Abstract. This paper concerns the question to what extent it can be efficiently determined whether an arbitrary program correctly solves a given problem. This question is investigated with programs of a very simple form, namely instruction sequences, and a very simple problem, namely the non-zeroness test on natural numbers. The instruction sequences concerned are of a kind by which, for each \( n > 0 \), each function from \( \{0, 1\}^n \) to \( \{0, 1\} \) can be computed. The established results include the time complexities of the problem of determining whether an arbitrary instruction sequence correctly implements the restriction to \( \{0, 1\}^n \) of the function from \( \{0, 1\}^* \) to \( \{0, 1\} \) that models the non-zeroness test function, for \( n > 0 \), under several restrictions on the arbitrary instruction sequence.

Keywords: non-zeroness test, instruction sequence, correctness problem, computational complexity.

1998 ACM Computing Classification: D.2.4; F.1.1; F.1.3.

1 Introduction

For each \( n > 0 \), each function from \( \{0, 1\}^n \) to \( \{0, 1\} \) can be computed by a finite instruction sequence that contains only instructions to set and get the content of Boolean registers, forward jump instructions, and a termination instruction. It is an intuitively evident fact that the correctness of an arbitrary instruction sequence of this kind as an implementation of the restriction to \( \{0, 1\}^n \) of a given function from \( \{0, 1\}^* \) to \( \{0, 1\} \), for \( n > 0 \), cannot be efficiently determined. In this paper, we investigate under what restrictions on the arbitrary instruction sequence the correctness can be efficiently determined in the case that the given function is the function that models the non-zeroness test on natural numbers with respect to their binary representations. To our knowledge, there are no previous investigations of this kind.

One of the main results of this work (Theorem 7) states, roughly, that the problem of determining the correctness of an arbitrary instruction sequence as an implementation of the restriction to \( \{0, 1\}^n \) of the function from \( \{0, 1\}^* \) to \( \{0, 1\} \) that models the non-zeroness test function, for \( n > 0 \), is co-NP-complete, even under the restriction on the arbitrary instruction sequence that its length
depends linearly on $n$. Another of the main results of this work (Theorem \textup{8}) states, roughly, that this problem can be decided in time polynomial in $n$ under the restriction on the arbitrary instruction sequence that its length is the length of the shortest possible correct implementations plus a constant amount and that it has a certain form. We expect that similar results can be established for many other functions, but possibly at considerable effort.

The question to what extent it can be efficiently determined whether an arbitrary program correctly solves a given problem is of importance to programming. We have chosen to investigate this question but, to our knowledge, there does not exist literature about it. This made us decide to start our investigation with programs of a very simple form, namely instruction sequences, and a very simple problem, namely the non-zeroness problem. Moreover, we decided to conduct our investigation as an application of program algebra, the algebraic theory of instruction sequences that we have developed (see below).

Instruction sequences are programs in their simplest form. Therefore, it is to be expected that it is somehow easier to understand the concept of an instruction sequence than to understand the concept of a program. The first objective of our work on instruction sequences that started with \textup{2}, and of which an enumeration is available at \textup{9}, is to understand the concept of a program. The basis of all this work is an algebraic theory of instruction sequences, called program algebra, and an algebraic theory of mathematical objects that represent in a direct way the behaviours produced by instruction sequences under execution, called basic thread algebra.\textsuperscript{1} The body of theory developed through this work is such that its use as a conceptual preparation for programming is practically feasible.

The notion of an instruction sequence appears in the work concerned as a mathematical abstraction for which the rationale is based on the objective mentioned above. In this capacity, instruction sequences constitute a primary field of investigation in programming comparable to propositions in logic and rational numbers in arithmetic. The structure of the mathematical abstraction at issue has been determined in advance with the hope of applying it in diverse circumstances where in each case the fit may be less than perfect. Until now, this work has, among other things, yielded an approach to computational complexity where program size is used as complexity measure, a contribution to the conceptual analysis of the notion of an algorithm, and new insights into such diverse issues as the halting problem, garbage collection, program parallelization for the purpose of explicit multi-threading and virus detection.

Like in the work on computational complexity (see \textup{3,5}) and the work on algorithmic equivalence of programs (see \textup{4}) referred to above, in the work presented in this paper, use is made of the fact that, for each $n > 0$, each function from $\{0,1\}^n$ to $\{0,1\}$ can be computed by a finite instruction sequence that contains only instructions to set and get the content of Boolean registers, forward jump instructions, and a termination instruction. Program algebra is parameterized by a set of uninterpreted basic instructions. In applications of

\textsuperscript{1} Both program algebra and basic thread algebra were first introduced in \textup{2}, but in that paper the latter was introduced under the name basic polarized process algebra.
program algebra, this set is instantiated by a set of interpreted basic instructions.
In a considerable part of the work belonging to our work on instruction sequences
that started with [2], the interpreted basic instructions are instructions to set
and get the content of Boolean registers.

This paper is organized as follows. First, we survey program algebra and the
particular fragment and instantiation of it that is used in this paper (Section 2).
Next, we present a simple non-zeroness test instruction sequence (Section 3).
After that, as a preparation for establishing the main results, we first present a
non-zeroness test instruction sequence whose length is minimal (Section 4) and
then introduce the set of all non-zeroness test instruction sequences of minimal
length (Section 5). Following this, we study the time complexity of several re-
strictions of the problem of deciding whether an arbitrary instruction sequence
correctly implements the restriction to \( \{0,1\}^n \) of the function from \( \{0,1\}^* \)
to \( \{0,1\} \) that models the non-zeroness test function, for \( n > 0 \) (Section 6). Finally,
we make some concluding remarks (Section 7).

As mentioned earlier, to our knowledge, there is no previous work that ad-
dresses a question similar to the question to what extent it can be efficiently
determined whether an arbitrary program correctly solves a given problem. For
this reason, there is no mention of related work in this paper.

The following should be mentioned in advance. The set \( \mathbb{B} \) of Boolean values
is a set with two elements whose intended interpretations are the truth values
\textit{false} and \textit{true}. As is common practice, we represent the elements of \( \mathbb{B} \) by the
bits 0 and 1 and we identify the elements of \( \mathbb{B} \) with their representation where
appropriate.

This paper draws somewhat from the preliminaries of earlier papers that
built on program algebra. The most recent one of those papers is [7].

2 Preliminaries: instruction sequences and computation

In this section, we present a brief outline of PGA (ProGram Algebra) and the
particular fragment and instantiation of it that is used in this paper. A mathema-
tically precise treatment of this particular case can be found in [3].

The starting point of PGA is the simple and appealing perception of a se-
quential program as a single-pass instruction sequence, i.e., a finite or infinite
sequence of instructions each of which is executed at most once and can be
dropped after it has been executed or jumped over.

It is assumed that a fixed but arbitrary set \( \mathcal{A} \) of \textit{basic instructions} has been
given. The intuition is that the execution of a basic instruction may modify a
state and produces a reply at its completion. The possible replies are 0 and 1.
The actual reply is generally state-dependent. Therefore, successive execu-
tions of the same basic instruction may produce different replies. The set \( \mathcal{A} \) is the basis
for the set of instructions of which the instruction sequences considered in PGA
are composed. The elements of the latter set are called \textit{primitive instructions}.
There are five kinds of primitive instructions, which are listed below:

- for each \( a \in \mathcal{A} \), a \textit{plain basic instruction} \( a \);
– for each \( a \in \mathcal{A} \), a positive test instruction \(+a\);
– for each \( a \in \mathcal{A} \), a negative test instruction \(-a\);
– for each \( l \in \mathbb{N} \), a forward jump instruction \(#l\);
– a termination instruction \(!\).

We write \( \mathcal{I} \) for the set of all primitive instructions.

On execution of an instruction sequence, these primitive instructions have the following effects:

– the effect of a positive test instruction \(+a\) is that basic instruction \( a \) is executed and execution proceeds with the next primitive instruction if 1 is produced and otherwise the next primitive instruction is skipped and execution proceeds with the primitive instruction following the skipped one — if there is no primitive instruction to proceed with, inaction occurs;
– the effect of a negative test instruction \(-a\) is the same as the effect of \(+a\), but with the role of the value produced reversed;
– the effect of a plain basic instruction \( a \) is the same as the effect of \(+a\), but execution always proceeds as if 1 is produced;
– the effect of a forward jump instruction \(#l\) is that execution proceeds with the \( l \)th next primitive instruction of the instruction sequence concerned — if \( l \) equals 0 or there is no primitive instruction to proceed with, inaction occurs;
– the effect of the termination instruction \(!\) is that execution terminates.

Inaction occurs if no more basic instructions are executed, but execution does not terminate.

To build terms, PGA has a constant for each primitive instruction and two operators. These operators are: the binary concatenation operator \( ; \) and the unary repetition operator \( \omega \). We use the notation \( \cdot^nP_i \), where \( k \leq n \) and \( P_1, \ldots, P_n \) are PGA terms, for the PGA term \( P_k; \ldots; P_n \). We use the convention that \( P; \cdot^nP_i \) and \( \cdot^nP_i; P \) stand for \( P \) if \( k > n \).

The instruction sequences that concern us in the remainder of this paper are the finite ones, i.e., the ones that can be denoted by PGA terms without variables in which the repetition operator does not occur. Moreover, the basic instructions that concern us are instructions to set and get the content of Boolean registers. More precisely, we take the set

\[
\{\text{in}:i.\text{get} \mid i \in \mathbb{N}_1\} \cup \{\text{out}:b \mid b \in \mathbb{B}\}
\]

\[
\cup \{\text{aux}:i.\text{get} \mid i \in \mathbb{N}_1\} \cup \{\text{aux}:i.\text{set} \mid i \in \mathbb{N}_1 \land b \in \mathbb{B}\}
\]

as the set \( \mathcal{A} \) of basic instructions.\(^2\)

Each basic instruction consists of two parts separated by a dot. The part on the left-hand side of the dot plays the role of the name of a Boolean register and the part on the right-hand side of the dot plays the role of a command to be carried out on the named Boolean register. The names are employed as follows:

\(^2\) We write \( \mathbb{N}_1 \) for the set \( \{n \in \mathbb{N} \mid n \geq 1\} \) of positive natural numbers.
– for each \( i \in \mathbb{N}_1 \), \( \text{in}:i \) serves as the name of the Boolean register that is used as \( i \)th input register in instruction sequences;
– \( \text{out} \) serves as the name of the Boolean register that is used as output register in instruction sequences;
– for each \( i \in \mathbb{N}_1 \), \( \text{aux}:i \) serves as the name of the Boolean register that is used as \( i \)th auxiliary register in instruction sequences.

On execution of a basic instruction, the commands have the following effects:

– the effect of \( \text{get} \) is that nothing changes and the reply is the content of the named Boolean register;
– the effect of \( \text{set}:0 \) is that the content of the named Boolean register becomes 0 and the reply is 0;
– the effect of \( \text{set}:1 \) is that the content of the named Boolean register becomes 1 and the reply is 1.

We write \( \text{IS} \) for the set of all instruction sequences that can be denoted by a PGA term without variables in which the repetition operator does not occur in the case that \( \mathcal{A} \) is taken as specified above. \( \text{IS} \) is the set of all instruction sequences that matter in the remainder of this paper.

We write \( \text{len}(X) \), where \( X \in \text{IS} \), for the length of \( X \).

Let \( n \in \mathbb{N} \), let \( f : \mathbb{B}^n \rightarrow \mathbb{B} \), and let \( X \in \text{IS} \). Then \( X \) computes \( f \) if there exists a \( k \in \mathbb{N} \) such that, for all \( b_1, \ldots, b_n \in \mathbb{B} \), on execution of \( X \) in an environment with input registers \( \text{in}:1, \ldots, \text{in}:n \), output register \( \text{out} \), and auxiliary registers \( \text{aux}:1, \ldots, \text{aux}:k \), if

– for each \( i \in \{1, \ldots, n\} \), the content of register \( \text{in}:i \) is \( b_i \) when execution starts;
– the content of register \( \text{out} \) is 0 when execution starts;
– for each \( i \in \{1, \ldots, k\} \), the content of register \( \text{aux}:i \) is 0 when execution starts;

then execution terminates and the content of register \( \text{out} \) is \( f(b_1, \ldots, b_n) \) when execution terminates.

We conclude these preliminaries with some terminology and notations that are used in the rest of this paper.

We refer to the content of a register when execution starts as the initial content of the register and we refer to the content of a register when execution terminates as the final content of the register.

The primitive instructions of the forms \( +\text{in}:i.\text{get} \) and \( -\text{in}:i.\text{get} \) are called read instructions. For a read instruction \( u \), the input register whose name appears in \( u \) is said to be the input register that is read by \( u \). For an \( X \in \text{IS} \) and \( m \in \mathbb{N}_1 \), an input register that is read by \( m \) occurrences of a read instruction in \( X \) is said to be an input register that is read \( m \) times in \( X \). For an \( X \in \text{IS} \), an occurrence of a read instruction in \( X \) that is neither immediately preceded nor immediately followed by a read instruction is said to be an isolated read instruction of \( X \). For an \( X \in \text{IS} \), an occurrence of two read instructions in a row in \( X \) that is neither immediately preceded nor immediately followed by a read instruction is said to be a read instruction pair of \( X \). We write \( \text{iregs}(X) \), where \( X \in \text{IS} \), for the set
of all \( i \in \mathbb{N}_1 \) such that \( \text{in;}i \) is read by some occurrence of a read instruction in \( X \).

