_s = \langle B \rangle \). Thus, \( \partial \phi_s \) is handled by the induction hypothesis, and all that is left are quotients \( \phi_s / \partial \phi_s = L_s(\phi) \).

In the next lemma, we denote the complete lattice induced on \( \mathcal{B}_n \) by \( \text{Lat}(\mathcal{B}_n) \). As \( \mathcal{B}_n \subseteq \text{im}(\phi) \), it follows that \( \text{Lat}(\mathcal{B}_n) \) is a sublattice of \( \text{Lat}(\phi) \).

**Lemma 6.6.** Let \( \phi \) be a finite inertia-free \((M,G)\)-filter. The set \( \mathcal{X} \subseteq G \) is \( \mathcal{B}_n \)-filtered if, and only if, \( \mathcal{X} \) is weakly-filtered by \( \phi \) and \( \cap \mathcal{X} \cap \mathcal{B}_n : \text{Lat}(\mathcal{B}_n) \rightarrow \text{Lat}(\mathcal{B}_n) \cap \mathcal{X} \) and \( \langle \cdot \rangle : \text{Lat}(\mathcal{B}_n) \cap \mathcal{X} \rightarrow \text{Lat}(\mathcal{B}_n) \).

**Proof.** The proof follows from the proof of Proposition 5.6. \( \square \)

**Proof of Theorem 6.1.** Let \( \mathcal{Y} \) be a graded pcgs for \( L(\phi) \) whose pre-image in \( G \) is denoted by \( \mathcal{X} \). By Lemma 4.20, \( \mathcal{X} \) is weakly-filtered by \( \phi \). It follows that \( \mathcal{X} \) is \( \mathcal{B}_0 \)-filtered since \( \phi \) is non-degenerate, so suppose \( n \geq 0 \) and \( \mathcal{X} \) is \( \mathcal{B}_n \)-filtered.

Let \( S \subseteq M \) such that \( \{ \phi_s \mid s \in S \} \subseteq \mathcal{B}_{n+1} \). Using Lemma 6.3, we assume, without loss of generality, that \( |S| \geq 2 \) and for all distinct \( s,t \in S \), \( \phi_s \parallel \phi_t \). First we show that

\[
(9) \quad \left( \prod_{s \in S} \phi_s \right) \cap \mathcal{X} = \bigcup_{s \in S} (\phi_s \cap \mathcal{X}).
\]
Since $\mathcal{X}$ is weakly-filtered by $\phi$, the “$\supseteq$”-containment of (9) holds. Thus, we just prove the “$\subseteq$”-containment. Let $H = \prod_{s \in S} \phi_s$ and $K = \prod_{s \in S} \partial \phi_s$. Then $H \cap \mathcal{X} = \left( (H \setminus K) \cap \mathcal{X} \right) \cup (K \cap \mathcal{X})$. By induction,

$$K \cap \mathcal{X} = \bigcup_{s \in S} (\partial \phi_s \cap \mathcal{X}) \subseteq \bigcup_{s \in S} (\phi_s \cap \mathcal{X}).$$

If $H = K$, then we are done, so suppose $H \neq K$. Proposition 6.4 implies that $H/K \cong \bigoplus_{s \in S} L_s(\phi)$. This implies that there exists $x \in (H \setminus K) \cap \mathcal{X}$ since $\mathcal{X}$ is a pre-image of the pcgs $\mathcal{Y}$ for $L(\phi)$. Let $y \in \mathcal{Y}$ be the element corresponding to $x$. Since $\mathcal{Y}$ is a graded pcgs for $L(\phi)$, there exists a unique $t \in M$ such that $y \in L_t(\phi)$. Thus, $x \in \phi_t \setminus \partial \phi_t$, so $t \in S$. Therefore, $x \in (\phi_t \cap \mathcal{X}) \subseteq \bigcup_{s \in S} (\phi_s \cap \mathcal{X})$. Therefore, (9) holds.

