DIFFERENTIAL-HENSELIANITY AND MAXIMALITY OF
ASYMPTOTIC VALUED DIFFERENTIAL FIELDS

NIGEL PYNN-COATES

Abstract. We show that asymptotic (valued differential) fields have unique maximal immediate
extensions. Connecting this to differential-henselianity, we prove that any differential-henselian
asymptotic field is differential-algebraically maximal, removing the assumption of monotonicity
from a theorem of Aschenbrenner, van den Dries, and van der Hoeven [1, Theorem 7.0.3]. Finally,
we use this result to show the existence and uniqueness of differential-henselizations of asymptotic
fields.

1. INTRODUCTION

The basic objects of this paper are valued differential fields with small derivation and their exten-
sions, by which we mean valued differential field extensions with small derivation. The issue of
uniqueness of maximal immediate extensions of such objects was first considered by Scanlon, who
obtained a positive result for monotone fields with many constants and linearly surjective differ-
ential residue field [7]. (In that result, and throughout this paper, all valued differential fields are
assumed to be of equicharacteristic 0.) Aschenbrenner, van den Dries, and van der Hoeven gener-
alized this to monotone fields with linearly surjective differential residue field [1, Theorem 7.4.3].
In [2], the same authors conjectured that any valued differential field with small derivation and
linearly surjective differential residue field should have unique maximal immediate extensions. Van
den Dries and the present author removed monotonicity from the previous result but required the
value group to be the union of its convex subgroups of finite archimedean rank [3]. Here, we prove
the conjecture when the valued differential field is asymptotic, a condition opposite in spirit to
monotonicity.

Theorem A. If an asymptotic valued differential field \( K \) has small derivation and linearly surjective
differential residue field, then any two maximal immediate extensions of \( K \) are isomorphic over \( K \).

Since there is an equivalence between algebraic maximality and henselianity for valued fields of
equicharacteristic 0, one might hope for a similar relationship in the setting of valued differential
fields after adding the prefix "differential," but it turns out to depend on the interaction between
the valuation and the derivation. In fact, any differential-algebraically maximal valued differential
field with small derivation and linearly surjective differential residue field is differential-henselian
[1, Theorem 7.0.1]. But there are differential-henselian monotone fields with many constants that
are not differential-algebraically maximal [1, example after Corollary 7.4.5]. However, in the case
of few constants, we prove the following, removing entirely the monotonicity assumption in [1,
Theorem 7.0.3].

Theorem B. If \( K \) is a valued differential field with small derivation and few constants that is
differential-henselian, then \( K \) is differential-algebraically maximal.

Note that by [1, Lemmas 7.1.8 and 9.1.1], any \( K \) as in the theorem above is in fact asymptotic.
Using Theorem B we then prove the following generalization of [3, Theorem 1.3].
Theorem C. Suppose $K$ is an asymptotic valued differential field with small derivation and linearly surjective differential residue field. Then $K$ has a differential-henselization. Moreover, any two differential-henselizations of $K$ are isomorphic over $K$.

1.A. Basic definitions and notation. To understand these results, we define the necessary conditions after setting up basic notation, which we keep close to that of [1]. We let $d$, $i$, $j$, $m$, and $n$ be in $\mathbb{N} = \{0, 1, 2, \ldots \}$. In the rest of this introduction, we let $r \in \mathbb{N}$; afterwards, we also allow $r$ to be $\infty > \mathbb{N}$ but restrict it to $r \geq 1$. Throughout, $K$ will be a valued differential field, that is, a field together with a surjective map $v : K^\times \to \Gamma$ and a map $\partial : K \to K$ satisfying, for all $x$, $y$ in their domain:

1. $v(xy) = v(x) + v(y)$;
2. $v(x + y) \geq \min\{v(x), v(y)\}$ whenever $x + y \neq 0$;
3. $\partial(x + y) = \partial(x) + \partial(y)$;
4. $\partial(xy) = x\partial(y) + \partial(x)y$.

Here, $\Gamma$ is a (totally) ordered abelian group called the value group of $K$. We introduce a symbol $\infty \notin \Gamma$ and extend the ordering to $\Gamma \cup \{\infty\}$ by $\infty > \Gamma$. We also set $\infty + \gamma = \gamma + \infty = : \infty$ for all $\gamma \in \Gamma$. This allows us to extend $v$ to $K$ by setting $v(0) = \infty$. We also set $\Gamma^\neq := \Gamma \setminus \{0\}$. We let $\mathcal{O} := \{a \in K : v(a) \geq 0\}$ be the valuation ring of $K$ and $\mathfrak{o} := \{a \in K : v(a) > 0\}$ its (unique) maximal ideal. We also set $\mathcal{O}^\neq := \mathcal{O} \setminus \{0\}$ and $\mathfrak{o}^\neq := \mathfrak{o} \setminus \{0\}$. Then $k := \mathcal{O}/\mathfrak{o}$ denotes the residue field of $K$. As it is often more intuitive, we define for $a$, $b \in K$:

$$\begin{align*}
a \preceq b &\iff v(a) \geq v(b), \quad a < b \iff v(a) > v(b), \\
a \sim b &\iff v(a) = v(b), \quad a \prec b \iff a - b < b.
\end{align*}$$

Regarding the derivation, we usually write $a'$ for $\partial(a)$ if the derivation is clear from context, and the field of constants of $K$ is denoted $C := \{a \in K : \partial(a) = 0\}$. For another valued differential field $L$, we apply the subscript $L$ to these symbols; for example, $\mathcal{O}_L$ denotes the valuation ring of $L$. Recall that a valued field extension $L$ of $K$ is said to be immediate if $k_L = k$ and $\Gamma_L = \Gamma$, where we identify $k$ with a subfield of $k_L$ and $\Gamma$ with an ordered subgroup of $\Gamma_L$ in the usual way. We call a pseudoCauchy sequence a pc-sequence and refer the reader to [1, §2.2 and §3.2] for definitions and basic facts about them.

We let $K\{Y\} := K[Y, Y', Y'', \ldots]$ denote the ring of differential polynomials over $K$ and set $K\{Y\}^\neq := K\{Y\} \setminus \{0\}$. Let $P$ range over $K\{Y\}^\neq$. The order of $P$ is the smallest $r$ such that $P \in K[Y, Y', \ldots, Y^{(r)}]$. Its degree is its total degree. If $r$ is the order of $P$, $m$ its degree in $Y^{(r)}$, and $n$ its total degree, then the complexity of $P$ is the triple $c(P) := (r, m, n)$; complexities are ordered lexicographically. For $i = (i_0, \ldots, i_r) \in \mathbb{N}^{1+r}$, we set $Y^i := Y^{i_0}(Y')^{i_1} \cdots (Y^{(r)})^{i_r}$. If $P$ has order at most $r$, then we decompose $P$ as $\sum_i P_i Y^i$, where $i$ ranges over $\mathbb{N}^{1+r}$. We also sometimes decompose $P$ into its homogeneous parts, so let $P_d$ denote the homogeneous part of $P$ of degree $d$ and set $P_{\leq d} := \sum_{i \leq d} P_i$ and $P_{> d} := \sum_{i > d} P_i$. Letting $|i| := i_0 + \cdots + i_r$, we note that $P_d = \sum_{|i|=d} P_i Y^i$. The multiplicity of $P$, denoted $\text{mul} P$, is the least $d$ with $P_d \neq 0$. We often use, for $a \in K$, the additive and multiplicative conjugates of $P$ by $a$ defined by $P_{+a}(Y) := P(a + Y)$ and $P_{\times a}(Y) := P(aY)$. For convenience, we also write $P_{-a}$ for $P_{-a}$. Note that $(P_{+a})_{+b} = (P_{+b})_{+a} = P_{+(a+b)}$ for $b \in K$, which we write $P_{+a+b}$. We define $P_{+a-b}$ likewise. The multiplicity of $P$ at $a$ is $\text{mul} P_{+a}$. Note that $(P_d)_{+a} = (P_{+a})_d$, which we denote by $P_{d,+a}$. For more on such conjugation, see [1, §4.3].

We extend the derivation of $K$ to $K\{Y\}$ in the natural way, and we also extend $v$ to $K\{Y\}$ by setting $v(P)$ to be the minimum valuation of the coefficients of $P$. The relations $\preceq$, $\prec$, and $\sim$ are also extended to $K\{Y\}$ in the obvious way. We recall how $v(P)$ behaves under additive and multiplicative conjugation of $P$ in §2.E.

There are two conditions we sometimes impose connecting the valuation and the derivation. First, we say $K$ is asymptotic if, for all $f$, $g \in \mathfrak{o}^\neq$,

$$f \prec g \iff f' \prec g'.$$
If $K$ is asymptotic, then $\partial$ is continuous with respect to the valuation topology on $K$ [1, Corollary 9.1.5]. It follows immediately from the definition that if $K$ is asymptotic, then $\nu(C^\infty) = \{0\}$, in which case we say that $K$ has few constants. This weaker condition is assumed in some lemmas, so as to delay the assumption that $K$ is asymptotic until §6. The class of asymptotic fields includes for example the ordered (valued) differential field of logarithmic-exponential transseries studied in [1], and, more generally, the class of differential-valued fields introduced by Rosenlicht [6].

The second condition is more basic and is assumed throughout: We say $K$ has small derivation if $\partial v \subseteq v$. Small derivation also implies that $\partial$ is continuous; in fact, $\partial$ is continuous if and only if $\partial v \subseteq av$ for some $a \in K^\times$ [1, Lemma 4.4.7]. It also implies $\partial O \subseteq O$ [1, Lemma 4.4.1], so $\partial$ induces a derivation on $k$. Let $r \geq 1$. Then we say that $k$ is $r$-linearly surjective if, for all $a_0, \ldots, a_r \in k$ with $a_i \neq 0$ for some $i$, the equation $a_0 + a_1 y + \cdots + a_r y^{(r)} = 0$ has a solution in $k$. We call $k$ linearly surjective (or $\infty$-linearly surjective) if $k$ is $r$-linearly surjective for each $r$. Generalizing the notion of henselianity for valued fields, we say $K$ is $r$-differential-henselian ($r$-d-henselian for short) if:

\begin{itemize}
  \item[(rDH1)] $k$ is $r$-linearly surjective, and
  \item[(rDH2)] whenever $P \in O\{Y\}$ has order at most $r$ and satisfies $P_0 \prec 1$ and $P_1 \prec 1$, there is $y \prec 1$ with $P(y) = 0$.
\end{itemize}

We say $K$ is differential-henselian (d-henselian for short) if it is $r$-d-henselian for each $r$. We use $\infty$-d-henselian as a synonym for “d-henselian.” These definitions are due to Aschenbrenner, van den Dries, and van der Hoeven [1, Chapter 7], although earlier notions were considered by Scanlon for monotone fields [7] and F.-V. Kuhlmann for differential-valued fields [4]. Connecting this to asymptoticity, we note that if $K$ is $r$-d-henselian and has few constants, then it is asymptotic [1, Lemmas 7.1.8 and 9.1.1].

Throughout, by an extension of $K$ we mean a valued differential field extension of $K$ with small derivation; similarly, embedding means “valued differential field embedding.” In analogy with the notion of a henselization of a valued field, we defined in [3] the notion of a differential-henselization of a valued differential field: We say an extension $L$ of $K$ is a differential-henselization (d-henselization for short) of $K$ if it is an immediate d-henselian extension of $K$ that embeds over $K$ into any immediate d-henselian extension of $K$. Finally, we call $K$ maximal if it has no proper immediate extension and differential-algebraically maximal (d-algebraically maximal for short) if it has no proper differentially algebraic immediate extension. Recall from [1, Chapter 7] that if the derivation induced on $k$ is nontrivial, then $K$ is d-algebraically maximal if and only if every pc-sequence in $K$ of d-algebraic type over $K$ has a pseudolimit in $K$ (see §2.C for this notion). It is also worth pointing out that by the main result of [2], $K$ is maximal in this sense if and only if $K$ is maximal as a valued field in the usual sense, which in turn is equivalent to every pc-sequence in $K$ having a pseudolimit in $K$.

1.B. Outline. The main technical tool of the paper is Proposition 3.1. Assuming this proposition, Theorems A, B, and C are proven in §3: Theorem A is Theorem 3.5, Theorem B is Theorem 3.6, and Theorem C is Theorem 3.8. The strategy to show Proposition 3.1 closely follows the approach taken to prove [1, Proposition 14.5.1], which is an analogue of Proposition 3.1 in the setting of $\omega$-free $H$-asymptotic differential-valued fields.

First, we adapt the differential newton diagram method of [1, §13.5] to the setting of valued differential fields with small derivation and divisible value group in §4, which relies in an essential way on the Equalizer Theorem [1, Theorem 6.0.1]; this is where divisibility is used. The main results are Proposition 4.4 and Corollary 4.5, which are then connected to pc-sequences in §4.A.

From there, we proceed to study asymptotic differential equations in §5, with the main technical notion being that of an unraveller, adapted from [1, §13.8]. There are three key steps in this section. First, the existence of an unraveller that is a pseudolimit of a pseudocauchy sequence in Lemma 5.8, via Proposition 5.5. Second, reducing the degree of an asymptotic differential equation
in Lemma 5.10. Third, finding a solution of an asymptotic differential equation in a d-henselian field that approximates an element in an extension of that field in §5.C.

Throughout this section, §6, based on [1, §14.4], is quite technical. It combines many results from the previous sections and culminates in Proposition 6.1 and its Corollary 6.14, which is essential to the proof of Proposition 3.1. One of the main steps here is Lemma 6.11, which allows us to use Lemma 5.10 to reduce the degree of an asymptotic differential equation.

There are four salient differences from the approach in [1]. The first is that the “dominant part” and “dominant degree” of differential polynomials replace their more technical cousins “newton polynomial” and “newton degree,” leading to the simplification of some proofs. The second is that since $K$ is not assumed to be $H$-asymptotic, we replace the convex valuation on $\Gamma^\neq$ given by $v(g) \mapsto v(g'/g)$ with that given by considering archimedean classes. Third, under the assumption of $\omega$-freeness, newton polynomials are of the form $C[Y](Y')^n$, but dominant parts need not have this special form. This leads to changes in §6, such as the need to take partial derivatives with respect to higher order derivatives of $Y$ than just $Y'$. Finally, Lemma 3.2 enables the generalization of Proposition 3.1 to nondivisible value group in Proposition 3.3.1

1.C. Review of assumptions. Throughout, $K$ is a field with nontrivial (surjective) valuation $v: K^\times \to \Gamma$ and nontrivial derivation $\partial: K \to K$. The valuation ring is $O$ with maximal ideal $\mathfrak{o}$, and we further assume that $K$ has small derivation, i.e., $\partial \mathfrak{o} \subseteq \mathfrak{o}$. Then the differential residue field is $k = O/\mathfrak{o}$. The field of constants is denoted $C$. Additional assumptions on $K$, $\Gamma$, and $k$ are indicated as needed. “Extension” is short for “valued differential field extension with small derivation” and “embedding” is short for “valued differential field embedding.” We let $d$, $i$, $j$, $m$, and $n$ be in $\mathbb{N} = \{0, 1, 2, \ldots\}$, and $r \in \mathbb{N} \cup \{\infty\}$ with $r \geq 1$.

2. Preliminaries

Throughout this section, $P \in K\{Y\}^\neq$.

2.A. Dominant parts of differential polynomials. We present in this subsection the notion of the dominant part of a differential polynomial over $K$ when $K$ has a monomial group $M$, i.e., a subgroup of $K^\times$ that is mapped bijectively onto $\Gamma$ by $v$. This assumption yields slightly improved versions of lemmas from [1, §6.6], where this notion is developed without the monomial group assumption. All the statements about dominant degree and dominant multiplicity given here remain true in that greater generality, and we freely use them later even when $K$ may not have a monomial group. The proofs are essentially the same, so are omitted.

Assumption. In this subsection, $K$ has a monomial group $M$.

Whenever $K$ has a monomial group $M$, we let $\partial_P \in M$ be the unique monomial such that $\partial_P \propto P$. For $Q = 0 \in K\{Y\}$, we set $\partial_Q := 0$.

Definition. Since $\partial_P^{-1}P \in O\{Y\}$, we define the dominant part of $P$ to be the differential polynomial

$$D_P := \partial_P^{-1}P = \sum_i (P_i/\partial_P)Y^i \in k\{Y\}^\neq.$$  

For $Q = 0 \in K\{Y\}$, we set $D_Q := 0 \in k\{Y\}$.

Then $\deg D_P \leq \deg P$ and $\ord D_P \leq \ord P$. We call $\deg P := \deg D_P$ the dominant degree of $P$ and $\mul P := \mul D_P$ the dominant multiplicity of $P$.

Note that if $P$ is homogeneous of degree $d$, then so is $D_P$.

Lemma 2.1. Let $Q \in K\{Y\}$. Then

(i) if $P \succ Q$, then $D_{P+Q} = D_P$.

1See [5] for the removal of the assumption of divisible value group from the corresponding results in [1, Chapter 14].
(ii) if $P \times Q$ and $P + Q \preceq P$, then $D_{P+Q} = D_P + D_Q$;
(iii) $D_{PQ} = D_P D_Q$.