Take an instruction sequence \( X \in \text{IS}_{\text{br}} \) and a function \( f : \mathbb{B}^n \rightarrow \mathbb{B} \) \((n \in \mathbb{N})\) such that \( X \) computes \( f \). Modify \( X \) by replacing all occurrences of \( +\text{in;}i.\text{get} \) by \( \#1 \), all occurrences of \( -\text{in;}i.\text{get} \) by \( \#2 \), and, for each \( j > i \), all occurrences of the register name \( \text{in;}j \) by \( \text{in;}j−1 \). Then the resulting instruction sequence computes the function \( f' : \mathbb{B}^{n−1} \rightarrow \mathbb{B} \) defined by \( f'(x_1, \ldots, x_{n−1}) = f(x_1, \ldots, x_{i−1}, 1, x_{i+1}, \ldots, x_{n−1}) \). If the occurrences of \( +\text{in;}i.\text{get} \) are replaced by \( \#2 \) instead of \( \#1 \) and the occurrences of \( -\text{in;}i.\text{get} \) is replaced by \( \#1 \) instead of \( \#2 \), then the resulting instruction sequence computes the function \( f'' : \mathbb{B}^{n−1} \rightarrow \mathbb{B} \) defined by \( f''(x_1, \ldots, x_{n−1}) = f(x_1, \ldots, x_{i−1}, 0, x_{i+1}, \ldots, x_{n−1}) \). Such register elimination and its generalization from one register to multiple registers are used a number of times in this paper. A notation for register elimination is introduced in the next paragraph.

For an \( X \in \text{IS}_{\text{br}} \) and a function \( \alpha \) from a finite subset of \( \mathbb{N}_1 \) to \( \mathbb{B} \) such that \( \text{iregs}(X) = \{i \in \mathbb{N}_1 \mid i \leq n\} \) for some \( n \in \mathbb{N}_1 \) and \( \text{dom}(\alpha) \) is a proper subset of \( \text{iregs}(X) \), we write \( X_\alpha \) for the instruction sequence obtained from \( X \) by replacing, for each \( i \in \text{dom}(\alpha) \), all occurrences of \( +\text{in;}i.\text{get} \) by \( \#1 \) if \( \alpha(i) = 1 \) and by \( \#2 \) if \( \alpha(i) = 0 \), all occurrences of \( -\text{in;}i.\text{get} \) by \( \#2 \) if \( \alpha(i) = 1 \) and by \( \#1 \) if \( \alpha(i) = 0 \), and, for each \( j \in \text{iregs}(X) \setminus \text{dom}(\alpha) \), all occurrences of the register name \( \text{in;}j \) by \( \text{in;}\beta(j) \), where \( \beta \) is the unique bijection from \( \text{iregs}(X) \setminus \text{dom}(\alpha) \) to \( \{i \in \mathbb{N}_1 \mid i \leq n - \text{card}(\text{dom}(\alpha))\} \) such that, for all \( i, j \in \text{iregs}(X) \setminus \text{dom}(\alpha) \) with \( i \leq j \), \( \beta(i) \leq \beta(j) \). For an \( X \in \text{IS}_{\text{br}} \) and an \( i \in \mathbb{N}_1 \) such that \( \text{iregs}(X) = \{i \in \mathbb{N}_1 \mid i \leq n\} \) for some \( n \in \mathbb{N}_1 \) and \( i \in \text{iregs}(X) \), we write \( X[\text{in;}i = b] \) for \( X_\alpha \), where \( \alpha \) is the function from \( \{i\} \) to \( \mathbb{B} \) defined by \( \alpha(i) = b \).

Register elimination is reminiscent of gate elimination as used in much work on circuit lower bounds (see e.g. Chapter 16 of [13]).

3 Simple non-zeroness test instruction sequences

The remainder of the paper goes into programming by means of instruction sequences of the kind introduced in Section 2. We consider the programming of a function from \( \mathbb{B}^* \) to \( \mathbb{B} \) that models a particular function from \( \mathbb{N} \) to \( \mathbb{B} \) with respect to the binary representations of the natural numbers by elements from \( \mathbb{B}^* \). The particular function is the non-zeroness test function \( \text{nzt} \) defined by the equations \( \text{nzt}(0) = 0 \) and \( \text{nzt}(k + 1) = 1 \). In this section, we present a simple instruction sequence computing the restriction to \( \mathbb{B}^n \) of the function from \( \mathbb{B}^* \) to \( \mathbb{B} \) that models this function, for \( n > 0 \).

\( \text{NZT}_n \), the restriction to \( \mathbb{B}^n \) of the function from \( \mathbb{B}^* \) to \( \mathbb{B} \) that models \( \text{nzt} \), is defined by

\[
\text{NZT}_n(b_1, \ldots, b_n) = 1 \quad \text{iff} \quad b_1 = 1 \quad \text{or} \quad \ldots \quad \text{or} \quad b_n = 1 .
\]

We define an instruction sequence \( \text{NZTIS}_n \) which is intended to compute \( \text{NZT}_n \) as follows:

\[
\text{NZTIS}_n \triangleq \gamma \sum_{j=1}^{n} (+\text{in;}j.\text{get} ; \text{out.set};1) ; 1 .
\]
The following proposition states that the instruction sequence $NZTIS_n$ correctly implements $NZT_n$.

**Proposition 1.** For each $n \in \mathbb{N}_1$, $NZTIS_n$ computes $NZT_n$.

**Proof.** We prove this proposition by induction on $n$. The basis step consists of proving that $NZTIS_1$ computes $NZT_1$. This follows easily by a case distinction on the content of in:1. The inductive step is proved in the following way. It follows directly from the induction hypothesis that on execution of $NZTIS_{n+1}$, after $\sum_{i=1}^{n} (+\text{in}:i\text{get;}\text{out.set}:1)$ has been executed, (a) the content of out equals 1 iff the content of at least one of the input registers in:1, ..., in:n equals 1 and (b) execution proceeds with the next instruction. From this, it follows easily by a case distinction on the content of in:$n+1$ that $NZTIS_{n+1}$ computes $NZT_{n+1}$. $\square$

The length of the instruction sequence $NZTIS_n$ defined above is as follows:

$$\text{len}(NZTIS_n) = 2 \cdot n + 1.$$  

$NZTIS_n$ is a simple instruction sequence to compute $NZT_n$. It computes $NZT_n$ by checking all input registers. This is rather inefficient because, once an input register is encountered whose content is 1, checking of the remaining input registers can be skipped. $NZTIS_n$ does, moreover, not belong to the shortest instruction sequences computing $NZT_n$. The shortest instruction sequences computing $NZT_n$ are the subject of Sections 4 and 5.

### 4 Shortest non-zeroness test instruction sequences

For $i \in \mathbb{N}_1$, we have that execution of the instruction sequences denoted by $+\text{in}:i\text{get;}\text{out.set}:1$ and $-\text{in}:i\text{get;}\text{out.set}:1$ yield the same final content of out for all initial contents of in:$i$ and in:$i+1$. In this section, we present an instruction sequence $NZTIS'_n$ which can be considered an adaptation of $NZTIS_n$ based on this fact. There are no instruction sequences shorter than $NZTIS'_n$ that compute $NZT_n$. Section 5 is concerned with the set of all instruction sequences of the same length as $NZTIS'_n$ that compute $NZT_n$.

We define an instruction sequence $NZTIS'_n$ which is intended to compute $NZT_n$ as follows:

$$\begin{align*}
NZTIS'_n & \triangleq \\
& \begin{cases}
\sum_{i=1}^{n/2} (-\text{in}:2i-1\text{get;}+\text{in}:2i\text{get;}\text{out.set}:1);! \\
& \text{if } n \text{ is even,}
\end{cases} \\
& \begin{cases}
\text{+in}:1\text{get;}\text{out.set}:1; \sum_{i=1}^{(n-1)/2} (-\text{in}:2i\text{get;}+\text{in}:2i+1\text{get;}\text{out.set}:1);! \\
& \text{if } n \text{ is odd.}
\end{cases}
\end{align*}$$

The following proposition states that the instruction sequence $NZTIS'_n$ correctly implements $NZT_n$.  

7
Proposition 2. For each \( n \in \mathbb{N}_1 \), \( \text{NZTIS}'_n \) computes \( \text{NZT}_n \).

Proof. We split the proof of this proposition into a proof for even \( n \) and a proof for odd \( n \). The proof for even \( n \) goes by induction on \( n \). The basis step consists of proving that \( \text{NZTIS}'_2 \) computes \( \text{NZT}_2 \). This follows easily by a case distinction on the contents of \( \text{in}:1 \) and \( \text{in}:2 \). The inductive step is proved in the following way. It follows directly from the induction hypothesis that on execution of \( \text{NZTIS}'_{n+2} \), \( \cdot \sum_{i=1}^{n/2} (\text{in}:2 \cdot i - 1 \cdot \text{get}; + \text{in}:2 \cdot i \cdot \text{get}; \text{out}:1) \) has been executed, (a) the content of \( \text{out} \) equals 1 iff the content of at least one of the input registers \( \text{in}:1, \ldots, \text{in}:n \) equals 1 and (b) execution proceeds with the next instruction. From this, it follows easily by a case distinction on the contents of \( \text{in}:n+1 \) and \( \text{in}:n+2 \) that \( \text{NZTIS}'_{n+2} \) computes \( \text{NZT}_{n+2} \). The proof for odd \( n \) is similar. \( \square \)

The length of the instruction sequence \( \text{NZTIS}'_n \) defined above is as follows:

\[
\text{len}(\text{NZTIS}'_n) = \begin{cases} 
3 \cdot \frac{n}{2} + 1 & \text{if } n \text{ is even,} \\
3 \cdot \frac{n+1}{2} & \text{if } n \text{ is odd.}
\end{cases}
\]

Proposition 3. For each \( n \in \mathbb{N}_1 \), we have \( \text{len}(\text{NZTIS}'_1) = 3, \text{len}(\text{NZTIS}'_{n+1}) = \text{len}(\text{NZTIS}'_n) + 2 \) if \( n \) is even, and \( \text{len}(\text{NZTIS}'_{n+1}) = \text{len}(\text{NZTIS}'_n) + 1 \) if \( n \) is odd.

Proof. This follows immediately from the fact that \( \text{len}(\text{NZTIS}'_n) = 3 \cdot n/2 + 1 \) if \( n \) is even and \( \text{len}(\text{NZTIS}'_n) = 3 \cdot (n + 1)/2 \) if \( n \) is odd. \( \square \)

Proposition 3 and the following corollary of this proposition are used in several proofs to come.

Corollary 1. We have \( \text{len}(\text{NZTIS}'_n) + 1 \leq \text{len}(\text{NZTIS}'_{n+1}) \leq \text{len}(\text{NZTIS}'_n) + 2 \) and \( \text{len}(\text{NZTIS}'_{n+2}) = \text{len}(\text{NZTIS}'_n) + 3 \).

We also have \( \text{len}(\text{NZTIS}'_1) = \text{len}(\text{NZTIS}'_1) \) and \( \text{len}(\text{NZTIS}'_n) < \text{len}(\text{NZTIS}_n) \) for each \( n > 1 \). In fact, \( \text{NZTIS}'_n \) belongs to the shortest instruction sequences computing \( \text{NZT}_n \). This is stated by the following theorem.

Theorem 1. For all \( n \in \mathbb{N}_1 \), for all \( X \in \text{IS}_{\text{br}} \), \( X \) computes \( \text{NZT}_n \) only if \( \text{len}(X) \geq \text{len}(\text{NZTIS}'_n) \).

Proof. We prove the following stronger result:

for all \( n \in \mathbb{N}_1 \), for all \( X \in \text{IS}_{\text{br}} \), \( X \) or \( \text{out}:1 \); \( X \) computes \( \text{NZT}_n \) only if \( \text{len}(X) \geq \text{len}(\text{NZTIS}'_n) \).

We use the following in the proof. Let \( \chi_i(X) \), where \( i \in \mathbb{N}_1 \), be obtained from \( X \) by replacing all occurrences of \( + \text{aux}:i \cdot \text{get} \) and \( - \text{aux}:i \cdot \text{get} \) by \( - \text{aux}:i \cdot \text{get} \) and \( + \text{aux}:i \cdot \text{get} \), respectively, and replacing, for each \( b \in \mathbb{B} \), all occurrences of \( \text{aux}:i \cdot \text{set}:b \), \( + \text{aux}:i \cdot \text{set}:b \), and \( - \text{aux}:i \cdot \text{set}:b \) by \( \text{aux}:i \cdot \text{set}:\overline{b} \), \( - \text{aux}:i \cdot \text{set}:\overline{b} \), and \( + \text{aux}:i \cdot \text{set}:\overline{b} \) respectively.
and \( +\text{aux} i . \text{set} \# 3 \), respectively. It follows directly from the proof of Theorem 8.1 from [4] that \( \chi_i(X) \) computes \( NZT_n \) if \( X \) computes \( NZT_n \) and \( X \) is of the form \( u : Y \) or \( \text{out.set}:1 ; u : Y \), where \( u \) is \( +\text{aux} i . \text{set}:1 \), \(+\text{aux} i . \text{set}:1 \) or \(-\text{aux} i . \text{set}:1 \). Moreover, \( \text{len}(\chi_i(X)) = \text{len}(X) \).

We prove the theorem by induction on \( n \).

The basis step consists of proving that for all \( X \in \text{IS}_{br} \), \( X \) or \( \text{out.set}:1 ; X \) computes \( NZT_1 \) only if \( \text{len}(X) \geq 3 \). The following observations can be made about all \( X \in \text{IS}_{br} \) such that \( X \) or \( \text{out.set}:1 ; X \) computes \( NZT_1 \): (a) there must be at least one occurrence of \(+\text{in} i . \text{get} \) or \(-\text{in} i . \text{get} \) in \( X \) — because otherwise the final content of \( \text{out} \) will not be dependent on the content of \( \text{in} i . \) (b) there must be at least one occurrence of \( \text{out.set}:1 \), \(+\text{out.set}:1 \) or \(-\text{out.set}:1 \) in \( X \) if \( X \) computes \( NZT_1 \) and there must be at least one occurrence of \( \text{out.set}:0 \), \(+\text{out.set}:0 \) or \(-\text{out.set}:0 \) in \( X \) otherwise — because otherwise the final content of \( \text{out} \) will always be the same; (d) there must be at least one occurrence of \( ! \) in \( X \) — because otherwise nothing will ever be computed. It follows trivially from these observations that, for all \( X \in \text{IS}_{br} \), \( X \) or \( \text{out.set}:1 ; X \) computes \( NZT_1 \) only if \( \text{len}(X) \geq 3 \).

