

Geometric Schottky groups and non-compact hyperbolic surfaces with infinite genus

JOHN A. ARRE DONDO
CAMILO RAMÍREZ MALUENDAS

The topological type of a non-compact Riemann surface is determined by its ends space and the ends having infinite genus. In this paper for a non-compact Riemann Surface $S_{m,s}$ with $s$ ends and exactly $m$ of them with infinite genus, such that $m, s \in \mathbb{N}$ and $1 < m \leq s$, we give a precise description of the infinite set of generators of a Fuchsian (geometric Schottky) group $\Gamma_{m,s}$ such that the quotient space $\mathbb{H}/\Gamma_{m,s}$ is homeomorphic to $S_{m,s}$ and has infinite area. For this construction, we exhibit a hyperbolic polygon with an infinite number of sides and give a collection of Mobius transformations identifying the sides in pairs.

1 Introduction

It is well known that for a manifold $M$ and a properly discontinuous action of a group $\Gamma$, the quotient $M/\Gamma$ correspond to a manifold. In particular, every compact Riemann surface of genus $g$ greater than one, is homeomorphic to $\mathbb{H}/\Gamma_g$, the space of orbits of the hyperbolic plane $\mathbb{H}$ under the action of some finitely generated subgroup $\Gamma_g$ of the automorphism group of $\mathbb{H}$, and the fundamental group of this compact Riemann surface $\mathbb{H}/\Gamma_g$ is isomorphic to $\Gamma_g$. In this stage, the construction of the Riemann surface $\mathbb{H}/\Gamma_g$ immediately puts in the map Fuchsian groups, and in particular, classical Schottky groups, in fact, every compact Riemann surface is the quotient of the Riemann sphere by a Schottky group (see e.g., [Bea84], [Sch11]). The previous discussion it is extended by the Uniformization Theorem (see e.g. [Abi81], [FK92]) to the world of non-compact Riemann surfaces with infinite genus, in this case the group $\Gamma$ is still Fuchsian, more precisely, we are interested in study a type of them, called geometric Schottky groups, which were recently introduced by Anna Zielicz [Zie15]. These groups can be constructed in a similar way to a classical Schottky group but they could be infinitely generated.

Non-compact Riemann surfaces are mainly distinguished by the ends space and the genus associated in each end. Among these surfaces stand out the Infinite Loch Ness monster (up to homeomorphims, it is the surface with only one end and infinite genus) and the Jacob’s ladder (up to homeomorphism, it is the only surface with two ends and each one having infinite genus) see [PS81] and [Ghy95], which are some of the usual examples in this field, in fact, in [ARM17] the authors give a precisely description of $\Gamma$ a subgroup of $PSL(2, \mathbb{Z})$ to hold the Infinite Loch Ness monster with hyperbolic structure as the quotient $\mathbb{H}/\Gamma$. Motivated by this particularity, the various investigations on non-compact Riemann surfaces (see e.g., [AMV17], [LT16], [Mat18], [RMV17] among others) and the characterization given by the Uniformization Theorem from the point of view of universal covers for Riemann surfaces, naturally arises the following inquiry: Given a non compact Riemann Surface $S_{m,s}$ with $s$ ends, and having exactly $m$ of them with infinite genus, such that $m, s \in \mathbb{N}$ and $1 < m \leq s$ (see Figure 1). Can one give a precise description of the set of generators of a Fuchsian group $\Gamma_{m,s}$, such that the quotient space $\mathbb{H}/\Gamma_{m,s}$ is homeomorphic to $S_{m,s}$?

The rest of the paper is dedicated to answering this question, we give a precise description of the set of generators of a Fuchsian (geometric Schottky) group uniformizing a surface of infinite topological type. More precisely we prove the following result:
Theorem 1  Let $m$ and $s$ be two positive integers satisfying $1 < m \leq s$ and let $\Gamma_{m,s}$ be the geometric Schottky group generated by the Möbius transformations

$$f_t(z) = \frac{-5tz + (25t^2 - 1)}{z - 5t},$$

$$g_{k,n}(z) = \frac{-(17 + (5k - 3) \cdot 2^n \cdot 10)z + (17 + (5k - 3) \cdot 2^n \cdot 10)(13 + (5k - 3) \cdot 2^n \cdot 10) - 1}{2^n \cdot 10z - (13 + (5k - 3) \cdot 2^n \cdot 10)},$$

$$h_{k,n}(z) = \frac{-(13 + (5k - 3) \cdot 2^n \cdot 10)z + (17 + (5k - 3) \cdot 2^n \cdot 10)(13 + (5k - 3) \cdot 2^n \cdot 10) - 1}{2^n \cdot 10z - (17 + (5k - 3) \cdot 2^n \cdot 10)},$$

and their inverse, where $t \in \{1, \ldots, s - 1\}$, $k \in \{1, \ldots, m\}$ and $n \in \mathbb{N}$. Then the quotient space $S_{m,s} := \mathbb{H}/\Gamma_{m,s}$ is a geodesic complete Riemann surface having $s$ ends, and exactly $m$ of them with infinite genus.

It follows from The Uniformization Theorem, see [Bea84, p.174].

Corollary 2  The fundamental group of the Riemann surface $S_{m,s}$ is isomorphic to the geometric Schottky group $\Gamma_{m,s}$.

The paper is organized as follows: In section 2 we collect the principal tools used through the paper and section 3 is dedicated to the proof of our main result, which is divided into five steps: In step 1 we define the group $\Gamma_{s,m}$, introducing $\mathcal{C}$ a suitable family of half circles of the hyperbolic plane, and $J$ the family of Möbius transformation having as isometric circles the elements of $\mathcal{C}$. Hence, the elements of $J$ generate the group $\Gamma_{s,m}$. In step 2 we prove that $\Gamma_{s,m}$ is a Fuchsian group with a geometric Schottky structure. In step 3 we prove that $\mathbb{H}/\Gamma_{s,m}$ is a complete geodesic Riemann surface. Finally in step 4 and step 5 we characterize the ends space and the genus of each end for the Riemman surface.

2 PRELIMINARIES

We dedicate this section to introduce some general results of surfaces that will be needed for the proof of the main theorem. Our text is not self-contained, hence we refer the reader to the references for details.
2.1 Ends spaces

By a surface $S$ we mean a connected and orientable 2-dimensional manifold.