Proof. Part (ii) is not in [1], so we give a proof. Suppose $P \times Q$ and $P + Q \preceq P$, so $\mathfrak{d}_{P+Q} = \mathfrak{d}_P = \mathfrak{d}_Q$. Then

$$D_{P+Q} = \sum_i (P + Q)_i/\mathfrak{d}_{P+Q} Y^i = \sum_i \left( P_i/\mathfrak{d}_P + Q_i/\mathfrak{d}_Q \right) Y^i = D_P + D_Q. \quad \square$$

Lemma 2.2. Let $a \in K$, $a \not\preceq 1$. Then

(i) $D_{P+\bar{a}} = (D_P)_{+\bar{a}}$, and thus $\text{ddeg } P_{+\bar{a}} = \text{ddeg } P$;
(ii) if $a \preceq 1$, then $D_{P_{\times a}} = (D_P)_{\times a}$, $\text{dmul } P_{\times a} = \text{dmul } P$, and $\text{ddeg } P_{\times a} = \text{ddeg } P$;
(iii) if $a < 1$, then $\text{ddeg } P_{\times a} \leq \text{dmul } P$.

It follows from (ii) that $\text{ddeg } P_y$ and $\text{dmul } P_y$ only depend on $vg$, for $g \in K^\times$. The next five results are exactly as in [1, §6.6], but are recalled here for the reader's convenience.

Corollary 2.3 ([1, 6.6.7]). Let $f, g \in K^\times$. Then $\text{mul } P = \text{mul } (P_y f) \leq \text{ddeg } P_y f$ and

$$f < g \implies \text{ddeg } P_y f \leq \text{ddeg } P_y f \leq \text{dmul } P_y g \leq \text{ddeg } P_y g.$$

Below, we let $\mathcal{E} \subseteq K^\times$ be nonempty and such that for $f, g \in K^\times$, $f \preceq g \in \mathcal{E}$ implies $f \in \mathcal{E}$. In this case, we say $\mathcal{E}$ is $\preceq$-closed, and we consider the dominant degree of $P$ on $\mathcal{E}$ defined by:

$$\text{ddeg } P := \max \{ \text{ddeg } P_y f : f \in \mathcal{E} \}.$$ 

Note that $\preceq$-closed sets correspond with nonempty upward-closed cuts in $\Gamma$. If for some $\gamma \in \Gamma$, $\mathcal{E} = \{ f \in K^\times : vg \geq \gamma \}$, then we let $\text{ddeg } \geq \gamma P := \text{ddeg } P$. For any $g \in K^\times$ with $vg = \gamma$ we set $\text{ddeg } \leq \gamma P := \text{ddeg } \geq \gamma P$, and by the previous result we have $\text{ddeg } \leq \gamma P \leq \text{ddeg } P_y$. We define $\text{ddeg } \geq \gamma P$ and $\text{ddeg } \leq \gamma P$ analogously.

Lemma 2.4 ([1, 6.6.9]). If $v(\mathcal{E})$ has no smallest element, then

$$\text{ddeg } P := \max \{ \text{dmul } (P_y f) : f \in \mathcal{E} \}.$$ 

Lemma 2.5 ([1, 6.6.10]). If $f \in \mathcal{E}$, then $\text{ddeg } P_{+f} = \text{ddeg } P$.

Corollary 2.6 ([1, 6.6.11]). Suppose $\text{ddeg } P = 1$ and $y \in \mathcal{E}$ satisfies $P(y) = 0$, and let $f \in \mathcal{E}$. Then

$$\text{mul } P_{+y, x, f} = \text{dmul } P_{+y, x, f} = \text{ddeg } P_{+y, x, f} = 1.$$ 

Corollary 2.7 ([1, 6.6.12]). If $a, b \in K$ and $\alpha, \beta \in \Gamma$ satisfy $v(b - a) \geq \alpha$ and $\beta \geq \alpha$, then

$$\text{ddeg } \geq \gamma P_{+a} \leq \text{ddeg } \geq \gamma P_{+b}.$$ 

2.B. Dominant degree in a cut. We recall the notion of “dominant degree in a cut” from [3] and some basic properties proved there. First, for later use we mention that the condition $\text{ddeg } P \geq 1$ is necessary for the existence of a zero $f \preceq 1$ of $P$ in an extension of $K$:

Lemma 2.8 ([3, 2.1]). Let $g \in K^\times$, and suppose $P(f) = 0$ for some $f \preceq g$ in some extension of $K$. Then $\text{ddeg } P_y g \geq 1$.

In the rest of this section, $(a_\rho)$ is a pc-sequence in $K$ with $\gamma_\rho := v(a_{\rho+1} - a_\rho)$; here and later $\rho + 1$ denotes the immediate successor of $\rho$ in the well-ordered set of indices.

Lemma 2.9 ([3, 2.2]). There is an index $\rho_0$ and a number $d(P,(a_\rho)) \in \mathbb{N}$ such that for all $\rho > \rho_0$,

$$\text{ddeg } \geq \gamma_\rho P_{+a_\rho} = d(P,(a_\rho)).$$ 

Whenever $(b_\sigma)$ is a pc-sequence in $K$ equivalent to $(a_\rho)$, we have $d(P,(a_\rho)) = d(P,(b_\sigma))$. 
We associate to each pc-sequence \((a_\rho)\) in \(K\) its cut in \(K\), denoted \(c_K(a_\rho)\), such that if \((b_\sigma)\) is a pc-sequence in \(K\), then
\[
c_K(a_\rho) = c_K(b_\sigma) \iff (b_\sigma) \text{ is equivalent to } (a_\rho).
\]
Throughout, \(a := c_K(a_\rho)\) and if \(L\) is an extension of \(K\), then \(a_L := c_L(a_\rho)\). Note that \(c_K(a_\rho + y)\) for \(y \in K\) depends only on \(a\) and \(y\), so we let \(a + y\) denote \(c_K(a_\rho + y)\) and \(a - y\) denote \(c_K(a_\rho - y)\). Similarly, \(c_K(a_\rho y)\) for \(y \in K^\times\) depends only on \(a\) and \(y\), so we let \(a \cdot y\) denote \(c_K(a_\rho y)\).

**Definition.** The dominant degree of \(P\) in the cut of \((a_\rho)\), denoted \(\text{ddeg}_{a} P\), is the natural number \(d(P,(a_\rho))\) from the previous lemma.

**Lemma 2.10** ([3, 2.3]). The dominant degree in a cut has the following properties:

(i) \(\text{ddeg}_{a} P \leq \deg P\);
(ii) \(\text{ddeg}_{a} P_{+y} = \text{ddeg}_{a+y} P\) for \(y \in K\);
(iii) if \(y \in K\) and \(v\) is in the width of \((a_\rho)\), then \(\text{ddeg}_{a} P_{+y} = \text{ddeg}_{a} P\);
(iv) \(\text{ddeg}_{a} P_{\times y} = \text{ddeg}_{a+y} P\) for \(y \in K^\times\);
(v) if \(Q \in K\{Y\}^\times\), then \(\text{ddeg}_{a} PQ = \text{ddeg}_{a} P + \text{ddeg}_{a} Q\);
(vi) if \(P(\ell) = 0\) for some pseudolimit \(\ell\) of \((a_\rho)\) in an extension of \(K\), then \(\text{ddeg}_{a} P \geq 1\);
(vii) if \(L\) is an extension of \(K\), then \(\text{ddeg}_{a} P = \text{ddeg}_{a_L} P\).

2.C. Constructing immediate extensions. We recall three lemmas about evaluating at pc-sequences and constructing immediate extensions. Recall from [1, §4.4] that a pc-sequence \((a_\rho)\) in \(K\) is of d-algebraic type over \(K\) if there is an equivalent pc-sequence \((b_\sigma)\) in \(K\) and a \(P \in K\{Y\}\) such that \(P(b_\sigma) \sim 0\). We call such a \(P\) of minimal complexity a minimal differential polynomial of \((a_\rho)\) over \(K\). If no such \((b_\sigma)\) and \(P\) exist, then we say \((a_\rho)\) is of d-transcendental type over \(K\).

**Assumption.** In this subsection, the derivation induced on \(k\) is nontrivial.

**Lemma 2.11** ([1, 6.8.1]). Let \((a_\rho)\) be a pc-sequence in \(K\) with pseudolimit \(a \in L\), where \(L\) is an extension of \(K\), and let \(G \in L\{Y\} \setminus L\). Then there exists an equivalent pc-sequence \((b_\sigma)\) in \(K\) such that \(G(b_\sigma) \sim G(a)\).

**Lemma 2.12** ([1, 6.9.1]). Let \((a_\rho)\) be a pc-sequence in \(K\) of d-transcendental type over \(K\). Then \(K\) has an immediate extension \(K\langle a \rangle\) with a d-transcendental over \(K\) and \(a_\rho \sim a\) such that for any extension \(L\) of \(K\) and any \(b \in L\) with \(a_\rho \sim b\), there is a unique embedding \(K\langle a \rangle \rightarrow L\) over \(K\) sending \(a\) to \(b\).

**Lemma 2.13** ([1, 6.9.3]). Let \((a_\rho)\) be a pc-sequence in \(K\) with minimal differential polynomial \(P\) over \(K\). Then \(K\) has an immediate extension \(K\langle a \rangle\) with \(P(a) = 0\) and \(a_\rho \sim a\) such that for any extension \(L\) of \(K\) and any \(b \in L\) with \(a_\rho \sim b\), there is a unique embedding \(K\langle a \rangle \rightarrow L\) over \(K\) sending \(a\) to \(b\).

2.D. Constructing immediate extensions and vanishing.

**Assumption.** In this subsection, the derivation induced on \(k\) is nontrivial and \(\Gamma\) has no least positive element.

The notion of minimal differential polynomial is not first-order, so we include here a first-order variant of Lemma 2.13 that is a special case of [2, Lemma 5.3]. We then connect it to dominant degree in a cut. Under the assumptions above, all extensions of \(K\) are strict [2, Lemma 1.3], and \(K\) is flexible [2, Lemma 1.15 and Corollary 3.4]. These notions are defined in [2] but are incidental here, and mentioned only since they occur in the corresponding lemmas of [2].

Let \(\ell \notin K\) be an element in an extension of \(K\) such that \(v(\ell - K) := \{v(\ell - x) : x \in K\}\) has no largest element (equivalently, \(\ell\) is the pseudolimit of some divergent pc-sequence in \(K\)). We say that \(P\) vanishes at \((K, \ell)\) if for all \(a \in K\) and \(v \in K^\times\) with \(a - \ell \prec v\), \(\text{ddeg}_{a} P_{+a} \geq 1\). Then \(Z(K, \ell)\) denotes the set of nonzero differential polynomials over \(K\) vanishing at \((K, \ell)\).
Lemma 2.14 ([2, 5.3]). Suppose \( Z(K, \ell) \not= \emptyset \), and \( P \in Z(K, \ell) \) has minimal complexity. Then \( K \) has an immediate extension \( K(f) \) such that \( P(f) = 0 \) and \( v(a - f) = v(a - \ell) \) for all \( a \in K \). Moreover, if \( M \) is an extension of \( K \) and \( s \in M \) satisfies \( P(s) = 0 \) and \( v(a - s) = v(a - \ell) \) for all \( a \in K \), then there is a unique embedding \( K(f) \to M \) over \( K \) sending \( f \) to \( s \).

Lemma 2.15 ([2, 4.6]). Suppose \( (a_\rho) \) is a divergent pc-sequence in \( K \) with \( a_\rho \sim \ell \). If \( P(a_\rho) \sim 0 \), then \( P \in Z(K, \ell) \).

Lemma 2.16 ([2, 4.7]). Suppose \( (a_\rho) \) is a divergent pc-sequence in \( K \) with \( a_\rho \sim \ell \). Then
\[
\text{ddeg}_a P = \min \{ \text{ddeg}_a P_{+a} : a - \ell < v \}.
\]
In particular, \( \text{ddeg}_a P \geq 1 \iff P \in Z(K, \ell) \).

Corollary 2.17. Suppose \( (a_\rho) \) is a divergent pc-sequence in \( K \) with \( a_\rho \sim \ell \). The following conditions on \( P \) are equivalent:

1. \( P \in Z(K, \ell) \) and has minimal complexity in \( Z(K, \ell) \);
2. \( P \) is a minimal differential polynomial of \( (a_\rho) \) over \( K \).

Proof. The proof is the same as that of [1, Corollary 11.4.13], using Lemma 2.14 in place of [1, Lemma 11.3.8], and Lemma 2.15 in place of [1, Lemma 11.4.11].

In particular, \( Z(K, \ell) = \emptyset \) if and only if \( (a_\rho) \) is of d-transcendental type over \( K \), and \( Z(K, \ell) \not= \emptyset \) if and only if \( (a_\rho) \) is of d-algebraic type over \( K \).

2.E. Archimedean classes and coarsening. For \( \gamma \in \Gamma \), we let \( [\gamma] \) denote its archimedean class. That is,
\[
[\gamma] := \{ \delta \in \Gamma : |\delta| \leq n|\gamma| \text{ and } |\gamma| \leq n|\delta| \text{ for some } n \}.
\]
We order the set \( [\Gamma] := \{ [\gamma] : \gamma \in \Gamma \} \) by \( [\delta] < [\gamma] \) if \( n|\delta| < |\gamma| \) for all \( n \). Giving the set of archimedean classes their reverse order, the map \( \gamma \mapsto [\gamma] \) is a convex valuation on \( \Gamma \). In particular, the implication \( [\delta] < [\gamma] \iff [\delta + \gamma] > [\gamma] \) is often used. Then for \( \phi \in K^\times \) with \( \phi \not= 1 \), the set \( \Gamma_\phi := \{ \gamma : [\gamma] < [\phi] \} \) is a convex subgroup of \( \Gamma \). We will use \( v_\phi \), the coarsening of \( v \) by \( \Gamma_\phi \), and its corresponding dominance relation, \( \preceq_\phi \), defined by
\[
v_\phi : K^\times \to \Gamma/\Gamma_\phi \\
a \mapsto va + \Gamma_\phi,
\]
and \( a \preceq_\phi b \) if \( v_\phi(a) \geq v_\phi(b) \). Note that \( v_\phi \) and \( \preceq_\phi \) also appeared in [1, §9.4], where they indicated a different coarsening of \( v \).

We first recall how \( v(P) \) changes as we additively and multiplicatively conjugate \( P \).

Lemma 2.18 ([1, 4.5.1]). Let \( f \in K \).

1. If \( f \not< 1 \), then \( P_{+f} \asymp P \); if \( f < 1 \), then \( P_{+f} \sim P \).
2. If \( f \not= 0 \), then \( v(P_{x f}) \in \Gamma \) depends only on \( v f \in \Gamma \).

Item (ii) allows us to define the function \( v_P : \Gamma \to \Gamma \) by \( v f \mapsto v(P_{x f}) \). The main property of this function is recorded in the following lemma. Here, for \( \alpha, \beta \in \Gamma \) we write \( \alpha = o(\beta) \) if \( [\alpha] < [\beta] \).

Lemma 2.19 ([1, 6.1.3 and 6.1.5]). Let \( P, Q \in K(Y)^\neq \) with \( P = P_m \) and \( Q = Q_n \). For \( \alpha, \beta \in \Gamma \) with \( \alpha \not= \beta \), we have
\[
v_P(\alpha) - v_P(\beta) = m(\alpha - \beta) + o(\alpha - \beta).
\]
It follows that, for \( \gamma \in \Gamma^\neq \),
\[
v_P(\gamma) - v_Q(\gamma) = v(P) - v(Q) + (m - n)\gamma + o(\gamma),
\]
and if \( m > n \), then \( v_P - v_Q \) is strictly increasing.
The lemmas from the rest of this subsection will play an important role in §6. Lemmas 2.20–2.25 are variants of lemmas from the end of [1, §9.4]. The first two are facts about valued fields, not involving the derivation.

**Lemma 2.20.** Let $f, g \in K^\times$ with $f, g \neq 1$. Then $f \prec_g g \implies f \prec_f g$.

**Proof.** From $f/g \prec_g 1$, we obtain $[vf - vg] \geq [vg]$. If $[vf - vg] < [vf]$, then $[vf] = [vf - vg - vf] = [vg]$, contradicting $[vf - vg] \geq [vg]$. Thus $[vf - vg] \geq [vf]$. But since $vf - vg > 0$, we have $f/g \prec_f 1$, that is, $f \prec_f g$.

**Lemma 2.21.** Let $\phi_1, \phi_2 \in K^\times$ with $\phi_1 \neq 1$ and $[v\phi_1] \leq [v\phi_2]$. Then for all $f, g \in K$

$$f \preceq_{\phi_1} g \implies f \preceq_{\phi_2} g \quad \text{and} \quad f \prec_{\phi_2} g \implies f \prec_{\phi_1} g.$$  

In particular, $f \prec_{\phi_1} g \implies f \prec_{\phi_2} g$.

**Proof.** Note that for $\phi \in K^\times$ with $\phi \neq 1$, $f \preceq_{\phi} g$ if and only if $vf - vg \in \Gamma_\phi$ or $vf > vg$, and $f \prec_{\phi} g$ if and only if $vf - vg \in \Gamma_\phi$. Both implications then follow from $\Gamma_{\phi_1} \subseteq \Gamma_{\phi_2}$.

**Lemma 2.22.** Suppose $P$ is homogeneous of degree $d$, and let $g \in K^\times$ with $g \neq 1$. Then $P_{\times g} \prec_g g^dP$.

**Proof.** By Lemma 2.19, $v(P_{\times g}) = vP + dvg + o(vg)$, so $v_g(P_{\times g}) = v_g(g^dP)$.

**Lemma 2.23.** Suppose $g \in K^\times$ with $g \prec 1$ and $d = \text{dmul } P = \text{mul } P$. Then $P_{\times g} \prec_g g^dP$.

**Proof.** Since $d = \text{dmul } P$, we have $P_i \preceq_P P_d$ for $i \geq d$. Since $g \prec 1$, we also have $g \prec_g 1$. Hence $g^dP_i \preceq_g P_d$ for $i > d$, so $P_{\times g} \prec_g P_d \times g^dP_d$ by Lemma 2.22. In view of $P_d \triangleright P$, this yields $P_{\times g} \prec_g g^dP$.