The inductive step is proved by contradiction. Suppose that \( X \in \text{IS}_{br} \), \( X \) or \( \text{out.set}:1 ; X \) computes \( NZT_{n+1} \) and \( \text{len}(X) < \text{len}(NZT_{n+1}) \). Assume that there does not exist an \( X' \in \text{IS}_{br} \) such that \( X' \) or \( \text{out.set}:1 ; X' \) computes \( NZT_{n+1} \) and \( \text{len}(X') < \text{len}(X) \). Obviously, this assumption can be made without loss of generality. From this assumption, it follows that \( X = u_1 : \ldots ; u_k \) where \( k < \text{len}(NZT_{n+1}) \), \( u_1, \ldots, u_k \in \mathcal{I} \), and \( u_1 \) is \(+\text{in} i . \text{get} \) or \(-\text{in} i . \text{get} \) for some \( i \in \mathbb{N}_1 \) such that \( i \leq n + 1 \). This can be seen as follows:

- if \( u_1 \) is \( ! \) or \# with \( l = 0 \) or \( l = k \), then \( X \) and \( \text{out.set}:1 ; X \) cannot compute \( NZT_{n+1} \);
- if \( u_1 \) is \# with \( 0 < l < k \), then there is an \( X' \in \text{IS}_{br} \) such that \( X' \) or \( \text{out.set}:1 ; X' \) computes \( NZT_{n+1} \) and \( \text{len}(X') < \text{len}(X) \) — which contradicts the assumption;
- if \( u_1 \) is \( \text{out.set}:0 \), \(+\text{out.set}:0 \) or \(-\text{out.set}:0 \), then \( u_1 \) can be replaced by \#1 or \#2 in \( X \) and so, there is an \( X' \in \text{IS}_{br} \) such that \( X' \) computes \( NZT_{n+1} \) and \( \text{len}(X') < \text{len}(X) \) — which contradicts the assumption;
- if \( u_1 \) is \( \text{out.set}:1 \), \(+\text{out.set}:1 \) or \(-\text{out.set}:1 \), then \( u_1 \) can be replaced by \#1 or \#2 in \( \text{out.set}:1 ; X \) and so, there is an \( X' \in \text{IS}_{br} \) such that \( \text{out.set}:1 ; X' \) computes \( NZT_{n+1} \) and \( \text{len}(X') < \text{len}(X) \) — which contradicts the assumption;
- if \( u_1 \) is \( \text{aux}.j . \text{set}:0 \), \(+\text{aux}.j . \text{set}:0 \), \(-\text{aux}.j . \text{set}:0 \), \( \text{aux}.j . \text{get} \), \(+\text{aux}.j . \text{get} \) or \(-\text{aux}.j . \text{get} \) for some \( j \in \mathbb{N}_1 \), then \( u_1 \) can be replaced by \#1 or \#2 in \( X \) and \( \text{out.set}:1 ; X \) and so, there is an \( X' \in \text{IS}_{br} \) such that \( X' \) or \( \text{out.set}:1 ; X' \) computes \( NZT_{n+1} \) and \( \text{len}(X') < \text{len}(X) \) — which contradicts the assumption;
- if \( u_1 \) is \( \text{aux}.j . \text{set}:1 \), \(+\text{aux}.j . \text{set}:1 \) or \(-\text{aux}.j . \text{set}:1 \) for some \( j \in \mathbb{N}_1 \), then \( \chi_j(u_1) \) can be replaced by \#1 or \#2 in \( \chi_j(X) \) and \( \text{out.set}:1 ; \chi_j(X) \) and so, because \( \chi_j(X) \) or \( \text{out.set}:1 ; \chi_j(X) \) also computes \( NZT_{n+1} \) and \( \text{len}(\chi_j(X)) = \text{len}(X) \),

\(^3\) Here, we write \( \overline{b} \) for the complement of \( b \).
there is an \( X' \in IS_{br} \) such that \( X' \) or \texttt{out.set:1}; \( X' \) computes \( NZT_{n+1} \) and \( \text{len}(X') < \text{len}(X) \) — which contradicts the assumption;

- if \( u_1 \) is \texttt{in.j.get} for some \( j \in \mathbb{N}_1 \), then \( u_1 \) can be replaced by \#1 in \( X \) and \texttt{out.set:1}; \( X \) and so there is an \( X' \in IS_{br} \) such that \( X' \) or \texttt{out.set:1}; \( X' \) computes \( NZT_{n+1} \) and \( \text{len}(X') < \text{len}(X) \) — which contradicts the assumption;

- if \( u_1 \) is \texttt{+in.j.get} or \texttt{-in.j.get} for some \( j \in \mathbb{N}_1 \) such that \( j > n + 1 \), then, because the final content of \( \text{out} \) is independent of the initial content of \( \text{in.j} \), \( u_1 \) can be replaced by \#1 and \#2 in \( X \) and so there is an \( X' \in IS_{br} \) such that \( X' \) or \texttt{out.set:1}; \( X' \) computes \( NZT_{n+1} \) and \( \text{len}(X') < \text{len}(X) \) — which contradicts the assumption.

So, we distinguish between the case that \( u_1 \) is \texttt{+in.i.get} and the case that \( u_1 \) is \texttt{-in.i.get}.

In the case that \( u_1 \) is \texttt{+in.i.get}, we consider the case that \( \text{in.i} \) contains 0. In this case, after execution of \( u_1 \), execution proceeds with \( u_3 \). Let \( Y = (u_3; \ldots; u_k) \) \( \text{[in.i = 0]} \). Then \( Y \) or \texttt{out.set:1}; \( Y \) computes \( NZT_n \). Moreover, by Corollary \( \text{[1]} \) we have that \( \text{len}(Y) = \text{len}(X) - 2 < \text{len}(NZTIS_{n}) \). Hence, there exists a \( Y' \in IS_{br} \) such that \( Y' \) or \texttt{out.set:1}; \( Y' \) computes \( NZT_n \) and \( \text{len}(Y') < \text{len}(NZTIS_{n}) \). This contradicts the induction hypothesis.

In the case that \( u_1 \) is \texttt{-in.i.get}, we consider the case that \( \text{in.i} \) contains 0. In this case, after execution of \( u_1 \), execution proceeds with \( u_2 \). Let \( Y = (u_2; \ldots; u_k) \) \( \text{[in.i = 0]} \). Then \( Y \) or \texttt{out.set:1}; \( Y \) computes \( NZT_n \). From here, because \( \text{len}(Y) = \text{len}(X) - 1 \), we cannot derive a contradiction immediately as in the case that \( u_1 \) is \texttt{+in.i.get}. A case distinction on \( u_2 \) is needed. With the exception of the cases that \( u_2 \) is \texttt{+in.j.get} or \texttt{-in.j.get}, for some \( j \in \mathbb{N}_1 \) such that \( i \neq j \) and \( j \leq n + 1 \), we still consider the case that \( \text{in.i} \) contains 0. In the cases that are not excepted above, a contradiction is derived as follows:

- if \( u_2 \) is \! or \#1 with \( l = 0 \) or \( l \geq k - 1 \), then \( Y \) and \texttt{out.set:1}; \( Y \) cannot compute \( NZT_n \);

- if \( u_2 \) is \#l with \( 0 < l < k - 1 \), then there is a \( Y' \in IS_{br} \) such that \( Y' \) or \texttt{out.set:1}; \( Y' \) computes \( NZT_n \) and, by Corollary \( \text{[1]} \) \( \text{len}(Y') < \text{len}(NZTIS_{n}) \) — which contradicts the induction hypothesis;

- if \( u_2 \) is \texttt{out.set:0}, \texttt{-out.set:0} or \texttt{-out.set:0}, then \( u_2 \) can be replaced by \#1 or \#2 in \( Y \) and so, there is a \( Y' \in IS_{br} \) such that \( Y' \) computes \( NZT_n \) and, by Corollary \( \text{[1]} \) \( \text{len}(Y') < \text{len}(NZTIS_{n}) \) — which contradicts the induction hypothesis;

- if \( u_2 \) is \texttt{out.set:1}, \texttt{+out.set:1} or \texttt{-out.set:1}, then \( u_2 \) can be replaced by \#1 or \#2 in \texttt{out.set:1}; \( Y \) and so, there is a \( Y' \in IS_{br} \) such that \( Y' \) or \texttt{out.set:1}; \( Y' \) computes \( NZT_n \) and, by Corollary \( \text{[1]} \) \( \text{len}(Y') < \text{len}(NZTIS_{n}) \) — which contradicts the induction hypothesis;

- if \( u_2 \) is \texttt{aux.j.set:0}, \texttt{+aux.j.set:0}, \texttt{-aux.j.set:0}, \texttt{aux.j.get}, \texttt{+aux.j.get} or \texttt{-aux.j.get} for some \( j' \in \mathbb{N}_1 \), then \( u_2 \) can be replaced by \#1 or \#2 in \( Y \) and so, there is a \( Y' \in IS_{br} \) such that \( Y' \) or \texttt{out.set:1}; \( Y' \) computes \( NZT_n \) and, by Corollary \( \text{[1]} \) \( \text{len}(Y') < \text{len}(NZTIS_{n}) \) — which contradicts the induction hypothesis;
In this section, we study the remaining instruction sequences of the same length as $NZTIS_n$ that compute $NZT_n$. The final outcome of this study is important for the proof of Theorem 5 in Section 6.

The following proposition states that change of the order in which the read instructions occur in $NZTIS_n$ yields again a correct implementation of $NZT_n$.

**Proposition 4.** For each $n \in \mathbb{N}_1$, for each bijection $\varphi$ on $\{k \in \mathbb{N}_1 \mid k \leq n\}$, $NZT_n$ is also computed by the instruction sequence obtained from $NZTIS_n$ by

5 More shortest non-zeroness test instruction sequences

In this section, we study the remaining instruction sequences of the same length as $NZTIS_n$ that compute $NZT_n$. The final outcome of this study is important for the proof of Theorem 5 in Section 6.

The following proposition states that change of the order in which the read instructions occur in $NZTIS_n$ yields again a correct implementation of $NZT_n$.

**Proposition 4.** For each $n \in \mathbb{N}_1$, for each bijection $\varphi$ on $\{k \in \mathbb{N}_1 \mid k \leq n\}$, $NZT_n$ is also computed by the instruction sequence obtained from $NZTIS_n$ by
replacing, for each \( j \in \mathbb{N}_1 \) with \( j \leq n \), all occurrences of the register name \( \text{in}:j \) in \( \text{NZTIS}_n^\prime \) by \( \text{in}:\varrho(j) \).

**Proof.** The proof is like the proof of Proposition 2 but with, for each \( j \in \mathbb{N}_1 \) with \( j \leq n \), all occurrences of the register name \( \text{in}:j \) in the proof replaced by \( \text{in}:\varrho(j) \).

The proof of Proposition 2 can be seen as a special case of the proof of Proposition 4, namely the case where \( \varrho \) is the identity function.

The following proposition states that, for instruction sequences \( X \) as considered in Proposition 4, in the case that \( n \) is odd, change of the position of the isolated read instruction of \( X \) yields again a correct implementation of \( \text{NZT}_n \).

**Proposition 5.** For each odd \( n \in \mathbb{N}_1 \), for each bijection \( \varrho \) on \( \{ k \in \mathbb{N}_1 \mid k \leq n \} \) and \( m \in \mathbb{N} \) with \( m \leq (n-1)/2 \), \( \text{NZT}_n \) is also computed by the instruction sequence \( \ast_{i=1}^m \left( -\text{in}:\varrho(2i-1).\text{get} ; +\text{in}:\varrho(2i).\text{get} ; \text{out.set:1} ; +\text{in}:\varrho(2m+1).\text{get} ; \text{out.set:1} \right) ;)! \). We prove that \( X_m \) computes \( \text{NZT}_n \) by induction on \( m \). The basis step follows immediately from Proposition 4. The inductive step goes as follows. Let \( Y = +\text{in}:\varrho(2m+1).\text{get} ; \text{out.set:1} ; -\text{in}:\varrho(2m+2).\text{get} ; +\text{in}:\varrho(2m+3).\text{get} ; \text{out.set:1} \) and \( Y' = -\text{in}:\varrho(2m+1).\text{get} ; +\text{in}:\varrho(2m+2).\text{get} ; \text{out.set:1} ; +\text{in}:\varrho(2m+3).\text{get} ; \text{out.set:1} \). Then \( X_{m+1} \) is \( X_m \) with the subsequence \( Y \) replaced by \( Y' \). From this, it follows easily by a case distinction on the contents of \( \text{in}:\varrho(2m+1) \), \( \text{in}:\varrho(2m+2) \), and \( \text{in}:\varrho(2m+3) \) that \( X_m \) and \( X_{m+1} \) compute the same function from \( \mathbb{B}^n \) to \( \mathbb{B} \). From this and the induction hypothesis, it follows that \( X_{m+1} \) computes \( \text{NZT}_n \). \( \square \)

Let \( X \) be an instruction sequence as considered in Propositions 4 or 5. Then replacement of one or more occurrences of \( \text{out.set:1} \) in \( X \) by \( +\text{out.set:1} \) yields again a correct implementation of \( \text{NZT}_n \) because the effects of these instructions on execution of \( X \) are always the same. Even replacement of one or more occurrences of \( \text{out.set:1} \) in \( X \) by \( -\text{out.set:1} \) yields again a correct implementation of \( \text{NZT}_n \) unless its last occurrence is replaced, because checking of the first of the remaining input registers can be skipped once an input register is encountered whose content is 1. Moreover, replacement of one or more occurrences of \( \text{out.set:1} \) in \( X \) by a forward jump instruction that leads to another occurrence of \( \text{out.set:1} \) yields again a correct implementation of \( \text{NZT}_n \) because, once an input register is encountered whose content is 1, checking of the remaining input registers can be skipped.