**Definition 2.1** [Fre31]. Let $U_1 \supset U_2 \supset \cdots$ be an infinite nested sequence of non-empty connected open subsets of $S$, such that:

* The boundary of $U_n$ in $S$ is compact for every $n \in \mathbb{N}$.
* For any compact subset $K$ of $S$ there is $l \in \mathbb{N}$ such that $U_l \cap K = \emptyset$. We shall denote the sequence $U_1 \supset U_2 \supset \cdots$ as $(U_n)_{n \in \mathbb{N}}$.

Two sequences $(U_n)_{n \in \mathbb{N}}$ and $(U'_n)_{n \in \mathbb{N}}$ are equivalent if for any $l \in \mathbb{N}$ it exists $k \in \mathbb{N}$ such that $U_l \supset U'_k$ and $n \in \mathbb{N}$ it exists $m \in \mathbb{N}$ such that $U'_n \supset U_m$. We will denote the set of ends by $\text{Ends}(S)$ and each equivalence class $[U_n]_{n \in \mathbb{N}} \in \text{Ends}(S)$ is called an end of $S$. For every non-empty open subset $U$ of $S$ which its boundary $\partial U$ is compact, we define the set $U^* := \{[U_n]_{n \in \mathbb{N}} \in \text{Ends}(S) : U_j \subset U \text{ for some } j \in \mathbb{N}\}$. The collection of all sets of the form $U^*$, with $U$ open with compact boundary of $S$, forms a base for the topology of $\text{Ends}(S)$.

For some surfaces their ends space carries extra information, namely, those ends that carry infinite genus. This data, together with the space of ends and the orientability class, determines the topology of $S$. The details of this fact are discussed in the following paragraphs. Given that, this article only deals with orientable surfaces; from now on, we dismiss the non-orientable case.

A surface is said to be planar if all of its compact subsurfaces are of genus zero. An end $[U_n]_{n \in \mathbb{N}}$ is called planar if there is $l \in \mathbb{N}$ such that $U_l$ is planar. The genus of a surface $S$ is the maximum of the genera of its compact subsurfaces. Remark that, if a surface $S$ has infinite genus, there is no finite set $\mathcal{C}$ of mutually non-intersecting simple closed curves with the property that $S \setminus \mathcal{C}$ is connected and planar. We define $\text{Ends}_\infty(S) \subset \text{Ends}(S)$ as the set of all ends of $S$ which are not planar or with infinite genus. It comes from the definition that $\text{Ends}_\infty(S)$ forms a closed subspace of $\text{Ends}(S)$.

**Theorem 2.2** (Classification of non-compact and orientable surfaces, [Ker23], [Ric63]) Two non-compact and orientable surfaces $S$ and $S'$ having the same genus are homeomorphic if and only if there is a homeomorphism $f : \text{Ends}(S) \to \text{Ends}(S')$ such that $f(\text{Ends}_\infty(S)) = \text{Ends}_\infty(S')$.

**Proposition 2.3** [Ric63, Proposition 3]. The space of ends of a connected surface $S$ is totally disconnected, compact, and Hausdorff. In particular, $\text{Ends}(S)$ is homeomorphic to a closed subspace of the Cantor set.

**Remark 2.4** [Spe49] A surface $S$ has exactly $n$ ends if and only if for all compact subset $K \subset S$ there is a compact $K' \subset S$ such as $K \subset K'$ and $S \setminus K'$ has $n$ connected component.

2.2 Isometric circles of the Hyperbolic plane

Given the Möbius transformation $f \in \text{PSL}(2, \mathbb{R})$ with $c \neq 0$, the half-circle $C(f) := \{z \in \mathbb{H} : |cz + d|^2 = 1\}$ will be called the isometric circle of $f$ (see e.g., [Mas88, p. 9]). We note that $\frac{-d}{c} \in \mathbb{R}$ the center of $C(f)$ is mapped by $f$ onto the infinity point $\infty$. Further, $f$ sends the half-circle $C(f)$ onto $C(f^{-1})$ the isometric circle of the Möbius transformation $f^{-1}$, such that $C(f^{-1}) = \{z \in \mathbb{H} : |cz + a|^2 = 1\}$. The inside and outside, respectively, of the circle $C(f)$ are the sets $\tilde{C}(f) := \{z \in \mathbb{H} : |cz + d|^2 < 1\}$ and $\tilde{C}(f) := \{z \in \mathbb{H} : |cz + d|^2 > 1\}$, respectively [Mas88].
Remark 2.5 The isometric circles $C(f)$ and $C(f^{-1})$ have the same radius $r = |c|^{-1}$, and their respective centers are $\alpha = -\frac{d}{c}$ and $\alpha^{-1} = \frac{a}{c}$.

If $C$ is a half-circle with center $\alpha \in \mathbb{R}$ and radius $r > 0$, the M"{o}bius transformation $f_C \in \text{PSL}(2, \mathbb{R})$ is said be inversion in $C$, if it has the hyperbolic geodesic $C$ as fixed points exchanging its the ends points, and maps $\hat{C}$ the inside of $C$ (respectively, $\hat{C}$ the outside of $C$) onto $\hat{C}$ the outside of $C$ (respectively, $\hat{C}$ the inside of $C$).

Remark 2.6 We let $L_{\alpha-2r}$ and $L_{\alpha+2r}$ be the two orthogonal straight lines to the real axis $\mathbb{R}$ through the points $\alpha - 2r$ and $\alpha + 2r$, respectively. Then the inversion $f_C$ sends $L_{\alpha-2r}$ (analogously, $L_{\alpha+2r}$) onto the half-circle whose ends points are $\alpha + \frac{r}{2}$ and $\alpha$ (respectively, $\alpha - \frac{r}{2}$ and $\alpha$). See the Figure 2. Given that $f_C$ is an element of $\text{PSL}(2, \mathbb{R})$, then for every $\epsilon < \frac{r}{2}$ the closed hyperbolic $\epsilon$-neighborhood of the half-circle $C$ does not intersect any of the hyperbolic geodesics $L_{\alpha-2r}, f_C(L_{\alpha-2r}), L_{\alpha+2r}$, and $f_C(L_{\alpha+2r})$.

