Data-Driven Chance Constrained Optimization under Wasserstein Ambiguity Sets

Ashish R. Hota, Ashish Cherukuri and John Lygeros

Abstract—We present a data-driven approach for distributionally robust chance constrained optimization problems (DRCCPs). We consider the case where the decision maker has access to a finite number of samples or realizations of the uncertainty. The chance constraint is then required to hold for all distributions that are close to the empirical distribution constructed from the samples (where the distance between two distributions is defined via the Wasserstein metric). We first reformulate DRCCPs under data-driven Wasserstein ambiguity sets and a general class of constraint functions. When the feasibility set of the chance constraint program is replaced by its convex inner approximation, we present a convex reformulation of the program and show its tractability when the constraint function is affine in uncertainty. For constraint functions concave in uncertainty, we show that a primal-dual algorithm converges to the optimal value of the constraint program. For constraint functions convex in uncertainty, we compare its feasibility set with other sample-based approaches for chance constrained programs.

I. INTRODUCTION

Numerous engineering applications encounter optimization problems with constraints dependent on uncertain parameters; examples include designing controllers for uncertain stochastic systems [11] and computing the optimal power flow with uncertain renewable energy generation [2]. Solution methodologies for such optimization problems fall broadly into two categories. In robust optimization, the aim is to take a decision that is feasible for all realizations of the uncertainty, that is, satisfying the constraints robustly [3]. This approach often yields conservative solutions with regard to the optimal value and requires the support of the uncertainty to be bounded and known to the decision maker. In contrast, a chance constrained program (CCP) has soft probabilistic constraints on the decision variable in place of the hard ones present in a robust optimization [4]. Specifically, the aim is to compute a solution that satisfies the constraint for most realizations of uncertainty, or more formally, the constraint is satisfied with high probability. CCPs are increasingly considered to be an appropriate modeling framework in many applications, such as, stochastic model predictive control [5], robotics [7], energy systems [9], [10] and autonomous driving [11].

In order to solve a CCP, the decision maker needs to know the distribution of the uncertain parameters. In practice however, this information is unavailable and instead, the decision maker has access to the uncertainty in the form of samples. Scenario [12], [13], [14] and sample approximation [15] approaches use this data to solve the CCP.

In the scenario approach, the constraint involving uncertainty is required to hold for every available sample, while in the sample approximation approach, it is required to hold for a large fraction of samples. Their main advantage is that if the samples are indeed drawn from a true underlying distribution and the number of samples is sufficiently large, the solutions are feasible to the original CCP with high probability. However, often in practice, samples may be few and not be drawn from the true distribution. In such a situation, it is desirable to find a solution to the CCP that is robust with respect to a family of distributions, termed as an ambiguity set. Specifically, the solution should satisfy the chance constraint for all distributions that belong to the ambiguity set. This class of problems is known as distributionally robust chance constrained programs (DRCCPs) and is the focus of this paper.

In distributionally robust stochastic optimization (DRSO) in general and DRCCPs in particular, the ambiguity set is defined either as a set of probability distributions that satisfy certain moment constraints [16], [18], [19], [20] or that are close under an appropriate distance function. In the context of distance based ambiguity sets, [21] considers ambiguity sets defined via the Prokhorov metric, while [22] considers an ambiguity set defined by \( \phi \)-divergence. Recent work in DRSO has shown that ambiguity sets based on Wasserstein distance [23] have desirable out-of-sample performance and asymptotic guarantees [24], [25]. Furthermore, Wasserstein ambiguity sets capture many relevant distributions that are not necessarily captured in \( \phi \)-divergence based ambiguity sets [24].

Motivated by these attractive features, we consider a data-driven approach for DRCCPs where the ambiguity set is defined as the set of distributions that are close (in the Wasserstein distance) to the empirical distribution induced by the observed samples (see Section II for a formal definition).

The literature on DRCCPs with Wasserstein ambiguity sets is limited. The authors in [27] first showed that it is strongly NP-Hard to solve a DRCCP with Wasserstein ambiguity sets and proposed a bi-criteria approximation scheme for covering constraints. While preparing this paper, we became aware of two recent working papers that presented reformulations and approximations of DRCCPs under Wasserstein ambiguity sets [28], [29] and for constraint functions that are affine in both the decision variable and uncertainty. Both [28], [29] show that

1DRCCPs with moment based ambiguity sets have recently been considered for designing controllers for stochastic systems [16] and to solve optimal power flow problems with uncertain renewable energy generation [17].

