Abstract

We consider functions on the $d$-dimensional unit cube whose partial derivatives up to order $r$ are bounded by one. It is known that the minimal number of function values that is needed to approximate the integral of such functions up to the error $\varepsilon$ is of order $(d/\varepsilon)^{d/r}$. Among other things, we show that the minimal number of function values that is needed to approximate such functions in the uniform norm is of order $(d^{r/2}/\varepsilon)^{d/r}$ whenever $r$ is even.

1 Introduction and results

We study the problem of the uniform recovery of functions by deterministic algorithms that use a finite number of function values. We are interested in the class

$$C^r_d = \{ f \in C^r([0,1]^d) \mid \| D^\beta f \|_\infty \leq 1 \text{ for all } \beta \in \mathbb{N}_0^d \text{ with } |\beta| \leq r \}$$

of real-valued functions on the $d$-dimensional unit cube whose partial derivatives up to order $r \in \mathbb{N}$ are continuous and bounded by one. It is well known that the integration of functions from $C^r_d$ suffers from the curse of dimensionality. In fact, the minimal number $n^{\text{int}}(\varepsilon,C^r_d)$ of function values that is needed to guarantee an integration error $\varepsilon \in (0,1/2)$ for any function from $C^r_d$ grows super-exponentially with the dimension. It is proven in [3] that there are positive constants $c_r$ and $C_r$
such that
\[ (c_d d^{1/r} \varepsilon^{-1/r})^d \leq n^{\text{int}}(\varepsilon, C_d^r) \leq (C_d d^{1/r} \varepsilon^{-1/r})^d \]
for all \( \varepsilon \in (0, 1/2) \) and \( d \in \mathbb{N} \). Roughly speaking \( n^{\text{int}}(\varepsilon, C_d^r) \) is of order \((d/\varepsilon)^{d/r}\). See Section \ref{sec:prelim} for a precise definition of the \( n^{\text{int}}(\varepsilon, C_d^r) \) and further notation.

Since an \( \varepsilon \)-approximation of the function immediately yields an \( \varepsilon \)-approximation of its integral, the uniform recovery of functions from \( C_d^r \) can only be harder. But how hard is the uniform recovery problem? Is it significantly harder than the integration problem? These questions were recently posed in \cite{12, Section 6}.

If \( r = 1 \), the answer is known. In this case, the minimal number \( n^{\text{app}}(\varepsilon, C_d^1) \) of function values that is needed to guarantee an approximation error \( \varepsilon > 0 \) for any function from \( C_d^1 \) in the uniform norm behaves similarly to \( n^{\text{int}}(\varepsilon, C_d^r) \). There are positive constants \( c \) and \( C \) such that
\[ (c_d d \varepsilon^{-1})^d \leq n^{\text{app}}(\varepsilon, C_d^1) \leq (C_d d \varepsilon^{-1})^d \]
for all \( \varepsilon \in (0, 1/2) \) and \( d \in \mathbb{N} \). This result is basically contained in \cite{9}. Nonetheless, we will present its proof. If \( r \geq 2 \) is even, we obtain the following result.

**Theorem 1.** Let \( r \in \mathbb{N} \) be even. Then there are positive constants \( c_r, C_r \) and \( \varepsilon_r \) such that
\[ (c_r \sqrt{d} \varepsilon^{-1/r})^d \leq n^{\text{app}}(\varepsilon, C_d^r) \leq (C_r \sqrt{d} \varepsilon^{-1/r})^d \]
for all \( d \in \mathbb{N} \) and \( \varepsilon \in (0, \varepsilon_r) \). The upper bound holds for all \( \varepsilon > 0 \).

Roughly speaking \( n^{\text{app}}(\varepsilon, C_d^r) \) is of order \((d^{r/2}/\varepsilon)^{d/r}\). If the error tolerance \( \varepsilon \) is fixed, the complexity grows like \( d^{d/2} \). This is in contrast to the case \( r = 1 \), where we have a growth of order \( d^d \). If \( r \geq 3 \) is odd, we only have a partial result.

**Theorem 2.** Let \( r \geq 3 \) be odd. Then there are positive constants \( c_r, C_r \) and \( \varepsilon_r \) such that
\[ (c_r \sqrt{d} \varepsilon^{-1/r})^d \leq n^{\text{app}}(\varepsilon, C_d^r) \leq (C_r d^{r+1} \varepsilon^{-1/r})^d \]
for all \( d \in \mathbb{N} \) and \( \varepsilon \in (0, \varepsilon_r) \). The upper bound holds for all \( \varepsilon > 0 \).

We point to the fact that \( n^{\text{app}}(\varepsilon, C_d^r) \leq n^{\text{app}}(\varepsilon, C_d^{r-1}) \) since the upper bound resulting from Theorem 1 may improve on the upper bound of Theorem 2 for \( d \gg \varepsilon^{-2/(r-1)} \) if \( r \geq 3 \) is odd. In this case, we do not know the exact behavior of \( n^{\text{app}}(\varepsilon, C_d^r) \) as a function of both \( d \) and \( \varepsilon \). If regarded as a function of \( \varepsilon \), the complexity is of order \( \varepsilon^{-d/r} \). If regarded as a function of \( d \), it is of order \( d^{d/2} \).