![Figure 2: Inversion in C.](image)

Lemma 2.7 Let $C_1$ and $C_2$ be two disjoint half-circles having centers and radius $\alpha_1, \alpha_2 \in \mathbb{R}$, and $r_1, r_2 > 0$, respectively. Suppose that $|\alpha_1 - \alpha_2| > (r_1 + r_2)$, then for every $\epsilon < \frac{\min\{r_1, r_2\}}{2}$ the closed hyperbolic $\epsilon$-neighborhoods of the half-circles $C_1$ and $C_2$ are disjoint.

Proof By hypothesis $|\alpha_1 - \alpha_2| > (r_1 + r_2)$, then the open strips $S_1 := \{z \in \mathbb{H} : \alpha_1 - 2r_1 < \text{Re}(z) < \alpha_1 + 2r_1\}$ and $S_2 := \{z \in \mathbb{H} : \alpha_2 - 2r_2 < \text{Re}(z) < \alpha_2 + 2r_2\}$ are disjoint. We remark that the half-circle $C_i$ belongs to the open strip $S_i$, for every $i \in \{1, 2\}$. Further, the reflection $f_C$,

$$z \mapsto \frac{r_1^2 + (r_1 r_2 (\alpha_2 - \alpha_1))}{\sqrt{r_1^2 + r_2^2}}$$

sends the open strip $S_1$ onto the open strip $S_2$ and vice versa. We denote $r = \min\{r_1, r_2\}$. For each $\epsilon < \frac{r}{2}$, let $U^i_\epsilon$ be the $\epsilon$-neighborhood of the half-circle $C_i$, with $i \in \{1, 2\}$, by Remark 2.6 $U^i_\epsilon \subset S_i$. Given that $f_C$ is an element of $\text{PSL}(2, \mathbb{R})$, then $f_C(U^i_\epsilon) = U^i_{\epsilon'}$. Hence, for all $\epsilon < \frac{r}{2}$, $U^i_\epsilon \cap U^i_{\epsilon'} = \emptyset$.

2.3 Fuchsian groups and Fundamental region

Definition 2.8 [Kat92] Given a Fuchsian group $\Gamma < \text{PSL}(2, \mathbb{R})$. A closed region $R$ of the hyperbolic plane $\mathbb{H}$ is said to be a fundamental region for $\Gamma$ if it satisfies the following facts:

(i) The union $\bigcup_{f \in \Gamma} f(R) = \mathbb{H}$.

(ii) The intersection of the interior sets $\text{Int}(R) \cap f(\text{Int}(R)) = \emptyset$ for each $f \in \Gamma \setminus \{\text{Id}\}$.

The difference set $\partial R = R \setminus \text{Int}(R)$ is called the boundary of $R$ and the family $\mathcal{F} := \{f(R) : f \in \Gamma\}$ is called the tessellation of $\mathbb{H}$.
If $\Gamma$ is a Fuchsian group and each one of its elements satisfy that $c \neq 0$, then the subset $R_0$ of $\mathbb{H}$ defined as follows
\begin{equation}
R_0 := \bigcap_{f \in \Gamma} \overline{C(f)} \subseteq \mathbb{H},
\end{equation}
is a fundamental domain for the group $\Gamma$ (see e.g., [For25], [Mas88, Theorem H.3 p. 32], [Kat92, Theorem 3.3.5]). The fundamental domain $R_0$ is well-known as the Ford region for $\Gamma$.

On the other hand, we can get a Riemann surface from any Fuchsian group $\Gamma$. It is only necessary to define the action $\alpha : \Gamma \times \mathbb{H} \to \mathbb{H}$ as follows $(f, z) \mapsto f(z)$, which is proper and discontinuous (see [Kat10, Theorem 8.6]). Now, we define the subset $W := \{w \in \mathbb{H} : f(w) = w \text{ for any } f \in \Gamma - \{Id\} \} \subseteq \mathbb{H}$. We note that the subset $W$ is countable and discrete, and the action $\alpha$ leaves invariant the subset $W$. Then the action $\alpha$ restricted to the hyperbolic plane $\mathbb{H}$ removing the subset $W$ is free, proper and discontinuous. Therefore, the quotient space $S := (\mathbb{H} \setminus W)/\Gamma$ is well-defined and via the projection map $\pi : (\mathbb{H} \setminus W) \to S$ such as $z \mapsto [z]$, it comes with a hyperbolic structure, it means, $S$ is a Riemann surface (see e.g., [Lee00]).

**Remark 2.9** If $R$ is a locally finite\(^1\) fundamental domain for the Fuchsian group $\Gamma$, then the quotient space $(\mathbb{H} \setminus W)/\Gamma$ is homeomorphic to $R/\Gamma$ (see Theorem 9.2.4 on [Bea83]).

### 2.4 Classical Schottky groups and Geometric Schottky groups

In general, by a classical Schottky group it is understood as a finitely generated subgroup of $\text{PSL}(2, \mathbb{C})$, generated by isometries sending the interior of one circle into the exterior of a different circle, both of them disjoint. From the various definitions, we consider the one given in [Mas88], but there are alternative and similar definitions that can be found in [But98], [Car12], [MT13].

Let $C_1, C_1', \ldots, C_n, C_n'$ be a set of disjoint countable circles in the extended complex plane $\hat{\mathbb{C}}$, for any $n \in \mathbb{N}$, bounding a common region $D$. For every $j \in \{1, \ldots, n\}$, we consider the Möbius transformation $f_j$, which sends the circle $C_j$ onto the circle $C_j'$, i.e., $f_j(C_j) = C_j'$ and $f_j(D) \cap D = \emptyset$. The group $\Gamma$ generated by the set \{ $f_j, f_j^{-1} : j \in \{1, \ldots, n\} \}$ is called a classical Schottky group.

The *Geometric Schottky groups* can be acknowledged as a nice generalization of the *Classical Schottky groups* because the definition of the first group is extended to the second one, in the sense that the Classical Schottky groups are finitely generated by definition, while the Geometric Schottky group can be infinitely generated. Geometric Schottky groups, defined by Anna Zielicz (see [Zie15, Section 3]) are a nice generalization of classical Schottky groups to infinitely many generators, and these are central to our main Theorem 1.