**Lemma 2.24.** Suppose $g \in K^\times$ with $g \prec 1$ and $d = \text{ddeg } P = \text{deg } P_{\times g}$. Then $gP_{\succ g} \prec_g g^dP$.

**Proof.** If $P_{\succ g} = 0$, then the result holds trivially, so assume $P_{\succ g} \neq 0$. Take $i > d$ such that $P_i \preceq_P P_{\succ g}$. Then Lemma 2.22 and the fact that $g \geq 1$ give

$$(P_{\times g})_i = (P_i)_{\times g} \preceq_g g^dP_i \succ g^{d+1}P_i \succ g^{d+1}P_{\succ g},$$

so $P_{\times g}_{\succ g} \succ g^{d+1}P_{\succ g}$. Since $d = \text{ddeg } P_{\times g}$, we also have $(P_{\times g})_d \succ (P_{\times g})_{\succ g}$. As $d = \text{deg } P = \text{ddeg } P_{\times g}$, $P_d \times P$, and so $g^dP \prec g^dP_d \preceq g^dP_{\succ g} \succ (P_{\times g})_{\succ g} \succ g^{d+1}P_{\succ g}$, using Lemma 2.22 again. Hence $P \succ g^dP_d$.

**Lemma 2.25.** Let $f, g \in K^\times$ with $f, g \neq 1$ and $[vf] < [vg]$. Then $P_{\times f} \prec_g P$.

**Proof.** Take $d$ with $P_{\times f} \preceq (P_{\times f})_d$, so $P_{\times f} \preceq f^dP_d$ by Lemma 2.22. Then Lemma 2.21 gives $P_{\times f} \prec g f^dP_d$. As $[vf] < [vg]$, we get $f \preceq_g 1$, and thus $P_{\times f} \preceq_g P_d \preceq P$, so $P_{\times f} \preceq g P$. Now, apply the same argument to $P_{\times f}$ and $f^{-1}$ in place of $P$ and $f$, using that $[vf^{-1}] = [-vf] = [vf]$, to get $P = (P_{\times f})_{\times f^{-1}} \preceq g P_{\times f}$, and hence $P \preceq g P_{\times f}$.

**Assumption.** In the next two lemmas, $K$ has a monomial group $M$.

Let $m, n$ range over $M$. These two lemmas are based on [1, Lemma 13.2.3 and Corollary 13.2.4].

**Lemma 2.26.** Suppose $n \neq 1$ and $[vn] < [vn]$. Suppose $P = Q + R$ with $R \prec_n P$. Then $D_{P_{\times m}} = D_{Q_{\times m}}$.  

$$D_{P_{\times m}} = D_{Q_{\times m}}.$$
Proof. From \( R \prec_n Q \), we get \( R \prec Q \), so if \( m = 1 \), then \( D_P = D_Q \). Now assume \( m \neq 1 \). Then Lemma 2.25 gives \( R_{\times m} \prec_n R \prec Q \prec Q_{\times m} \), so \( R_{\times m} \prec Q_{\times m} \), and hence \( D_{P_{\times m}} = D_{Q_{\times m}} \). \( \square \)

**Corollary 2.27.** Suppose \( n > 1 \) and \( d \deg P = d \deg P_{\times n} = d \). Let \( Q := P_{\leq d} \). Then for all \( m \) with \([vm] < [vn]\) and all \( g \prec 1 \) in \( K \), we have

\[
D_{P_{+g \times m}} = D_{Q_{+g \times m}}.
\]

**Proof.** Let \( R := P - Q = P_{>d} \). Then Lemma 2.24 gives

\[
R \prec_n n^{-1} P \prec P.
\]

Let \( g \prec 1 \). Then \( R_{+g} \prec R \) and \( P_{+g} \prec P \) by Lemma 2.18(i). Thus we have \( R_{+g} \prec_n P_{+g} \), so it remains to apply the previous lemma. \( \square \)

3. Main results

**Assumption.** In this section, the induced derivation on \( k \) is nontrivial.

Assuming Proposition 3.1, we prove here the main results of this paper concerning the uniqueness of maximal immediate extensions, the relationship between \( d \)-algebraic maximality and \( d \)-henselianity, and the existence of \( d \)-henselizations. The proof of Proposition 3.1 is given in §7.

**Proposition 3.1.** Suppose \( K \) is asymptotic, \( \Gamma \) is divisible, and \( k \) is \( r \)-linearly surjective. Suppose \((a_\rho)\) is a \( pc \)-sequence in \( K \) with minimal differential polynomial \( G \) over \( K \) of order at most \( r \). Then \( d \deg_a G = 1 \).

3.A. Removing divisibility. In the next lemmas, we construe the algebraic closure \( K^{ac} \) of \( K \) as a valued differential field: the derivation of \( K \) extends uniquely to \( K^{ac} \) [1, Lemma 1.9.2] and we equip \( K^{ac} \) with any valuation extending that of \( K \). This determines \( K^{ac} \) as a valued differential field extension of \( K \) up to isomorphism over \( K \), with value group the divisible hull \( Q\Gamma \) of \( \Gamma \) and residue field the algebraic closure \( k^{ac} \) of \( k \). If \( K \) is henselian, then its valuation extends uniquely to \( K^{ac} \) (see [1, Proposition 3.3.11]). By [1, Proposition 6.2.1], \( K^{ac} \) has small derivation.

**Lemma 3.2.** Suppose \( K \) is henselian. Let \((a_\rho)\) be a \( pc \)-sequence in \( K \) with minimal differential polynomial \( P \) over \( K \). Then \( P \) remains a minimal differential polynomial of \((a_\rho)\) over the algebraic closure \( K^{ac} \) of \( K \).

**Proof.** We may suppose that \((a_\rho)\) is divergent in \( K \), the other case being trivial. Then \((a_\rho)\) is still divergent in \( K^{ac} \). If it had a pseudolimit \( a \in K^{ac} \), then we would have \( Q(a_\rho) \nq 0 \), where \( Q \in K[Y] \) is the minimum polynomial of \( a \) over \( K \) (see [1, Proposition 3.2.1]). But since \( K \) is henselian, it is algebraically maximal (see [1, Corollary 3.3.21]), and then \((a_\rho)\) would have a pseudolimit in \( K \).

Now suppose to the contrary that \( Q \) is a minimal differential polynomial of \((a_\rho)\) over \( K^{ac} \) with \( c(Q) < c(P) \). Take an extension \( L \subseteq K^{ac} \) of \( K \) with \([L : K] = n \) and \( Q \in L\{Y\} \). Then as \( K \) is henselian,

\[
[L : K] = [\Gamma_L : \Gamma] \cdot [k_L : k]
\]

(see [1, Corollary 3.3.49]), so we have a valuation basis \( B = \{e_1, \ldots, e_n\} \) of \( L \) over \( K \) (see [1, Proposition 3.1.7]). That is, \( B \) is a basis of \( L \) over \( K \), and for all \( a_1, \ldots, a_n \in K \),

\[
v \left( \sum_{i=1}^n a_i e_i \right) = \min_{1 \leq i \leq n} v(a_i e_i).
\]

Then by expressing the coefficients of \( Q \) in terms of the valuation basis,

\[
Q(Y) = \sum_{i=1}^n R_i(Y) \cdot e_i.
\]
where $R_i \in K \{ Y \}$ for $1 \leq i \leq n$.

Since $Q$ is a minimal differential polynomial of $(a_\rho)$ over $K^{ac}$, by Lemma 2.13 we have an immediate extension $K^{ac}(a)$ of $K^{ac}$ with $a_\rho \rightsquigarrow a$ and $Q(a) = 0$. Then by Lemma 2.11, there is a pc-sequence $(b_\rho)$ in $K$ equivalent to $(a_\rho)$ such that $Q(b_\rho) \rightsquigarrow Q(a) = 0$. Finally, by passing to a cofinal subsequence, we take $i$ with $Q(b_\rho) \asymp R_i(b_\rho) \cdot e_i$ for all $\rho$. Then $R_i(b_\rho) \rightsquigarrow 0$ and $c(R_i) < c(P)$, contradicting the minimality of $P$. \hfill \Box

Since minimal differential polynomials are irreducible, note that a corollary of this lemma is that minimal differential polynomials over henselian $K$ (with nontrivial induced derivation on $k$) are absolutely irreducible. We can now replace the divisibility assumption in the main proposition with that of henselianity.

**Proposition 3.3.** Suppose $K$ is asymptotic and henselian, and $k$ is linearly surjective. Let $(a_\rho)$ be a pc-sequence in $K$ with minimal differential polynomial $G$ over $K$. Then $ddeg_a G = 1$.

**Proof.** By the previous lemma, $G$ remains a minimal differential polynomial of $(a_\rho)$ over $K^{ac}$. Note that the value group of $K^{ac}$ is divisible, and its differential residue field is linearly surjective, as an algebraic extension of $k$ [1, Corollary 5.4.3]. But then $ddeg_{a,k^{ac}} G = 1$ by Proposition 3.1. Hence by Lemma 2.10(vii), $ddeg_a G = 1$. \hfill \Box

### 3.B. Main results.

The next lemma is immediate from Proposition 3.3 and [3, Lemma 4.1].

**Lemma 3.4.** Suppose $K$ is asymptotic and henselian, and $k$ is linearly surjective. Let $(a_\rho)$ be a pc-sequence in $K$ with minimal differential polynomial $G$ over $K$. Let $L$ be a $d$-algebraically maximal extension of $K$ such that $k_L$ is linearly surjective. Then there is $b \in L$ with $a_\rho \rightsquigarrow b$ and $G(b) = 0$.

For the next result, we copy the proof of [3, Theorem 4.2], except for an argument involving henselizations.

**Theorem 3.5.** Suppose $K$ is asymptotic and $k$ is linearly surjective. Then any two maximal immediate extensions of $K$ are isomorphic over $K$. Also, any two $d$-algebraically maximal $d$-algebraic immediate extensions of $K$ are isomorphic over $K$.

**Proof.** Let $L_0$ and $L_1$ be maximal immediate extensions of $K$. By Zorn’s lemma we have a minimal isomorphism $\mu : F_0 \cong F_1$ between valued differential subfields $F_i \supseteq K$ of $L_i$ for $i = 0, 1$, where “maximal” means that $\mu$ does not extend to an isomorphism between strictly larger such valued differential subfields. First, $F_i$ is asymptotic by [1, Lemmas 9.4.2 and 9.4.5], and $k_{F_i}$ is linearly surjective, as $F_i$ is an immediate extension of $K$ for $i = 0, 1$. Next, they must be henselian, because the henselization of $F_i$ in $L_i$ is algebraic over $F_i$, and thus a valued differential subfield of $L_i$ for $i = 0, 1$. Now suppose towards a contradiction that $F_0 \neq L_0$. Then $F_0$ is not spherically complete, so we have a divergent pc-sequence $(a_\rho)$ in $F_0$.

Suppose $(a_\rho)$ is of $d$-transcendental type over $F_0$. The spherical completeness of $L_0$ and $L_1$ then yields $f_0 \in L_0$ and $f_1 \in L_1$ such that $a_\rho \rightsquigarrow f_0$ and $\mu(a_\rho) \rightsquigarrow f_1$. Hence by Lemma 2.12 we obtain an isomorphism $F_0(f_0) \cong F_1(f_1)$ extending $\mu$, contradicting the maximality of $\mu$.

Suppose $(a_\rho)$ is of $d$-algebraic type over $F_0$, with minimal differential polynomial $G$ over $F_0$. Then Lemma 3.4 gives $f_0 \in L_0$ with $a_\rho \rightsquigarrow f_0$ and $G(f_0) = 0$, and $f_1 \in L_1$ with $\mu(a_\rho) \rightsquigarrow f_1$ and $G^\mu(f_1) = 0$. Now Lemma 2.13 gives an isomorphism $F_0(f_0) \cong F_1(f_1)$ extending $\mu$, and we have again a contradiction. Thus $F_0 = L_0$ and hence $F_1 = L_1$ as well.

The proof of the second statement is the same, using only Lemma 2.13. \hfill \Box

The following shows that monotonicity can be removed from [1, Theorem 7.0.3] without any further assumptions. Its proof is the same as that of [3, Theorem 4.3], and its corollary has the same proof as [3, Corollary 4.4].

**Theorem 3.6.** If $K$ is asymptotic and $d$-henselian, then it is $d$-algebraically maximal.
Corollary 3.7. If $K$ is asymptotic and henselian, $k$ is linearly surjective, $L$ is a $d$-henselian asymptotic extension of $K$, and $(a_\rho)$ is a pc-sequence in $K$ with minimal differential polynomial $G$ over $K$, then there is $b \in L$ with $a_\rho \sim b$ and $G(b) = 0$.

The following generalizes [3, Theorem 1.3], removing the assumption on the value group. Its proof is the same, except for the use of the henselization.

Theorem 3.8. Suppose $K$ is asymptotic and $k$ is linearly surjective. Then $K$ has a $d$-henselization, and any two $d$-henselizations of $K$ are isomorphic over $K$.

Proof. We can assume that $K$ is henselian, as $K$ has a henselization that embeds (uniquely) over $K$ into any $d$-henselian extension of $K$. By [1, Corollary 9.4.11] we have an immediate asymptotic $d$-henselian extension $K^{\text{dh}}$ of $K$ that is $d$-algebraic over $K$ and has no proper $d$-henselian subfields containing $K$. By Theorems 3.6 and 3.5, there is up to isomorphism over $K$ just one such extension.

Let $L$ be an immediate $d$-henselian extension of $K$; then $L$ is asymptotic by [1, Lemmas 9.4.2 and 9.4.5]. To see that $K^{\text{dh}}$ embeds over $K$ into $L$, use an argument similar to that in the proof of Theorem 3.5, using Corollary 3.7 in place of Lemma 3.4. Thus $K^{\text{dh}}$ is a $d$-henselization of $K$ and any $d$-henselization of $K$ is isomorphic over $K$ to $K^{\text{dh}}$. 

In fact, the argument shows that $K^{\text{dh}}$ as in the proof of Theorem 3.8 embeds over $K$ into any (not necessarily immediate) asymptotic $d$-henselian extension of $K$. This corollary has the same proof as [3, Corollary 4.6].

Corollary 3.9. Suppose $K$ is asymptotic and $k$ is linearly surjective. Then any immediate $d$-henselian extension of $K$ that is $d$-algebraic over $K$ is a $d$-henselization of $K$.

3.C. Additional results. We also record versions of the above results relativized to differential polynomials of a given order. In these results, we assume that $\Gamma$ is divisible but not that $K$ is henselian. The proofs are the same as above, except for using Proposition 3.1 in place of Proposition 3.3.

Let $r \in \mathbb{N}$ with $r \geq 1$. We call $K$ $r$-$d$-algebraically maximal if the derivation induced on $k$ is nontrivial and every pc-sequence in $K$ with minimal differential polynomial over $K$ of order at most $r$ has a pseudolimit in $K$.

Theorem 3.10. If $K$ is asymptotic, $\Gamma$ is divisible, and $k$ is $r$-linearly surjective, then any two $r$-$d$-algebraically maximal $d$-algebraic immediate extensions of $K$ are isomorphic over $K$.

Theorem 3.11. If $K$ is asymptotic and $r$-$d$-henselian, and $\Gamma$ is divisible, then $K$ is $r$-$d$-algebraically maximal.

Additionally, we say an extension $L$ of $K$ is an $r$-$d$-henselization of $K$ if it is an immediate $r$-$d$-henselization of $K$ that embeds over $K$ into any $r$-$d$-henselian extension of $K$.

Theorem 3.12. Suppose $K$ is asymptotic, $\Gamma$ is divisible, and $k$ is $r$-linearly surjective. Then $K$ has an $r$-$d$-henselization, and any two $r$-$d$-henselizations of $K$ are isomorphic over $K$.

4. Newton diagrams

We develop a differential newton diagram method for valued differential fields with small derivation. This approach is closely modelled on the differential newton diagram method for a certain class of asymptotic fields developed in [1, §13.5]. In §4.A, we connect this to dominant degree in a cut, adapting two lemmas from [1, §13.6]. The assumption of divisible value group allows us to use the Equalizer Theorem, which underlies this method:

Theorem 4.1 ([1, 6.0.1]). Let $P, Q \in K(Y)^\neq$ be homogeneous of degrees $m, n$, respectively, with $m > n$. Suppose $(m-n)\Gamma = \Gamma$. Then there exists a unique $\alpha \in \Gamma$ such that $v_P(\alpha) = v_Q(\alpha)$.
Assumption. In this section, $K$ has a monomial group $\mathcal{M}$.

Let $P$ range over $K\{Y\}^\neq$, $f$, $g$ over $K$, and $m$, $n$ over $\mathcal{M}$. Let $\partial_f$ be the unique monomial with $\partial_f \prec f$, and for $f \neq 0$, let $u_f := f/\partial_f \times 1$.

Lemma 4.2. Suppose $\Gamma$ has no least positive element. Suppose $f \ll m$. If $f \prec m$, let $u := 0$; if $f \succ m$, let $u := u_f$. Then
\[
\deg_{< m} P_f = \mul(D_{P \times m})_+ u.
\]
In particular, $\deg_{< m} P = \mul P_{\times m}$.