Altogether, our results justify the following comparison.
Corollary 1. The uniform recovery problem on the class $\mathcal{C}_r^d$ is significantly harder than the integration problem if and only if $r \geq 3$.

Except for the case $r = 1$, the lower bounds of the previous theorems even hold for the smaller class

$$\tilde{\mathcal{C}}_r^d = \{ f \in \mathcal{C}^r([0,1]^d) | \|\partial_{\theta_1} \cdots \partial_{\theta_r} f\|_\infty \leq 1 \text{ for all } \ell \leq r \text{ and } \theta_i \in S_{d-1} \} \quad (2)$$

of functions whose directional derivatives up to order $r \in \mathbb{N}$ are bounded by one.

For this class, we obtain sharp bounds on the $\varepsilon$-complexity of the uniform recovery problem for any $r \in \mathbb{N}$. The minimal number $n^{\text{app}}(\varepsilon, \tilde{\mathcal{C}}_r^d)$ of function values that is needed to guarantee an approximation error $\varepsilon$ for every function from $\tilde{\mathcal{C}}_r^d$ in the uniform norm satisfies the following.

Theorem 3. Let $r \in \mathbb{N}$. There are positive constants $c_r$, $C_r$ and $\varepsilon_r$ such that

$$\left(c_r \sqrt{d \varepsilon^{-1/r}} \right)^d \leq n^{\text{app}}(\varepsilon, \tilde{\mathcal{C}}_r^d) \leq \left(C_r \sqrt{d \varepsilon^{-1/r}} \right)^d$$

for all $d \in \mathbb{N}$ and $\varepsilon \in (0, \varepsilon_r)$. The upper bound holds for all $\varepsilon > 0$.

Before we turn to the proofs, we shortly discuss some related problems.

Remark 1 (Global optimization). We obtain analogous estimates for the complexity of global optimization on $F = \mathcal{C}_r^d$ or $F = \tilde{\mathcal{C}}_r^d$. This is because the minimal number $n^{\text{opt}}(\varepsilon, F)$ of function values that is needed to guarantee an $\varepsilon$-approximation of the maximum of a function from $F$ satisfies \cite{5, 11}

$$n^{\text{app}}(2\varepsilon, F) \leq n^{\text{opt}}(\varepsilon, F) \leq n^{\text{app}}(\varepsilon, F).$$

Remark 2 (Infinite smoothness). It is proven in \cite{7} that even the uniform recovery of functions from

$$\mathcal{C}_d^\infty = \{ f \in \mathcal{C}^\infty([0,1]^d) | \|D^\beta f\|_\infty \leq 1 \text{ for all } \beta \in \mathbb{N}_0^d \}$$

suffers from the curse of dimensionality. For $r \in \mathbb{N}$, we have seen that the complexity $n^{\text{app}}(\varepsilon, \mathcal{C}_r^d)$ in fact depends super-exponentially on the dimension. It would be interesting to verify whether this is also true for $r = \infty$. We remark that the uniform recovery problem does not suffer from the curse if the target function lies
within the modified class

\[
\widetilde{C}_d^\infty = \left\{ f \in C^\infty ([0,1]^d) \mid \sum_{|\beta| = k} \|D^\beta f\|_\infty \leq 1 \text{ for all } k \in \mathbb{N}_0 \right\}
\]

of smooth functions. This is proven in [10].

**Remark 3 (Algorithms).** This paper is not concerned with explicit algorithms. Nonetheless, our proof shows that there are optimal algorithms in the sense of Theorem 1, 2 and 3 whose information is given by function values at a regular grid and small clouds around the grid points. This information can be used for a subcubewise Taylor approximation of the target function around the grid points, where the partial derivatives of order less than \( r \) are replaced by divided differences. The resulting algorithm is indeed optimal for the class \( \widetilde{C}_d^r \). However, the author does not know whether it is also optimal for \( C_d^r \).

**Remark 4 (Other domains).** Our lower bounds are still valid, if the domains \([0,1]^d\) are replaced by any other sequence of domains \( D_d \subset \mathbb{R}^d \) that satisfies \( \text{vol}_d(D_d) \geq a^d \) for some \( a > 0 \) and all \( d \in \mathbb{N} \). The upper bounds, however, heavily exploit the geometry of the unit cube. We remark that the curse of dimensionality for the integration problem on general domains is studied in the recent paper [4].

**Remark 5 (Integration for \( \widetilde{C}_d^r \)).** Note that the right behavior of the complexity \( n^{\text{int}}(\varepsilon, \widetilde{C}_d^r) \) of the integration problem for \( \widetilde{C}_d^r \) as a function of \( d \) and \( \varepsilon \) is still open.

## 2 The setting

Let \( d \in \mathbb{N} \) and let \( F \) be a class of continuous real-valued functions on \([0,1]^d\). We study the problem of uniform approximation on \( F \) via function values in the worst case setting. An algorithm for numerical approximation is a mapping \( A = \varphi \circ N \) built from an information map \( N : F \to \mathbb{R}^n \) for some \( n \in \mathbb{N} \) and an arbitrary map \( \varphi : \mathbb{R}^n \to L_\infty ([0,1]^d) \). The information map is of the form

\[
N(f) = (f(x_1), \ldots, f(x_n)),
\]

where the points \( x_i \in [0,1]^d \) may be chosen based on the already computed function values \( f(x_1), \ldots, f(x_{i-1}) \) for \( i = 1, \ldots, n \). The cost of the algorithm is the number \( n \) of computed function values and denoted by \( \text{cost}(A) \). Its worst case error is the
quantity
\[ e^{\text{app}}(A, F) = \sup_{f \in F} \| f - A(f) \|_{\infty}. \]

See Novak and Woźniakowski [6, Chapter 4] for a detailed discussion of algorithms and their errors and cost in various settings.