Consider an open interval $A$ in the real line $\mathbb{R}$. Let $\partial A$ denote its boundary in $\mathbb{R}$, which consists of two points. The two points of $\partial A$ determine a geodesic $\gamma_A$ in $\mathbb{H}$. This geodesic in turn defines two closed half-planes in $\mathbb{H}$. The boundary at infinity of one of these two closed half-planes is equal to the closure $\overline{A} := A \cup \partial A$ and we will denote this closed half-plane by $\hat{A}$. A demonstration of $A$, $\gamma_A$ and $\hat{A}$ has been depicted in Figure 3:

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure3.png}
\caption{Objects $A$, $\gamma_A$ and $\hat{A}$.}
\end{figure}

\(^1\)In the sense due to Beardon on [Bea83, Definition 9.2.3].
We note that any Schottky description $U$ is a symmetric subset of $\mathbb{Z}$ and let $\{f_k : k \in I\}$ be a subset of $PSL(2, \mathbb{R})$. The pair
\[ (\cup I(A_k, f_k, I), \{f_k\}_{k\in I}) \]
is called a Schottky description$^3$ if it satisfies the following conditions:

1. The closures subsets $\overline{A}_k$ in $\mathbb{C}$ are mutually disjoint.
2. None of the $\overline{A}_k$ contains a closed half-circle.
3. For every $k \in I$, we denote as $C_k$ the half-circle whose ends points coincide to the ends points of $\overline{A}_k$, which is the isometric circle of $f_k$. Analogously, the half-circle $C_{-k}$ is the isometric circle of $f_{-k} := f_k^{-1}$.
4. For each $k \in I$, the Möbius transformation $f_k$ is hyperbolic.
5. There is an $\epsilon > 0$ such that the closed hyperbolic $\epsilon$-neighborhood of the half-circles $C_k$, $k \in I$ are pairwise disjoint.

A subgroup $\Gamma$ of $PSL(2, \mathbb{R})$ is called Schottky type if there exists a Schottky description $U(A_k, f_k, I)$ such that the generated group by the set $\{f_k : k \in I\}$ is equal to $\Gamma$, i.e., we have
\[ \Gamma = \langle f_k : k \in I \rangle. \]

A subgroup $\Gamma$ of $PSL(2, \mathbb{R})$ together a Schottky description $U(A_k, f_k, I)$ satisfying property 4 will be referred to as geometric Schottky group.

We note that any Schottky description $U(A_k, f_k, I)$ defines a Geometric Schottky group.

Every Geometric Schottky group $\Gamma$ is a Fuchsian group.

The standard fundamental domain for the Geometric Schottky group $\Gamma$ having Schottky description $U(A_k, f_k, I)$ is the intersection of all outside of the half-circle associated to the transformations $f_k$, i.e.,
\[ F(\Gamma) := \bigcap_{k \in I} \overline{C}_k \subset \mathbb{H}. \]

The standard fundamental domain $F(\Gamma)$ is a fundamental domain for the Geometric Schottky group $\Gamma$.

## 3 Proof of main result

**Step 1. Building the group $\Gamma$.** Given that we shall construct a Riemann Surface with $s$ ends for $s \in \mathbb{N}$, then for each $t \in \{1, \ldots, s - 1\}$ we denote as $C(f_t) := \{z \in \mathbb{H} : |z - 5t| = 1\}$ and $C(f_t^{-1}) := \{z \in \mathbb{H} : |z + 5t| = 1\}$ the half-circle having center $5t$ and $-5t$ in the real line, respectively, and the same radius equality to 1 (see Figure 4). Let $f_t$ and $f_t^{-1}$ be the Möbius transformations having as isometric circle the half-circle $C(f_t)$ and $C(f_t^{-1})$ respectively. Using Remark 2.5 we compute and get the values of the coefficients of $f_t$ and $f_t^{-1}$, it means
\[ f_t(z) = \frac{-5tz + (25t^2 - 1)}{z - 5t}, \quad f_t^{-1}(z) = \frac{-5tz - (25t^2 - 1)}{-z - 5t}. \]

---

$^2$A subset $I \subseteq \mathbb{Z}$ is called symmetric if it satisfies that $0 \notin I$ and for every $k \in I$ implies $-k \in I$.

$^3$The writer gives this definition to the Poincaré disc and we use its equivalent to the half plane.
Geometric Schottky groups and non-compact hyperbolic surfaces with infinite genus

Remark 3.1 For each \( t \in \{1, \ldots, s-1\} \), we note that the Möbius transformations \( f_t \) and \( f_t^{-1} \) are both hyperbolic.

In order to hold the Riemann surface having \( m \leq s \) ends with infinite genus, it is necessary to introduce the following infinite families of half-circles and Möbius transformations.

For each \( k \in \{1, \ldots, m\} \) we consider the closed intervals \( I_k := [5k-3, 5k-2] \) and \( \hat{I}_k := [-(5k-2), -(5k-3)] \) on the real line, which can be written as the following union of closed subintervals

\[
I_k = \bigcup_{n \in \mathbb{N}} \left[5k-3 + \frac{1}{2^n}, 5k-2 + \frac{1}{2^{n-1}}\right],
\]

\[
\hat{I}_k = \bigcup_{n \in \mathbb{N}} \left[-\left(5k-3 + \frac{1}{2^n}\right), -\left(5k-2 + \frac{1}{2^{n-1}}\right)\right].
\]

We shall introduce the following notation for the closed subintervals in equation (7) (see Figure 5).

\[
I_{k,n} := \left[5k-3 + \frac{1}{2^n}, 5k-2 + \frac{1}{2^{n-1}}\right],
\]

\[
\hat{I}_{k,n} := \left[-\left(5k-3 + \frac{1}{2^n}\right), -\left(5k-2 + \frac{1}{2^{n-1}}\right)\right].
\]

Now, we consider the following two points in \( I_{k,n} \)

\[
\alpha_{k,n} := 5k-3 + \frac{1}{2^n} + \frac{3}{2^n \cdot 10} = \frac{13 + (5k-3) \cdot 2^n \cdot 10}{2^n \cdot 10},
\]

\[
\beta_{k,n} := 5k-3 + \frac{7}{2^n \cdot 10} = \frac{17 + (5k-3) \cdot 2^n \cdot 10}{2^n \cdot 10}.
\]

Analogously, we consider the following two points in \( \hat{I}_{k,n} \)

\[
\alpha_{k,n}^{-1} := -\frac{17 + (5k-3) \cdot 2^n \cdot 10}{2^n \cdot 10}, \quad \beta_{k,n}^{-1} := -\frac{13 + (5k-3) \cdot 2^n \cdot 10}{2^n \cdot 10}.
\]
Note that $\alpha_{k,n}^{-1}$ is not equal to $-\alpha_{k,n}$, but to $-\beta_{k,n}$. Then we denote as $C(g_{k,n})$, $C(h_{k,n})$, $C(h_{k,n}^{-1})$ the half-circles with center in $\alpha_{k,n}$, $\alpha_{k,n}^{-1}$, $\beta_{k,n}$, and $\beta_{k,n}^{-1}$ respectively, and radius $r_n := \frac{1}{2^n . 10}$ (see Figures 6 and 7).