2DRSO with Wasserstein ambiguity sets were recently applied in optimal power flow problems [10] and uncertain Markov decision processes [20].
the exact feasibility set of DRCCPs with affine constraints can be reformulated as mixed integer conic programs.3

In contrast, the goal of this paper is to lay the foundations for tractable computation of (approximate) solutions of DRCCPs under data-driven Wasserstein ambiguity sets for a broad class of constraint functions.

Summary of Contributions

We first reformulate DRCCPs under Wasserstein ambiguity sets under general continuity and boundedness assumptions on the constraint functions (as opposed to the affine case considered in [28, 29]) in Section III. We then focus on developing tractable reformulations and algorithms for DRCCPs. Since the feasibility set of (DR)CCPs is nonconvex except for restrictive special cases [30], we henceforth consider constraint functions that are convex in the decision variable, and replace the exact feasibility set of the DRCCP with its convex conditional value-at-risk (CVaR) approximation following [31].

In Section IV we reformulate the CVaR approximation of DRCCPs as a convex optimization problem. We then present a tractable reformulation of the CVaR approximation when the constraint is a piecewise maximum of functions affine in the uncertainty, and the support of the uncertainty is a polyhedron. Our result generalizes those in [28, 29] obtained affine constraint functions and unbounded support ($\mathbb{R}^m$). When the constraint is concave in uncertainty, we develop a primal-dual or saddle point algorithm, and prove its convergence to the optimal value of the CVaR approximation of the DRCCP. When the constraint function is convex in uncertainty, we compare the feasibility set of the CVaR approximation with the those of the sample approximation approach [15] and the scenario approach [12, 13] in Section VI.

Notation

The set of real, positive real, non-negative real, and natural numbers are denoted by $\mathbb{R}$, $\mathbb{R}_{>0}$, $\mathbb{R}_{\geq 0}$, and $\mathbb{N}$, respectively. For $N \in \mathbb{N}$, we let $[N] := \{1, 2, \ldots, N\}$. The closure of a set $S$ is represented by $\overline{S}$. Feasibility sets constructed using data are denoted by $\overline{\cdot}$. For a set $S$ and any $N \in \mathbb{N}$, we denote the $N$-fold cartesian product as $S^N := \Pi_{n=1}^N S$. Similar notation holds for the $N$-fold product of any probability distribution. For brevity, we denote max$(x, 0)$ by $x_+$.

II. TECHNICAL PRELIMINARIES

Here we collect preliminary notions and results on chance constrained programs, conditional value-at-risk, Wasserstein ambiguity sets, and stochastic min-max equality.

3Specifically, Xie [28] studies individual chance constraints and joint chance constraints with right hand side uncertainty, while Chen et. al., [29] consider general affine joint chance constraints. Both papers appeared subsequent to the appearance of a preliminary version of our work.

A. Chance Constrained Programs and CVaR Approximation

Let $\Xi$ be a complete separable metric space with metric $d$. Let $B(\Xi)$ and $P(\Xi)$ be the Borel $\sigma$-algebra and the set of Borel probability measures on $\Xi$, respectively. A canonical chance constrained program (CCP) is of the form

$$\min_{x \in X} \ c^T x \quad \text{s.t.} \quad P(F(x, \xi) \leq 0) \geq 1 - \alpha,$$

where $X \subseteq \mathbb{R}^n$ is a closed convex set, $c \in \mathbb{R}^n$, $\alpha \in (0, 1)$, $P \in P(\Xi)$, and $F : \mathbb{R}^n \times \Xi \rightarrow \mathbb{R}$. Solving a CCP is difficult as the feasibility set can be nonconvex for certain types of distributions even when $X$ is convex and $F$ is convex in $x$ for every $\xi$ [30]. Several convex approximations exist that overcome this intractability. Next we describe the approximation framework developed in [31] that plays a central role in our results. Consider a function $\psi : \mathbb{R} \rightarrow \mathbb{R}$ that is nonnegative, nondecreasing, and convex satisfying $\psi(t) > \psi(0) = 1$ for all $t > 0$. Such a function is referred to as a moment generating function. For a given probability distribution $P \in P(\Xi)$ for the random variable $\xi$, define $\Psi_P : \mathbb{R}^n \times \mathbb{R} \rightarrow \mathbb{R}$ as