The \( n \)th minimal worst case error is the smallest worst case error of algorithms using at most \( n \) function values, that is
\[ e^{\text{app}}(n, F) = \inf \{ e^{\text{app}}(A, F) \mid \text{cost}(A) \leq n \}. \]

Finally, we formally define the minimal number of function values needed to approximate an unknown function from \( F \) up to the error \( \varepsilon > 0 \) in the uniform norm as
\[ n^{\text{app}}(\varepsilon, F) = \min \{ n \in \mathbb{N}_0 \mid e^{\text{app}}(n, F) \leq \varepsilon \}. \]

Our results are concerned with the classes \( F = C^r_d \) and \( \tilde{C}^r_d \) for \( r \in \mathbb{N}_0 \) and \( d \in \mathbb{N} \) as defined in (1) and (2). Here, \( D^\beta \) denotes the partial derivative of order \( \beta \in \mathbb{N}_0^d \) and \( |\beta| = \sum_{i=1}^d \beta_i \). Moreover, \( \partial_\theta \) denotes the directional derivative in the direction \( \theta \in S_{d-1} \), where \( S_{d-1} \) is the euclidean unit sphere in \( \mathbb{R}^d \). These classes are convex and symmetric. Our proofs are based on the following fact.

**Lemma 1** (see [2]). Let \( d \in \mathbb{N} \) and \( F \subset C([0,1]^d) \) be convex and symmetric. Then
\[ e^{\text{app}}(n, F) = \inf_{P \subset [0,1]^d} \sup_{f \in F} \| f \|_{\infty}. \]

Under the assumptions of Lemma 1 we even know that linear algorithms are optimal. That is, for each \( n \in \mathbb{N} \), there are functions \( g_1, \ldots, g_n \in L_\infty([0,1]^d) \) and points \( x_1, \ldots, x_n \in [0,1]^d \) such that the algorithm
\[ A^*_n : F \to L_\infty([0,1]^d), \quad A^*_n(f) = \sum_{i=1}^n f(x_i)g_i \]
satisfies
\[ e^{\text{app}}(A^*_n, F) = e^{\text{app}}(n, F). \]

These results go back to Bakhvalov [1] and Smolyak [3]. We refer to Creutzig and Wojtaszczyk [2] for a proof.

We also talk about numerical integration on \( F \) in the worst case setting. Similarly to numerical approximation, an algorithm for numerical integration is a functional
$A = \varphi \circ N$ built from an information map $N : F \to \mathbb{R}^n$ like above and an arbitrary map $\varphi : \mathbb{R}^n \to \mathbb{R}$. Its cost is $n$ and its worst case error is

$$e^{\text{int}}(A, F) = \sup_{f \in F} \left| A(f) - \int_{[0,1]^d} f(x) \, dx \right|.$$ 

The $n$th minimal worst case error is the smallest worst case error of algorithms using at most $n$ function values, that is

$$e^{\text{int}}(n, F) = \inf \{ e^{\text{int}}(A, F) \mid \text{cost}(A) \leq n \}.$$ 

The minimal number of function values that is needed to guarantee an $\varepsilon$-approximation of the integral of a function from $F$ is formally defined as

$$n^{\text{int}}(\varepsilon, F) = \min \{ n \in \mathbb{N}_0 \mid e^{\text{int}}(n, F) \leq \varepsilon \}.$$

### 3 Upper bounds

To estimate $e^{\text{app}}(n, C_d^r)$ from above, Lemma 1 says that we can choose any point set $P$ with cardinality at most $n$ and give an upper bound on the maximal value of a function $f \in C_d^r$ that vanishes on $P$. In fact, we can choose any point set $Q$ with cardinality at most $n/(d+1)^{r-1}$ and assume that not only $f$ but all its derivatives of order less than $r$ are arbitrarily small on $Q$. More precisely, for any $\delta > 0$, any $r \in \mathbb{N}_0$, $d \in \mathbb{N}$ and $Q \subset [0,1]^d$, we define the subclasses

$$C_d^r(Q, \delta) = \{ f \in C_d^r \mid |D^\alpha f(x)| \leq \delta^{2^{r-|\alpha|-1}} \text{ for all } x \in Q \text{ and } |\alpha| < r \}$$

and the auxiliary quantities

$$E(Q, C_d^r, \delta) = \sup_{f \in C_d^r(Q, \delta)} \| f \|_{\infty} \quad \text{and} \quad E(Q, C_d^r) = \lim_{\delta \downarrow 0} E(Q, C_d^r, \delta)$$

and obtain the following.