Now, we shall calculate the values of the coefficients of the Möbius transformation $g_{k,n}(z) = \frac{a_{k,n}z + b_{k,n}}{c_{k,n}z + d_{k,n}}$ and its respective inverse $g_{k,n}^{-1}(z) = \frac{d_{k,n}z - b_{k,n}}{-c_{k,n}z + a_{k,n}}$, which have as isometric circles the half-circles $C(g_{k,n})$ and $C(g_{k,n}^{-1})$, respectively. By Remark 2.5 we get $c_{k,n} = 2^n \cdot 10$, $a_{k,n} = -(17 + (5k - 3) \cdot 2^n \cdot 10)$ and $d_{k,n} = -(13 + (5k - 3) \cdot 2^n \cdot 10)$.

Now, we substitute these values in the determinant $a_{1,n}d_{1,n} - b_{1,n}c_{1,n} = 1$, and computing we hold

$$b_{k,n} = \frac{(17 + (5k - 3) \cdot 2^n \cdot 10)(13 + (5k - 3) \cdot 2^n \cdot 10) - 1}{2^n \cdot 10}.$$

Hence, we get

$$g_{k,n}(z) = \frac{-(17 + (5k - 3) \cdot 2^n \cdot 10)z + (17 + (5k - 3) \cdot 2^n \cdot 10)(13 + (5k - 3) \cdot 2^n \cdot 10) - 1}{2^n \cdot 10z - (13 + (5k - 3) \cdot 2^n \cdot 10)},$$

(11)

$$g_{k,n}^{-1}(z) = \frac{-(13 + (5k - 3) \cdot 2^n \cdot 10)z - (17 + (5k - 3) \cdot 2^n \cdot 10)(13 + (5k - 3) \cdot 2^n \cdot 10) - 1}{-2^n \cdot 10z - (17 + (5k - 3) \cdot 2^n \cdot 10)}.$$

**Remark 3.3** The Möbius transformations $g_{k,n}$ and $g_{k,n}^{-1}$ are hyperbolic.
Likewise, we shall calculate the the values of the coefficients of the Möbius transformation 
\[ h_{k,n}(z) = \frac{a_{k,n}z + b_{k,n}}{c_{k,n}z + d_{k,n}} \]
and its respective inverse \( h_{k,n}^{-1}(z) = \frac{d_{k,n}z - b_{k,n}}{-c_{k,n}z + a_{k,n}} \), which have as isometric circles the half-circles \( C(h_{k,n}) \) and \( C(h_{k,n}^{-1}) \), respectively. By Remark 2.5 we get \( c_{k,n} = 2^n \cdot 10 \), \( a_{k,n} = -(13 + (5k - 3) \cdot 2^n \cdot 10) \) and \( d_{k,n} = -(17 + (5k - 3) \cdot 2^n \cdot 10) \). Now, we substitute these values in the determinant \( a_{k,n}d_{k,n} - b_{k,n}c_{k,n} = 1 \), and computing we hold
\[
bg = \frac{(17 + (5k - 3) \cdot 2^n \cdot 10)(13 + (5k - 3) \cdot 2^n \cdot 10) - 1}{2^n \cdot 10}.
\]
Hence, we get
\[
h_{k,n}(z) = \frac{-(13 + (5k - 3) \cdot 2^n \cdot 10)z + (17 + (5k - 3) \cdot 2^n \cdot 10)(13 + (5k - 3) \cdot 2^n \cdot 10) - 1}{2^n \cdot 10 - (17 + (5k - 3) \cdot 2^n \cdot 10)},
\]
(12)
\[
h_{k,n}^{-1}(z) = \frac{-(17 + (5k - 3) \cdot 2^n \cdot 10)z - (17 + (5k - 3) \cdot 2^n \cdot 10)(13 + (5k - 3) \cdot 2^n \cdot 10) - 1}{-2^n \cdot 10z - (13 + (5k - 3) \cdot 2^n \cdot 10)}.
\]

Remark 3.4  The Möbius transformations \( h_{k,n} \) and \( h_{k,n}^{-1} \) are hyperbolic.

From the previous construction of Möbius transformations and their respectively half-circles (see equations (6), (11), and (12)) we define the sets
\[
J := \{ f_t, f_t^{-1}, g_{k,n}, g_{k,n}^{-1}, h_{k,n}, h_{k,n}^{-1} : t \in \{1, \ldots, s - 1\}, k \in \{1, \ldots, m\}, n \in \mathbb{N}\},
\]
(13)
\[
C := \{ C(f_t), C(f_t^{-1}), C(g_{k,n}), C(g_{k,n}^{-1}), C(h_{k,n}), C(h_{k,n}^{-1}) : t \in \{1, \ldots, s - 1\}, k \in \{1, \ldots, m\}, n \in \mathbb{N}\}.
\]
Then let \( \Gamma_{m,s} \) be the subgroup of \( \text{PSL}(2, \mathbb{R}) \) generated by \( J \). By construction the elements of \( \Gamma_{m,s} \) are hyperbolic and the half-circle of \( C \) are pairwise disjoint.

Step 2. The group \( \Gamma_{m,s} \) is a Fuchsian group. We will prove that \( \Gamma_{m,s} \) is a Geometric Schottky group i.e., we shall define a Schottky description for \( \Gamma_{m,s} \). Hence, by Proposition 2.13 we will conclude that \( \Gamma_{m,s} \) is Fuchsian.