Proof. For $n \prec m$, let $e = nm^{-1} \in \mathcal{M}$. Then
\[
P_{f \times n} = P_{\times m} + f \times e,
\]
so by replacing $P$ with $P_{\times m}$ and $f$ with $m^{-1}f$, we may assume $m = 1$. Set $Q := P_{+f}$, so by Lemma 2.2(i), $D_Q = (D_P)_{+f} = (D_P)_{+u}$. Thus $\mul(D_P)_{+u} = \mul Q$, so it remains to show
\[
\deg_{< 1} Q = \mu Q.
\]
First, $\deg_{< 1} Q \leq \mu Q$ by Corollary 2.3. For the other direction, let $d := \mu Q$. We have $v(Q_d) < v(Q_i)$ for all $i < d$, so take $g < 1$ with $v g$ small enough that
\[
v(Q_d) + (d + 1) vg < v(Q_i) \quad \text{for all } i < d.
\]
It follows that
\[
v(Q_d) + d vg + o(vg) < v(Q_i) + i vg + o(vg) \quad \text{for all } i < d,
\]
so $v(Q_{d \times g}) < v(Q_{i \times g})$ for all $i < d$ by Lemma 2.19. Hence $\mu Q \times g \geq d$. But
\[
\deg_{< 1} Q = \max\{\mu Q \times g : g < 1\}
\]
by Lemma 2.4, so $\deg_{< 1} Q \geq d$, as desired. \hfill \square

We call $y \in K^\times$ an approximate zero of $P$ if, for $m := \partial_y$ and $u := u_y$, $D_{P \times m}(\bar{u}) = 0$. If $y$ is an approximate zero of $P$, we define its multiplicity to be $\mul(D_{P \times m}) \bar{u}$. We call $m$ an algebraic starting monomial for $P$ if $D_{P \times m}$ is not homogeneous. In particular, if $m$ is an algebraic starting monomial for $P$, then $\deg P_{\times m} \geq 1$. Note that $m$ is an algebraic starting monomial for $P$ if and only if $m/n$ is an algebraic starting monomial for $P_{\times n}$. By Corollary 2.3, $P$ has at most $\deg P - \mu P$ algebraic starting monomials.

Assumption. In the rest of this section, $\Gamma$ is divisible.

The existence of algebraic starting monomials is an easy corollary of the Equalizer Theorem, and is crucial to what follows.

Lemma 4.3. Let $P$, $Q \in K\{Y\}^\neq$ be homogeneous of different degrees. Then there exists a unique $m$ such that $D_{(P+Q) \times m}$ is not homogeneous.

Proof. By Theorem 4.1, there is a unique $m$ such that $P_{\times m} \times Q_{\times m}$. Then
\[
D_{(P+Q) \times m} = D_{P \times m + Q \times m} = D_{P \times m} + D_{Q \times m}
\]
by Lemma 2.1(ii), so $D_{(P+Q) \times m}$ is not homogeneous. For $n \neq m$, we have $D_{(P+Q) \times n} = D_{P \times n}$ or $D_{(P+Q) \times n} = D_{Q \times n}$ by Lemma 2.1(i), since $P_{\times n} \succ Q_{\times n}$ or $P_{\times n} \prec Q_{\times n}$. \hfill \square

For $P$ and $Q$ as in Lemma 4.3, we let $e(P, Q)$ denote the unique monomial that lemma yields and call it the equalizer for $P$, $Q$. We are interested in the case that these two differential polynomials are homogeneous parts of $P$. Let $J := \{ j \in \mathbb{N} : P_j \neq 0 \}$ and note that $\deg P_{\times m} \in J$ for all $m$. For distinct $i$, $j \in J$, let $e(P_i, P_j) := e(P_i, P_j)$, and so any algebraic starting monomial for $P$ is of the form $e(P_i, P_j)$ for some distinct $i$, $j \in J$.

In the next two results, let $\mathcal{E} \subseteq K^\times$ be $\prec$-closed. Recall this means that $\mathcal{E} \neq \emptyset$ and $f \in \mathcal{E}$ whenever $f \ll g$ with $g \in \mathcal{E}$. 

Proposition 4.4. There exist $i_0, \ldots, i_n \in J$ and equalizers

$$\epsilon(P, i_0, i_1) \prec \epsilon(P, i_1, i_2) \prec \cdots \prec \epsilon(P, i_{n-1}, i_n)$$

with $\text{mul} P = i_0 < \cdots < i_n = \text{ddeg}_E P$ such that

(i) the algebraic starting monomials for $P$ in $E$ are the $\epsilon(P, i_m, i_{m+1})$ for $m < n$;

(ii) for $m < n$ and $m = \epsilon(P, i_m, i_{m+1})$, we have $\text{dmul} P \times m = i_m$ and $\text{ddeg} P \times m = i_{m+1}$.

Proof. Let $i, j$ range over $J$ and $d = \text{ddeg}_E P$. Then $\text{mul} P \leq d \leq \text{deg} P$, and we proceed by induction on $d - \text{mul} P$. If $d = \text{mul} P$, then for all $m \in E$, $D_{P \times m}$ is homogeneous of degree $d$, so there is no algebraic starting monomial for $P$ in $E$.

Now assume $d > \text{mul} P$ and take $i < d$ such that $\epsilon = \epsilon(P, i, d) \succ \epsilon(P, j, d)$ for all $j < d$. First, we show that $\epsilon \in E$. We have $P_{d \times x} \sim P_{i \times x}$ by the previous lemma, so $v_{P_d}(v_\epsilon) = v_{P_i}(v_\epsilon)$. By Lemma 2.19, the function $v_{P_d} - v_\epsilon$ is strictly increasing, so for any $g < \epsilon$, $v_{P_d}(v_g) > v_\epsilon(v_g)$, that is, $P_{d \times g} < P_{i \times g}$. Hence $\text{ddeg} P_{\times g} < d$. To obtain $\epsilon \in E$, take $g \in E$ with $\text{ddeg} P_{\times g} = d$, so $\epsilon \prec g$.

Next, we show $\text{ddeg} P_{\times x} = d$. If $\text{ddeg} P_{\times x} = j < d$, then $P_{d \times x} \prec P_{j \times x}$. By Lemma 2.19 again, the function $v_{P_d} - v_{P_j}$ is strictly increasing, so it follows that $\epsilon \prec \epsilon(P, j, d)$, contradicting the maximality of $\epsilon$.

From this and $P_{i \times x} \sim P_{d \times x}$, we get $(D_{P_{\times x}})_{i} = D_{P_{\times x}} \neq 0$ and $(D_{P_{\times x}})_{d} = D_{P_{\times x}} \neq 0$, and hence $\epsilon$ is an algebraic starting monomial for $P$. In fact, $\epsilon$ is the largest algebraic starting monomial for $P$ in $E$. Suppose to the contrary that $n \in E$ is an algebraic starting monomial for $P$ with $n \succ \epsilon$. Then $d = \text{ddeg} P_{\times x} \leq \text{ddeg} P_{\times n}$ by Corollary 2.3, so $\text{ddeg} P_{\times n} = d$. It follows that $n = \epsilon(P, j, d)$ for some $j < d$, contradicting the maximality of $\epsilon$.

If $i > \text{dmul} P_{\times x}$, then for $j := \text{dmul} P_{\times x}$, the uniqueness in Lemma 4.3 yields $\epsilon(P, j, d) = \epsilon$. By replacing $i$ with $j$, we assume $i = \text{dmul} P_{\times x}$. Then by Lemma 4.2, we also have $\text{ddeg}_{\times x} P = i$. To complete the proof, we apply the inductive assumption with $(g \in K: g \succ \epsilon)$ replacing $E$. □

The tuple $(i_0, \ldots, i_n)$ from Proposition 4.4 is uniquely determined by $K$, $P$, and $E$. Note that if $\text{mul} P = \text{ddeg}_E P$, then $n = 0$ and the tuple is $(\text{mul} P)$. For $1 \leq m \leq n$, set $\epsilon_m := \epsilon(P, i_{m-1}, i_m)$. We now show how $\text{dmul} P_{\times g}$ and $\text{ddeg} P_{\times g}$ behave as $g$ ranges over $E$.

Corollary 4.5. Suppose $\text{mul} P \neq \text{ddeg}_E P$, so $n \geq 1$. Let $g$ range over $E$. Then $\text{dmul} P_{\times g}$ and $\text{ddeg} P_{\times g}$ are in $\{i_0, \ldots, i_n\}$ and we have:

- $\text{dmul} P_{\times g} = i_0 \iff g \sim \epsilon_1$;
- $\text{ddeg} P_{\times g} = i_0 \iff g \prec \epsilon_1$;
- $\text{dmul} P_{\times g} = i_m \iff \epsilon_m \prec g \prec \epsilon_{m+1}$, $(1 \leq m < n)$;
- $\text{ddeg} P_{\times g} = i_m \iff \epsilon_m \prec g \prec \epsilon_{m+1}$, $(1 \leq m < n)$;
- $\text{dmul} P_{\times g} = i_n \iff \epsilon_n \prec g$;
- $\text{ddeg} P_{\times g} = i_n \iff \epsilon_n \prec g$.

Proof. We first prove the third equivalence, so let $1 \leq m < n$. Then for $\epsilon_m \prec g \prec \epsilon_{m+1}$, Proposition 4.4 and Corollary 2.3 give

$$i_m = \text{ddeg} P_{\times i_m} \leq \text{dmul} P_{\times g} \leq \text{ddeg} P_{\times g} \leq \text{dmul} P_{\times i_{m+1}} = i_m,$$

which yields the right-to-left direction since if $g \prec \epsilon_{m+1}$, then $\text{dmul} P_{\times g} = \text{dmul} P_{\times i_{m+1}} = i_m$. For the converse, note that similarly, if $g \prec \epsilon_m$, then $\text{dmul} P_{\times g} \leq \text{dmul} P_{\times i_m} = i_{m-1}$, and if $g \succ \epsilon_{m+1}$, then $\text{dmul} P_{\times g} \geq \text{ddeg} P_{\times i_{m+1}} = i_{m+1}$. The fourth equivalence is proven in the same way.

For the first equivalence, if $g \prec \epsilon_1$, then

$$i_0 = \text{mul} P \leq \text{dmul} P_{\times g} \leq \text{ddeg} P_{\times g} \leq \text{dmul} P_{\times i_1} = i_0,$$

and if $g \succ \epsilon_1$, then $\text{dmul} P_{\times g} = \text{dmul} P_{\times i_1} = i_0$. The converse follows as in the third equivalence. The remaining equivalences are proven similarly. □
4.A. Application to dominant degree in a cut.

Lemma 4.6. Suppose \( (a_\rho) \) is a \( \rho \)-sequence in \( K \) with \( a_\rho \rightarrow 0 \). Let

\[
E := \{ g \in K^\times : g < a_\rho, \text{ eventually} \}.
\]

(i) If \( E \neq \emptyset \), then \( \deg_{a_\rho} P = \deg_{E} P \).

(ii) If \( E = \emptyset \), then \( \deg_{a_\rho} P = \mu P \).

Proof. Set \( \gamma_\rho := v(a_{\rho+1} - a_\rho) \). By removing some initial terms, we may assume that \( \gamma_\rho \) is strictly increasing and \( v(a_\rho) = \gamma_\rho \in \Gamma \) for all \( \rho \). Then by Lemma 2.5,

\[
\deg_{\geq \gamma_\rho} P_{+a_\rho} = \deg_{\geq \gamma_\rho} P = \deg_{P_{x_{a_\rho}}} P,
\]

so \( \deg_{a_\rho} P \) is the eventual value of \( \deg_{P_{x_{a_\rho}}} P \). If \( P \) is homogeneous, then \( \deg_{P_{xg}} = \deg P = \mu P \) for all \( g \in K^\times \), so the statements about \( \deg_{a_\rho} P \) are immediate.

Suppose now that \( P \) is not homogeneous, so \( \mu P < \deg P \). If \( E \neq \emptyset \), we may then use Corollary 4.5 with \( K^\times \) in the role of \( E \), and we have the tuple \( (i_0, \ldots, i_n) \) with \( i_n = \deg P \). By removing further initial terms, we may assume that \( \deg_{P_{x_{a_\rho}}} P \) is constant. If \( \deg_{P_{x_{a_\rho}}} P = i_0 \), then \( a_\rho < e_1 \). Thus for any \( g \in E \), we have \( g < e_1 \), and hence \( \deg_{E} P = i_0 \). If \( \deg_{P_{x_{a_\rho}}} = i_m \) for any \( 1 \leq m \leq n \), then \( e_m \leq a_\rho \). As \( \gamma_\rho \) is strictly increasing, \( e_m < a_\rho \) for all \( \rho \), so \( e_m \in E \). Hence \( \deg_{E} P \geq \deg_{P_{x_{e_m}}} P = i_m \).

If \( E = \emptyset \), let \( i_0 := \mu P \). Then for all \( i > i_0 \), by Lemma 2.19,

\[
v_{P_i}(\gamma_\rho) - v_{P_{i_0}}(\gamma_\rho) = v(P_i) - v(P_{i_0}) + (i - i_0)\gamma_\rho + o(\gamma_\rho).
\]

As \( \gamma_\rho \) is cofinal in \( \Gamma \), we thus have \( v_{P}(\gamma_\rho) = v_{P_{i_0}}(\gamma_\rho) < v_{P}(\gamma_\rho) \), eventually, for all \( i > i_0 \), and so \( \deg_{P_{x_{a_\rho}}} P = i_0 \), eventually.

With \( (a_\rho) \) and \( E \) as in the above lemma, if \( E = \emptyset \), then \( (a_\rho) \) is in fact a cauchy sequence in \( K \) (see [1, §2.2]), since \( \gamma_\rho \) is cofinal in \( \Gamma \), but this is not used later.

Corollary 4.7. Suppose \( (b_\rho) \) is a \( \rho \)-sequence in \( K \) with pseudolimit \( b \in K \). Let \( b := c_K(b_\rho) \) and

\[
E := \{ g \in K^\times : g < b - b, \ \text{eventually} \}.
\]

(i) If \( E \neq \emptyset \), then \( \deg_{b} P = \deg_{E} P_{+b} \).

(ii) If \( E = \emptyset \), then \( \deg_{b} P = \mu P_{+b} \).

Proof. Set \( a_\rho := b_\rho - b \). By Lemma 2.10(ii), we have

\[
\deg_{b} P = \deg_{a_\rho+b} P = \deg_{a} P_{+b}.
\]

It remains to apply the previous lemma with \( P_{+b} \) in place of \( P \). \( \square \)

5. Asymptotic differential equations

Assumption. In this section, \( K \) has a monomial group \( \mathfrak{M} \) and \( \Gamma \) has no least positive element.

Let \( m \) range over \( \mathfrak{M} \) and \( f, g \) over \( K \). We let \( P \in K[Y]^\neq \) with order at most \( r \). An asymptotic differential equation over \( K \) is something of the form

\[
P(Y) = 0, \quad Y \in E,
\]

where \( E \subseteq K^\times \) is \( \leq \)-closed. That is, it consists of an algebraic differential equation with an asymptotic condition on solutions. If \( E = \{ g \in K^\times : g < f \} \) for some \( f \in K^\times \), then we write \( Y \prec f \) for the asymptotic condition instead of \( Y \in E \), and similarly with "\( \leq \)."

For the rest of this section, we fix such an asymptotic differential equation \( (E) \). Then the dominant degree of \( (E) \) is defined to be \( \deg_{E} P \). A solution of \( (E) \) is a \( y \in E \) such that \( P(y) = 0 \). An approximate solution of \( (E) \) is an approximate zero of \( P \) that lies in \( E \), and the multiplicity of an approximate solution of \( (E) \) is its multiplicity as an approximate zero of \( P \). The following is used frequently and follows from Lemma 4.2.
Corollary 5.1. Let $y \in \mathcal{E}$. Then

(i) $y$ is an approximate solution of (E) $\iff$ $\deg_{\prec y} P_{+y} \geq 1$;

(ii) if $y$ is an approximate solution of (E), then its multiplicity is $\deg_{\prec y} P_{+y}$.

A starting monomial for (E) is a starting monomial for $P$ that lies in $\mathcal{E}$. An algebraic starting monomial for (E) is an algebraic starting monomial for $P$ that lies in $\mathcal{E}$. So if $\deg_{\prec} P = 0$, then (E) has no algebraic starting monomials. By Proposition 4.4, if $\Gamma$ is divisible and mult $P < \deg_{\prec} P$, then there is an algebraic starting monomial for (E) and $\deg_{\prec} P = \deg_{\prec} P_{x_e}$, where $e$ is the largest algebraic starting monomial for (E).

It will be important to alter $P$ and $\mathcal{E}$ in certain ways. Namely, let $\mathcal{E}' \subseteq \mathcal{E}$ be $\prec$-closed and let $f \in \mathcal{E} \cup \{0\}$. We call the asymptotic differential equation

$$P_{+f}(y) = 0, \quad Y \in \mathcal{E}'$$

(E')

a refinement of (E). Below, (E') refers to a refinement of this form. By Lemma 2.5,

$$\deg_{\prec} P = \deg_{\prec} P_{+f} \geq \deg_{\prec} P_{+f},$$

so the dominant degree of (E') is at most the dominant degree of (E). Note also that if $y$ is a solution of (E') and $f + y \neq 0$, then $f + y$ is a solution of (E). The same is true with “approximate solution” replacing “solution,” provided that $y \not\approx -f$.

Here is a sufficient condition for being an approximate solution.

Lemma 5.2. Let $f \neq 0$ with $f > g$ for all $g \in \mathcal{E}'$, and suppose

$$\deg_{\prec} P_{+f} = \deg_{\prec} P \geq 1.$$

Then $f$ is an approximate solution of (E).