In the preceding paragraph, the clarifying intuitions for the statements made do not sufficiently verify the statements. Below, the statements are incorporated into Theorem 2 and verified via the proof of that theorem.
We define a set $NZT_{IS}^n$ of instruction sequences with Propositions 4 and 5 and the statements made above in mind.

For even $n$, we define a subset $NZT_{IS}^n$ of IS$_{br}$ as follows:

$X \in NZT_{IS}^n$ iff

\[
X = \sum_{i=1}^{n/2} (-\text{in}; \varphi(2i-1).\text{get}; +\text{in}; \varphi(2i).\text{get}; \varphi(i)) ; !
\]

for some function $\varphi$ from $\{k \in \mathbb{N}_1 \mid k \leq n/2\}$ to $\mathcal{I}$ such that

\[
\varphi(j) \in \{#3k \mid k \in \mathbb{N}_1 \land k \leq n/2 - j\}
\]

\[
\cup \{\text{out.set}:1, +\text{out.set}:1, -\text{out.set}:1\}
\]

\[
\varphi(n/2) \in \{\text{out.set}:1, +\text{out.set}:1\}
\]

and some bijection $\varphi$ on $\{k \in \mathbb{N}_1 \mid k \leq n\}$.

For odd $n$, we define a subset $NZT_{IS}^n$ of IS$_{br}$ as follows:

$X \in NZT_{IS}^n$ iff

there exists an $m \in \{k \in \mathbb{N} \mid k \leq (n-1)/2\}$ such that

\[
X = \sum_{i=1}^{m} (-\text{in}; \varphi(2i-1).\text{get}; +\text{in}; \varphi(2i).\text{get}; \varphi_m(i)) ; !
\]

\[
+\text{in}; \varphi(2m+1).\text{get}; \varphi_m((m+1)) ; !
\]

\[
\cdot \sum_{i=m+1}^{(n-1)/2} (-\text{in}; \varphi(2i).\text{get}; +\text{in}; \varphi(2i+1).\text{get}; \varphi_m((i+1))) ; !
\]

for some function $\varphi_m$ from $\{k \in \mathbb{N}_1 \mid k \leq (n-1)/2\}$ to $\mathcal{I}$ such that

\[
\varphi_m(j) \in \{#3k-1 \mid k \in \mathbb{N}_1 \land k \leq (n+1)/2 - j \land \neg j \leq m < j + k\}
\]

\[
\cup \{#3k \mid k \in \mathbb{N}_1 \land k \leq (n+1)/2 - j \land \neg j \leq m < j + k\}
\]

\[
\cup \{\text{out.set}:1, +\text{out.set}:1, -\text{out.set}:1\}
\]

\[
\varphi_m((n+1)/2) \in \{\text{out.set}:1, +\text{out.set}:1\}
\]

and some bijection $\varphi$ on $\{k \in \mathbb{N}_1 \mid k \leq n\}$.

Obviously, we have that $NZT_{IS}^n \subseteq NZT_{IS}^n$ and, for each $X \in NZT_{IS}^n$, $\text{len}(X) = \text{len}(NZT_{IS}^n)$.

The following theorem states that each instruction sequence from $NZT_{IS}^n$, correctly implements NZT$_n$.

**Theorem 2.** For all $n \in \mathbb{N}_1$, for all $X \in IS_{br}$, $X \in NZT_{IS}^n$ only if $X$ computes NZT$_n$.

**Proof.** For convenience, forward jump instructions, out.set:1, +out.set:1, and −out.set:1 are called replaceable instructions in this proof.

Let $n \in \mathbb{N}_1$, and let $X \in IS_{br}$ be such that $X \in NZT_{IS}^n$. Let $Y \in IS_{br}$ be obtained from $X$ by replacing all occurrences of a replaceable instruction other
than \texttt{out.set}:1 in \( X \) by \texttt{out.set}:1. It follows immediately from Propositions \ref{prop:nzt_n} and \ref{prop:equiv_nzt_n} that \( Y \) computes \( \text{NZT}_n \). Hence, it remains to be proved that \( X \) and \( Y \) compute the same function from \( \mathbb{B}^n \) to \( \mathbb{B} \).

The fact that \( X \) and \( Y \) compute the same function from \( \mathbb{B}^n \) to \( \mathbb{B} \) is proved by induction on the number of occurrences of replaceable instructions other than \texttt{out.set}:1 in \( X \). The basis step is trivial. The inductive step goes as follows. Let \( X' \in \text{IS}_{br} \) be obtained from \( X \) by replacing the first occurrence of a replaceable instruction other than \texttt{out.set}:1 in \( X \) by \texttt{out.set}:1. From the induction hypothesis and the fact that \( Y \) computes \( \text{NZT}_n \), it follows that \( X' \) computes \( \text{NZT}_n \). Clearly, execution of \( X \) and \( X' \) yield the same final content of \( \text{out} \) if the initial contents of \( \text{in}:1, \ldots, \text{in}:n \) are such that execution of \( X' \) does not proceed at some point with the replacing occurrence of \texttt{out.set}:1. What remains to be shown is that execution of \( X \) and \( X' \) yield the same final content of \( \text{out} \) if the initial contents of \( \text{in}:1, \ldots, \text{in}:n \) are such that execution of \( X' \) proceeds at some point with the replacing occurrence of \texttt{out.set}:1. Call this case the decisive case. If the decisive case occurs, then the content of at least one of the input registers \( \text{in}:1, \ldots, \text{in}:n \) is 1. From this and the fact that \( X' \) computes \( \text{NZT}_n \), it follows that on execution of \( X' \) the final content of \( \text{out} \) is 1 in the decisive case. Execution of \( X \) and \( X' \) have the same effects in the decisive case until the point where \( X' \) proceeds with the replacing occurrence of \texttt{out.set}:1. At that point, execution of \( X \) proceeds with the replaced occurrence of a replaceable instruction other than \texttt{out.set}:1 instead. From this, the fact that \( X \) contains no instructions by which the content of \( \text{out} \) can become 0, and the fact that \( X \) contains only forward jump instructions that lead in one or more steps to a replaceable instruction other than a forward jump instruction, it follows that on execution of \( X \) the final content of \( \text{out} \) is also 1 in the decisive case. Hence, \( X \) and \( Y \) compute the same function from \( \mathbb{B}^n \) to \( \mathbb{B} \).

There are instruction sequences in \( \text{NZTIS}'_n \) in which there is only one occurrence of \texttt{out.set}:1 and no occurrences of \(+\text{out.set}:1\) or \(-\text{out.set}:1\). These instruction sequences compute \( \text{NZT}_n \) much more efficiently than \( \text{NZTIS}'_n \), because, once an input register is encountered whose content is 1, checking of the remaining input registers is skipped.

Not all instruction sequences with the same length as \( \text{NZTIS}'_n \) that correctly implement \( \text{NZT}_n \) belong to \( \text{NZTIS}'_n \). If \( n \) is odd and \( n > 1 \), \#2 may occur once in an instruction sequence that belongs to \( \text{NZTIS}'_n \). Let \( X \in \text{NZTIS}'_n \) be such that \#2 occurs in \( X \), and let \( i \in \mathbb{N}_1 \) be such that \(+\text{in}:i\text{.get}\) or \(-\text{in}:i\text{.get}\) occurs before \#2 in \( X \). If the occurrence of \#2 will only be executed if the content of \( \text{in}:i \) is 0, then its replacement by an occurrence of \(+\text{in}:i\text{.get}\) yields a correct implementation of \( \text{NZT}_n \) that does not belong to \( \text{NZTIS}'_n \). Because of this, we introduce an extension of \( \text{NZTIS}'_n \).

We define a subset \( \text{NZTIS}^*_n \) of \( \text{IS}_{br} \) as follows:

- if no input register is read more than once in \( X \), then \( X \in \text{NZTIS}^*_n \) iff \( X \in \text{NZTIS}'_n \);
- if at least two input registers are read more than once in \( X \) or at least one input register is read more than twice in \( X \), then \( X \notin \text{NZTIS}^*_n \).
– if exactly one input register is read more than once in $X$ and the input register concerned is read exactly twice in $X$, then $X \in NZTIS^*_n$ iff
(a) no chain of zero or more forward jump instructions in $X$ that begins at or before its $(k + 2)$th primitive instruction leads to its $l$th primitive instruction of $X$,
(b) the $l$th primitive instruction of $X$ is $+\text{in}:i.\text{get}$ for some $i \leq n$,
(c) $X' \in NZTIS'_n$,
where $k$ and $l$, with $k \neq l$, are such that the same input register is read by the $k$th and $l$th primitive instruction of $X$, and where $X'$ is $X$ with the $l$th primitive instruction of $X$ replaced by $\#2$.

Obviously, we have that $NZTIS'_n \in NZTIS^*_n$, and for each $X \in NZTIS^*_n$, $\text{len}(X) = \text{len}(NZTIS'_n)$. Moreover, we have that $NZTIS'_n = NZTIS^*_n$ if $n$ is even and $NZTIS'_n \neq NZTIS^*_n$ if $n$ is odd and $n > 3$.

The following theorem states that each instruction sequence from $NZTIS^*_n$ correctly implements $NZT_n$.

**Theorem 3.** For all $n \in \mathbb{N}_1$, for all $X \in IS_{br}$, $X \in NZTIS^*_n$ only if $X$ computes $NZT_n$.

**Proof.** By Theorem 2, it suffices to show that $X$ computes $NZT_n$ if exactly one input register is read more than once in $X$, that input register is read exactly twice in $X$, and $X$ satisfies conditions (a), (b), and (c) from the definition of $NZTIS^*_n$.

We know from the definition of $NZTIS'_n$, that $\#2$ occurs at most once in an instruction sequence from $NZTIS'_n$. By conditions (b) and (c), there is a $Y \in NZTIS'_n$ in which $\#2$ occurs such that $X$ is $Y$ with the (unique) occurrence of $\#2$ replaced by $+\text{in}:i.\text{get}$ for some $i \leq n$. Let $k$ and $l$, with $k \neq l$, be such that the same input register is read by the $k$th and $l$th primitive instruction of $X$ and the $l$th primitive instruction of $X$ is the replacing instruction.

If $k > l$ and the initial content of the register read by the replacing instruction is 0, its execution has the same effect as the execution of $\#2$ and consequently $X$ computes $NZT_n$. If $k > l$ and the initial content of the register read by the replacing instruction is 1, although its execution has the same effect as the execution of $\#1$, the $k$th primitive instruction is eventually executed and consequently $X$ computes $NZT_n$.

If $k < l$, by Theorem 2 and the definition of $NZTIS'_n$, $X$ computes $NZT_n$ iff this replacing instruction is executed only in the case that its execution has the same effect as the execution of $\#2$ or its execution is preceded by the execution of an occurrence of $\text{out.set}:1$, $+\text{out.set}:1$ or $-\text{out.set}:1$. So, what is left to be shown is the following claim:

if $k < l$, the replacing instruction is executed only in the case that the initial content of the input register involved is 0 or its execution is preceded by the execution of an occurrence of $\text{out.set}:1$, $+\text{out.set}:1$ or $-\text{out.set}:1$.  

15
By the definition of $NZTIS_n^*$, this claim is right if the following conditions are satisfied:

(1) no chain of forward jump instructions that begins before the $k$th primitive instruction of $X$ leads to the $l$th primitive instruction of $X$;

(2) the chain of (zero or more) forward jump instructions that begins at the $(k+1)$th primitive instruction of $X$ if the $(k+1)$th primitive instruction of $X$ is not a read instruction and at the $(k+2)$th primitive instruction of $X$ otherwise does not lead to the $l$th primitive instruction of $X$.

We know from the definition of $NZTIS_n^*$ that the $(k+1)$th primitive instruction of $X$ is not a read instruction if the $(k+2)$th primitive instruction of $X$ is a read instruction. Therefore, conditions (1) and (2) are satisfied if condition (a) from the definition of $NZTIS_n^*$ is satisfied. Hence, the claim is right, and the proof is complete.

The following theorem states that each instruction sequence with the same length as $NZTIS_n^*$ that correctly implements $NZT_n$ belongs to $NZTIS_n^*$.

**Theorem 4.** For all $n \in \mathbb{N}_1$, for all $X \in IS_{br}$ with $\text{len}(X) = \text{len}(NZTIS_n^*)$, $X$ computes $NZT_n$ only if $X \in NZTIS_n^*$.

**Proof.** We prove this theorem by induction on $n$. In the proof, we use the notation $\chi_i(X)$, where $i \in \mathbb{N}_1$, defined at the beginning of the proof of Theorem 1.

The basis step consists of proving that for all $X \in IS_{br}$ with $\text{len}(X) = 3$, $X$ computes $NZT_1$ only if $X \in NZTIS_1^*$. This follows trivially from the observations made at the beginning of the proof of Theorem 1.

The inductive step goes in the following way. Suppose that $X \in IS_{br}$, $\text{len}(X) = \text{len}(NZTIS_n^*)$, and $X$ computes $NZT_n$ such that $\text{len}(X') < \text{len}(NZTIS_n^*)$ — which contradicts Theorem 1.