Now we show that the intersection equality holds; namely

$$\bigcap_{s \in S} \phi_s = \left\langle \bigcap_{s \in S} (\phi_s \cap \mathcal{X}) \right\rangle.$$  

Since $\phi_s \in \mathfrak{B}_{n+1}$, there exists $B_s \subseteq \mathfrak{B}_n$ such that $\partial \phi_s = \langle B_s \rangle$. Therefore,

$$\left\langle \bigcap_{s \in S} \phi_s \cap \mathcal{X} \right\rangle = \left\langle \bigcap_{s \in S} \partial \phi_s \cap \mathcal{X} \right\rangle \quad \text{(Proposition 6.4)}$$

$$= \left\langle \bigcap_{s \in S} \left( \prod_{H \in B_s} H \right) \cap \mathcal{X} \right\rangle \quad \text{ ($B_s \in \mathfrak{B}_n$, $\partial \phi_s = \langle B_s \rangle$)}$$

$$= \left\langle \bigcap_{s \in S} \bigcup_{H \in B_s} (H \cap \mathcal{X}) \right\rangle \quad \text{ (equation (9))}$$

$$= \bigcap_{s \in S} \bigcup_{H \in B_s} (H \cap \mathcal{X}) \quad \text{ (induction and Lemma 6.6)}$$

$$= \bigcup_{s \in S} \bigcap_{H \in B_s} (H \cap \mathcal{X}) \quad \text{ (weakly-filtered)}$$

$$= \bigcup_{s \in S} \partial \phi_s \quad \text{(Proposition 6.4)}$$

Therefore, $\mathcal{X}$ is $\mathfrak{B}_{n+1}$-filtered. Since $\phi$ is finite and inertia-free, $\mathcal{X}$ is filtered by $\phi$. Since $\mathcal{X}$ is a pre-image of a graded pcgs, $\mathcal{X}$ is faithfully filtered by $\phi$. □

Example 2.3 illustrates one instance of a filter that is not faithful. This problem seems to comes up naturally, and this phenomenon arises again in an example in Section 7. It is not known if a method exists in general to address the issue in Example 2.3 similarly to the way in which Theorem 4.13 addresses Example 2.2.

6.2. Proof of Theorem B. The crux of Theorem B is not the bijection between $G$ and $L(\phi)$—though that is necessary for our purposes—the main point is actually the induced bijection between graded pcgs of $L(\phi)$ and pcgs of $G$ filtered by $\phi$. This is critical to proving Theorem C. Consider Example 2.4. There, $L(\phi)$ and $G$ are in bijection, but the bijection does not help us lift isomorphisms of graded Lie rings to group isomorphisms.
Proof of Theorem B. Let $Y = (y_1, \ldots, y_r)$ be a minimal graded pcgs for $L(\phi)$ and $X = (x_1, \ldots, x_r)$ a pre-image of $Y$ in $G$. We use the same notation from the proof of Theorem A, see (7) for details. By Theorem 6.1, $X$ is faithfully filtered by $\phi$. From the proof of Theorem 4.4, the map the $\pi_Y : L(\phi) \to G$ is a surjection of sets.

By Lemma 4.20, $X$ contains a pcgs of $G$. Suppose for some $x \in X$, the set $X \setminus \{x\}$ still contains a pcgs for $G$. Let $y$ denote the element corresponding to $x$ in $Y$. Since $x$ is faithfully filtered by $\phi$, for each $i \in \{1, \ldots, r\}$, there exists a unique $s_i \in M$ such that $x_i \in \phi_{s_i} \setminus \partial \phi_{s_i}$ and $y_i \in L_{s_i}(\phi)$. In particular, there exists unique $s \in M$ such that $x \in \phi_s \setminus \partial \phi_s$. Let $\{x_1, \ldots, x_n\} = (X \cap \phi_s) \setminus \{x\} \cup \partial \phi_s$, so there exists integers $e_{ij}$ such that
\begin{equation}
(11) \quad x^{-1} (x_{i_1}^{e_{i_1}} \cdots x_{i_n}^{e_{i_n}}) \in \partial \phi_s.
\end{equation}

If $y_{i_j}$ is the element of $Y$ corresponding to $x_{i_j}$, then (11) implies that in $L_s(\phi)$:
\begin{equation}
(12) \quad y = e_{i_1} \cdot y_{i_1} + \cdots + e_{i_n} \cdot y_{i_n}.
\end{equation}

However, by minimality $Y \setminus \{y\}$ is not a pcgs of $L(\phi)$, so (12) implies a contradiction. Hence, $X$ is a pcgs for $G$, and therefore, every $g \in G$ is expressed by a unique normal word in $X$. Therefore, $\pi$ is injective. \hfill \Box