Proof. We have, using Lemma 2.5 for the equality,

$$\deg_{\prec} P_{+f} \leq \deg_{\prec} P_{+f} \leq \deg_{\prec} P_{+f} = \deg_{\prec} P_{+f} \leq \deg_{\prec} P.$$

Hence $\deg_{\prec} P_{+f} = \deg_{\prec} P \geq 1$, so $f$ is an approximate solution of (E). $\square$

Note that by the previous proof, $\deg_{\prec} P_{+f} \leq \deg_{\prec} P$ for all $f \in \mathcal{E}$.

Lemma 5.3. Suppose $d := \deg_{\prec} P \geq 1$. Then the following are equivalent:

(i) $\deg_{\prec} P_{+f} < d$ for all $f \in \mathcal{E}$;

(ii) $\deg_{\prec} P_{+f} < d$ for all $f \in \mathcal{E}$ with $\deg P_{x_f} = d$;

(iii) there is no approximate solution of (E) of multiplicity $d$.

Proof. The equivalence of (i) and (iii) is given by Corollary 5.1. Now, let $f \in \mathcal{E}$ and suppose $\deg P_{x_f} < d$. Then, using Lemma 2.5 for the first equality,

$$\deg_{\prec} P_{+f} \leq \deg_{\prec} P_{+f} = \deg_{\prec} P = \deg P_{x_f} < d.$$ 

This gives (ii) $\implies$ (i), and the converse is trivial. $\square$

We say that (E) is unravelled if $d := \deg_{\prec} P \geq 1$ and the conditions in Lemma 5.3 hold. In particular, if $d \geq 1$ and (E) does not have an approximate solution, then (E) is unravelled. And if (E) is unravelled and has an approximate solution, then $d \geq 2$ by Lemma 5.3(iii).

We now introduce unravellers and partial unravellers, which correspond to special refinements of (E). In the proof of Proposition 5.5, we construct a sequence of partial unravellers ending in an unravelled asymptotic differential equation. Suppose $d \geq 1$, and let $f \in \mathcal{E} \cup \{0\}$ and $\mathcal{E}' \subseteq \mathcal{E}$ be $\prec$-closed. We say that $(f, \mathcal{E}')$ is a partial unraveller for (E) if $\deg_{\prec} P_{+f} = d$. By Lemma 2.5, $(f, \mathcal{E}')$ is a partial unraveller for (E). Note that if $(f, \mathcal{E}')$ is a partial unraveller for (E) and $(f_1, \mathcal{E}_1)$ is a partial unraveller for $(E')$, then $(f + f_1, \mathcal{E}_1)$ is a partial unraveller for (E). An unraveller for (E) is a partial unraveller $(f, \mathcal{E})$ for (E) with unravelled $(E')$.

The following is routine but used later.
Lemma 5.4. Suppose \( \text{ddeg}_E P \geq 1 \). Let \( a \in K^\times \) and set \( aE := \{ ay \in K^\times : y \in E \} \). Consider the asymptotic differential equation

\[
P_{\alpha a^{-1}}(Y) = 0, \quad Y \in aE. \tag{aE}
\]

(i) The dominant degree of \((aE)\) equals the dominant degree of \((E)\).
(ii) If \((f, E')\) is a partial unraveller for \((E)\), then \((af, aE')\) is a partial unraveller for \((aE)\).
(iii) If \((f, E')\) is an unraveller for \((E)\), then \((af, aE')\) is an unraveller for \((aE)\).
(iv) If \( a \in \mathbb{R} \), then the algebraic starting monomials for \((aE)\) are exactly the \( \alpha \), where \( \alpha \) ranges over the algebraic starting monomials for \((E)\).

The next proposition is about the existence of unravellers, and is a key ingredient in the proof of Proposition 3.1. Recall that \( r \in \mathbb{N} \cup \{ \infty \} \) with \( r \geq 1 \) and that \( K \) is called \( r \text{-d-algebraically maximal} \) if the derivation induced on \( k \) is nontrivial and every pc-sequence in \( K \) with minimal differential polynomial over \( K \) of order at most \( r \) has a pseudolimit in \( K \). Note that \( K \) is \( \infty \text{-d-algebraically maximal} \) if and only if it is \( d \text{-algebraically maximal} \) and the derivation induced on \( k \) is nontrivial.

Proposition 5.5. Suppose \( K \) is \( r \text{-d-algebraically maximal} \) and \( \Gamma \) is divisible. Suppose that \( d := \text{ddeg}_E P \geq 1 \) and that there is no \( f \in E \cup \{ 0 \} \) with \( \text{mul} P_{+ f} = d \). Then there exists an unraveller for \((E)\).

Proof. We construct a sequence \( ((f_\lambda, E_\lambda))_{\lambda \prec \rho} \) of partial unravellers for \((E)\) indexed by an ordinal \( \rho > 0 \) such that:

(i) \( E_\lambda \supset E_\mu \) for all \( \lambda < \mu < \rho \);
(ii) \( f_\lambda - f_\mu > f_\nu - f_\mu \) for all \( \lambda < \mu < \nu < \rho \);
(iii) \( f_{\lambda+1} - f_\lambda \in E_\lambda \setminus E_{\lambda+1} \) for all \( \lambda \) with \( \lambda + 1 < \rho \).

For \( \rho = 1 \), we set \((f_0, E_0) := (0, E)\) and these conditions are vacuous. Below, we frequently use that by (ii) we have \( f_\mu - f_\lambda \succ f_{\lambda+1} - f_\lambda \) for all \( \lambda < \mu < \rho \).

First, suppose that \( \rho \) is a successor ordinal, so \( \rho = \sigma + 1 \), and consider the refinement

\[
P_{+ f_\sigma}(Y) = 0, \quad Y \in E_\sigma \tag{E_\sigma}
\]

of \((E)\). If \((E_\sigma)\) is unravelled, then \((f_\sigma, E_\sigma)\) is an unraveller for \((E)\) and we are done, so suppose \((E_\sigma)\) is not unravelled. Take \( f \in E_\sigma \) such that \( \text{ddeg}_{E_\sigma}(P_{+ f_\sigma} + f) \neq d \). Then

\[
E_\rho := \{ y \in K^\times : y < f \} \subset E_\sigma
\]

is \( \prec \)-closed with

\[
\text{ddeg}_{E_\rho}(P_{+ f_\rho} + f) = d,
\]

so \((f, E_\rho)\) is a partial unraveller for \((E_\sigma)\). Thus, setting \( f_\rho := f_\sigma + f \), we have that \((f_\rho, E_\rho)\) is a partial unraveller for \((E)\). Conditions (i) and (iii) on \((f_\lambda, E_\lambda))_{\lambda \prec \rho+1} \) with \( \rho + 1 \) in place of \( \rho \) are obviously satisfied. For (ii), it is sufficient to check that \( f_{\lambda+1} - f_\lambda > f_\rho - f_\sigma = f \) for \( \lambda < \sigma \), which follows from \( f_{\lambda+1} - f_\lambda \notin E_\sigma \).

Now suppose that \( \rho \) is a limit ordinal. By (ii), \((f_\lambda)_{\lambda \prec \rho} \) is a pc-sequence in \( K \), so we let \( f := c_K(f_\lambda) \) and claim that \( \text{ddeg}_f P = d \). To see this, set \( g_\lambda := f_{\lambda+1} - f_\lambda \) for \( \lambda \) with \( \lambda + 1 < \rho \). By (iii), we have, using Lemma 2.5 in the third line,

\[
d = \text{ddeg}_{E_{\lambda+1}} P_{+ f_{\lambda+1}} \leq \text{ddeg}_{g_\lambda} P_{+ f_{\lambda+1}}
= \text{ddeg}_{g_\lambda}(P_{+ f_\lambda} + f_{\lambda+1} - f_\lambda)
= \text{ddeg}_{g_\lambda} P_{+ f_\lambda}
\leq \text{ddeg}_{E_\lambda} P_{+ f_\lambda} = d.
\]
Thus $\deg_{g_\lambda} P_{\lambda} = d$ for all $\lambda < \rho$, so $\deg_f P = d$. By Lemma 2.16 and Corollary 2.17, $(f_\lambda)_{\lambda < \rho}$ has a minimal differential polynomial over $K$ of order at most $r$, so since $K$ is $r$-d-algebraically maximal, we may take $f_\rho \in K$ with $f_\rho \asymp f_\rho$. Now set

$$\mathcal{E}_\rho := \bigcap_{\lambda < \rho} \mathcal{E}_\lambda = \{ y \in K^\times : y \leq g_\lambda \text{ for all } \lambda < \rho \},$$

where the equality follows from (iii). If $\mathcal{E}_\rho = \emptyset$, then by Corollary 4.7,

$$d = \deg_f P = \mul P_{\lambda},$$

contradicting the hypothesis. So $\mathcal{E}_\rho \neq \emptyset$, and thus Corollary 4.7 yields

$$d = \deg_f P = \deg_{\mathcal{E}_\rho} P_{\lambda},$$

so $(f_\rho, \mathcal{E}_\rho)$ is a partial unraveller for $(E)$. For $((f_\lambda, \mathcal{E}_\lambda))_{\lambda < \rho+1}$, conditions (i) and (iii) with $\rho + 1$ in place of $\rho$ are obviously satisfied. For (ii), it is enough to check that $f_{\lambda+1} - f_\lambda \asymp f_\rho - f_\mu$ for $\lambda < \mu < \rho$, which follows from $f_\rho - f_\mu \asymp f_{\mu+1} - f_\mu$.

This inductive construction must end, and therefore there exists an unraveller for $(E)$.

5.A. **Behaviour of unravellers under immediate extensions.** In this subsection, we fix an immediate extension $L$ of $K$, and we use the monomial group of $K$ as a monomial group for $L$. We consider how unravellers change under immediate extensions and connect this to pseudolimits of pc-sequences. Lemma 5.8 is a key step in the proof of Proposition 3.1.

Given $\mathcal{E}$, the set $\mathcal{E}_L := \{ y \in L^\times : vy \in v\mathcal{E} \}$ is also $\preceq$-closed with $\mathcal{E}_L \cap K = \mathcal{E}$. Consider the asymptotic differential equation

$$(P(Y) = 0, \quad Y \in \mathcal{E}_L) \quad (E_L)$$

over $L$, which has the same dominant degree as $(E)$, i.e., $\deg_{\mathcal{E}_L} P = \deg_{\mathcal{E}} P$. Note that $y \in K$ is an approximate solution of $(E)$ if and only if it is an approximate solution of $(E_L)$. If so, its multiplicities in both settings agree. Thus if $(E_L)$ is unravelled, then $(E)$ is unravelled. For the other direction, if $y \in L$ is an approximate solution of $(E_L)$ of multiplicity $\deg_{\mathcal{E}_L} P$, then any $z \in K$ with $z \sim y$ is an approximate solution of $(E)$ of multiplicity $\deg_{\mathcal{E}} P = \deg_{\mathcal{E}_L} P$. The next lemma follows from this.

**Lemma 5.6.** Suppose $\deg_{\mathcal{E}} P \geq 1$, and let $f \in \mathcal{E} \cup \{0\}$ and $\mathcal{E}' \subseteq \mathcal{E}$ be $\preceq$-closed. Then:

(i) $(f, \mathcal{E}')$ is a partial unraveller for $(E)$ if and only if $(f, \mathcal{E}'_L)$ is a partial unraveller for $(E_L)$;

(ii) $(f, \mathcal{E}')$ is an unraveller for $(E)$ if and only if $(f, \mathcal{E}'_L)$ is an unraveller for $(E_L)$.

**Lemma 5.7.** Suppose the derivation induced on $K$ is nontrivial. Let $(a_\rho)$ be a divergent pc-sequence in $K$ with minimal differential polynomial $P$ over $K$ and $a_\rho \sim \ell \in L$. Then $\mul (P_{+\ell}) \leq 1$.

**Proof.** Let $Q \in K\{Y\}^\times$ be of lower complexity than $P$. If $Q(\ell) = 0$, then by Lemma 2.11 and Lemma 2.15, $Q \in Z(K, \ell)$, which contradicts Corollary 2.17. Hence $Q(\ell) \neq 0$ for all $Q$ of lower complexity than $P$. In particular, $S_P(\ell) \neq 0$, where $S_P := \partial P / \partial Y^r$ and $r$ is the order of $P$. To see that $\mul (P_{+\ell}) \leq 1$, write

$$P_{+\ell} = \sum_{i=0}^S F_i \cdot (Y^\ell)^i \quad \text{ and } \quad S_{P_{+\ell}} = \sum_{i=1}^S iF_i \cdot (Y^\ell)^{i-1},$$

with $F_i \in K[Y, \ldots, Y^{(r-1)}]$, $i = 0, \ldots, S$. From $S_{P_{+\ell}} = (S_P)_{+\ell}$ and $S_P(\ell) \neq 0$ we get $F_1(0) \neq 0$, so $\mul F_1 = 0$, and thus $\mul P_{+\ell} \leq 1$. \hfill $\Box$

**Lemma 5.8.** Suppose $\Gamma$ is divisible and the derivation induced on $K$ is nontrivial. Let $(a_\rho)$ be a divergent pc-sequence in $K$ with minimal differential polynomial $P$ over $K$, and $a_\rho \sim \ell \in L$. Suppose $L$ is $r$-d-algebraically maximal and $\deg_{a} P \geq 2$. Let $a \in K$ and $v \in K^\times$ be such that
Then there exists an unraveler \((f, \mathcal{E})\) for \((5.1)\) over \(L\) such that:

\((i)\) \(f \neq 0\);
\((ii)\) \(\text{ddeg}_{<} P_{a+f} = \text{ddeg}_{a} P\);
\((iii)\) \(a_{\rho} \sim a + f + z\) for all \(z \in \mathcal{E} \cup \{0\}\).

**Proof.** We first reduce to the case \(a = 0\). Take \(g \in K^\times\) with \(a - \ell \sim -g\), so \(g \prec \mathbf{v}\). Then, using Lemma 2.5, we have

\[
\text{ddeg}_{<g} P_{a+g} \leq \text{ddeg}_{<} P_{a+g} = \text{ddeg}_{<} P_{a} = \text{ddeg}_{a} P.
\]

Conversely, as \((a + g) - \ell \prec g\), Lemma 2.16 gives \(\text{ddeg}_{a} P \leq \text{ddeg}_{<g} P_{a+g}\), so

\[
\text{ddeg}_{a} P = \text{ddeg}_{<} P_{a} = \text{ddeg}_{<g} P_{a+g}.
\]

Also, \(P_{a+g}\) is a minimal differential polynomial of \((a_{\rho} - (a + g))\) over \(K\) and, by Lemma 2.10(ii),

\[
\text{ddeg}_{a-(a+g)} P_{a+g} = \text{ddeg}_{a} P.
\]

We can replace \(P, (a_{\rho}), \ell,\) and \(\mathbf{v}\) with \(P_{a+g}, (a_{\rho} - (a + g)), \ell - (a + g),\) and \(g,\) respectively, to arrange \(a = 0\). To see that this works, suppose \(\mathcal{E} \subseteq L^\times\) is \(\prec\)-closed in \(L\) with \(\mathcal{E} \prec g\), and \((h, \mathcal{E})\) is an unraveler for the asymptotic differential equation

\[
P_{a+g}(Y) = 0, \quad Y \prec g
\]

over \(L\) with \(a_{\rho} - (a + g) \sim h + z\) for all \(z \in \mathcal{E} \cup \{0\}\). In particular, \(h \prec g\), so \(g + h \neq 0\), and it is clear from \(\text{ddeg}_{<g} P_{a} = \text{ddeg}_{<g} P_{a+g}\) that \((g + h, \mathcal{E})\) is an unraveler for \((5.1)\). Condition (iii) is also obviously satisfied. For condition (ii), note that as \(h \prec g\), using Lemma 2.5 in the middle equality,

\[
\text{ddeg}_{<g+h} P_{a+g+h} = \text{ddeg}_{<g} P_{a+g+h} = \text{ddeg}_{<g} P_{a+g} = \text{ddeg}_{a} P,
\]

Thus it remains to show that there is an unraveler \((f, \mathcal{E})\) for \((5.1)\) in \(L\) (with \(a = 0\)) such that \(a_{\rho} \sim f + z\) for all \(z \in \mathcal{E} \cup \{0\}\). Consider the set

\[
\mathcal{Z} := \{z \in L^\times : z \prec a_{\rho} - \ell, \text{ eventually}\}.
\]

For any \(z \in \mathcal{Z} \cup \{0\}\), we have \(a_{\rho} \sim z + \ell,\) so by Lemma 5.7,

\[
\text{mul}(P_{+\ell+z}) \leq 1 < 2 \leq \text{ddeg}_{a} P.
\]

By Corollary 4.7, \(\mathcal{Z} \neq \emptyset\), so \(\mathcal{Z}\) is \(\preceq\)-closed and \(\text{ddeg}_{\mathcal{Z}} P_{+\ell} = \text{ddeg}_{a} P\). Then Proposition 5.5 yields an unraveler \((s, \mathcal{E})\) for the asymptotic differential equation

\[
P_{+\ell}(Y) = 0, \quad Y \in \mathcal{Z}
\]

over \(L\). Setting \(f := \ell + s, (f, \mathcal{E})\) is an unraveler for \((5.1)\) with \(a_{\rho} \sim f + z\) for all \(z \in \mathcal{E} \cup \{0\}\). \(\Box\)

5.B. Reducing degree. In this subsection, we consider a refinement of \((E)\) and then truncate it by removing monomials of degree higher than the dominant degree of \((E)\). Given an unraveler for \((E)\), we show how to find an unraveler for this truncated refinement in Lemma 5.10, an essential component in the proof of Proposition 6.1.