- if $u_1$ is ! or #l with $l = 0$ or $l > k$, then $X$ cannot compute $NZT_{n+1}$;
- if $u_1$ is #l with $0 < l < k$, then there is an $X' \in IS_{br}$ that computes $NZT_{n+1}$ such that $\text{len}(X') < \text{len}(NZTIS_n^*)$ — which contradicts Theorem 1;
- if $u_1$ is out.set:0, +out.set:0 or −out.set:0, then $u_1$ can be replaced by #1 or #2 in $X$ and so there is an $X' \in IS_{br}$ that computes $NZT_{n+1}$ such that $\text{len}(X') < \text{len}(NZTIS_n^*)$ — which contradicts Theorem 1;
- if $u_1$ is out.set:1 or +out.set:1, then, by Corollary 2 $\text{len}(X) > \text{len}(NZTIS_n^*)$ — which contradicts the assumption that $\text{len}(X) = \text{len}(NZTIS_n^*)$;
- if $u_1$ is −out.set:1, then $u_1 : u_2$ can be replaced by out.set:1 in $X$ and so there is an $X' \in IS_{br}$ that computes $NZT_{n+1}$ such that $\text{len}(X') < \text{len}(NZTIS_n^*)$ — which contradicts Theorem 1;
- if $u_1$ is aux:j.set:0, +aux:j.set:0, −aux:j.set:0, aux:j.get, +aux:j.get or −aux:j.get for some $j \in \mathbb{N}_1$, then $u_1$ can be replaced by #1 or #2 in $X$ and so there is an $X' \in IS_{br}$ that computes $NZT_{n+1}$ such that $\text{len}(X') < \text{len}(NZTIS_n^*)$ — which contradicts Theorem 1;
- if $u_1$ is aux:j.set:1, +aux:j.set:1 or −aux:j.set:1 for some $j \in \mathbb{N}_1$, then $\chi_j(u_1)$ can be replaced by #1 or #2 in $\chi_j(X)$ and so, because $\chi_j(X)$ also computes $NZT_{n+1}$ and $\text{len}(\chi_j(X)) = \text{len}(X)$, there is an $X' \in IS_{br}$ such that
$X'$ computes $NZT_{n+1}$ and $\text{len}(X') < \text{len}(NZTIS'_{n+1})$ — which contradicts Theorem[1]

- if $u_1$ is $\text{in}:j: \text{get}$ for some $j \in \mathbb{N}_1$, then $u_1$ can be replaced by #1 in $X$ and so there is an $X' \in \text{IS}_{br}$ that computes $NZT_{n+1}$ such that $\text{len}(X') < \text{len}(NZTIS'_{n+1})$ — which contradicts Theorem[1]
- if $u_1$ is $\text{+in}:j: \text{get}$ or $\text{-in}:j: \text{get}$ for some $j \in \mathbb{N}_1$ such that $j > n + 1$, then, because the final content of $\text{out}$ is independent of the initial content of $\text{in}:j$, $u_1$ can be replaced by #1 and #2 in $X$ and so there is an $X' \in \text{IS}_{br}$ that computes $NZT_{n+1}$ such that $\text{len}(X') < \text{len}(NZTIS'_{n+1})$ — which contradicts Theorem[1]

So, we distinguish between the case that $u_1$ is $\text{+in}:i: \text{get}$ and the case that $u_1$ is $\text{-in}:i: \text{get}$. In both cases, we further distinguish between the case that $n$ is even and the case that $n$ is odd.

The case that $u_1$ is $\text{+in}:i: \text{get}$ and $n$ is even goes as follows. Let $Y = u_3; \ldots; u_k$, and let $Y' = Y[\text{in}:i = 0]$. Then $Y'$ computes $NZT_n$. Moreover, by Proposition[8] $\text{len}(Y') = \text{len}(NZTIS'_n)$. Hence, by the induction hypothesis, $Y' \in NZTIS'_n$. From this and the fact that $n$ is even, it follows that #1 and #2 do not occur in $Y'$. Consequently, $Y$ is simply $Y'$ with, for each $j \in \mathbb{N}_1$ with $i < j \leq n + 1$, all occurrences of the register name $\text{in}:j$ replaced by $\text{in}:j$. Moreover, because $X$ computes $NZT_{n+1}$, $u_2$ is $\text{out}.set:1, + \text{out}.set:1, - \text{out}.set:1$ or a forward jump instruction that leads to an occurrence of such an instruction. Hence, $X \in NZTIS'_{n+1}$.

The case that $u_1$ is $\text{+in}:i: \text{get}$ and $n$ is odd goes as follows. Let $Y = u_3; \ldots; u_k$, and let $Y' = Y[\text{in}:i = 0]$. Then $Y'$ computes $NZT_n$. Moreover, by Proposition[8] $\text{len}(Y') = \text{len}(NZTIS'_n) - 1$. This contradicts Theorem[1] Hence, this case cannot occur.

The case that $u_1$ is $\text{-in}:i: \text{get}$ and $n$ is odd goes as follows. Let $Y = u_2; \ldots; u_k$, and let $Y' = Y[\text{in}:i = 0]$. Then $Y'$ computes $NZT_n$. Moreover, by Proposition[8] $\text{len}(Y') = \text{len}(NZTIS'_n)$. Hence, by the induction hypothesis, $Y' \in NZTIS'_n$. From this and the fact that $n$ is odd, it follows that #1 does not occur in $Y'$ and #2 may occur at most once in $Y'$. If #2 occurs in $Y'$, then it occurs immediately before the unique isolated read instruction of $Y'$. However, because $X$ computes $NZT_{n+1}$ and $\text{len}(X) = \text{len}(NZTIS'_{n+1})$, $u_2$ must be a positive read instruction. Therefore, $u_2$ is the unique isolated read instruction of $Y'$. From this, it follows that #2 does not occur in $Y'$. Consequently, $Y$ is $Y'$ with, for each $j \in \mathbb{N}_1$ with $i < j \leq n + 1$, all occurrences of the register name $\text{in}:j$ replaced by $\text{in}:j$. Hence, $X \in NZTIS'_{n+1}$.

The case that $u_1$ is $\text{-in}:i: \text{get}$ and $n$ is even goes as follows. Let $Y = u_2; \ldots; u_k$, and let $Y' = Y[\text{in}:i = 0]$. Then $Y'$ computes $NZT_n$. We cannot derive a contradiction immediately as in the previous three cases. A case distinction on $u_2$ is needed. All cases other than the case that $u_2$ is $\text{+in}:j: \text{get}$ and the case that $u_2$ is $\text{-in}:j: \text{get}$, for some $j \in \mathbb{N}_1$ such that $i \neq j$ and $j \leq n + 1$, cannot occur because a contradiction can be derived. This can be seen as follows:

- if $u_2$ is ! or #1 with $l = 0$ or $l \geq k - 1$, then $Y'$ cannot compute $NZT_n$.
- if $u_2$ is #1 or #2, then, because $\text{-in}:i: \text{get}; \#1$ can be replaced by $\text{+in}:i: \text{get}$ in $X$ and $\text{-in}:i: \text{get}; \#2$ can be replaced by $\text{+in}:i: \text{get}$ in $X$, there is an $X' \in \text{IS}_{br}$ that
computes $NZT_{n+1}$ such that $\text{len}(X') < \text{len}(NZTIS'_{n+1})$ — which contradicts Theorem 1.

- if $u_2$ is not #l with $2 < l < k - 1$, then there is an $Y'' \in IS_{br}$ such that $Y''$ computes $NZT_n$ and, by Proposition 3, $\text{len}(Y'') < \text{len}(NZTIS'_n)$ — which contradicts Theorem 1.

- if $u_2$ is out.set:0, +out.set:0 or -out.set:0, then $u_2$ can be replaced by #1 or #2 in $X$ and so, because $\text{in}:i\text{.get;}#1$ can be replaced by $\text{in} : i\text{.get;}#2$ can be replaced by $\text{in} : i\text{.get;}#2$, there is an $X' \in IS_{br}$ that computes $NZT_{n+1}$ such that $\text{len}(X') < \text{len}(NZTIS'_{n+1})$ — which contradicts Theorem 1.

- if $u_2$ is out.set:1 or +out.set:1, then we make a case distinction on the initial content of $\text{in} : i$:
  - (a) if $\text{in} : i$ contains 0, then, because $X$ computes $NZT_{n+1}$, execution of $Y$ yields the right final content of $\text{out}$; hence $Y$ computes $NZT_{n+1}$ and so there is an $X' \in IS_{br}$ that computes $NZT_{n+1}$ such that $\text{len}(X') < \text{len}(NZTIS'_{n+1})$ — which contradicts Theorem 1.
  - (b) if $\text{in} : i$ contains 1, then, because $X$ computes $NZT_{n+1}$, execution of $u_3 ; \ldots ; u_k$ always yields 1 as the final content of $\text{out}$ and consequently, because there exist no instructions to read the content of $\text{out}$, $Y$ always yields 1 as the final content of $\text{out}$; hence $Y$ computes $NZT_{n+1}$ and so there is an $X' \in IS_{br}$ that computes $NZT_{n+1}$ such that $\text{len}(X') < \text{len}(NZTIS'_{n+1})$ — which contradicts Theorem 1.

- if $u_2$ is aux:j'.set:1, then $u_2$ can be replaced by aux:j'.set:1 in $Y'$ and so, by Proposition 3, there is a $Y'' \in IS_{br}$ of the form aux:j'.set:1; $Z$ such that $Y''$ computes $NZT_n$ and $\text{len}(Y'') = \text{len}(NZTIS'_n)$ and consequently, by the induction hypothesis, $Y'' \in NZTIS^*_n$ — which contradicts the fact that $Y''$ is of the form aux:j'.set:1; $Z$.

- if $u_2$ is aux:j'.set:1 for some $j' \in \mathbb{N}_1$, then $\chi_{j'}(u_2)$ can be replaced by #1 in $\chi_{j'}(Y')$ and so, by Proposition 3, there is a $Y'' \in IS_{br}$ that computes $NZT_n$ such that $\text{len}(Y'') = \text{len}(NZTIS'_n)$ and consequently, by the induction hypothesis, $Y'' \in NZTIS^*_n$; therefore an instruction of the form aux:j'.get, +aux:j'.get or -aux:j'.get does not occur in $Y'$ and so, because $\text{in} : i\text{.get;}#1$ can be replaced by $\text{in} : i\text{.get;}#2$, there is an $X' \in IS_{br}$ that computes $NZT_{n+1}$ such that $\text{len}(X') < \text{len}(NZTIS'_{n+1})$ — which contradicts Theorem 1.

- if $u_2$ is aux:j'.set:1 for some $j' \in \mathbb{N}_1$, then $u_2$ can be replaced by aux:j'.set:1 in $Y'$ and so, by Proposition 3, there is a $Y'' \in IS_{br}$ of the form aux:j'.set:1; $Z$ such that $\text{len}(Y'') = \text{len}(NZTIS'_n)$ and consequently, by the induction hypothesis, $Y'' \in NZTIS^*_n$ — which contradicts the fact that $Y''$ is of the form aux:j'.set:1; $Z$.

- if $u_2$ is in:j'.get for some $j' \in \mathbb{N}_1$, then in:j'.get can be replaced by #1 in $X$ and so, because $\text{in} : i\text{.get;}#1$ can be replaced by $\text{in} : i\text{.get;}#2$, there is an $X' \in IS_{br}$ that computes $NZT_{n+1}$ such that $\text{len}(X') < \text{len}(NZTIS'_{n+1})$ — which contradicts Theorem 1.
• if $u_2$ is $\text{+in:}j'.\text{get}$ or $\text{-in:}j'.\text{get}$ for some $j' \in \mathbb{N}_1$ such that $j' > n + 1$, then, because the final content of $\text{out}$ is independent of the initial content of $\text{in:}j'$, $u_2$ can be replaced by $\#1$ and $\#2$ in $X$ and so, because $\text{-in:}j'.\text{get}; \#1$ can be replaced by $\text{in:}j'.\text{get}$ and $\text{-in:}j'.\text{get}; \#2$ can be replaced by $\text{+in:}j'.\text{get}$, there is an $X' \in \text{IS}_{n+1}$ that computes $\text{NZT}_{n+1}$ such that $\text{len}(X') < \text{len}(\text{NZTIS}_{n+1}')$ — which contradicts Theorem[4]

• if $u_2$ is $\text{+in:i'.get}$ or $\text{-in:i'.get}$, then, because $\text{-in:i'.get}; \text{+in:i'.get}$ can be replaced by $\text{+in:i'.get}$ in $X$ and $\text{-in:i'.get}$ can be replaced by $\text{+in:i'.get}$ in $X$, there is an $X' \in \text{IS}_{n+1}$ that computes $\text{NZT}_{n+1}$ such that $\text{len}(X') < \text{len}(\text{NZTIS}_{n+1}')$ — which contradicts Theorem[4]

So, we distinguish between the case that $u_2$ is $\text{+in:}j'.\text{get}$ and the case that $u_2$ is $\text{-in:}j'.\text{get}$.

The case that $u_2$ is $\text{-in:}j'.\text{get}$ goes as follows. Let $Y = u_3; \ldots; u_k$, and let $Y' = Y[\text{in:}j = 0]$. Then, because $X$ computes $\text{NZT}_{n+1}$, we have: (i) if the initial content of $\text{in:i}$ is 1, execution of $Y$ yields 1 as final content of $\text{out}$, (ii) if the initial content of $\text{in:i}$ is 0, execution of $Y'$ yields 1 as final content of $\text{out}$ iff the initial content of at least one of the input registers $\text{in:}1, \ldots, \text{in:n+1}$ other than $\text{in:}j$ is 1. From (i), it follows that, if the initial content of $\text{in:i}$ is 1, execution of $Y'$ yields 1 as final content of $\text{out}$. From this and (ii), it follows that, $Y'$ computes $\text{NZT}_{n}$. Moreover, by Proposition[3] $\text{len}(Y') = \text{len}(\text{NZTIS}_{n}')$. Hence, by the induction hypothesis, $Y' \in \text{NZTIS}_{n}'$. Consequently, knowing that $n$ is even, we have that (a) $\text{in:}j$ is not read by a primitive instruction occurring in $u_3; \ldots; u_k$ — because otherwise there are occurrences of $\#1$ or $\#2$ in $Y'$, which contradicts $Y' \in \text{NZTIS}_{n}'$ — and (b) $u_3$ is $\text{-in:}j'.\text{get}$ and $u_4$ is $\text{+in:}j'.\text{get}$, for $j'$ and $j''$ such that $j' \neq j''$. From this, it follows that execution of $X$ yields 0 as final content of $\text{out}$ if the initial content of $\text{in:}j$ is 1 and the initial content of all other $n$ input registers is 0. This contradicts the fact that $X$ computes $\text{NZT}_{n+1}$. Hence, also this case cannot occur.