**Lemma 2.** Let $d \in \mathbb{N}$, $r \in \mathbb{N}$ and $n \in \mathbb{N}_0$. If the cardinality of $Q \subset [0,1]^d$ is at most $n/(d+1)^{r-1}$, then

$$e^{\text{app}}(n, C_d^r) \leq E(Q, C_d^r).$$

**Proof.** Let $\delta \in (0,1)$. We will construct a point set $P \subset [0,1]^d$ with cardinality at most $n$ such that any $f \in C_d^r$ with $f|_P = 0$ is contained in $C_d^r(Q, \delta)$. Then Lemma 1
yields
\[ e^{\text{app}} (n, C_d^r) \leq \sup_{f \in C_d^r} \|f\|_{\infty} \leq \sup_{f \in C_d^r(Q, \delta)} \|f\|_{\infty} = E(Q, C_d^r, \delta). \]

Letting \( \delta \) tend to zero yields the statement.

If \( r = 1 \), we can choose \( P = Q \). Let us start with the case \( r = 2 \). Given a set \( M \subseteq [0,1]^d \) and \( h \in (0,1/2] \), we define
\[ M[h] = M \cup \bigcup_{(x,j) \in M \times \{1, \ldots, d\}} \{x + he_j\} \cup \bigcup_{(x,j) \in M \times \{1, \ldots, d\}} \{x - he_j\}. \]

Obviously, the cardinality of \( M[h] \) is at most \((d + 1) |M|\). Furthermore, we have
\[ f \in C_d^2 \text{ with } |f| \leq h^2 \text{ on } M[h] \quad \Rightarrow \quad \left| \frac{\partial f}{\partial x_j} \right| \leq 3h \text{ on } M \text{ for } j = 1 \ldots d. \quad (3) \]

This is a simple consequence of the mean value theorem: For any \( j \in \{1 \ldots d\} \) and \( x \in M \) with \( x + he_j \in [0,1]^d \) there is some \( \eta \in (0,h) \) with
\[ \left| \frac{\partial f}{\partial x_j} (x + he_j) \right| = \left| \frac{f(x + he_j) - f(x)}{h} \right| \leq 2h. \]

The same estimate holds for some \( \eta \in (-h,0) \), if \( x + he_j \notin [0,1]^d \). The fundamental theorem of calculus yields
\[ \left| \frac{\partial f}{\partial x_j} (x) \right| \leq \left| \frac{\partial f}{\partial x_j} (x + \eta e_j) \right| + |\eta| \cdot \max_{|t| \leq \eta} \left| \frac{\partial^2 f}{\partial x^2_j} (x + te_j) \right| \leq 3h. \]

This means that we can choose \( P = Q[\delta/3] \).

For \( r > 2 \) we repeat this procedure \( r - 1 \) times. We use the notation
\[ M[h_1, \ldots, h_i] = M[h_1, \ldots, h_{i-1}] [h_i] \]
for \( i > 1 \). We choose the point set
\[ P = Q[h_1, \ldots, h_{r-1}], \quad \text{where} \quad h_i = 3(\delta/9)^{2^{i-1}} \]
for \( i = 1 \ldots r - 1 \). Note that \( 3h_i = h_{i-1}^2 \) for each \( i \geq 2 \). Clearly, the cardinality of \( P \) is at most \((d + 1)^{r-1} |Q| \) and hence bounded by \( n \). Let \( f \in C_d^r \) vanish on \( P \) and let \( \frac{\partial^\ell f}{\partial x_{j_1} \ldots \partial x_{j_\ell}} \) be any derivative of order \( \ell < r \). Fact (3) yields:
\[ f \in C^r_d \quad \text{with} \quad |f| = 0 \leq h^{2}_{r-1} \quad \text{on} \quad Q[h_1, \ldots, h_{r-1}] \]
\[ \Rightarrow \frac{\partial f}{\partial x_{j_1}} \in C^{r-1}_d \quad \text{with} \quad \left| \frac{\partial f}{\partial x_{j_1}} \right| \leq 3h_{r-1} = h^2_{r-2} \quad \text{on} \quad Q[h_1, \ldots, h_{r-2}] \]
\[ \Rightarrow \frac{\partial^2 f}{\partial x_{j_1} \partial x_{j_2}} \in C^{r-2}_d \quad \text{with} \quad \left| \frac{\partial^2 f}{\partial x_{j_1} \partial x_{j_2}} \right| \leq 3h_{r-2} \quad \text{on} \quad Q[h_1, \ldots, h_{r-3}] \]
\[ \Rightarrow \quad \vdots \]
\[ \Rightarrow \frac{\partial^\ell f}{\partial x_{j_1} \ldots \partial x_{j_\ell}} \in C^{r-\ell}_d \quad \text{with} \quad \left| \frac{\partial^\ell f}{\partial x_{j_1} \ldots \partial x_{j_\ell}} \right| \leq 3h_{r-\ell} \quad \text{on} \quad Q[h_1, \ldots, h_{r-\ell-1}] \].

Since \( Q \) is contained in \( Q[h_1, \ldots, h_{r-\ell-1}] \) and \( 3h_{r-\ell} \leq \delta^{2\ell-1} \), the lemma is proven. \( \square \)

We can prove the desired upper bounds on \( e(n, C^r_d) \) by choosing \( Q \) as a regular grid. We set
\[ Q^d_m = \{0, 1/m, 2/m, \ldots, 1\}^d \]
for \( m \in \mathbb{N} \). The following recursive formula is crucial.