6.3. Proof of Theorem C.

Proof. Suppose $\beta : G_1 \to G_2$ is an isomorphism. Then $\beta$ induces a group homomorphism $\alpha : L(\phi^{(1)}) \to L(\phi^{(2)})$. Since $\phi^{(1)}$ and $\phi^{(2)}$ are $M$-determined and characteristic, for every $s \in M$, $\phi_s^{(1)} \beta = \phi_s^{(2)}$. This implies that $\alpha$ is an $M$-graded Lie ring isomorphism. In particular $\alpha$ maps a pcgs, $Y^{(1)}$, for $L(\phi^{(1)})$ to a pcgs for $L(\phi^{(2)})$. By Theorem B, a pre-image $X^{(1)}$ of $Y^{(1)}$ is a pcgs for $G_1$. Set $X_s^{(1)} = (\phi_s \setminus \partial \phi_s) \cap X^{(1)}$ for all $s \in M$. Since $\phi$ is faithful, we identity the disjoint union with the union:
\begin{equation}
(14) \quad \bigcup_{s \in L_{\phi^{(1)}}} X_s^{(1)} = \bigcup_{s \in L_{\phi^{(2)}}} X_s^{(2)} = X^{(1)}.
\end{equation}

Thus, there exists a transversal $r_s^{(2)} : L_s(\phi^{(2)}) \to \phi_s^{(2)}$ such that the partial lift $\psi : X^{(1)} \to G_2$, mapping $x \in X_s^{(1)}$ to $(\partial \phi_s x) \circ r_s^{(2)}$, is equal to the restriction of $\beta$ on $X^{(1)}$. Since $X^{(1)}$ is a pcgs for $G_1$, it follows that $\psi$ induces a group isomorphism, namely $\psi$ induces $\beta$. Hence, every isomorphism $\beta : G_1 \to G_2$ is realized as a lift of an $M$-graded Lie ring isomorphism. \hfill \Box

7. Examples

Example 7.1. Let $G$ be the group of $4 \times 4$ upper unitriangular matrices over $\mathbb{Z}$. We define two characteristic subgroups of $G$:
\begin{equation}
H = \begin{bmatrix}
1 & * & * & * \\
1 & 0 & * & * \\
1 & * & * & * \\
1 & * & * & 0
\end{bmatrix}, \quad K = \begin{bmatrix}
1 & 0 & * & * \\
1 & * & * & 0 \\
1 & * & * & 0 \\
1 & * & * & 0
\end{bmatrix}.
\end{equation}

Let $M = (\mathbb{N}^2, \leq_+)$, and set $e_1 = (1, 0)$ and $e_2 = (0, 1)$. Since $G = HK$, we define $\phi_{e_1} = H$ and $\phi_{e_2} = K$ in our $(M, G)$-filter $\phi$. We apply the generating formula from [W] to generate a filter from this data—together with $\phi_0 = G$. We plot $\phi$ in Figure 7. As abelian groups, $L(\phi) \cong \mathbb{Z}^6$, and the $(M, G)$-filter is faithful and
inertia-free, with \( X = \{ 1 + E_{ij} \mid 1 \leq i < j \leq 4 \} \), where \( E_{ij} \) is the matrix with a 1 in the \((i,j)\) entry and 0 elsewhere.

\[
\begin{array}{cccc}
2 & 1 & 1 & 1 \\
1 & K & \gamma_2 & \gamma_3 & 1 \\
0 & G & H & \gamma_3 & 1 \\
0 & 1 & 2 & 3 \\
\end{array}
\]

Figure 7. The filter from Example 7.1.

**Example 7.2.** We consider a group examined in [ELGO, Section 12.1] and [M1, Section 5]. For a fixed odd prime \( p \), we define a \( p \)-group \( G \) by a power-commutator presentation, where all trivial commutators are omitted

\[ G = \langle g_1, \ldots, g_{13} \mid [g_{10}, g_6] = g_{11}, [g_{10}, g_7] = g_{12}, [g_2, g_1] = [g_4, g_3] = [g_8, g_5] = [g_8, g_9] = [g_{10}, g_9] = g_{13}, \text{exponent } p \rangle. \]

In [M1], we defined an \((\mathbb{N}^2, G)\)-filter, \( \tau \), where \( \mathbb{N}^2 \) is totally ordered by \( \preceq \).