We consider \( P = \{ p_n \}_{n \in \mathbb{N}} \) the set conformed by all primes numbers. Hence, the map \( \psi : J \to \mathbb{Z} \) defined by
\[
\begin{align*}
  f_t & \mapsto p_1^t, & f_t^{-1} & \mapsto -p_1^t, \\
  g_{k,n} & \mapsto p_2 \cdot p_{4+n}^k, & g_{k,n}^{-1} & \mapsto -p_2 \cdot p_{4+n}^k, \\
  h_{k,n} & \mapsto p_3 \cdot p_{4+n}^k, & h_{k,n}^{-1} & \mapsto -p_3 \cdot p_{4+n}^k,
\end{align*}
\]
is injective, for every \( t, k, n \in \mathbb{N} \). We remark that \( I := \psi(J) \), the image of \( J \) under \( \psi \) is a symmetric subset of the integers numbers, then for each element \( k \) of \( I \) there is a unique Möbius transformation \( f \) belonging to \( J \) such that \( \psi(f) = k \), then we label the transformation \( f \) as \( f_k \). Therefore, we re-write the sets in the equation (13) as
\[
J := \{ f_k : k \in I \}, \quad C := \{ C(f_k) : k \in I \}.
\]
Similarly, the center and radius of each half circle \( C(f_k) \) is re-written as \( \alpha_k \) and \( r_k \), respectively. Now, we define the set \( \{ A_k : k \in I \} \) being \( A_k \) the straight segment in the real line \( \mathbb{R} \) having as ends point the same ones of the half circle \( C(f_k) \). So, we shall prove that the pair
\[
\mathcal{U}(A_k, f_k, I) := (\{ A_k \}, \{ f_k \})_{k \in I}
\]
is a Schottky description. We note that by the inductive construction of the family \( J \) described above (see equation (14)), the object \( \mathcal{U}(A_k, f_k, I) \) satisfies conditions 1 to 4 in Definition 2.10. Thus, we must only prove that the requirement 5 of the Definition 2.10 is done.

Given the Möbius transformation \( f_k \in J \) and its respective half circle \( C(f_k) \in \mathcal{C} \) we construct the open vertical strip \( M_k := \{ z \in \mathbb{H} : \alpha_k - 2r_k < \text{Re}(z) < \alpha_k + 2r_k \} \), being \( \alpha_k \) and \( r_k \) the center and radius of \( C(f_k) \), respectively.
Remark 3.5 We have the following facts.

1. The half circle \( C(f_k) \) is contained into the open strips \( M_k \) i.e., \( C(f_k) \subset M_k \).
2. The \( \epsilon \)-neighborhood \( B_k^\epsilon \) of the half circle \( C(f_k) \) is contained into the open strips \( M_k \), choosing \( \epsilon < \frac{1}{M} \).
3. For any two transformations \( f_k \neq f_j \in \mathcal{J} \) the intersection of their open strips associated is empty, \( M_k \cap M_j = \emptyset \).

On the other hand, there is an element \( i \in I \) such that the radius \( r_i \) of the half circle \( C(f_i) \in C \) is equal to 1 i.e., \( r_i = 1 \).

So, \( r_k \leq r_i = 1 \) for all \( k \in I \). Then, by construction we have the relation \( |\alpha_k - \alpha_i| > r_k + r_i = r_k + 1 \), for all \( k \in I \), applying Lemma 2.7 we have that for every \( \epsilon < \frac{\min\{r_k, r_i\}}{2} = \frac{r_i}{2} = \frac{1}{2} \) the closure of the \( \epsilon \)-neighborhoods \( B_k^\epsilon \) and \( B_i^\epsilon \) of the half circles \( C(f_k) \) and \( C(f_i) \) are disjoint. Moreover, this lemma assures that the closure of the \( \epsilon \)-neighborhood \( B_k^\epsilon \) is contained in the open strip \( M_k \). This implies that the closed hyperbolic \( \epsilon \)-neighborhood \( B_k^\epsilon \), \( k \in I \), are pairwise disjoint, fixing \( \epsilon < \frac{1}{2} \). Therefore, requirement 5 of Definition 2.10 is done, then we can conclude that \( \mathcal{U}(A_k, f_k, I) \) is a Schottky description. Finally, we consider the set \( \mathcal{J} \) described in equation (14). Then from Proposition 2.13 we hold that the Geometric Schottky group \( \Gamma_{m,s} := \langle f_k : k \in I \rangle \) is a Fuchsian group.

Step 3. Holding the suitable surface. We remember that the Fuchsian group \( \Gamma_{m,s} \) defined above acts freely and properly discontinuously on the subset \( \mathbb{H} \setminus W \), being \( W := \{ w \in \mathbb{H} : f(w) = w \text{ for any } \Gamma_{m,s} \setminus \{ \text{Id} \} \} \). Nevertheless, in this case the set \( W \) is the empty set, because the half circles belonging to \( C \) are pairwise disjoint. Then, the quotient space

\[
S_{m,s} := \mathbb{H}/\Gamma_{m,s}
\]

is a geodesic complete Riemann surface via the projection map \( \pi : \mathbb{H} \to S_{m,s} \), such as \( z \mapsto [z] \) (see [Sch11]).

Step 4. The surface \( S_{m,s} \) has \( s \) ends. We claim that the surface \( S_{m,s} \) has \( s \) ends and exactly \( m \) of them with infinite genus. To prove this, it is necessary to introduce the following construction.

Construction 3.6 For the hyperbolic plane \( \mathbb{H} \) there is an increasing sequence of connected compact sets \( K_1 \subset K_2 \subset \ldots \) such that \( \mathbb{H} = \bigcup_{l \in \mathbb{N}} K_l \), and whose complements define the only one end of the hyperbolic plane. In other words, \( \mathbb{H} \setminus K_1 \supset \mathbb{H} \setminus K_2 \supset \ldots \) the infinite nested sequence of non-empty connected subsets of \( \mathbb{H} \), defines the equivalent class \( \{ \mathbb{H} \setminus K_l \}_{l \in \mathbb{N}} \), which is the only one end of \( \mathbb{H} \) (see Definition 2.1). More precisely, for each \( l \in \mathbb{N} \), we define the compact subset

\[
K_l := \left\{ z \in \mathbb{H} : -5(s-1) - l \leq \text{Re}(z) \leq 5(s-1) + l \text{ and } \frac{1}{l} \leq \text{Im}(z) \leq l + 1 \right\}.
\]

We remark that if \( K \) is a compact subset of \( \mathbb{H} \), then there is \( l \in \mathbb{N} \) such that \( K \subset K_l \) (see Figure 8).