**Lemma 3.** Let \( m \in \mathbb{N}, \quad d \geq 2 \quad \text{and} \quad r \geq 2 \). Then
\[ E(Q^d_m, C^r_d) \leq E(Q^{d-1}_m, C^{r-1}_d) + \frac{1}{8m^2} E(Q^{d-2}_m, C^{r-2}_d). \]

**Proof.** We will prove for any \( \delta > 0 \) that
\[ E(Q^d_m, C^r_d, \delta) \leq E(Q^{d-1}_m, C^{r-1}_d, \delta) + \frac{1}{8m^2} E(Q^{d-2}_m, C^{r-2}_d, \delta). \quad (4) \]

Letting \( \delta \) tend to zero yields the statement.

Let \( f \in C^r_d(Q^d_m, \delta) \). We need to show that \( \|f\|_\infty \) is bounded by the right hand side of \( \text{(4)} \). Since \( f \) is continuous, there is some \( z \in [0, 1]^d \) such that \( |f(z)| = \|f\|_\infty \).

We distinguish two cases.

If \( z_d \in \{0, 1\} \), the restriction \( f|_H \) of \( f \) to the hyperplane
\[ H = \{x \in [0, 1]^d \mid x_d = z_d\} \]
is contained in \( C^r_{d-1}(Q^{d-1}_m, \delta) \). This implies that
\[ |f(z)| = \|f|_H\|_\infty \leq E(Q^{d-1}_m, C^{r-1}_{d-1}, \delta) \]
and the statement is proven.

Let us now assume that \( z_d \in (0, 1) \). Then we have \( \frac{\partial f}{\partial x_d}(z) = 0 \). We choose \( y \in [0, 1]^d \) such that \( y_j = z_j \) for \( j < d \) and \( y_d \in Q_m \) with \( |y_d - z_d| \leq 1/(2m) \). The restriction \( f|_{H_0} \) of \( f \) to the hyperplane

\[
H_0 = \{ x \in [0, 1]^d \mid x_d = y_d \}
\]

is contained in \( C^{r-1}_{d-1}(Q_m^d, \delta) \). This implies that

\[
|f(y)| = \|f|_{H_0}\|_\infty \leq E(Q_m^d, C^{r-1}_{d-1}, \delta).
\]

Moreover, the second derivative \( \frac{\partial^2 f}{\partial x_d^2} \) is contained in \( C^{r-2}_d(Q_m^d, \delta) \) and hence

\[
\left\| \frac{\partial^2 f}{\partial x_d^2} \right\|_\infty \leq E(Q_m^d, C^{r-2}_d, \delta).
\]

By Taylor’s theorem, there is some \( \xi \) on the line segment between \( y \) and \( z \) such that

\[
f(y) = f(z) + \frac{1}{2} \frac{\partial^2 f}{\partial x_d^2}(\xi) \cdot (y_d - z_d)^2.
\]

We obtain

\[
|f(z)| \leq |f(y)| + \frac{(y_d - z_d)^2}{2} \cdot \left\| \frac{\partial^2 f}{\partial x_d^2} \right\|_\infty
\]

\[
\leq E(Q_m^{d-1}, C^{r}_{d-1}, \delta) + \frac{1}{8m^2} \cdot E(Q_m^d, C^{r-2}_d, \delta),
\]

as it was to be proven. \( \Box \)

By a double induction on \( r \) and \( d \) we obtain the following result for even \( r \).

**Lemma 4.** Let \( d \in \mathbb{N}, m \in \mathbb{N} \) and \( r \in \mathbb{N}_0 \) be even. Then

\[
E(Q_m^d, C^{r}_d) \leq \frac{ed^{r/2}}{(2m)^r}.
\]

**Proof.** We give a proof by induction on \( d \). Let \( \delta > 0 \) and \( f \in C^{r}_d(Q_m, \delta) \) for some even number \( r \). Since \( f \) is continuous, there is some \( z \in [0, 1] \) such that \( |f(z)| = \|f\|_\infty \). Let \( y \in Q_m \) with \( |y - z| < 1/(2m) \). By Taylor’s theorem, there is
some $\xi$ between $y$ and $z$ such that

$$f(z) = \sum_{k=0}^{r-1} \frac{f^{(k)}(y)}{k!} (z - y)^k + \frac{f^{(r)}(\xi)}{r!} (z - y)^r.$$  

Using that $|f^{(k)}(y)| \leq \delta^{r-k-1} \leq \delta^{r-k}$, we obtain for $\delta \leq 1/(2m)$ that

$$\|f\|_\infty \leq \sum_{k=0}^{r} \frac{\delta^{r-k}}{k!} \left(\frac{1}{2m}\right)^k \leq \left(\frac{1}{2m}\right)^r \sum_{k=0}^{r} \frac{1}{k!} \leq \frac{e}{(2m)^r}.$$  

Since this is true for any such $f$ and any $\delta \leq 1/(2m)$, this proves the case $d = 1$.

Let now $d \geq 2$. We assume that the statement holds for every dimension smaller than $d$. To show that it also holds in dimension $d$, we use induction on $r$. For $r = 0$ the statement is trivial since $E(Q^d_{m, C^0_d}) = 1$. Let $r \geq 2$ be even and assume that the statement holds in dimension $d$ for any even smoothness smaller than $r$.