The case that $u_2$ is $\text{+in:}j'.\text{get}$ goes as follows. Let $Y = u_4; \ldots; u_k$, and let $Y' = Y[\text{in:i} = 0][\text{in:}j = 0]$. Then $Y'$ computes $\text{NZT}_{n-1}$. Moreover, by Corollary[1] $\text{len}(Y') = \text{len}(\text{NZTIS}_{n-1}')$. Hence, by the induction hypothesis, $Y' \in \text{NZTIS}_{n-1}'$. From this and the fact that $n - 1$ is odd, it follows that $\#1$ does not occur in $Y'$ and $\#2$ may occur at most once in $Y'$. If $\#2$ does not occur in $Y'$, then $Y = Y'$. If $\#2$ occurs in $Y'$, then it occurs immediately before the unique isolated read instruction of $Y'$. Moreover, if $\#2$ occurs in $Y'$, then it replaces an occurrence of $\text{+in:i'.get}$ or $\text{+in:}j'.\text{get}$ in $Y$. Consequently, if $\#2$ occurs in $Y'$, $Y$ is $Y'$ with either, for each $j' \in \mathbb{N}_1$ with $i < j' \leq n + 1$, all occurrences of the register name $\text{in:}j' - 1$ replaced by $\text{in:}j'$ and the single occurrence of $\#2$ in $Y'$ replaced by $\text{+in:i'.get}$ or, for each $j' \in \mathbb{N}_1$ with $j < j' \leq n + 1$, all occurrences of the register name $\text{in:}j' - 1$ replaced by $\text{in:}j'$ and the single occurrence of $\#2$ in $Y'$ replaced by $\text{+in:}j'.\text{get}$. Moreover, because $X$ computes $\text{NZT}_{n+1}$ and $\text{len}(X) = \text{len}(\text{NZTIS}_{n+1}')$, $u_3$ must be $\text{out:set}:1; +\text{out:set}:1; -\text{out:set}:1$ or a forward jump instruction that leads to an occurrence of such an instruction. Hence, $X \in \text{NZTIS}_{n+1}'$.

The following corollary of Theorems[3] and[4] is used in Section[6].

□
Corollary 3. For all $n \in \mathbb{N}_1$, for all $X \in IS_{br}$ with $\text{len}(X) = \text{len}(NZTIS_n')$, $X$ computes $NZT_n$ iff $X \in NZTIS_n^*$. 

The following corollary of Theorem 1 and Corollary 3 is interesting because it tells us that the use of auxiliary Boolean registers is lacking in all shortest instruction sequences computing $NZT_n$ (cf. [5]).

Corollary 4. For all $n \in \mathbb{N}_1$, for all $X \in IS_{br}$ that compute $NZT_n$, $\text{len}(X) > \text{len}(NZTIS_n')$ if a register name of the form $\text{auxi}$ appears in a primitive instruction occurring in $X$.

6 The Complexity of the Correctness Problem

In this section, we study the time complexity of several restrictions of the problem of deciding whether an arbitrary instruction sequence from $IS_{br}$ correctly implements the function $NZT_n$, for $n > 0$. The restrictions considered, with the exception of one, concern only the length of the arbitrary instruction sequence. The model of computation used for time complexities in this section is the random access machine (RAM) as described in [8]. This is made explicit in the formulation of theorems and lemmas by the phrase on a RAM, but left implicit in their proofs.

A RAM consists of a read-only input tape, a write-only output tape, a memory consisting of an unbounded number of direct and indirect addressable registers that can contain an arbitrary integer, and a program. The program for a RAM is a sequence of instructions, where the instructions include input/output instructions, arithmetic instructions, copy instructions, and jump instructions. The RAM model of computation described in [8] differs slightly from the one described in [1, Chapter 1]. The main difference is that multiplication and division instructions are absent in the former model and present in the latter model.

Time complexities on a RAM are usually under one of the following two cost criteria: the uniform cost criterion and the logarithmic cost criterion (terminology from [1, Chapter 1]). The time complexities mentioned in this section are time complexities under the uniform cost criterion. It is a well-known fact that, if a problem can be solved in $O(T(n))$ time on a RAM (without multiplication and division instructions) under the uniform cost criterion, then it can be solved in $O(T^3(n))$ time on a multi-tape Turing machine.

Most primitive instructions that may occur in instruction sequences from $IS_{br}$ can be looked upon as consisting of two parts: a form of instruction and a natural number. In the case that the RAM model of computation described in [8] is used, it is contributive to the efficiency of algorithms to represent each instruction by two integers: one representing a form of instruction and the other being a natural number if that is needed for the form of instruction concerned and $-1$ otherwise. Therefore, the time complexities mentioned in this section are based on such a representation of primitive instructions.

Firstly, we consider the problem of determining whether an arbitrary instruction sequence from $IS_{br}$ whose length is $\text{len}(NZTIS_n')$ correctly implements the
function $NZT_n$, for $n > 0$. The following theorem states that this problem can be solved in $O(n^2)$ time on a RAM.

**Theorem 5.** The problem of deciding whether an $X \in IS_{br}$ such that $\text{len}(X) = \text{len}(NZT_{n}^{'})$ computes $NZT_n$, for $n \in \mathbb{N}_1$, can be solved in $O(n^2)$ time on a RAM.

**Proof.** Let $n \in \mathbb{N}_1$, and let $X \in IS_{br}$ be such that $\text{len}(X) = \text{len}(NZT_{n}^{'})$. By Corollary 5, $X$ computes $NZT_n$ iff $X \in NZTIS_{n}^*$. That is why we alternatively prove that the membership problem for $NZTIS_{n}^*$ can be solved in $O(n^2)$ time.

We start with proving that the membership problem for $NZTIS_{n}^*$ can be solved in $O(n^2)$ time. The definition of $NZTIS_{n}^*$ shows that the members of $NZTIS_{n}^*$ have a common pattern of primitive instructions which can be described by a regular grammar. This pattern allows $NZTIS_{n}^*$ to be characterized as follows: $X \in NZTIS_{n}^*$ iff (i) $X$ has this pattern, (ii) each of the input register names in:1, $\ldots$, in:$n$ appears in one occurrence of a read instruction in $X$, (iii) each occurrence of a forward jump instruction in $X$ leads, possibly via other forward jump instructions, to an occurrence of $\text{out:1}$, $\text{out:1} \pm \text{out:1}$ or $-\text{out:1}$, and (iv) $\text{len}(X) = \text{len}(NZT_{n}^{'})$. Because this theorem concerns only $X \in IS_{br}$, with $\text{len}(X) = \text{len}(NZT_{n}^{'})$, (iv) does not have to be checked. Checking (i), (ii), and (iii) in a straightforward way takes $O(n)$ steps, $O(n^2)$ steps, and $O(n^2)$ steps, respectively. Hence, the membership problem for $NZTIS_{n}^*$, for $n \in \mathbb{N}_1$, can be solved in $O(n^2)$ time.

We go on with proving that the membership problem for $NZTIS_{n}^*$ can also be solved in $O(n^2)$ time. The membership problem for $NZTIS_{n}^*$, for $n \in \mathbb{N}_1$, can be solved by first checking whether $X \in NZTIS_{n}^*$ and then, if the answer is negative, checking whether exactly one input register is read more than once in $X$ and the input register concerned is read exactly twice in $X$, determining the $k$ and $l$ such that $k$th and $l$th primitive instruction of $X$ are the ones that read the same input register, and checking whether the conditions (a), (b), and (c) from the definition of $NZTIS_{n}^*$ are satisfied. Checking whether exactly one input register is read more than once in $X$ and the input register concerned is read exactly twice in $X$ takes $O(n^2)$ steps, determining the $k$ and $l$ takes $O(n)$ steps, and checking whether conditions (a), (b), and (c) from the definition of $NZTIS_{n}^*$ are satisfied takes $O(n^2)$ steps, $O(n)$ steps, and $O(n^2)$ steps, respectively. Hence, the membership problem for $NZTIS_{n}^*$, for $n \in \mathbb{N}_1$ can be solved in $O(n^2)$ time.

Secondly, we consider the problem of determining whether an arbitrary instruction sequence from $IS_{br}$ whose length is $\text{len}(NZT_{n}^{'})$ plus a constant amount $m$ correctly implements the function $NZT_n$, for $n > 0$ and $m > 0$. The following theorem states that this problem can be solved in $O((n + m) \cdot 2^n)$ time on a RAM.

**Theorem 6.** The problem of deciding whether an $X \in IS_{br}$ such that $\text{len}(X) = \text{len}(NZT_{n}^{'}) + m$ computes $NZT_n$, for $n, m \in \mathbb{N}_1$, can be solved in $O((n + m) \cdot 2^n)$ time on a RAM.
Proof. This problem can be solved by trying out whether execution of $X$ yields the right final content of out for all $2^n$ possible combinations of the initial contents of in:1, ..., in:n. For each of these combinations, the trial takes $O(n + m)$ steps. Hence, the problem of deciding whether an $X \in IS_{br}$ such that $\text{len}(X) = \text{len}(NZTIS'_{in}) + m$ computes $NZT_n$, for $n, m \in \mathbb{N}$, can be solved in $O(2^n \cdot (n + m))$ time.

If a problem can be solved in $O(2^n \cdot (n + m))$ time, then it can be solved in $O(2^{2n} \cdot m)$ time. This justifies the statement that the problem mentioned in Theorem 6 can be solved in time exponential in $n$ and linear in $m$ on a RAM.

Thirdly, we consider the problem of determining whether an arbitrary instruction sequence from IS_{br} whose length is $\text{len}(NZTIS'_{in})$ plus an amount that depends linearly on $n$ correctly implements the function $NZT_n$, for $n > 0$. The following theorem states that this problem is co-NP-complete.

**Theorem 7.** Let $q \in \mathbb{Q}$ be such that $q > 0$ and $m \in \mathbb{N}$ be such that $m > 3$. Then the problem of deciding whether an $X \in IS_{br}$ such that $\text{len}(X) \geq \text{len}(NZTIS'_{in}) + [q \cdot n] + m$ computes $NZT_n$, for $n \in \mathbb{N}$, is co-NP-complete.

Proof. We call this problem CORRECT_{NZT}. Let $b_1, \ldots, b_n \in \mathbb{B}$ be such that execution of $X$ with $b_1 \ldots b_n$ as the initial contents of in:1, ..., in:n, respectively does not yield $NZT_n(b_1, \ldots, b_n)$ as final content of out. Then we can verify that $X$ does not compute $NZT_n$ by simulating the execution of $X$ with $b_1 \ldots b_n$ as the initial contents of in:1, ..., in:n, respectively. The simulation of this execution of $X$ takes $O(n)$ steps. Hence, CORRECT_{NZT} is in co-NP. We still have to show that CORRECT_{NZT} is co-NP-hard.

We show that CORRECT_{NZT} is co-NP-hard by proving that co-SAT, i.e., the complement of SAT, is reducible to CORRECT_{NZT}. The proof is based on the idea that, for each proposition $P$ containing $n$ variables, an instruction sequence can be constructed of which the first part computes $NZT_n'$, where $n' \geq n$ and $n'$ depends linearly on the length of $P$, the second part computes the truth function $f : \mathbb{B}^n \rightarrow \mathbb{B}$ expressed by $P$, and the third part negates the result of the first part if the result of the second part is 0. The length of a proposition $P$ is the number of occurrences of variables and connectives in $P$. In this proof, we write $\text{len}(P)$ for the length of $P$.

For the construction outlined above, use is made of a polynomial-time computable function from the set of all propositions to IS_{br} that is introduced in the proof of Proposition 4 from [3]. The function concerned associates a given proposition with an instruction sequence that computes the truth function expressed by the given proposition and whose length depends linearly on the length of the given proposition. In [3], this function is denoted by $\text{inseq}_{\text{bf}}$. In this proof, we denote this function shortly by $\Phi$.

Let $c \in \mathbb{N}$ be such that, for all propositions $P$, $\text{len}(\Phi(P)) < c \cdot \text{len}(P)$. Let $\Phi^*$ be such that, for all propositions $P$, $\Phi(P) = \Phi^*(P) ; \text{out:1} ; !$. Let $NZTIS'_{in}$ be such that $NZTIS'_{in} = NZTIS'_{in} ; !$, and let $NZTIS'_{in}$ be $NZTIS'_{in}$ with each occurrence of out in $NZTIS'_{in}$ replaced by aux:1. Let $c' \in \mathbb{N}$ be such that $(c' - 1) \cdot q < 1 < c' \cdot q$. Let $\Psi$ be the transformation from the set of all propositions
to IS_{br} such that, for all \( n \in \mathbb{N}_1 \), for all propositions \( P \) with \( \text{len}(P) = n \), \( \Psi(P) = \text{NZTIS}_{c,c',n}^\ast; \Phi(P); \#4; + \text{aux.1.get}; \text{out.set}; 1;!; + \text{aux.1.get}; + \text{out.set.0}; \text{out.set}; 1;! \).

Because \( \Phi \) is polynomial-time computable, \( \Psi \) is polynomial-time computable.

Let \( n \in \mathbb{N}_1 \), and let \( P \) be a proposition with \( \text{len}(P) = n \). Then the part \( \text{NZTIS}_{c,c',n}^\ast \) of \( \Psi(P) \) reads \( c \cdot c' \cdot n \) input registers. The part \( \Phi^*(P) \) of \( \Psi(P) \) does not read additional input registers because at most \( n \) variables can occur in a proposition of length \( n \). Hence, \( \Psi(P) \) reads \( c \cdot c' \cdot n \) input registers, which is linear in \( n \).