![Figure 8: Geometric representation of the compact subset \( K_i \) on the hyperbolic plane.](image)

Now, for each \( t \in \{1, \ldots, s\} \) we define the open subset \( U_t \) of the hyperbolic plane \( \mathbb{H} \) as follows

\[
\begin{align*}
* & \text{If } t \in \{1, \ldots, s-1\}, \text{ then } U_t \text{ is the union} \\
(17) & U_t := \left\{ z \in \mathbb{H} : -5t \leq \text{Re}(z) \leq -5(t-1) \text{ and } 0 < \text{Im}(z) < 1 \right\} \cup \\
& \left\{ z \in \mathbb{H} : 5(t-1) \leq \text{Re}(z) \leq 5t \text{ and } 0 < \text{Im}(z) < 1 \right\}.
\end{align*}
\]
We remark that the open subsets $U_t = U_s$ is the complement

\[(18) \quad U_t = U_s := \mathbb{H} \setminus \{z \in \mathbb{H} : -5(t - 1) \leq \text{Re}(z) \leq 5(t - 1) \text{ and } 0 < \text{Im}(z) \leq 1\}.
\]

We remark that the open subsets $U_1, \ldots, U_s$ are pair disjoint.

On the other hand, following Proposition 2.14 the standard fundamental domain

\[(19) \quad F(\Gamma_{m,s}) = \bigcap_{k \in I} \overline{C}(f_k) \subset \mathbb{H},
\]

is a fundamental domain for the Fuchsian group $\Gamma_{m,s}$. We note that the fundamental domain $F(\Gamma_{m,s})$ is connected, locally connected and its boundary is the set of half circles $C$ (see equation (13)). It is easy to check that the hyperbolic area of $F(\Gamma_{m,s})$ is infinite.

By construction, if $\gamma$ is a horizontal line belonged to the horizontal strip $M := \{z \in \mathbb{H} : 0 < \text{Im}(z) < 1\}$, then the image of $\gamma \cap F(\Gamma_{m,s})$ under $\pi$ are $s$ disjoint curves. We shall abuse of the language and the word horocycle would mean horizontal line. Contrary, if $\gamma$ is a horocycle belonged to $\mathbb{H} \setminus M$, then the image of $\gamma \cap F(\Gamma_{m,s}) = \gamma$ under the projection $\pi$ is a curve. Considering the objects described in Construction 3.6, it implies that for each $t \in \{1, \ldots, s\}$ and each $l \in \mathbb{N}$ the image of $(U_t \setminus K_l) \cap F(\Gamma_{m,s})$ under $\pi$ is a path-wise connected subset of $S_{m,s}$, then the open subset

\[(20) \quad C_{l,t} := \pi((U_t \setminus K_l) \cap F(\Gamma_{m,s})) \subset S_{m,s}
\]

is connected and its boundary in $S_{m,s}$ is compact for each $l \in \mathbb{N}$ and $t \in \{1, \ldots, s\}$. By definition of $K_l$ we hold that

\[S_{m,s} \setminus \pi(K_l) = S_{m,s} \setminus \pi(K_l \cap F(\Gamma_{m,s})) = \bigcup_{t=1}^{s} C_{l,t}.
\]

Let $\tilde{K}$ be a compact subset of $S_{m,s}$, by Remark 2.4 we must prove that there exist a compact subset $K'$ of $S_{m,s}$ such that $\tilde{K} \subset K'$ and $S_{m,s} \setminus K'$ are exactly $s$ connected component. Let $K$ denote the compact subset of $\mathbb{H}$ such that $\pi(K) = \tilde{K}$. From Construction 3.6 there is a compact subset $K_l$ of the hyperbolic plane $\mathbb{H}$ such that $K \subset K_l$ for any $l \in \mathbb{N}$. Let $K'$ be the image of $K_l \cap F(\Gamma_{m,s})$ under the projection $\pi$, $K' := \pi(K_l \cap F(\Gamma_{m,s}))$. Then we shall prove that $S_{m,s} \setminus K'$ are exactly $s$ connected components, it means that $S_{m,s} \setminus K'$ is the disjoint union

\[S_{m,s} \setminus K' = \bigcup_{t=1}^{s} C_{l,t}.
\]

We just should prove that the subsets $C_{l,t}$ are disjoint. We will proceed by contradiction and will suppose that there is $u \neq t \in \{1, \ldots, s\}$ such that $C_{u,l} \cap C_{l,t} \neq \emptyset$. Let $z$ be an element in the fundamental domain $F(\Gamma_{m,s})$ such that $\pi(z) \in C_{u,l} \cap C_{l,t}$, then $z \in (U_u \setminus K_l) \cap F(\Gamma_{m,s})$ and $z \in (U_l \setminus K_l) \cap F(\Gamma_{m,s})$, which implies that $z$ is an element on the intersection of $U_u \cap U_l$. Clearly, this is a contradiction because the open subsets $U_s$ are disjoint (see Construction 3.6). This proves that the surface $S_{m,s}$ has $s$ ends.

**Step 5. The surface $S_{m,s}$ has $m$ ends with infinite genus.** Given the exhaustion of $\mathbb{H} = \bigcup_{l \in \mathbb{N}} K_l$ by compact subsets in Construction 3.6, the image of each element of the family $\{K_l \cap F(\Gamma_{m,s})\}_{l \in \mathbb{N}}$ under the projection $\pi$ is a compact subset of $S_{m,s}$, which we denote as $K_l$. Hence, the family $\{K_l\}_{l \in \mathbb{N}}$ is also an exhaustion of $S_{m,s} = \bigcup_{l \in \mathbb{N}} K_l$ by compact subsets. Using the ideas above, we can write the set

\[S_{m,s} \setminus K_l = \bigcup_{t=1}^{s} C_{l,t}.
\]
a. The image of \((M_{k,n} \cup \hat{M}_{k,n}) \setminus K_1\) under \(\pi\) is the subsurface \(S_k\).

b. The subsurface \(S_k\) is topologically equivalent to two squares with identifications.

c. Identifying the sides \(C(g_{k,2n}^{-1})\) and \(C(h_{k,2n})\).

d. Cutting we get three triangles.

e. Identifying the sides \(C(g_{k,2n})\) and \(C(g_{k,2n}^{-1})\); \((C(h_{k,2n}^{-1}))\) and \(C(h_{k,2n})\); and \((C(h_{k,2n}^{-1}))\) with \((C(h_{k,2n}^{-1}))\), respectively.

f. Finally is obtained a torus with two punctured.