Lemma 3 yields

$$E(Q^d_{m, C^r_d}) \leq \frac{ed^{r/2}}{(2m)^r} \left(1 - \frac{1}{d}\right)^{r/2} + \frac{1}{(2m)^r} \leq \frac{e^r}{8m^2} \leq \varepsilon,$$

which completes the inner and therefore the outer induction.

This immediately yields the upper bound of Theorem 1.

Proof of Theorem 1 (Upper Bound). Let $d \in \mathbb{N}$, $r \in \mathbb{N}$ be even and $\varepsilon > 0$. We set

$$n = (d+1)^{r-1}(m+1)^d,$$

where $m = \left\lfloor \frac{e^{1/r}}{2} \sqrt{d} \varepsilon^{-1/d} \right\rfloor$.

Lemmas 2 and 4 yield

$$e^{\text{app}}(n, C^r_d) \leq E(Q^d_{m, C^r_d}) \leq \frac{ed^{r/2}}{(2m)^r} \leq \varepsilon.$$

Hence,

$$n^{\text{app}}(\varepsilon, C^r_d) \leq n$$

and this implies the result.

To derive the upper bounds for odd $r$, we use the following recursive formula.
Lemma 5. Let $m \in \mathbb{N}$, $d \in \mathbb{N}$ and $r \in \mathbb{N}$. Then
\[
E \left( Q^d_m, C^r_d \right) \leq \frac{d}{2m} E \left( Q^d_m, C^{r-1}_d \right).
\]

Proof. It suffices to show for any $\delta > 0$ that
\[
E \left( Q^d_m, C^r_d, \delta \right) \leq \delta^{2^{r-1}} + \frac{d}{2m} E \left( Q^d_m, C^{r-1}_d, \delta \right).
\]

Letting $\delta$ tend to zero yields the statement. Let $f \in C^r_d \left( Q^d_m, \delta \right)$ and let $z \in [0, 1]^d$ such that $|f(z)| = \|f\|_\infty$. There is some $y \in Q^d_m$ such that $y$ and $z$ are connected by an axis-parallel polygonal chain of length at most $d/(2m)$. For every $j \in \{1, \ldots, d\}$, the partial derivative $\frac{\partial f}{\partial x_j}$ is contained in $C^{r-1}_d \left( Q^d_m, \delta \right)$. Integrating along the curve yields
\[
|f(z)| \leq |f(y)| + \frac{d}{2m} \max_{j=1}^d \left\| \frac{\partial f}{\partial x_j} \right\|_\infty \leq \delta^{2^{r-1}} + \frac{d}{2m} E \left( Q^d_m, C^{r-1}_d, \delta \right).
\]

This proves the lemma.

Now, the upper bounds of Theorem 2 follow from the results for even $r$. Note that the upper bound for $r = 1$ is included.

Proof of Theorem 2 (Upper Bound). Let $d \in \mathbb{N}$, $r \in \mathbb{N}$ be odd and $\varepsilon > 0$. For any $m \in \mathbb{N}$, Lemma 4 and 5 yield
\[
E \left( Q^d_m, C^r_d \right) \leq \frac{e^{d(r+1)/2}}{(2m)^r}.
\]

We set
\[
n = (d+1)^{r-1}(m+1)^d, \quad \text{where} \quad m = \left\lfloor \frac{e^{1/r}}{2d^{r+1} \varepsilon^{-1/r}} \right\rfloor.
\]

We obtain
\[
e^{\text{app}}(n, C^r_d) \leq E \left( Q^d_m, C^r_d \right) \leq \varepsilon
\]
and hence
\[
n^{\text{app}}(\varepsilon, C^r_d) \leq n.
\]

We proceed similarly to prove of the upper bound of Theorem 3 For any $\delta > 0$,
any \( r \in \mathbb{N}_0, \ d \in \mathbb{N} \) and \( Q \subset [0,1]^d \), we define the subclasses

\[
\widetilde{C}^r_d(Q, \delta) = \left\{ f \in \widetilde{C}^r_d \mid |\partial_{\theta_1} \cdots \partial_{\theta_r} f(x)| \leq \delta^{2^r - 1} \text{ for } x \in Q, \ l < r, \ \theta_1 \ldots \theta_r \in S_{d-1} \right\}
\]

and the auxiliary quantities

\[
E \left( Q, \widetilde{C}^r_d, \delta \right) = \sup_{f \in \widetilde{C}^r_d(Q, \delta)} \| f \|_\infty \quad \text{and} \quad E \left( Q, \widetilde{C}^r_d \right) = \lim_{\delta \downarrow 0} E \left( Q, \widetilde{C}^r_d, \delta \right)
\]

and obtain the following.

**Lemma 6.** Let \( d, r \in \mathbb{N} \) and \( n \in \mathbb{N}_0 \). If the cardinality of \( Q \subset [0,1]^d \) is at most \( n/(d + 1)^{r-1} \), then

\[
e^{\text{app}} \left( n, \tilde{C}^r_d \right) \leq E \left( Q, \tilde{C}^r_d \right).
\]