$$\Psi_P(x, t) := tE_P[\psi(t^{-1}F(x, \xi))].$$

Note that if $x \mapsto F(x, \xi)$ is convex for every $\xi \in \Xi$, then $\Psi_P$ is convex in $x$ and $t$. Furthermore, we have

$$\inf_{t>0} [\Psi_P(x, t) - t\alpha] \leq 0 \implies P(F(x, \xi) \leq 0) \geq 1 - \alpha.$$

Therefore, replacing the chance constraint by $\inf_{t>0} [\Psi_P(x, t) - t\alpha] \leq 0$ gives a convex conservative approximation of the CCP (1).

In this paper, we specifically consider the generating function $\psi^C(z) := (z + 1)_+ = \max(z + 1, 0)$. The convex conservative approximation under $\psi^C$ is equivalent to replacing the probabilistic constraint with its conditional value-at-risk. Note that the CVaR of a random variable $Z$ with distribution $P$ at level $\alpha$ is formally defined (in [32]) as

$$\text{CVaR}_P^{(\alpha)}(Z) := \inf_{t \in \mathbb{R}} [\alpha^{-1} E_P[(Z + t)_+] - t].$$

Observe now that for $\psi^C(z) := (z + 1)_+$, the left-hand side of (5) satisfies

$$\inf_{t>0} [\Psi^C_P(x, t) - t\alpha] \leq 0 \iff \inf_{t \in \mathbb{R}} [E_P[F(x, \xi) + t]_+] - t\alpha] \leq 0 \iff \text{CVaR}_P^{\alpha}(F(x, \xi)) \leq 0.$$
B. Data-driven Stochastic Optimization

We now introduce data-driven Wasserstein ambiguity sets. Let \( P_p(\Xi) \subseteq P(\Xi) \) be the set of Borel probability measures with finite \( p \)-th moment for \( p \in [1, \infty) \), that is,

\[
P_p(\Xi) := \{ \mu \in P(\Xi) \mid \int_{\Xi} d^p(\xi) \mu(d\xi) < \infty \},
\]

for some \( \omega \in \Xi \). Recall that \( d \) is the metric on \( \Xi \). Following [23], we define Wasserstein distance between two probability measures below.

**Definition II.1.** [23] For \( p \in [1, \infty) \), the \( p \)-Wasserstein distance between two probability measures \( \mu, \nu \in P_p(\Xi) \) is

\[
(W_p(\mu, \nu))^p := \min_{\gamma \in \mathcal{H}(\mu, \nu)} \left\{ \int_{\Xi \times \Xi} d^p(\xi, \omega) \gamma(d\xi, d\omega) \right\},
\]

where \( \mathcal{H}(\mu, \nu) \) is the set of all distributions on \( \Xi \times \Xi \) with marginals \( \mu \) and \( \nu \).

In particular, the Wasserstein distance captures the closeness of two distributions via the underlying metric on the support \( \Xi \), and is closely connected to optimal transportation problems [23]. The minimum in (6) is attained because \( d \) is lower semicontinuous [24].

In this paper, we define the ambiguity set as the set of all distributions that are close to the empirical distribution induced by the observed samples. Specifically, let \( \hat{P}_N := \frac{1}{N} \sum_{i=1}^N \delta_{\hat{x}_i} \) be the empirical distribution constructed from the observed samples \( \{\hat{x}_i\}_{i \in [N]} \). We define the data-driven Wasserstein ambiguity set as

\[
\mathcal{M}_\theta^0 := \{ \mu \in P_p(\Xi) \mid W_p(\mu, \hat{P}_N) \leq \theta \},
\]

which contains all distributions that are within a distance \( \theta \geq 0 \) of \( \hat{P}_N \). If \( \theta = 0 \), \( \mathcal{M}_\theta^0 \) only contains \( \hat{P}_N \).

We now present a duality theorem for distributionally robust stochastic optimization over Wasserstein ambiguity sets from [24] that is central to proving our reformulations.