Because \( 1 < c' \cdot q \), we have that, for all \( n \in \mathbb{N}_1 \), \( c \cdot n \leq q \cdot c \cdot c' \cdot n \). Using this, we find that, for all \( n \in \mathbb{N}_1 \), for all propositions \( P \) with \( \text{len}(P) = n \),

\[
\text{len}(\Psi(P)) = \text{len}(\text{NZTIS}_{c,c',n}^\ast) + \text{len}(\Phi(P)) + 5 \leq \text{len}(\text{NZTIS}_{c,c',n}^\ast) + c \cdot n + m \leq \text{len}(\text{NZTIS}_{c,c',n}^\ast) + [q \cdot c \cdot c' \cdot n] + m.
\]

Hence, for all \( n \in \mathbb{N}_1 \), for all propositions \( P \) with \( \text{len}(P) = n \), \( \Psi(P) \) is an instance of CORRECT_{NZT} that reads \( c \cdot c' \cdot n \) input registers.

Let \( P \) be a proposition. Then, because \( \Phi \) associates \( P \) with an instruction sequence that computes the truth function expressed by \( P \), we have that (a) if \( \text{co-SAT}(P) \), then execution of \( \Psi(P) \) yields the correct final content of output for each initial content of the input registers and (b) if not \( \text{co-SAT}(P) \), then execution of \( \Psi(P) \) yields the complement of the the correct final content of output for some initial content of the input registers. Hence, for all proposition \( P \), \( \text{co-SAT}(P) \) iff \( \text{CORRECT}_{NZT}(\Psi(P)) \).

To make the problem mentioned in Theorem 7 more concrete, we mention that the instruction sequence \( \text{NZTIS}_n \) from Section 3 is an instance of this problem.

In the proof of Theorem 7, we could have used, instead of \( \Psi \), a less obvious transformation in which no auxiliary registers are used at the cost of \( \Phi^*(P) \) occurring twice in the transformation of proposition \( P \). In that case, the transformation would yield good instruction sequences in the sense defined in the second next paragraph.

Below we present a theorem stating that the problem of determining whether an arbitrary instruction sequence from IS_{br} whose length is \( \text{len}(\text{NZTIS}_{n}^\ast) \) plus a constant amount \( m \) correctly implements the function \( \text{NZT}_n \), for \( n > 0 \), can be solved in \( O(2^{6 \cdot m} \cdot (n + m) + n \cdot (n + m)) \) time on a RAM if the instruction sequences are restricted to good instruction sequences.

A good instruction sequence is defined as an instruction sequence that is of the form \( X : \text{out.set}; 1;! \), where \( X \in \text{IS}_{br} \) is such that only read instructions and forward jump instructions \#l, where \( l > 0 \), occur in \( X \). A very good instruction sequence is a good instruction sequence in which no input register name appears in more than one occurrence of a read instruction. A good instruction sequence for \( \text{NZT}_n \) is a good instruction sequence \( X \) such that \( \text{iregs}(X) = \{ i \in \mathbb{N}_1 \mid i \leq n \} \) and \( X \) computes \( \text{NZT}_n \). A very good instruction sequence for \( \text{NZT}_n \) is a very good instruction sequence \( X \) such that \( \text{iregs}(X) = \{ i \in \mathbb{N}_1 \mid i \leq n \} \) and \( X \) computes \( \text{NZT}_n \).

Notice that instructions concerning auxiliary registers do not occur in good instruction sequences and very good instruction sequences.
Lemma 1. Let \( n, k \in \mathbb{N}_1 \), and let \( X \) be a very good instruction sequence for \( NZT_n \) in which there are \( k \) occurrences of \#1 or \#2. Then \( X \) can be transformed into a very good instruction sequence for \( NZT_n \) that is at least \( k - 1 \) primitive instructions shorter than \( X \) and in which \#1 does not occur and \#2 occurs at most once.

Proof. Obviously, it is sufficient to prove that \( X \) can be transformed into a very good instruction sequence for \( NZT_n \) that is not longer than \( X \) and in which \#1 does not occur and \#2 occurs at most once.

The following properties of \( X \) are useful in the proof:

(a) \( X \) is an instruction sequence in which, for each \( j \leq n \) for which the occurrence of +\( \text{in}:j.\text{get} \) or \( -\text{in}:j.\text{get} \) in \( X \) is not the last occurrence of a read instruction in \( X \), after execution of the occurrence of +\( \text{in}:j.\text{get} \) or \( -\text{in}:j.\text{get} \) in \( X \), execution proceeds such that execution of the next occurrence of a read instruction in \( X \) will take place if the initial content of \( \text{in}:j \) is 0;

(b) \( X \) is an instruction sequence in which, for each \( j \leq n \), either +\( \text{in}:j.\text{get} \) or \( -\text{in}:j.\text{get} \) occurs;

(c) \( X \) is an instruction sequence in which three or more read instructions in a row do not occur;

(d) \( X \) can be transformed into a very good instruction sequence for \( NZT_n \) that is not longer than \( X \) and in which two or more forward jump instructions in a row do not occur;

(e) an isolated read instruction of \( X \) is of the form +\( \text{in}:i.\text{get} \) if \( n > 1 \) and two or more forward jump instructions in a row do not occur;

(f) a read instruction pair of \( X \) is of the form \( -\text{in}:i.\text{get} \); +\( \text{in}:j.\text{get} \) if \( n > 2 \) and two or more forward jump instructions in a row do not occur;

(g) - if the number of isolated read instructions in \( X \) is odd, then \( X \) can be transformed into a very good instruction sequence for \( NZT_n \) that is not longer than \( X \) and has the form \( \text{Y} +\text{in}:i.\text{get} ; \text{out.set}:1 ; ! \), where no isolated read instructions occur in \( Y \), if \( n > 1 \) and the form \( +\text{in}:1.\text{get} ; \text{out.set}:1 ; ! \) if \( n = 1 \);

- if the number of isolated read instructions in \( X \) is even, then \( X \) can be transformed into a very good instruction sequence for \( NZT_n \) that is not longer than \( X \) and has the form \( \text{Y} -\text{in}:i.\text{get} ; +\text{in}:j.\text{get} ; \text{out.set}:1 ; ! \), where no isolated read instructions occur in \( Y \), if \( n > 2 \) and the form

\[-\text{in}:i.\text{get} ; +\text{in}:j.\text{get} ; \text{out.set}:1 ; ! \text{ if } n = 2.\]

Property (a) holds because otherwise, on execution of \( X \), the final content of \( \text{out} \) is 0 in the case where the input register to be read by the next occurrence of a read instruction contains 1.

Property (b) holds because otherwise, on execution of \( X \), the final content of \( \text{out} \) is 0 in the case where, for some \( j \leq n \) for which neither +\( \text{in}:j.\text{get} \) nor \( -\text{in}:j.\text{get} \) occurs in \( X \), in\( :j \) contains 1.

That property (c) holds can be seen by assuming that \( X \) is of the form

\[ u_1 ; u_2 ; u_3 ; X''' \text{ or } X' ; u_1 ; u_2 ; u_3 ; X''', \]

where \( u_1, u_2, \) and \( u_3 \) are read instructions by which respectively in\( :i \), in\( :i' \), and in\( :i'' \), for some \( i, i', i'' \leq n \), are read. Let \( R \) be \( \text{iregs}(X') \) if \( X \) is of the second form
and \( \emptyset \) otherwise. On execution of \( X \), if the initial content of all input registers \( \text{in}:j \) with \( j \in R \) is 0 and the initial content of \( \text{in}:i \) is 1, then, by property (a), \( u_1 : u_2 ; u_3 ; X'' \) is eventually executed and so execution of \( u_3 ; X'' \) must yield 1 as final content of \( \text{out} \). However, on execution of \( X \), if the initial content of all input registers is 0, then, by property (a), \( u_3 ; X'' \) is eventually executed and must yield upon execution 0 as final content of \( \text{out} \). Hence, the assumption leads to a contradiction.

That property (d) holds can be seen by assuming that \( X \) is of one of the following forms:

(i) \( \# l ; \# l' ; X'' \), (ii) \( u ; \# l ; \# l' ; X'' \), (iii) \( X' ; u ; \# l ; \# l' ; X'' \),

where \( u \) is a read instruction by which \( \text{in}:i \), for some \( i \leq n \), is read. Let \( R \) be \( \text{iregs}(X') \cup \{ i \} \) if \( X \) is of form (iii), \( \{ i \} \) if \( X \) is of form (ii), and \( \emptyset \) otherwise, and let \( \alpha : R \to \mathbb{B} \) be such that \( \alpha(j) = 0 \) for all \( j \in R \). In case (i), \( \# l \) and the \( l-1 \) next instructions can be removed from \( X \). In cases (ii) and (iii), in the case that \( u \) is \( \text{in}:i.\text{get} \), on execution of \( X \), if the initial content of \( \text{in}:i \) and all input registers \( \text{in}:j \) with \( j \in R \) is 0, then, by property (a), \( \# l' ; X'' \) is eventually executed and so, by property (b), \( \# l' ; X^n'' \) computes \( \text{NZT}_n \) for some \( n' < n \). However, the suffix of \( X^n'' \) obtained by removing its first \( l' - 1 \) instructions computes the same function. Hence, \( \# l' \) and the \( l' - 1 \) next instructions can be removed from \( X \) after replacing chains of forward jumps by direct jumps where needed because of removed jump instructions. In cases (ii) and (iii), in the case that \( u \) is \( \text{in}:i.\text{get} \), it can be similarly shown that \( \# l \) and the \( l-1 \) next instructions can be removed from \( X \) after replacing chains of forward jumps by direct jumps where needed.

That property (e) holds can be seen by assuming that \( X \) is of the form

\[-\text{in}:i.\text{get}; \# l' ; X'' \text{ or } X' ; \# l ; \text{in}:i.\text{get}; \# l' ; X'' ,\]

where \( i \leq n \). Let \( R \) be \( \text{iregs}(X') \) if \( X \) is of the second form and \( \emptyset \) otherwise. On execution of \( X \), if the initial content of \( \text{in}:i \) and all input registers \( \text{in}:j \) with \( j \in R \) is 0, then, by property (a), \( -\text{in}:i.\text{get}; \# l' ; X'' \) is eventually executed, but, after execution of its first instruction, execution proceeds such that execution of the next occurrence of a read instruction in \( X \) will not take place if \( n > 1 \) and \( l' > 1 \). Hence, the assumption leads to a contradiction with property (a) if \( l' > 1 \). If instead \( l' = 1 \), then execution of the next occurrence of a read instruction in \( X \) will take place, but the final content of \( \text{out} \) will not depend on the content of \( \text{in}:i.\text{get} \). Hence, the assumption leads to a contradiction with the fact that \( X \) computes \( \text{NZT}_n \) if \( l' = 1 \).

That property (f) holds can be seen by assuming that \( X \) is of one of the following forms:

(i) \( +\text{in}:i.\text{get}; +\text{in}:j.\text{get}; \# l' ; X'' \), (ii) \( X' ; \# l ; +\text{in}:i.\text{get}; +\text{in}:j.\text{get}; \# l' ; X'' ,\)

(iii) \( +\text{in}:i.\text{get}; -\text{in}:j.\text{get}; \# l' ; X'' \), (iv) \( X' ; \# l ; +\text{in}:i.\text{get}; -\text{in}:j.\text{get}; \# l' ; X'' ,\)

(v) \( -\text{in}:i.\text{get}; -\text{in}:j.\text{get}; \# l' ; X'' \), (vi) \( X' ; \# l ; -\text{in}:i.\text{get}; -\text{in}:j.\text{get}; \# l' ; X'' ,\)

where \( i, j \leq n \). Let \( R \) be \( \text{iregs}(X') \) if \( X \) is of form (ii), (iv) or (vi) and \( \emptyset \) otherwise, and let \( \alpha : R \to \mathbb{B} \) be such that \( \alpha(j) = 0 \) for all \( j \in R \). In cases (i)–(iv), on
execution of \(X\), if the initial content of \(in:i\) and all input registers \(in:j\) with \(j \in R\) is 0, then, by property (a), \(+in:i.get; +in:j.get; \#l' ; X''\) (cases (i)–(iii)) or \(+in:i.get; -in:j.get; \#l' ; X''\) (cases (iii)–(iv)) is eventually executed but, after execution of the first instruction of either instruction sequence, execution does not proceed with the execution of the next instruction. Hence, in cases (i)–(iv), the assumption leads to a contradiction with property (a). In cases (v) and (vi), on execution of \(X\), if the initial content of \(in:i\) and all input registers \(in:j\) with \(j \in R\) is 0, then, by property (a), \(-in:j.get; \#l' ; X''\) is eventually executed and so, by property (b), \(-in:j.get; \#l' ; X''\) is a very good instruction sequence for \(NZT_n'\) for some \(n' < n\). Hence, in cases (v) and (vi), the assumption leads to a contradiction with property (e) if \(n > 2\) and two or more forward jump instructions in a row do not occur.

That property (g) holds follows directly from properties (c)–(f), the fact that \(X\) with each chain of two or more forward jump instructions in \(X\) replaced by a single jump instruction that leads to the same instruction is also a very good instruction sequence for \(NZT_n\), and the following claim: if there are no chains of two or more forward jump instructions in \(X\), then

- if \(X\) is of the form \(+in:i_1.get; \#l; -in:i_2.get; +in:i_3.get; u; X''\), where \(u\) is either a jump instruction or \(out.set:1\), then \(-in:i_1.get; +in:i_2.get; \#l-1; +in:i_3.get; u; X''\) is also a very good instruction sequence for \(NZT_n\);
- if \(X\) is of the form \(X' ; \#l_1 +in:i_1.get; \#l_2; -in:i_2.get; +in:i_3.get; u; X''\), where \(u\) is either a jump instruction or \(out.set:1\), then \(X' ; \#l_1; -in:i_1.get; +in:i_2.get; \#l_2-1; +in:i_3.get; u; X''\) is also a very good instruction sequence for \(NZT_n\);
- if \(X\) is of the form \(+in:i_1.get; \#l; +in:i_2.get; u; X''\), where \(u\) is either a jump instruction or \(out.set:1\), then \(-in:i_1.get; +in:i_2.get; u; X''\) is also a very good instruction sequence for \(NZT_n\);
- if \(X\) is of the form \(X' ; \#l_1 +in:i_1.get; \#l_2; +in:i_2.get; u; X''\), where \(u\) is either a jump instruction or \(out.set:1\), then \(X' ; \#l_1; -in:i_1.get; +in:i_2.get; u; X''\) is also a very good instruction sequence for \(NZT_n\).