**Proof.** Let \( \delta \in (0,1) \). In the proof of Lemma 2 we constructed a point set \( P \) with cardinality at most \( n \) such that any \( f \in C^r_d \) with \( f|_P = 0 \) is contained in \( C^r_d(Q, \delta) \). In particular, any \( f \in \tilde{C}_d \) with \( f|_P = 0 \) satisfies \( |D^\alpha f(x)| \leq \delta^{2^{\alpha_{r-1}}} \) for all \( x \in Q \) and \( |\alpha| < r \). Taking into account that for \( x \in [0,1]^d, \ l < r \) and \( \theta_1 \ldots \theta_r \in S_{d-1} \) we have

\[
|\partial_{\theta_1} \cdots \partial_{\theta_r} f(x)| \leq d^{l/2} \max_{|\alpha| = \ell} |D^\alpha f(x)|,
\]

we obtain that \( f \in \tilde{C}^r_d(Q, d^{l/2}) \) and hence

\[
e^{\text{app}} \left( n, \tilde{C}^r_d \right) \leq \sup_{f \in \tilde{C}^r_d, f|_P = 0} \| f \|_\infty \leq \sup_{f \in \tilde{C}^r_d(Q, d^{(r-1)/2} \delta)} \| f \|_\infty = E \left( Q, \tilde{C}^r_d, d^{r-1} \delta \right).
\]

Letting \( \delta \) tend to zero yields the statement. \( \square \)

For these classes, it is enough to consider the following single-step recursion.

**Lemma 7.** Let \( m \in \mathbb{N}, \ d \in \mathbb{N} \) and \( r \in \mathbb{N} \). Then

\[
E \left( Q^d_m, \tilde{C}^r_d \right) \leq \frac{\sqrt{d}}{2m} E \left( Q^d_m, \tilde{C}^{r-1}_d \right).
\]

**Proof.** It suffices to show for any \( \delta > 0 \) that

\[
E \left( Q^d_m, \tilde{C}^r_d, \delta \right) \leq \delta^{2^{r-1}} + \frac{\sqrt{d}}{2m} E \left( Q^d_m, \tilde{C}^{r-1}_d, \delta \right).
\]

To this end, let \( f \in \tilde{C}^r_d(Q^d_m, \delta) \) and let \( z \in [0,1]^d \) such that \( |f(z)| = \| f \|_\infty \). There is some \( y \in Q^d_m \) such that \( y \) and \( z \) are connected by a line segment of length at
most $\sqrt{d}/(2m)$. The directional derivative $\partial_\theta f$ with $\theta = \frac{z-y}{\|z-y\|_2}$ is contained in $\tilde{C}_d^{r-1} (Q_m^d, \delta)$. Integrating along the line yields

$$|f(z)| \leq |f(y)| + \frac{\sqrt{d}}{2m} \|\partial_\theta f\|_\infty \leq \delta^{3r-1} + \frac{\sqrt{d}}{2m} E\left(Q_m^d, \tilde{C}_d^{r-1}, \delta\right).$$

Letting $\delta$ tend to zero yields the statement.

The upper bound of Theorem 3 can now be proven by induction on $r$.

Proof of Theorem 3 (Upper Bound). Lemma 4 and $E(Q_m^d, \tilde{C}_d^0) = 1$ yield

$$E\left(Q_m^d, \tilde{C}_d^r\right) \leq \left(\frac{\sqrt{d}}{2m}\right)^r$$

for any $m \in \mathbb{N}$, $d \in \mathbb{N}$ and $r \in \mathbb{N}_0$. Let now $d \in \mathbb{N}$, $r \in \mathbb{N}$ and $\varepsilon > 0$. We set

$$n = (d+1)^{r-1}(m+1)^d, \quad \text{where} \quad m = \left\lceil \frac{1}{2} \sqrt{d\varepsilon^{-1/r}} \right\rceil.$$

Lemma 6 yields

$$e_{\text{app}}(n, \tilde{C}_d^r) \leq E\left(Q_m^d, \tilde{C}_d^r\right) \leq \varepsilon$$

and hence

$$n_{\text{app}}(\varepsilon, \tilde{C}_d^r) \leq n.$$

\[\square\]

4 Lower bounds

By Lemma 1 we can estimate $e(n, \tilde{C}_d^r)$ from below as follows. For any point set $P$ with cardinality at most $n$, we construct a function $f \in \tilde{C}_d^r$ that vanishes on $P$ but has a large maximum in $[0,1]^d$, a so called fooling function. We will use the following lemma. Note that

$$\|f\|_{r,d} = \sup_{\ell \leq r, \theta \in S_{d-1}} \|\partial_{\theta_1} \cdots \partial_{\theta_\ell} f\|_\infty$$

defines a norm on the space of smooth functions $f : \mathbb{R}^d \to \mathbb{R}$ with compact support.
Lemma 8. There exists a sequence \((g_d)_{d \in \mathbb{N}}\) of smooth functions \(g_d : \mathbb{R}^d \to \mathbb{R}\) with compact support in the unit ball that satisfy \(g_d(0) = 1\) and

\[
\sup_{d \in \mathbb{N}} \|g_d\|_{r,d} < \infty \quad \text{for all} \quad r \in \mathbb{N}_0.
\]

Proof. Take any function \(h \in C^\infty(\mathbb{R})\) which equals one on \((-\infty, 0]\) and zero on \([1, \infty)\). Then the radial functions

\[
g_d : \mathbb{R}^d \to \mathbb{R}, \quad g_d(x) = h(\|x\|_2^2)
\]

for \(d \in \mathbb{N}\) have the desired properties. This follows from the fact that the directional derivative \(\partial_{\theta_1} \cdots \partial_{\theta_r} g_d(x)\) only depends on the length of \(x\) and the angles between each pair of vectors \(\theta_1, \ldots, \theta_r \in S_{d-1}\) and \(x \in \mathbb{R}^d\). As soon as \(d\) is large enough to enable all constellations of lengths and angles, the norm \(\|g_d\|_{r,d}\) is independent of \(d\). \(\square\)

To obtain a suitable fooling function for a given point set \(P\), it is enough to shrink and shift the support of \(g_d\) to the largest euclidean ball that does not intersect with \(P\). The radius of this ball can be estimated by a simple volume argument.