**Assumption.** In this subsection, \(\Gamma\) is divisible.
Suppose \( d := \text{ddeg}_E P \geq 1 \), and we have an unraveller \((f, \mathcal{E}')\) for (E). That is, the refinement
\[
P_{+f}(Y) = 0, \quad Y \in \mathcal{E}' \tag{E'}
\]
of (E) is unravelled with dominant degree \( d \). Now suppose \( d > \text{mul}(P_{+f}) \), so (E') has an algebraic starting monomial, and let \( \varepsilon \) be its largest. Suppose \( g \in K^* \) satisfies \( \varepsilon < g < f \), and consider another refinement of (E):
\[
P_{+f-g}(Y) = 0, \quad Y \preceq g. \tag{E_g}
\]
Set \( \mathcal{E}_g' := \{ y \in \mathcal{E}' : y < g \} \), so \( \varepsilon \in \mathcal{E}_g' \).

**Lemma 5.9.** The asymptotic differential equation \((E_g)\) has dominant degree \( d \) and \((g, \mathcal{E}_g')\) is an unraveller for \((E_g)\).

**Proof.** First, since \( \varepsilon \) is the largest algebraic starting monomial for \((E')\), Proposition 4.4 gives
\[
d = \text{ddeg}_{P_{+f},x} = \text{ddeg}_{E,\varepsilon_{\leq}} P_{+f}.
\]
Note that \( f - g \sim f \in \mathcal{E} \). Now, by Lemma 2.5 we obtain
\[
d = \text{ddeg}_{E,\varepsilon} P_{+f} \leq \text{ddeg}_{E,g} P_{+f} = \text{ddeg}_{E,g} P_{+f-g} \leq \text{ddeg}_{E} P_{+f-g} = \text{ddeg}_{E} P = d,
\]
which gives that \((E_g)\) has dominant degree \( d \). Similarly,
\[
d = \text{ddeg}_{E,\varepsilon} P_{+f} \leq \text{ddeg}_{E,g} P_{+f} \leq \text{ddeg}_{E} P_{+f} = \text{ddeg}_{E} P = d,
\]
and thus the asymptotic differential equation
\[
P_{+f}(Y) = 0, \quad Y \in \mathcal{E}_g',
\]
which is a refinement of both \((E_g)\) and \((E')\), has dominant degree \( d \). Finally, since \((E')\) is unravelled, the pair \((g, \mathcal{E}_g')\) is an unraveller for \((E_g)\). \( \Box \)

We now turn to ignoring terms of degree higher than the dominant degree of (E). First, some notation. Recall that for \( F \in K\{Y\} \), we set \( F_{\leq n} := F_0 + F_1 + \cdots + F_n \). Note that if \( n \geq \text{ddeg} F \), then \( D_F = D_{F_{\leq n}} \). Now set \( F := P_{+f-g} \), so \( d \geq \text{ddeg} F_{\text{km}} \) for all \( m \ll g \). Consider the “truncation”
\[
F_{\leq d}(Y) = 0, \quad Y \ll g. \tag{E_{g,\leq d}}
\]
of \((E_g)\) as an asymptotic differential equation over \( K \). We have, for all \( m \ll g \),
\[
D_{F_{\text{km}}} = D_{(F_{\text{km})}_{\leq d}} = D_{(F_{\leq d})_{\times m}}.
\]
so \((E_{g,\leq d})\) has the same algebraic starting monomials and dominant degree as \((E_g)\). Next, we show that under suitable conditions the unraveller \((g, \mathcal{E}_g')\) for \((E_g)\) from the previous lemma remains an unraveller for \((E_{g,\leq d})\). Recall that \([\gamma]\) denotes the archimedean class of \( \gamma \in \Gamma \) and that such classes are ordered in the natural way; see §2.E.

**Lemma 5.10.** Suppose \([v(\varepsilon/g)] < [v(g/f)]\). Then \((g, \mathcal{E}_g')\) is an unraveller for \((E_{g,\leq d})\), and \( \varepsilon \) is the largest algebraic starting monomial for the unravelled asymptotic differential equation
\[
(F_{\leq d}+g)(Y) = 0, \quad Y \in \mathcal{E}_g'. \tag{E_{g,\leq d}}
\]

**Proof.** First, we reduce to the case \( g \gg 1 \): set \( g := \partial_g \) and replace \( P, f, g, \mathcal{E}, \) and \( \mathcal{E}' \) by \( P_{xg}, f/g, g/g, g^{-1}\mathcal{E}, \) and \( g^{-1}\mathcal{E}' \), respectively, and use Lemma 5.4. Now note that \( \varepsilon \ll f \) and \([v\varepsilon] < [vf]\).

Since \( F = P_{+f-g} \) and \( g \gg 1 \), we have \( \text{ddeg} F = \text{ddeg}_{E,1} F = d \) by Lemma 5.9, so
\[
d \leq \text{ddeg}_{E,f} F = \text{ddeg}_{E} F = d,
\]
using Corollary 2.3 and Lemma 2.5. This yields \( d = \text{ddeg} F = \text{ddeg} F_{\times f} \). For \( m \) with \([vm] < [vf]\) we may thus apply Corollary 2.27 with \( F \) and \( D_f \) in place of \( P \) and \( n \) to get
\[
D_{P_{+f,xm}} = D_{F_{+g,xm}} = D_{(F_{\leq d}+g,xm)}. \tag{5.2}
\]
In particular, this holds if \( e \ll m < 1 \), as then \([vm] \leq [ve] < [vf] \). Thus \( e \) is the largest algebraic starting monomial for \((E_{g,\leq d})\), since it is the largest such for \((E')\).

For \((g, E_g')\) to be an unraveller for \((E_{g,\leq d})\), we now show:

(i) \( \text{ddeg}_{E_g'}(F_{\leq d} + g) = d \);
(ii) \( \text{ddeg}_{-h}(F_{\leq d} + g + h) < d \) for all \( h \in E_g' \).

For (i), if \( e \ll m \in E_g' \), then by Corollary 4.5 and (5.2) we have
\[
d = \text{ddeg} P_{+f,\times m} = \text{ddeg}(F_{\leq d} + g, \times m).
\]
For (ii), let \( h \in E_g' \), so \( h \in E' \) and \( h < 1 \). Setting \( \bar{h} := \partial_h \) and \( u := h/\bar{h} \). Applying Lemma 4.2, we have
\[
d \leq \text{ddeg}_{-h}(F_{\leq d} + g + h) = \text{mul}(D_{(F_{\leq d} + g)} + \bar{u});
\]
\[
\text{ddeg}_{-h} P_{+f + h} = \text{mul}(D_{P_{+f,\times h}} + \bar{u}).
\]

First suppose \( e \ll h \), so then combining (5.2), for \( m = \bar{h} \), with (5.3) and (5.4) we have
\[
\text{ddeg}_{-h}(F_{\leq d} + g + h) = \text{ddeg}_{-h} P_{+f + h} < d,
\]
since \((E')\) is unravelled. Now suppose \( h < e \). If \( e'^2 \ll h < e \), then \([vh] = [ve] < [vf] \), and thus by (5.2) and Corollary 4.5,
\[
\text{ddeg}(F_{\leq d} + g, \times h) = \text{ddeg} P_{+f,\times h} < \text{ddeg} P_{+f,\times e} = d.
\]
By Corollary 2.3, \( \text{ddeg}(F_{\leq d} + g, \times h) < d \) remains true for any \( h < e \). Hence, by (5.3),
\[
\text{ddeg}_{-h}(F_{\leq d} + g + h) = \text{mul}(D_{(F_{\leq d} + g)} + \bar{u}) \leq \text{ddeg}(F_{\leq d} + g, \times h) < d,
\]
which completes the proof of (ii). \( \square \)

5.C. Finding solutions in differential-henselian fields. We now use d-henselianity to find solutions of asymptotic differential equations. Given an element of an extension of \( K \), when \( K \) has few constants we find a solution closest to that element.

We say that \((E)\) is quasilinear if \( \text{ddeg} E = 1 \). Note that if \( K \) is d-henselian and \((E)\) is quasilinear, then \( P \) has a zero in \( E \cup \{0\} \) by [1, Lemma 7.1.1]. Note that even in this case, \((E)\) may not have a solution, since those are required to be nonzero.

Lemma 5.11. Suppose \( K \) is \( r \)-d-henselian. Let \( g \in K^\times \) be an approximate zero of \( P \) such that \( \text{ddeg} P_{xg} = 1 \). Then there exists \( y \sim g \) in \( K \) such that \( P(y) = 0 \).

Proof. Let \( m := \partial_g \) and \( u := g/\partial_g \), so \( D_{P_{x,\times m}}(\bar{u}) = 0 \) and thus
\[
\text{dmul} P_{x,\times m + u} = \text{mul}(D_{P_{x,\times m}} + \bar{u}) \geq 1.
\]
By Lemma 2.2, we also have
\[
\text{dmul} P_{x,\times m + u} \leq \text{ddeg} P_{x,\times m + u} = \text{ddeg} P_{x,\times m} = 1.
\]
Thus \( \text{dmul} P_{x,\times m + u} = 1 \), so as \( K \) is \( r \)-d-henselian, there is \( z \ll 1 \) with \( P_{x,\times m + u}(z) = 0 \). Setting \( y := (u + z)m \), we have \( P(y) = 0 \) and \( y \sim um = g \). \( \square \)

Now let \( f \) be an element of an extension of \( K \). We say a solution \( y \) of \((E)\) best approximates \( f \) (among solutions of \((E)\)) if \( y - f \ll z - f \) for each solution \( z \) of \((E)\). Note that if \( f \in K^\times \) is a solution of \((E)\), then \( f \) is the unique solution of \((E)\) that best approximates \( f \). Also, if \( f \gg E \), then \( y - f \gg f \) for all \( y \in E \), and so each solution of \((E)\) best approximates \( f \). First, we see that this is preserved under multiplicative conjugation.

Lemma 5.12. Let \( f \) be an element of an extension of \( K \) and let \( g \in E \) with \( f \ll g \). Suppose \( y \) is a solution of the asymptotic differential equation
\[
P_{xg}(Y) = 0, \quad Y \ll 1
\]
that best approximates \( g^{-1}f \). Then the solution \( gy \) of \((E)\) best approximates \( f \).
Proof. Let \( z \) be a solution of \((E)\). If \( z \succ g \succ f \), then \( z - f \sim z \). As \( y \preceq 1 \) and \( f \preceq g \), we have \( gy - f \preceq g \). Combining these two yields \( gy - f \preceq z - f \). If \( z \preceq g \), then \( g^{-1}z \preceq 1 \) is a solution of the above asymptotic differential equation and so by assumption on \( y \), we have \( y - g^{-1}f \preceq g^{-1}z - g^{-1}f \), and hence \( gy - f \preceq z - f \). \( \square \)

**Lemma 5.13.** Suppose \( K \) is \( r \)-d-henselian and \( C \subseteq \mathcal{O} \). Suppose \((E)\) is quasilinear and has a solution. Let \( f \) be an element of an extension of \( K \). Then \( f \) is best approximated by some solution of \((E)\).

Proof. By the comment above Lemma 5.12, we may assume that \( f \not\in \mathcal{E} \). Thus we may take \( g \in \mathcal{E} \) with \( f \preceq g \) such that \((E)\) has a solution \( y \preceq g \) and

\[
\deg_{\mathcal{E}} P_{\times g} = \deg_{\mathcal{E}} P = 1.
\]

By Lemma 5.12, we may replace \( P \) by \( P_{\times g} \) and \( \mathcal{E} \) by \( \mathcal{O} \) in order to assume \( \mathcal{E} = \mathcal{O} \). Suppose \( f \) is not best approximated by any solution of \((E)\). Then for each \( i \) we get \( y_i \neq 0 \) such that:

(i) \( y_i \) is a solution of \((E)\), i.e., \( P(y_i) = 0 \) and \( y_i \preceq 1 \);
(ii) \( y_i - f \succ y_{i+1} - f \);
(iii) \( \deg_{\mathcal{E}} + y_i = \deg_{\mathcal{E}} P = 1 \) (by Lemma 2.2).

Item (ii) implies \( y_{i+1} - y_i \sim y_i - f \), contradicting [1, Lemma 7.5.5]. \( \square \)

**Lemma 5.14.** Suppose \( K \) is \( r \)-d-henselian, \((E)\) is quasilinear, and \( f \in \mathcal{E} \) is an approximate solution of \((E)\). Then \((E)\) has a solution \( y_0 \sim f \), and every solution \( y \) of \((E)\) that best approximates \( f \) satisfies \( y \sim f \).

Proof. By Corollary 5.1, \( \deg_{\mathcal{E}^c} P_{+f} \geq 1 \). By Corollary 2.5 we have

\[
\deg_{\mathcal{E}^c} P_{+f} \leq \deg_{\mathcal{E}} P_{+f} = \deg_{\mathcal{E}} P = 1,
\]

so \( \deg_{\mathcal{E}^c} P_{+f} = 1 \). By [1, Lemma 7.1.1], there is \( z \prec f \) in \( K \) with \( P(f + z) = 0 \), so \( y_0 := f + z \) is a solution of \((E)\) with \( y_0 \sim f \). If \( y \) is a solution of \((E)\) that best approximates \( f \), then \( y \sim f \), as

\[
y - f \preceq (f + z) - f = z \prec f.
\]

For the next lemma, recall from §5.A that given an immediate extension \( L \) of \( K \), we extend the asymptotic differential equation \((E)\) over \( K \) to \((E_L)\) over \( L \). Note that if \((E)\) is quasilinear, then so is \((E_L)\).

**Lemma 5.15.** Suppose \( K \) is \( r \)-d-henselian and let \( L \) be an immediate extension of \( K \). Suppose \((E)\) is quasilinear, \( \mathcal{E}' \subseteq \mathcal{E} \) is \( \prec \)-closed, and \( f \in \mathcal{E}_L \) is such that the refinement

\[
P_{+f}(Y) = 0, \quad Y \in \mathcal{E}_L'
\]

of \((E_L)\) is also quasilinear. Suppose \( y \preceq f \) is a solution of \((E)\) that best approximates \( f \).

Then \( f - y \in \mathcal{E}_L' \cup \{0\} \).

Proof. The case \( f = y \) being trivial, suppose \( f \neq y \) and set \( m := \partial_{f - y} \). As \( f - y \in \mathcal{E}_L \), we have \( m \in \mathcal{E} \). Now suppose towards a contradiction that \( f - y \not\in \mathcal{E}_L' \). Then \( \mathcal{E}_L' \prec m \in \mathcal{E} \), so by quasilinearity and Lemma 2.5,

\[
1 = \deg_{\mathcal{E}_L'} P_{+f} \leq \deg_{\mathcal{E} \ominus m} P_{+f} = \deg_{\mathcal{E} \ominus m} P_{+y} \leq \deg_{\mathcal{E}} P_{+y} = \deg_{\mathcal{E}} P = 1.
\]

Hence the asymptotic differential equation

\[
P_{+y}(Y) = 0, \quad Y \preceq m
\]

over \( K \) is also quasilinear. Also, by the quasilinearity of \((E_L)\), we have

\[
\deg_{\mathcal{E} \ominus m}(P_{+y} + (f - y)) = \deg_{\mathcal{E} \ominus m} P_{+f} \geq \deg_{\mathcal{E}_L'} P_{+f} = 1,
\]

which is a contradiction. \( \square \)
so $f - y$ is an approximate solution of (5.5) over $L$, by Corollary 5.1. Take $g \in K^x$ with $g \sim f - y$, so $g$ is an approximate solution of (5.5) over $K$, and, by the quasilinearity of (5.5),

$$d\deg P_{+y \times g} = d\deg_{\hat{y} + m} P_{+y} = 1.$$ 

Then by Lemma 5.11 there is $z \sim g \sim f - y$ in $K$ such that $P(y + z) = 0$. We must have $y + z \neq 0$, as otherwise $f \not\ll y - f$, contradicting $y \not\ll f$. From $y \not\ll f$, we also obtain $y + z \not\ll f$, so $y + z \in \mathcal{E}$. Since $y + z - f \not\ll y - f$, this contradicts that $y$ best approximates $f$. $\square$

6. Reducing complexity

This is a technical section whose main goal is Proposition 6.1. This proposition, or rather its consequence Corollary 6.14, is the linchpin of Proposition 3.1, and its proof uses all of the previous sections and some additional results from [1].

**Assumption.** In this section, $K$ is asymptotic and has a monomial group $\mathfrak{M}$, $\Gamma$ is divisible, and $k$ is $r$-linearly surjective.

Let $m$, $n$ range over $\mathfrak{M}$. As usual, we let $P \in K\{Y\}^\neq$ with order at most $r$. As in the previous section, let $\mathcal{E} \subseteq K^x$ be $\ll$-closed, so we have an asymptotic differential equation

$$P(Y) = 0, \quad Y \in \mathcal{E} \quad (E)$$

over $K$. Set $d := d\deg_{\mathcal{E}} P$ and suppose $d \geq 1$. We fix an immediate asymptotic $r$-d-henselian extension $\hat{K}$ of $K$ and use $\mathfrak{M}$ as a monomial group of $\hat{K}$.