Observe from the presentation that \( G \) has class 2 and \( \gamma_2 = \langle g_{11}, g_{12}, g_{13} \rangle. \) The following subgroups are characteristic

\[
\begin{align*}
J_1 &= \langle g_1, \ldots, g_9, \gamma_2 \rangle, & J_4 &= \langle g_9, \gamma_2 \rangle, \\
J_2 &= \langle g_1, \ldots, g_5, g_8, g_9, \gamma_2 \rangle, & H &= \langle g_{13} \rangle, \\
J_3 &= \langle g_5, g_8, g_9, \gamma_2 \rangle.
\end{align*}
\]

The details of this are given in [M1]. The image of \( \tau \) produces the following characteristic series

\[ G > J_1 > J_2 > J_3 > J_4 > \gamma_2 > H > 1. \]

Using techniques developed in [BW], the \( \mathbb{F}_p \)-bilinear map \([,] : G/\gamma_2 \times G/\gamma_2 \to \gamma_2 \) yields more characteristic subgroups. In fact, as \( * \)-algebras, the adjoint ring has the following Taft decomposition

\[ \text{Adj}(\phi) \cong J \oplus (X(2, \mathbb{F}_p) \oplus S(4, \mathbb{F}_p)), \]

where the simple \( * \)-algebras \( X(n, \mathbb{F}_p) \) and \( S(n, \mathbb{F}_p) \) are defined in [BW]. As \( \mathbb{F}_p \)-algebras, \( X(2, \mathbb{F}_p) \cong M_2(\mathbb{F}_p)^2 \) and \( S(4, \mathbb{F}_p) \cong M_4(\mathbb{F}_p) \). The simple \( * \)-algebras \( X(2, \mathbb{F}_p) \) and \( S(4, \mathbb{F}_p) \) determine new characteristic subgroups:

\[ E = \langle g_5, \ldots, g_{10}, \gamma_2 \rangle, \quad S = \langle g_1, \ldots, g_4, \gamma_2 \rangle. \]

Let \( M = \mathbb{N}^2 \times \mathbb{N} \times \mathbb{N} \), where \( M \) is ordered by the direct product ordering: for \((s, i, j), (t, k, l) \in M\), \((s, i, j) \preceq (t, k, l)\) if \( s \preceq t \), \( i \leq k \) and \( j \leq l \). Let

\[ D = \{(s, 0, 0) \in M \mid s \in \mathbb{N}^2 \} \cup \{e_2, e_3\}, \quad E = M \setminus D. \]

We define a function, \( \pi_1 \), on \( D \) into \( \text{Nor}(G) \) via \( \pi_{(s,0,0)} = \tau_s \), \( \pi_{e_2} = E \), and \( \pi_{e_3} = S \).

Using J.B. Wilson’s generation formula [W], we define an \((M, G)\)-filter \( \phi \) such that for \( s \in M \),

\[ \phi_s = \prod_{r \in R_{G(s)}} [\pi_r]. \]
From [W, Theorem 3.3], $\phi$ is an $(M,G)$-filter. We plot $\phi$ in Figure 8 along with its lattice $\text{Lat}(\phi)$. Since $\tau$ is inertia-free, $\phi$ is inertia-free. If $\mathcal{X} = \{g_1, \ldots, g_{13}\}$, then $\mathcal{X}$ is filtered by $\phi$. However, $\phi$ is not a faithful filter.

One can define a new filter $\theta$ from $\phi$ such that $\theta$ is faithful and inertia-free, but it is not known if such a filter always exists. It is also not known how this affects the associated Lie ring. Of course Theorem B states they are in bijection, but it is not clear if, for example, the center of the Lie ring is larger than the center of the group. In addition, $\phi$ was defined arbitrarily from $\tau$. It is not clear if there is a “best” way to refine a filter.

![Lattice Diagram]

**Figure 8.** We plot the $(M,G)$-filter from Example 7.2. We construct the lattice $\text{Lat}(\phi)$ generated by $\text{im}(\phi)$ in Figure 8(A). Since $M = \mathbb{N}^2 \times \mathbb{N} \times \mathbb{N}$ is ordered by the direct product ordering of three total orders, we can plot $\phi$ on a three axes. In Figures 8(B), 8(C), and 8(D), we plot $\phi$ given $(x,y,z) \in M$ for fixed $z$-values.

**Acknowledgements**

The author is indebted to J. B. Wilson for encouraging this research and providing endless feedback along the way. We also thank P. A. Brooksbank, A. Hulpke, and T. Penttila for many helpful discussions. We are grateful for the referee whose thorough comments have greatly improved the quality of the paper.