Lemma 9. Let \(d \in \mathbb{N}\) and \(P \subset [0,1]^d\) with cardinality \(n \in \mathbb{N}\). Then there exists a point \(z \in [0,1]^d\) with

\[
\text{dist}_2 (z, P) \geq \frac{\sqrt{d}}{5n^{1/d}}.
\]

Proof. The set

\[
B_R(P) = \bigcup_{p \in P} B_R(p)
\]

of points within a distance \(R > 0\) of \(P\) has the volume

\[
\text{vol}_d (B_R(P)) \leq n R^d \text{vol}_d (B_1(0)) = \frac{n R^d \pi^{d/2}}{\Gamma \left( \frac{d}{2} + 1 \right)}.
\]

By Stirling’s Formula, this can be estimated from above by

\[
\text{vol}_d (B_R(P)) \leq \frac{n R^d \pi^{d/2}}{\sqrt{2\pi} \left( \frac{d}{2e} \right)^{d/2}} \leq \left( \frac{n^{1/4} e^{3/2}}{\sqrt{d}} R \right)^d.
\]

If \(R = \frac{\sqrt{d}}{5n^{1/d}}\), the volume is less than one and \([0,1]^d \setminus B_R(P)\) must be nonempty. \(\square\)

We are ready to prove the lower bound of Theorem 3.
**Proof of Theorem 3 (Lower Bound).** Let \( r \in \mathbb{N}, d \in \mathbb{N} \) and \( n \in \mathbb{N} \). Let \( P \) be any subset of \([0,1]^d\) with cardinality at most \( n \). Let \( g_d \) be like in Lemma 8 and set
\[
K_r = \sup_{d \in \mathbb{N}} \|g_d\|_{r,d} \quad \text{and} \quad R = \min \left\{ 1, \frac{\sqrt{d}}{5n^{1/d}} \right\}.
\]
By Lemma 9 there is a point \( z \in [0,1]^d \) such that \( B_R(z) \) does not contain any element of \( P \). Hence, the function
\[
f^* : [0,1]^d \to \mathbb{R}, \quad f^*(x) = \frac{R^r}{K_r} g_d \left( \frac{x - z}{R} \right)
\]
is an element of \( \tilde{C}_d \) and vanishes on \( P \). We obtain
\[
\sup_{f \in \tilde{C}_d} \|f\|_{\infty} \geq \|f^*\|_{\infty} \geq f^*(z) = \frac{R^r}{K_r} = \min \left\{ \frac{1}{K_r}, \frac{d^{r/2}}{5^r K_r n^{r/d}} \right\}.
\]
Since this is true for any such \( P \), Lemma 1 yields
\[
e_{\text{app}}(n, \tilde{C}_d) \geq \min \left\{ \frac{1}{K_r}, \frac{d^{r/2}}{5^r K_r n^{r/d}} \right\}.
\]
We set \( \varepsilon_r = 1/K_r \). Given \( \varepsilon \in (0, \varepsilon_r) \), the right hand side in (5) is larger than \( \varepsilon \) for any \( n \) smaller than \( d^{d/2}/(5^r K_r d^{r/2} \varepsilon^{d/r}) \). This yields
\[
n_{\text{app}}(\varepsilon, \tilde{C}_d) \geq \left( (5^r K_r)^{-1/r} \sqrt{d} \varepsilon^{-1/r} \right)^d
\]
as it was to be proven.

In the same way, we obtain lower bounds for the case that the domains \([0,1]^d\) are replaced by other domains \( D_d \subset \mathbb{R}^d \) that satisfy \( \text{vol}_d(D_d) \geq a^d \) for some \( a > 0 \) and all \( d \in \mathbb{N} \). We simply have to multiply the radii in the previous proofs by \( a \).

We now turn to the lower bounds of Theorem 1 and 2.

**Proof of Theorem 1 and 2 (Lower Bounds).** Note that \( C_d \) contains \( \tilde{C}_d \) and hence
\[
n_{\text{app}}(\varepsilon, C_d) \geq n_{\text{app}}(\varepsilon, \tilde{C}_d).
\]
Furthermore, any \( \varepsilon \)-approximation of a function on \([0,1]^d\) immediately yields an
$\varepsilon$-approximation of its integral and hence

$$n^{\text{app}} (\varepsilon, C^r_d) \geq n^{\text{int}} (\varepsilon, C^r_d).$$

With these relations at hand, the desired lower bounds for $r \geq 2$ immediately follow from Theorem\ref{thm:complexity}. The lower bound for $r = 1$ follows from the complexity of numerical integration as studied by Hinrichs, Novak, Ullrich and Woźniakowski \cite{hinrichs2017product}.

Acknowledgements. I wish to thank Erich Novak for many fruitful discussions in the context of this paper.