Let $\hat{\mathcal{E}} := \mathcal{E}_{\hat{K}} = \{y \in \hat{K}^x : vy \in v\mathcal{E}\}$, so we have the asymptotic differential equation

$$P(Y) = 0, \quad Y \in \hat{\mathcal{E}} \quad (\hat{E})$$

over $\hat{K}$ with dominant degree $d$. Suppose $(\hat{E})$ is not unravelled, and that this is witnessed by an $\hat{f} \in \hat{\mathcal{E}}$ such that $(\hat{f}, \hat{E}')$ is an unraveller for $(\hat{E})$. That is, $d\deg_{\ll f} P_{+\hat{f}} = d$, and the refinement

$$P_{+\hat{f}}(Y) = 0, \quad Y \in \hat{\mathcal{E}'} \quad (\hat{E}')$$

of $(\hat{E})$ is unravelled with dominant degree $d$. By Lemma 5.3, $d \geq 2$. By Corollary 5.1, $\hat{f}$ is an approximate solution of $(\hat{E})$ of multiplicity $d$. Note also that $\hat{E}' = \mathcal{E}'_{\hat{K}}$ for the $\ll$-closed set $\mathcal{E}' := \hat{E}' \cap K \subseteq \mathcal{E}$. Since $(\hat{E})$ is not unravelled, neither is $(E)$ by the discussion preceding Lemma 5.6. Suppose also that $\text{mul} P_{+\hat{f}} < d$, so by Proposition 4.4, $(\hat{E}')$ has an algebraic starting monomial; let $\varepsilon$ be the largest such.

**Proposition 6.1.** There exists $f \in \hat{K}$ such that one of the following holds:

(i) $\hat{f} - f \not\ll \varepsilon$ and $A(f) = 0$ for some $A \in K\{Y\}$ with $c(A) < c(P)$ and $\deg A = 1$;

(ii) $\hat{f} \sim f$, $\hat{f} - a \not\ll f - a$ for all $a \in K$, and $A(f) = 0$ for some $A \in K\{Y\}$ with $c(A) < c(P)$ and $d\deg A_{\times f} = 1$.

6.1. Special case. We first prove Proposition 6.1 in the special case that $d\deg_{\mathcal{E}} P = \deg P$ and later reduce to this case using Lemma 6.13. Below, we consider the differential polynomial

$$P_{+\hat{f}, \times \varepsilon} \in \hat{K}\{Y\};$$

note that $d\deg P_{+\hat{f}, \times \varepsilon} = d$ by the choice of $\varepsilon$. Let $s \leq r$ be the order of $P$. For $i \in \mathbb{N}^{1+s}$, we let

$$\partial^i := \partial^{[i]} \partial Y_{i_0} \ldots \partial (Y^{(s)})^{i_s}$$

denote the partial differential operator on $\hat{K}\{Y\}$ that differentiates $i_n$ times with respect to $Y^{(n)}$ for $n = 0, \ldots, s$. (We also use additive and multiplicative conjugates of partial differential operators;
see [1, §12.8].) For any partial differential operator (in the sense of [1, §12.7]) \( \Delta \) on \( \hat{K}\{Y\} \), any \( Q \in \hat{K}\{Y\} \), and any \( a \in \hat{K} \),

\[
\Delta(Q_{+a}) = (\Delta Q)_{+a}
\]

by [1, Lemma 12.8.7], so we write \( \Delta Q_{+a} \) and do not distinguish between these. If \( a \in \hat{K}^\times \), note that, by [1, Lemma 12.8.8],

\[
\Delta Q_{x a} := \Delta(Q_{x a}) = (\Delta_{x a} Q)_{x a},
\]

Note that, when no parentheses are used, we intend additive and multiplicative conjugation of \( Q \) to take place before \( \Delta \) is applied, in order to simplify notation.

Now, choose \( i \in \mathbb{N}^{1+s} \) such that \( \deg(\partial^i Y) = 1 \) for some \( j \in \mathbb{N}^{1+s} \) with \( |j| = d \) and \( (P_{f, x^\epsilon})_j \approx P_{f, x^\epsilon} \).

In particular, \( |i| = d - 1 \) and

\[
d\deg \partial^i P_{f, x^\epsilon} = d\deg D_{\partial^i P_{f, x^\epsilon}} = d\deg \partial^i D_{P_{f, x^\epsilon}} = 1.
\]

We consider the partial differential operator \( \Delta := (\partial^i)_{x^\epsilon} \) on \( \hat{K}\{Y\} \). We have

\[
(\Delta P)_{f, x^\epsilon} = \partial^i P_{f, x^\epsilon}
\]

by [1, Lemmas 12.8.7 and 12.8.8]. Hence the asymptotic differential equation

\[
\Delta P_{f, x^\epsilon}(Y) = 0, \quad Y \ll \epsilon
\]

is quasilinear.

**Lemma 6.2.** Suppose \( \epsilon \ll \hat{f} \) and the asymptotic differential equation

\[
\Delta P(Y) = 0, \quad Y \in \hat{E}
\]

over \( \hat{K} \) is quasilinear. Then (6.1) has a solution \( y \sim \hat{f} \), and if \( f \) is any solution of (6.1) that best approximates \( \hat{f} \), then \( f - \hat{f} \ll \epsilon \).

**Proof.** By Lemma 2.5, we have

\[
d\deg_{\ll \hat{f}} \Delta P_{f, x^\epsilon} \leq d\deg_{\hat{E}} \Delta P_{\hat{f}, x^\epsilon} = d\deg_{\hat{E}} \Delta P = 1.
\]

But from \( \epsilon \ll \hat{f} \), we also have

\[
1 = d\deg_{\ll \epsilon} \Delta P_{\hat{f}, x^\epsilon} \leq d\deg_{\ll \hat{f}} \Delta P_{\hat{f}, x^\epsilon},
\]

so \( d\deg_{\ll \hat{f}} \Delta P_{\hat{f}, x^\epsilon} = 1 \). Then since \( \hat{K} \) is \( r \)-d-henselian, there is \( y \sim \hat{f} \) with \( \Delta P(y) = 0 \).

For the second statement, the refinement

\[
\Delta P_{\hat{f}, x^\epsilon}(Y) = 0, \quad Y \ll \epsilon
\]

of (6.1) is quasilinear, so we can apply Lemma 5.15 with \( \hat{K} \) in the roles of both \( L \) and \( K \), and \( \Delta P \), \( \hat{f} \), and \( f \) in the roles of \( P \), \( f \), and \( y \), respectively. \( \Box \)

We now conclude the proof of Proposition 6.1 in the case that \( \deg P = d \). Recall that \( d \geq 2 \).

**Lemma 6.3.** Suppose \( \deg P = d \). Then there exist \( f \in \hat{K} \) and \( A \in \hat{K}\{Y\} \) such that \( \hat{f} - f \ll \epsilon \), \( A(f) = 0 \), \( c(A) < c(P) \), and \( \deg A = 1 \).
Proof. Since deg $P = d$, we also have deg $P_{+f,\varepsilon} = d$, and hence
\[
\deg \Delta P = \deg(\Delta P)_{+f,\varepsilon} = \deg \partial^i P_{+f,\varepsilon} = 1,
\]
by the choice of $i$. Hence (6.1) is quasilinear.

If $f \not\succ \varepsilon$, then $f = 0$ and $A := Y$ work, so assume $\varepsilon \prec f$. First, Lemma 6.2 yields a solution $y \sim \hat{f}$ of (6.1). As $\hat{K}$ has few constants, Lemma 5.13 gives that $\hat{f}$ is best approximated by some solution $f$ of (6.1). So applying Lemma 6.2 again, we have $f - \hat{f} \not\preceq \varepsilon$. Then $\Delta P(f) = 0$, $c(\Delta P) < c(P)$, and deg $\Delta P = 1$, so we may take $A := \Delta P$.  \[\square\]

6.B. Tschirnhaus refinements. Set $\hat{f} := \partial \hat{f}$, and we now consider the differential polynomial $P_{x\hat{f}} \in \hat{K}\{Y\}$. If $\varepsilon \not\succ \hat{f}$, then the first case of Proposition 6.1 holds for $f := 0$ and $A := Y$, so in the rest of this subsection we suppose $\varepsilon \prec \hat{f}$. Then we have, by the choice of $\varepsilon$ and Lemma 2.5,
\[
d = \deg_{\varepsilon,\delta} P_{+f} = \deg_{\varepsilon,\delta} P_{+f} = \deg_{\varepsilon,\delta} P \leq \deg \hat{P} = d,
\]
and thus $\deg P_{x\hat{f}} = d$.

Now, choose $i \in \mathbb{N}^{1+s}$ so that $\deg(\partial^i Y)_{\varepsilon,\delta} = 1$ for some $j \in \mathbb{N}^{1+s}$ with $|j| = d$ and $(P_{x\hat{f}})_{j} \succ P_{x\hat{f}}$. Thus we have $|i| = d - 1$ and
\[
D_{\partial^i P_{x\hat{f}}} = \partial^i D_{P_{x\hat{f}}},
\]
and so $\deg \partial^i P_{x\hat{f}} = 1$. We consider the partial differential operator $\Delta := (\partial^i)_{x\hat{f}}$ on $\hat{K}\{Y\}$. By [1, Lemma 12.8.8],
\[
(\Delta P)_{x\hat{f}} = \partial^i P_{x\hat{f}},
\]
and thus the asymptotic differential equation
\[
\Delta P(Y) = 0, \quad Y \not\prec \hat{f}
\]
over $\hat{K}$ is quasilinear. The next lemma follows immediately from this by Corollary 2.6.

Lemma 6.4. Suppose $f \in \hat{K}$ is a solution of (6.2). Then for all $g \in \hat{K}^\times$ with $g \not\prec \hat{f}$ we have
\[
\mul (\Delta P)_{+f,xg} = \deg (\Delta P)_{+f,xg} = 1,
\]
and hence $(\Delta P)_{+f}$ has no algebraic starting monomial $g \in \mathcal{M}$ with $g \not\prec f$.

Lemma 6.5. The element $\hat{f} \in \hat{K}$ is an approximate solution of (6.2).

Proof. Set $u := f/\hat{f}$. Since $\hat{f}$ is an approximate zero of $P$ of multiplicity $d = \deg P_{x\hat{f}} = \deg D_{P_{x\hat{f}}}$,
\[
(D_{P_{x\hat{f}}})_{+\bar{u}} = \sum_{|j|=d} (D_{P_{x\hat{f}}})_{j} Y^j,
\]
by [1, Lemma 4.3.1]. Then
\[
(\partial^i D_{P_{x\hat{f}}})_{+\bar{u}} = \partial^i (D_{P_{x\hat{f}}})_{+\bar{u}} = \sum_{|j|=d} (D_{P_{x\hat{f}}})_{j} \partial^i Y^j,
\]
so the multiplicity of $\partial^i D_{P_{x\hat{f}}}$ at $\bar{u}$ is 1. In view of
\[
D_{(\Delta P)_{x\hat{f}}} = D_{\partial^i P_{x\hat{f}}} = \partial^i D_{P_{x\hat{f}}},
\]
$\hat{f}$ is an approximate solution of (6.2). \[\square\]

Let $f \in \hat{K}$ with $f \sim \hat{f}$, so $\deg_{\varepsilon,\delta} P_{+f} = \deg_{\varepsilon,\delta} P_{+\hat{f}} = d$ by Lemma 2.5. That is, the refinement
\[
P_{+f}(Y) = 0, \quad Y \prec f
\]
of (Ê) still has dominant degree $d$. As $\hat{f}$ is an approximate solution of (6.2), Lemmas 5.14 and 5.13 give a solution $f_0 \in \hat{K}$ of (6.2) that best approximates $\hat{f}$ with $f_0 \sim \hat{f} \sim f$. Thus

\[
d\deg_{\prec f} \Delta P_{+f} = d\deg_{\prec f} \Delta P_{+f_0} = 1
\]

by Lemmas 2.5 and 6.4. Hence the refinement

\[
\Delta P_{+f}(Y) = 0, \quad Y \prec f \quad (\Delta T)
\]

of (6.2) is also quasilinear.

**Definition.** A Tschirnhaus refinement of (Ê) is an asymptotic differential equation (T) over $\hat{K}$ as above with $\hat{f} \sim f \in \hat{K}$ such that some solution $f_0 \in \hat{K}$ of (6.2) over $\hat{K}$ best approximates $\hat{f}$ and satisfies $f_0 - \hat{f} \sim f - \hat{f}$.

**Definition.** Let $f, \hat{g} \in \hat{K}$ and $m$ satisfy

\[
m \prec f - \hat{f} \prec \hat{g} \prec f,
\]

so in particular $f \sim \hat{f}$. With (T) as above, but not necessarily a Tschirnhaus refinement of (Ê), we say the refinement

\[
P_{+f+\hat{g}}(Y) = 0, \quad Y \preceq m \quad (TC)
\]

of (T) is compatible with (T) if it has dominant degree $d$ and $\hat{g}$ is not an approximate solution of (T).

**Lemma 6.6.** Let $f, f_0, \hat{g} \in \hat{K}$ and $m$ be such that

\[
m \prec f_0 - \hat{f} \sim f - \hat{f} \preceq \hat{g} \prec f,
\]

and (TC) has dominant degree $d$. Then $\hat{g}$ is an approximate solution of (T) and of

\[
P_{+f_0}(Y) = 0, \quad Y \prec f. \quad (T_0)
\]

**Proof.** First, $\hat{g}$ is an approximate solution of (T) by Lemma 5.2, since $m \prec \hat{g}$ and

\[
d\deg_{\preceq m} P_{+f+\hat{g}} = d = d\deg_{\prec f} P_{+f}.
\]

From $f_0 - f \preceq f - \hat{f} \preceq \hat{g}$ and $m \prec \hat{g}$, we obtain, using Lemma 2.5 in the first equality,

\[
d\deg_{\preceq \hat{g}} P_{+f_0+\hat{g}} = d\deg_{\preceq \hat{g}} P_{+f+\hat{g}} \geq d\deg_{\preceq m} P_{+f+\hat{g}} = d \geq 1,
\]

so $\hat{g}$ is an approximate solution of (T) by Corollary 5.1.

**Lemma 6.7.** Let $f, f_0, \hat{g} \in \hat{K}$ with

\[
f_0 - \hat{f} \sim f - \hat{f} \preceq \hat{g} \prec f.
\]

Then $\hat{g}$ is an approximate solution of $(\Delta T)$ if and only if $\hat{g}$ is an approximate solution of

\[
\Delta P_{+f_0}(Y) = 0, \quad Y \prec f. \quad (\Delta T_0)
\]

**Proof.** Again, since $f_0 - f \preceq f - \hat{f} \preceq \hat{g}$, by Lemma 2.5 we have

\[
d\deg_{\preceq \hat{g}} \Delta P_{+f_0+\hat{g}} = d\deg_{\preceq \hat{g}} \Delta P_{+f+\hat{g}}.
\]

The result then follows from Corollary 5.1, since $\hat{g} \prec f$. \qed

Note that, for any $f_0 \sim f$, the equation $(\Delta T_0)$ in the previous lemma is quasilinear by Lemma 2.5, since $(\Delta T)$ is. We now exhibit compatible refinements of (T) when $e \prec f - \hat{f}$.

**Lemma 6.8.** Suppose (T) is a Tschirnhaus refinement of (Ê). Suppose $e \prec f - \hat{f}$. Then, with $\hat{g} := \hat{f} - f$ and $m := e$, the refinement (TC) of (T) is compatible with (T).
Proof. Since $e$ is the largest algebraic starting monomial for $(\hat{E}')$,
$$\text{ddeg}_{<t} P_{+f+\hat{g}} = \text{ddeg}_{<t} P_{+f} = \text{ddeg} P_{+f, x_t} = d,$$
and so $(\text{TC})$ has dominant degree $d$.

As $(T)$ is a Tschirnhaus refinement of $(\hat{E})$, let $f_0 \in \hat{K}$ be a solution of (6.2) that best approximates $\hat{f}$ and satisfies $f - \hat{f} \sim f_0 - \hat{f}$. Suppose towards a contradiction that $\hat{g}$ is an approximate solution of $(\Delta T)$, so by Lemma 6.7, $\hat{g}$ is also an approximate solution of $(\Delta T_0)$. Then by Lemma 5.14, $(\Delta T_0)$ has a solution $y \sim \hat{g} \sim \hat{f} - f_0$. Thus $\Delta P(f_0 + y) = 0$, so $f_0 + y$ is a solution of (6.2), since $f_0 + y \not\equiv \hat{f}$. But also
$$f_0 + y - \hat{f} = y - (\hat{f} - f_0) \sim \hat{f} - f_0,$$
contradicting that $f_0$ best approximates $\hat{f}$. Hence $\hat{g}$ is not an approximate solution of $(\Delta T)$, and so $(\text{TC})$ is compatible with $(T)$.

In fact, the proof above shows that $(\Delta T_0)$ has no approximate solution $h$ with $h \sim \hat{f} - f_0$. We now consider the effect of multiplicative conjugation by $f$ on the asymptotic differential equations considered so far.

Lemma 6.9. Consider the asymptotic differential equation
$$P_{x_f}(Y) = 0, \quad Y \in f^{-1} \mathcal{E} \quad (f^{-1}E)$$
over $K$. Then $(f^{-1}f, f^{-1}\hat{E}')$ is an unraveler for
$$P_{x_f}(Y) = 0, \quad Y \in f^{-1} \hat{\mathcal{E}} \quad (f^{-1}\hat{E})$$
over $K$, and $\text{ddeg}_{<1}(P_{x_f})_{+f^{-1}f} = d = \text{ddeg}_{<1} \hat{\mathcal{E}} P_{x_f}$. Moreover, if $(T)$ is a Tschirnhaus refinement of $(\hat{E})$, then
$$(P_{x_f})_{+f^{-1}f}(Y) = 0, \quad Y \prec 1 \quad (f^{-1}T)$$
is a Tschirnhaus refinement of $(f^{-1}\hat{E})$. If $(\text{TC})$ is a compatible refinement of $(T)$, then
$$(P_{x_f})_{+f^{-1}(f+\hat{g})}(Y) = 0, \quad Y \preceq f^{-1}m \quad (f^{-1}\text{TC})$$
is a compatible refinement of $(f^{-1}T)$.