This claim is easy to check by case distinction on the content of the input registers involved, using the fact that, in order to compute \(NZT_n\), all occurrences of jump instructions in \(X\) immediately following an occurrence of a read instruction of the form \(+in:i.get\) must lead to the last but one instruction of \(X\).

Notice the following concerning properties (a) and (b): for each of the properties (c)–(g), property (a) is used to show that it holds and, for each of the properties (d) and (f), property (b) is used in addition to show that it holds.

It follows directly from properties (c)–(g) that:

- if \(n\) is even, then \(X\) can be transformed into a very good instruction sequence for \(NZT_n\) that is not longer than \(X\) and has the form \(Y ; out.set:1 ; l, \) where \(Y\) consists of read instruction pairs separated by instructions of the form \#l with \(l \geq 2\);
- if \(n\) is odd and \(n > 1\), then \(X\) can be transformed into a very good instruction sequence for \(NZT_n\) that is not longer than \(X\) and has the form
This follows directly from the definition of Proof.

Let Lemma 3.

(ii) for each function \( \alpha \) from \( R \) to \( B \) such that \( \alpha(i) = 1 \) for at least one \( i \in R \), \( X_\alpha \) yields upon execution 1 as final content of \( \text{out} \) for each combination of initial contents of the input registers whose numbers belong to \( \text{iregs}(X_\alpha) \).

Proof. This follows directly from the definition of \( \text{NZT}_n \).
Lemma 4. The problem of deciding whether an \( X \in IS_{br} \) such that \( X \) is a very good instruction sequence and \( \text{len}(X) = n \) yields upon execution 1 as final content of \( \text{out} \) for each combination of initial content of the input registers whose numbers belong to \( \text{iregs}(X) \), for \( n \in \mathbb{N}_1 \), can be solved in \( O(n) \) time on a RAM.

Proof. Let \( X^k \), for \( 1 \leq k \leq n \), be the suffix of \( X \) whose length is \( k \). Clearly, for \( k > 2 \), \( X^k \) is a very good instruction sequence. Moreover, we know that execution of \( X^1 \) never yields 1 as final content of \( \text{out} \) and execution of \( X^2 \) always yields 1 as final content of \( \text{out} \). Below, we use the convention that \( X^k = ! \) for all \( k \leq 0 \).

Let \( k > 1 \) and \( l > 0 \). Then:

- if \( X^{k+1} = +\text{in} ; X^k \), then execution of \( X^{k+1} \) always yields 1 as final content of \( \text{out} \) iff both execution of \( X^k \) and execution of \( X^{k-1} \) always do so;
- if \( X^{k+1} = -\text{in} ; X^k \), then execution of \( X^{k+1} \) always yields 1 as final content of \( \text{out} \) iff both execution of \( X^k \) and execution of \( X^{k-1} \) always do so;
- if \( X^{k+1} = \#l ; X^k \), then execution of \( X^{k+1} \) always yields 1 as final content of \( \text{out} \) iff execution of \( X^{k+1-l} \) always does so.

The first two implications from left to right are easily proved by a case distinction on the content of \( \text{in} \). It is trivial to prove the last implication from left to right and the three implications from right to left.

Now, let \( S \) be the set of all \( k \geq 1 \) for which \( X^k \) always yields 1 as final content of \( \text{out} \). Then, using the above bi-implications, the \( k \)'s which belong to \( S \) can be determined in increasing order as follows:

- \( 1 \notin S \);
- \( 2 \in S \);
- if \( X^{k+1} = +\text{in} ; X^k \), then \( k+1 \in S \) iff \( k \in S \) and \( k-1 \in S \);
- if \( X^{k+1} = -\text{in} ; X^k \), then \( k+1 \in S \) iff \( k \in S \) and \( k-1 \in S \);
- if \( X^{k+1} = \#l ; X^k \) and \( l \leq k \), then \( k+1 \in S \) iff \( k+1-l \in S \);
- if \( X^{k+1} = \#l ; X^k \) and \( l > k \), then \( k+1 \notin S \).

Execution of \( X \) always yields 1 as final content of \( \text{out} \) iff \( n \) is the last \( k \) for which it can be determined in this way that it belongs to \( S \). Clearly, this can be determined in \( O(n) \) time if the set \( S \) is represented by its characteristic function. \( \square \)

Lemma 5. The problem of deciding whether an \( X \in IS_{br} \) such that \( X \) is a very good instruction sequence, \( \text{len}(X) = \text{len}(NZTIS_n^i) + m \), and \( \text{iregs}(X) = \{ i \in \mathbb{N}_1 \mid i \leq n \} \) computes \( NZT_n \), for \( n, m \in \mathbb{N}_1 \), can be solved in \( O(n \cdot (n + m)) \) time on a RAM.

Proof. Consider the following procedure:

step 1: determine whether execution of \( X \) yields 0 as the final content of \( \text{out} \) if the initial content of each input register whose numbers belong to \( \text{iregs}(X) \) is 0; if this is the case, then go on with step 2; otherwise \( X \) does not compute \( NZT_n \) and we are finished;

step 2: determine, for each \( i \in \text{iregs}(X) \), whether execution of \( X[\text{in} ; i = 1] \) yields 1 as the final content of \( \text{out} \) for each combination of initial content of the input registers whose numbers belong to \( \text{iregs}(X) \setminus \{ i \} \); if this is the case,
then $X$ computes $NZT_n$ and we are finished; otherwise $X$ does not compute $NZT_n$ and we are finished.

Clearly, together steps 1 and 2 cover all combinations of the initial contents of the input registers whose numbers belong to $\text{iregs}(X)$. Step 1 can be done in $O(n + m)$ time. By Lemma 4 per $i$, step 2 can also be done in $O(n + m)$ time. Because $\text{card}(\text{iregs}(X)) = n$, step 2 as a whole can be done in $O(n \cdot (n + m))$ time. Consequently, the whole procedure can be done in $O(n \cdot (n + m))$ time. □

**Theorem 8.** The problem of deciding whether an $X \in \text{IS}_{br}$ such that $X$ is a good instruction sequence, $\text{len}(X) = \text{len}(\text{NZTIS'}_n) + m$, and $\text{iregs}(X) = \{i \in \mathbb{N}_1 \mid i \leq n\}$ computes $NZT_n$, for $n, m \in \mathbb{N}_1$, can be solved in $O(2^{6 \cdot m} \cdot (n + m) + n \cdot (n + m))$ time on a RAM.

**Proof.** Consider the following procedure:

step 1: determine the subset $R$ of $\{k \in \mathbb{N}_1 \mid k \leq n\}$ such that $i \in R$ iff in$i$ appears in more than one occurrence of a read instruction in $X$; if $\text{card}(R) < 6 \cdot m$, then go on with step 2; otherwise, by Lemma 2, $X$ does not compute $NZT_n$ and we are finished;

step 2: for the unique function $\alpha_0$ from $R$ to $\mathbb{B}$ such that $\alpha_0(i) = 0$ for all $i \in R$, determine whether $X_{\alpha_0}$ computes $NZT_{n - \text{card}(R)}$; if this is the case, then go on with step 3; otherwise $X$ does not compute $NZT_n$ and we are finished;

step 3: for each function $\alpha$ from $R$ to $\mathbb{B}$ such that $\alpha(i) = 1$ for at least one $i \in R$, determine whether $X_{\alpha}$ yields upon execution 1 as final content of out for each combination of initial contents of the input registers whose numbers belong to $\text{iregs}(X_{\alpha})$; if this is the case, then, by Lemma 3, $X$ computes $NZT_n$ and we are finished; otherwise $X$ does not compute $NZT_n$ and we are finished.

Clearly, step 1 can be done in $O(n + m)$ time. By their construction, $X_{\alpha_0}$ and all $X_{\alpha}$’s are very good instruction sequences. Hence, by Lemma 4, step 2 can be done in $O(n \cdot (n + m))$ time and, by Lemma 4 per $\alpha$, step 3 can be done in $O(n + m)$ time. Because there may be $2^{6 \cdot m} - 1$ $\alpha$’s, step 3 as a whole can be done in $O(2^{6 \cdot m} \cdot (n + m))$ time. Consequently, the whole procedure can be done in $O(2^{6 \cdot m} \cdot (n + m) + n \cdot (n + m))$ time. □

If a problem can be solved in $O(2^{6 \cdot m} \cdot (n + m) + n \cdot (n + m))$ time, then it can be solved in $O(2^{7 \cdot m} \cdot n^2)$ time. This justifies the statement that the problem mentioned in Theorem 8 can be solved in time quadratic in $n$ and exponential in $m$ on a RAM. It is an open question whether Theorem 8 goes through if the restriction to good instruction sequences is dropped.

The following result is a corollary of the proof of Theorem 8 and the remark about that proof made following it.

**Corollary 5.** Let $q \in \mathbb{Q}$ be such that $q > 0$ and $m \in \mathbb{N}$. Then the problem of deciding whether an $X \in \text{IS}_{br}$ such that $X$ is a good instruction sequence and $\text{len}(X) \leq \text{len}(\text{NZTIS'}_n) + [q \cdot n] + m$ computes $NZT_n$, for $n \in \mathbb{N}_1$, is co-NP-complete.
So, the problem of determining whether an instruction sequence from \( IS_{n,} \) whose length is \( \text{len}(NZTIS_{n}^{\prime}) \) plus an amount that depends linearly on \( n \) correctly implements the non-zerooness test function \( NZT_{n} \) remains co-NP-complete if the instruction sequences are restricted to good instruction sequences. It can easily be shown that this problem can be solved in time polynomial in \( n \) on a RAM if the instruction sequences are restricted to very good instruction sequences. Hence, if no input register name may appear in more than one occurrence of a read instruction, then we get a better result.

7 Concluding Remarks

Within the context of finite instruction sequences that contain only instructions to set and get the content of Boolean registers, forward jump instructions, and a termination instruction, we have investigated under what restrictions on these instruction sequences the correctness of an arbitrary instruction sequence as an implementation of the restriction to \( \mathbb{B}^{n} \) of the function from \( \mathbb{B}^{\ast} \) to \( \mathbb{B} \) that models the non-zerooness test function on natural numbers with respect to their binary representations, for \( n > 0 \), can be efficiently determined. We expect that results similar to the main results established for this function, i.e., Theorems 5, 7, and 8 can be established for many other functions, but also that finding such results is a challenging problem. To our knowledge, the idea of looking for such results is new.

An important step in establishing the main results has been the determination of a shortest instruction sequence that correctly implements the function that models the non-zerooness test on natural numbers less than \( 2^{n} \) (cf. Theorem 1). In [3], an approach to computational complexity is presented in which instruction sequence size is used as complexity measure. The step just mentioned, provides a lower bound (in fact the greatest lower bound) for the instruction sequence size complexity of this function. Moreover, it provides answers to concrete questions like “what is the length of the shortest instruction sequence that correctly implements the function that models the non-zerooness test on natural numbers less than \( 2^{64} \)?”.

The work presented in this paper concerns the question to what extent it can be efficiently determined, for \( n > 0 \), whether the restriction to \( \mathbb{B}^{n} \) of a given function from \( \mathbb{B}^{\ast} \) to \( \mathbb{B} \) is correctly implemented by an arbitrary instruction sequence from a set by which, for all \( m > 0 \), all functions from \( \mathbb{B}^{m} \) to \( \mathbb{B} \) can be computed. To our knowledge there is no previous work related to programming that addresses a question similar to this one. Because each function from \( \mathbb{B}^{m} \) to \( \mathbb{B} \) can be computed by a Boolean circuit as well, there is of course the question to what extent it can be efficiently determined, for \( n > 0 \), whether the restriction to \( \mathbb{B}^{n} \) of a given function from \( \mathbb{B}^{\ast} \) to \( \mathbb{B} \) is correctly implemented by an arbitrary Boolean circuit.

There are computational problems concerning Boolean circuits that can be viewed as correctness problems. For example, the complement of the satisfiability problem for Boolean circuits (see e.g. [10]) can be viewed as the problem
of determining whether an arbitrary Boolean circuit correctly implements the restriction to \( B^n \) of the function from \( B^* \) to \( B \) whose value is constantly 0, for \( n > 0 \). However, as far as we know, there is no work on Boolean circuits that pays attention to limitations on Boolean circuits under which problems concerning Boolean circuits that can be viewed as correctness problems can be solved in polynomial time. In other words, to our knowledge, there is no work on Boolean circuits that addresses a question related to the one addressed in this paper.

In [5], it was shown that, for the parity function, shortest correct instruction sequences require the use of auxiliary registers. This is not the case for the function that models the non-zeroness test (cf. Corollary 1). In [5], in addition to the commands \( \text{set}:0 \), \( \text{set}:1 \), and \( \text{get} \), the command \( \text{com} \) is used. This command serves for complementing the content of an auxiliary register. In [6], where \( \text{com} \) is denoted by \( c/c \), it is shown that this command is not needed for functional completeness, but that its addition gives sometimes rise to shorter instruction sequences. In the current paper, using \( \text{com} \) would have only one consequence: it would make it possible to drop the restriction to \( m > 3 \) in Theorem 7.

Acknowledgements

We thank two anonymous referees for carefully reading a preliminary version of this paper, for pointing out several flaws in it, and for suggesting improvements of the presentation.