Figure 9: Graphic description of the process of taking a fundamental region on the Hyperbolic plane and through the quotient with a geometric Schottky group arise a non-compact Riemann surface.

where each \(C_{t,l}\) with \(t \in \{1, \ldots, s\}\) and \(l \in \mathbb{N}\) is a connected component whose boundary is compact in \(S_{m,s}\) and, \(C_{t,l} \supseteq C_{t,l+1}\). In other words, the ends space \(\text{Ends}(S_{m,s})\) are all the nested sequences \((C_{t,l})_{l \in \mathbb{N}}\) i.e., \(\text{Ends}(S_{m,s}) = \{[C_{t,l}]_{l \in \mathbb{N}} : t \in \{1, \ldots, s\}\}\). By construction follows that the ends \([C_{t,l}]_{l \in \mathbb{N}}\) with \(t \in \{m+1, \ldots, s\}\) is planar because of the subsurface \(C_{t,l}\) is homeomorphic to the cylinder for all \(l \in \mathbb{N}\) and all \(t \in \{m+1, \ldots, s\}\).

Now, we shall prove that the end \([C_{k,l}]_{l \in \mathbb{N}}\) with \(k \in \{1, \ldots, m\}\) have infinite genus. In other words, we will prove that each subsurface \(C_{k,l}\) of \(S_{m,s}\) has infinite genus with \(k \in \{1, \ldots, m\}\) and \(l \in \mathbb{N}\).

Given the end \([C_{k,l}]_{l \in \mathbb{N}}\) and the closed intervals \(I_k = \bigcup_{k \in \mathbb{N}} I_{k,n}\) and \(\hat{I}_k = \bigcup_{k \in \mathbb{N}} \hat{I}_{k,n}\) (see equations (7) and (8)) with \(k \in \{1, \ldots, m\}\), we define the two vertical strips

\[
M_{k,n} := \{ z \in \mathbb{H} : \text{Re}(z) \in \text{Int}(I_{k,2n-1} \cup I_{2k,n}) \text{ and, } 0 < \text{Im}(z) < 1 \} \subset F(\Gamma_{m,s}),
\]

\[
\hat{M}_{k,n} := \{ z \in \mathbb{H} : \text{Re}(z) \in \text{Int}(\hat{I}_{k,2n-1} \cup \hat{I}_{2k,n}) \text{ and, } 0 < \text{Im}(z) < 1 \} \subset F(\Gamma_{m,s}).
\]

For \(l = 1\), the image \((M_{k,n} \cup \hat{M}_{k,n}) \setminus K_1\) under \(\pi\) is a subsurface of \(C_{t,1}\), denote as \(S_k := \pi((M_{k,n} \cup \hat{M}_{k,n}) \setminus K_1)\).
which is homeomorphic to the torus punctured by 2 points, for each \( k \in \mathbb{N} \) (see Figure 9). We remark that if \( u \neq k \in \mathbb{N} \), then the subsurface \( S_u \) and \( S_k \) are disjoint, \( S_u \cap S_k = \emptyset \), this implies that the subsurface \( C_{t,1} \) of \( S_{m,s} \) has infinite genus.

For \( l = 2 \), the image of \( (M_{k,n} \cup \hat{M}_{k,n}) \setminus K_2 \) under \( \pi \) is a subsurface of \( C_{t,2} \), denote as \( S_k := \pi((M_{k,n} \cup \hat{M}_{k,n}) \setminus K_2) \), which is homeomorphic to the torus punctured by 2 points, for each \( k > 1 \). We remark that if \( u \neq k \in \mathbb{N} \), then the subsurface \( S_u \) and \( S_k \) are disjoint, \( S_u \cap S_k = \emptyset \), this implies that the subsurface \( C_{t,2} \) of \( S_{m,s} \) has infinite genus.

For each \( l \in \mathbb{N} \), the image \( (M_{k,n} \cup \hat{M}_{k,n}) \setminus K_l \) under \( \pi \) is a subsurface of \( C_{t,l} \), denote as \( S_k := \pi((M_{k,n} \cup \hat{M}_{k,n}) \setminus K_l) \), which is homeomorphic to the torus punctured by 2 points, for each \( k > l \). We remark that if \( u \neq k \in \mathbb{N} \), then the subsurface \( S_u \) and \( S_k \) are disjoint, \( S_u \cap S_k = \emptyset \), this implies that the subsurface \( C_{t,l} \) of \( S_{m,s} \) has infinite genus. Hence we conclude that the end \( \{C_{k,l}\}_{l \in \mathbb{N}} \) has infinite genus, for each \( k \in \{1, \ldots, m\} \).

\[ \square \]

**Corollary 3** The fundamental group of the Riemann surface \( S_{s,m} \) is isomorphic to \( \Gamma_{s,m} \).

**Corollary 4** Let \( \Gamma_s \) be the subgroup of \( \text{PSL}(2,\mathbb{R}) \) generated by the set \( \{f_1, f_1^{-1}, \ldots, f_{s-1}, f_{s-1}^{-1}\} \) (see equation 6) then the quotient \( S_s := \mathbb{H}/\Gamma_s \) is complete Riemann surface having exactly \( s \) ends and genus zero. Moreover, the fundamental group of the Riemann surface \( S_s \) is isomorphic to \( \Gamma_s \).

**Remark 1** Following the same ideas of the proof of Theorem 1 it is easy to check that the Riemann surface \( \mathbb{H}/\Gamma \) has ends space homeomorphic to the closure of the set \( \{\frac{1}{n} : n \in \mathbb{N}\} \subset \mathbb{R} \), where \( \Gamma \) is the set generated by \( \{f_t, f_t^{-1} : t \in \mathbb{N}\} \) (see equation 6).