Proof. The claims in the second sentence follow directly from Lemma 5.4. The other claims are direct but tedious calculations; however, it is important to recall that $\Delta = (\partial^f)_{xf}$, so depends on $f$, and, by [1, Lemma 12.8.8],
$$(\partial^f)_{xf} P_{xf} = \partial^f P_{xf}.$$  \hfill \Box

6.C. The Slowdown Lemma. In this subsection, we assume that $(T)$ is a Tschirnhaus refinement of $(\hat{E})$ and $(\text{TC})$ is a compatible refinement of $(T)$. Set $g := \partial \hat{g}$, with $\hat{g}$ as in $(\text{TC})$. The main result of this subsection is Lemma 6.11, called the Slowdown Lemma. A consequence of this, Lemma 6.13, gives the reduction to the special case of Proposition 6.1 considered in §6.A. We first prove the following preliminary lemma.

Lemma 6.10. Suppose $f = 1$. Then
$$\Delta P_{+f}(\hat{g}) \preceq g \Delta P_{+f}.$$ 

Proof. Let $f_0 \in \hat{K}$ be a solution of (6.2) that best approximates $\hat{f}$ and satisfies $f - \hat{f} \sim f_0 - \hat{f}$; in particular, $f_0 \sim f \sim \hat{f} \prec 1$. For this proof, set $Q := \Delta P$.

Since $(\text{TC})$ is compatible with $(T)$, $\hat{g}$ is not an approximate solution of $(\Delta T)$, and thus, with $u := \hat{g}/g$,
$$D_{Q_{+f, x_g}}(u) \neq 0.$$

Proof. Let $f_0 \in \hat{K}$ be a solution of (6.2) that best approximates $\hat{f}$ and satisfies $f - \hat{f} \sim f_0 - \hat{f}$; in particular, $f_0 \sim f \sim \hat{f} \prec 1$. For this proof, set $Q := \Delta P$.

Since $(\text{TC})$ is compatible with $(T)$, $\hat{g}$ is not an approximate solution of $(\Delta T)$, and thus, with $u := \hat{g}/g$,
$$D_{Q_{+f, x_g}}(u) \neq 0.$$
This yields
\[ Q_{+f}(\hat{g}) = Q_{+f, \times g}(u) \asymp Q_{+f, \times g}. \]
Now, since \( f - f_0 \prec g \), Lemma 2.18(i) gives
\[ Q_{+f, \times g} = Q_{\times g, +f/g} \sim Q_{\times g, +f_0/g} = Q_{+f_0, \times g}. \]
As \( f_0 \) is a solution of (6.2), we have
\[ \text{mul} Q_{+f_0, \times g} = \text{ddeg} Q_{+f_0, \times g} = 1 \]
by Lemma 6.4. Using Lemma 2.23 and Lemma 2.18(i) again, we get
\[ Q_{+f_0, \times g} \asymp g Q_{+f_0} \sim g Q_{+f}. \]
Finally, we obtain the desired result by combining these steps:
\[ Q_{+f}(\hat{g}) \asymp g Q_{+f}. \]
\[ \square \]

Using this result, we now turn to the proof of the Slowdown Lemma. The idea, as Aschenbrenner, van den Dries, and van der Hoeven note, is that “the step from (E) to (T) is much larger than the step from (T) to (TC)” [1, p. 661 or arXiv p. 565].

**Lemma 6.11** (Slowdown Lemma). With \( m \) the monomial appearing in (TC), we have
\[ \left[ v \left( \frac{m}{g} \right) \right] < \left[ v \left( \frac{g}{f} \right) \right]. \]

**Proof.** By Lemma 6.9, we may assume that \( f - \hat{f} \prec g \prec 1 \) and \( \Delta = \partial^\delta \). Set \( F := P_+ F \) and note that \( \text{ddeg} F_{+\hat{g}} = \text{ddeg} F = d \) by Lemma 2.2(i).

**Claim 6.11.1.** \( g (F_{+\hat{g}})_d \prec_n (F_{+\hat{g}})_{d-1} \).

**Proof of Claim 6.11.1.** By Lemma 6.10, we have \( g \partial^\delta F \asymp g \partial^\delta F(\hat{g}) \), and hence it suffices to show that \( (F_{+\hat{g}})_d \asymp \partial^\delta F \) and \( \partial^\delta F(\hat{g}) \asymp (F_{+\hat{g}})_{d-1} \).

By the choice of \( i \), we have \( \partial^\delta P \asymp P \), so \( \partial^\delta F \asymp F_{+\hat{g}} \) by Lemma 2.18(i). As \( \text{ddeg} F_{+\hat{g}} = d \), we have \( F_{+\hat{g}} \asymp (F_{+\hat{g}})_d \), and thus \( (F_{+\hat{g}})_d \asymp \partial^\delta F \). By Taylor expansion, \( \partial^\delta F(\hat{g}) \) is, up to a factor from \( Q^\times \), the coefficient of \( Y^1 \) in \( F_{+\hat{g}} \). Since \( |i| = d - 1 \), this yields \( \partial^\delta F(\hat{g}) \asymp (F_{+\hat{g}})_{d-1} \).

**Claim 6.11.2.** \( n \prec_n g \implies \text{ddeg} F_{+\hat{g}, \times x} \leq d - 1 \).

**Proof of Claim 6.11.2.** Suppose \( n \prec_n g \). Then \( n \prec 1 \), so by Corollary 2.3,
\[ \text{ddeg} F_{+\hat{g}, \times x} \leq \text{ddeg} F_{+\hat{g}} = d, \]
and hence it suffices to show that \( (F_{+\hat{g}, \times x})_d \prec_n (F_{+\hat{g}, \times x})_{d-1} \). By Lemma 2.22, for all \( i \),
\[ (F_{+\hat{g}, \times x})_i = (F_{+\hat{g}})_i \times_n n^i (F_{+\hat{g}})_i, \]
so we show that \( n (F_{+\hat{g}})_d \prec_n (F_{+\hat{g}})_{d-1} \). First, as \( (F_{+\hat{g}})_d \neq 0 \), we have \( n (F_{+\hat{g}})_d \prec_n g (F_{+\hat{g}})_d \). Second, \( n \prec g \prec 1 \) implies \( |v_n g| \leq |v_m| \), so the first claim and Lemma 2.21 yield \( g (F_{+\hat{g}})_d \prec_n (F_{+\hat{g}})_{d-1} \). Combining these two relations, we obtain \( n (F_{+\hat{g}})_d \prec_n (F_{+\hat{g}})_{d-1, n} \), as desired.

To finish the proof of the lemma, note that \( \text{ddeg} F_{+\hat{g}, \times m} = d \), because (TC) is compatible. Then the second claim gives \( g \prec_n m \), and so \( g \prec_\times m \), by Lemma 2.20. But since \( m \prec g \), we must have \( m \prec_\times g \), which means \( |v_m - v_g| \leq |v_g| \), as desired. \[ \square \]
6.D. Consequences of the Slowdown Lemma.

**Corollary 6.12.** If (T) is a Tschirnhaus refinement of (Ê), then

\[ \epsilon < \hat{f} - f \implies \left[ v\left( \frac{\epsilon}{f - f} \right) \right] < \left[ v\left( \frac{\hat{f} - f}{f} \right) \right]. \]

**Proof.** This follows immediately from Lemmas 6.8 and 6.11. \( \square \)

**Lemma 6.13.** Suppose (T) is a Tschirnhaus refinement of (Ê) and \( \epsilon < \hat{f} - f \). Let \( F := P_{+f}, \) \( \hat{g} := \hat{f} - f, \) and \( g := \vartheta_{g} \). Then the asymptotic differential equation

\[ F_{\leq d}(Y) = 0, \quad Y \preceq g \quad (Ê'_{g, \leq d}) \]

has dominant degree \( d \). Moreover, with \( \hat{E}^*_g := \{ y \in \hat{E}' : y < g \} \), \( (\hat{g}, \hat{E}'_g) \) is an unraveller for \( (Ê'_{g, \leq d}) \) and \( \epsilon \) is the largest algebraic starting monomial for the unravelled asymptotic differential equation

\[ (F_{\leq d} + \hat{g})(Y) = 0, \quad Y \in \hat{E}_{g}' \quad (Ê'_{g, \leq d}) \]

over \( \hat{K} \).

**Proof.** This follows from Corollary 6.12 by applying Lemma 5.10 with \( \hat{K}, \hat{f}, \hat{g}, \hat{E}, \hat{E}', \) and \( \hat{E}^*_g \) in the roles of \( K, f, f - g, g, E, E', \) and \( E^*_g \), respectively. \( \square \)

6.E. Proposition 6.1 and its consequence. Finally, we return to the proof of the main proposition of this section. Recall the statement:

**Proposition 6.1.** There exists \( f \in \hat{K} \) such that one of the following holds:

1. \( \hat{f} - f \preceq \epsilon \) and \( A(f) = 0 \) for some \( A \in K\{Y\} \) with \( c(A) < c(P) \) and \( \deg A = 1 \);
2. \( \hat{f} \sim f, \hat{f} - a \preceq f - a \) for all \( a \in K \), and \( A(f) = 0 \) for some \( A \in K\{Y\} \) with \( c(A) < c(P) \) and \( \deg A_{\times f} = 1 \).

**Proof.** As noted already, if \( \epsilon \succ f \), then case (i) holds with \( f := 0 \) and \( A := Y \), so suppose \( \epsilon < f \). By Lemma 6.5, \( \hat{f} \) is an approximate solution of (6.2), so by Lemmas 5.14 and 5.13, we have a solution \( f_0 \sim \hat{f} \) in \( \hat{K} \) of (6.2) that best approximates \( \hat{f} \). If \( \hat{f} - a \preceq f_0 - a \) for all \( a \in K \), then case (ii) holds with \( f := f_0 \) and \( A := \Delta P \). Now suppose to the contrary that there is some \( f \in K \) with \( \hat{f} - f > f_0 - f \). That is, \( f_0 - \hat{f} \sim f - \hat{f} \), so in view of \( f_0 \sim \hat{f} \), we have \( f \sim \hat{f} \). Hence (T) is a Tschirnhaus refinement of (Ê).

If \( \hat{f} - f \preceq \epsilon \), then case (i) holds with \( A := Y - f \), so for the rest of the proof, assume \( \epsilon < \hat{f} - f \), and set \( \hat{g} := \hat{f} - f \) and \( g := \vartheta_{g} \). This puts us in the situation of the previous lemma, so \( (Ê'_{g, \leq d}) \) has dominant degree \( d \) and \( (\hat{g}, \hat{E}_{g}') \) is an unraveller for \( (Ê'_{g, \leq d}) \). In particular, \( \deg_{g} (F_{\leq d} + \hat{g}) = d \), since

\[ \deg_{g} (F_{\leq d} + \hat{g}) \geq \deg_{\vartheta_{g}} (F_{\leq d} + \hat{g}) = d. \]

Also, \( \epsilon \) is the largest algebraic starting monomial for \( (Ê'_{g, \leq d}) \). Now since \( f \in K \), we can view \( (Ê'_{g, \leq d}) \) as an asymptotic differential equation over \( K \). We also have \( \deg F_{\leq d} = d \) and \( \mul(F_{\leq d} + \hat{g}) < d \), since otherwise \( (F_{\leq d} + \hat{g}) \) would be homogeneous and so not have any algebraic starting monomials. Thus with \( (Ê'_{g, \leq d}) \) in place of (E) and \( (\hat{g}, \hat{E}'_{g}) \) in place of \( (\hat{f}, \hat{E}'_g) \), Lemma 6.3 applies. Hence we have \( g \in \hat{K} \) and \( B \in K\{Y\} \) such that \( \hat{g} - g \preceq \epsilon \), \( B(\hat{g}) = 0 \), \( c(B) < c(F_{\leq d}) \), and \( \deg B = 1 \). Finally, case (i) holds with \( f + g \) in place of \( f \) and with \( A := B_{-f} \), completing the proof. \( \square \)

We do not use Proposition 6.1 directly in the proof of Proposition 3.1, but rather this corollary concerning pc-sequences.

**Corollary 6.14.** Suppose \( (a_{\varphi}) \) is a divergent pc-sequence in \( K \) with pseudolimit \( \hat{f} \in \hat{K} \) and minimal differential polynomial \( P \) over \( K \). Then there exist \( f \in \hat{K} \) and \( A \in K\{Y\} \) such that \( \hat{f} - f \preceq \epsilon \), \( A(f) = 0 \), \( c(A) < c(P) \), and \( \deg A = 1 \).
Proof. Suppose otherwise, so Proposition 6.1 gives $f \in \hat{K}$ and $A \in K\{Y\}$ such that $f - a \ll f - a$ for all $a \in K$, $A(f) = 0$, and $c(A) < c(P)$. Since $(a,\rho)$ has no pseudolimit in $K$, $\hat{f} \not\in K$, and so $f \not\in K$. Hence we may take a divergent pc-sequence $(b_\sigma)$ in $K$ such that $\hat{f} - b_\sigma \ll f$. Since $\hat{f} - b_\sigma \not\ll f - b_\sigma$ for all $\sigma$, we have $b_\sigma \not\sim \hat{f}$. They must also have the same width, since they have no pseudolimit in $K$ but a common pseudolimit in $\hat{K}$, and so $(a,\rho)$ and $(b_\sigma)$ are equivalent pc-sequences in $K$. Thus $a_\rho \not\sim f$; applying Lemma 2.11 to $A$ and $f$ contradicts the minimality of $P$. \hfill $\square$

7. Proof of Proposition 3.1

In this section, we prove the main proposition, derived from the work of the previous sections. This completes the proof of the main results.

**Proposition 3.1.** Suppose $K$ is asymptotic, $\Gamma$ is divisible, and $k$ is $r$-linearly surjective. Suppose $(a,\rho)$ is a pc-sequence in $K$ with minimal differential polynomial $G$ over $K$ of order at most $r$. Then $d\deg_a G = 1$.

**Proof.** Let $d := d\deg_a G$. We may assume that $(a,\rho)$ has no pseudolimit in $K$, as otherwise, up to scaling, $G$ is of the form $Y - a$ for some pseudolimit $a$ of $(a,\rho)$, and hence $d = 1$. By Zorn’s lemma, we may take a d-algebraically maximal immediate extension $\hat{K}$ of $K$. By the proof of [1, Theorem 7.0.1], $\hat{K}$ is $r$-d-henselian. Note that as an immediate extension of $K$, $\hat{K}$ is also asymptotic by [1, Lemmas 9.4.2 and 9.4.5].

Now, take $\ell \in \hat{K}$ such that $a_\rho \prec \ell$, so $G \in Z(K, \ell)$ and has minimal complexity by Corollary 2.17. Lemma 2.16 gives $d \geq 1$, as well as $a \in K$ and $v \in K^\times$ such that $a - \ell < v$ and $d\deg_{v^r} G +_{+a} = d$. Towards a contradiction, suppose $d \geq 2$. Lemma 5.8 then yields an unraveller $(f, \hat{E})$ for the asymptotic differential equation

$$G +_{+a} (Y) = 0, \quad Y < v$$

(7.1)

over $\hat{K}$ such that:

(i) $\hat{f} \neq 0$;

(ii) $d\deg_{\hat{f}} G +_{+a+\hat{f}} = d$;

(iii) $a_\rho \prec a + \hat{f} + g$ for all $g \in \hat{E} \cup \{0\}$;

(iv) $\mul G +_{+a+\hat{f}} < d$,

where (iv) follows from (iii) by Lemma 5.7. Suppose first that $K$ has a monomial group, so the results of the previous section are available. Consider the pc-sequence $(a_\rho - a)$ with minimal differential polynomial $P := G +_{+a}$ over $K$, and let $\epsilon$ be the largest algebraic starting monomial for the asymptotic differential equation

$$P +_{+f} (Y) = 0, \quad Y \in \hat{E}$$

over $\hat{K}$. Then applying Corollary 6.14 to $(a_\rho - a)$ and $P$, we obtain $f \in \hat{K}$ and $A \in K\{Y\}$ such that $f - f \ll \epsilon$, $A(f) = 0$, and $c(A) < c(P)$. But by Corollary 4.5, we must have $\epsilon \in \hat{E}$, so $f - f \in \hat{E} \cup \{0\}$. But then $a_\rho - a \prec f$, so applying Lemma 2.11 to $A$ and $f$ contradicts the minimality of $P$.

Finally, we reduce to the case that $K$ has a monomial group. Consider $K$ as a valued differential field with a predicate for $K$ and pass to an $\mathbb{N}_1$-saturated elementary extension of this structure. In particular, the new $K$ has a monomial group [1, Lemma 3.3.39]. In doing this, we preserve all the relevant first order properties: small derivation, $r$-linearly surjective differential residue field, divisible value group, asymptotic, $r$-d-henselianity of $\hat{K}$, and that $G \in Z(K, \ell)$ but $H \not\in Z(K, \ell)$ for all $H \in K\{Y\}$ with $c(H) < c(G)$.

However, it is possible that $\hat{K}$ is no longer d-algebraically maximal, in which case we pass to an d-algebraically maximal immediate extension of $\hat{K}$ (and hence of $K$). It is also possible that $(a_\rho)$ is no longer divergent in $K$, in which case we replace $(a_\rho)$ with a divergent pc-sequence $(b_\sigma)$ in $K$. 

with \( b_\sigma \sim \ell \). By Corollary 2.17, \( G \) is a minimal differential polynomial of \( (b_\sigma) \) over \( K \), and by Lemma 2.16, \( \text{ddeg}_b G = d \), where \( b := c_K(b_\sigma) \). By the argument above used in this new structure, \( d = 1 \), as desired.