Let \( H : \Xi \rightarrow \mathbb{R} \) be an upper semicontinuous function. Assume that if \( \Xi \) is not bounded, then \( H \) satisfies

\[
\limsup_{d(\xi, \xi_0) \rightarrow \infty} \frac{H(\xi) - H(\xi_0)}{d^p(\xi, \xi_0)} < \infty.
\]

Consider the following primal and dual optimization problems

- **Primal**
  \[
  v_p := \sup_{\mu \in P_p(\Xi)} \left\{ \int_{\Xi} H(\xi) \mu(d\xi) \mid W_p(\mu, \hat{P}_N) \leq \theta \right\},
  \]

- **Dual**
  \[
  v_D := \inf_{\lambda \geq 0} \left\{ \lambda^p + \frac{1}{N} \sum_{i=1}^N \sup_{\xi \in \Xi} [H(\xi) - \lambda d^p(\xi, \hat{x}_i)] \right\}.
  \]

The following strong duality theorem is due to [24].

**Theorem II.2.** (Zero-duality gap): The problem [DUAL] always admits a minimizer \( \lambda^* \). Furthermore, \( v_p = v_D < \infty \).

We conclude with the stochastic min-max theorem due to [33] which will be required in proving one of our key results.

**Theorem II.3.** (Stochastic min-max equality): Let \( \mathcal{M} \) be a nonempty (not necessarily convex) set of probability measures on \( (\Xi, \mathcal{B}(\Xi)) \) where \( \Xi \subseteq \mathbb{R}^m \) and \( \mathcal{B}(\Xi) \) is the Borel \( \sigma \)-algebra. Assume that \( \mathcal{M} \) is weakly compact. Let \( T \subseteq \mathbb{R}^n \) be a closed convex set. Consider a function \( g : \mathbb{R}^n \times \Xi \rightarrow \mathbb{R} \). Assume that there exists a convex neighborhood \( V \) of \( T \) such that for all \( t \in V \), the function \( g(t, \cdot) \) is measurable, integrable with respect to all \( \mathcal{P} \in \mathcal{M} \), and \( \sup_{\mathcal{P} \in \mathcal{M}} \mathbb{E}_\mathcal{P}[g(t, \xi)] < \infty \). Further assume that \( g(\cdot, \xi) \) is convex on \( V \) for all \( \xi \in \Xi \). Let \( \xi \in \text{argmin}_{t \in T} \mathbb{E}_{\mathcal{P} \in \mathcal{M}}[g(t, \xi)] \). Assume that for every \( t \) in a neighborhood of \( \xi \), the function \( g(t, \cdot) \) is bounded and upper semicontinuous on \( \Xi \) and the function \( g(t, \cdot) \) is bounded and continuous on \( \Xi \). Then,

\[
\inf_{t \in T} \sup_{\mathcal{P} \in \mathcal{M}} \mathbb{E}_\mathcal{P}[g(t, \xi)] = \inf_{t \in T} \sup_{\mathcal{P} \in \mathcal{M}} \mathbb{E}_\mathcal{P}[g(t, \xi)].
\]

Note that the above theorem requires the ambiguity set to be weakly compact. This is indeed the case for Wasserstein ambiguity sets constructed from data as stated below.

**Proposition II.4** (Corollary 2, [24]). The Wasserstein ambiguity set \( \mathcal{M}_\theta^0 \) is tight and weakly-compact.

We now start by presenting exact reformulations of DRC-CPs with data-driven ambiguity set \( \mathcal{M}_\theta^0 \).

**III. Distributionally Robust Chance Constrained Program and Exact Reformulation**

In this section, we describe our problem of interest: distributionally robust chance constrained program (DRC-CP) with Wasserstein ambiguity sets. Following that, we present two exact reformulations of the DRC-CP that have simpler representations. Let \( \Xi \) be a complete separable metric space with metric \( d \). Let \( \mathcal{B}(\Xi) \) and \( P(\Xi) \) be the Borel \( \sigma \)-algebra and the set of Borel probability measures on \( \Xi \), respectively. A DRC-CP is of the form

\[
\min_{x \in X} c^T x
\]

s.t. \( \mathbb{P}(F(x, \xi) \leq 0) \geq 1 - \alpha, \quad \forall \mathcal{P} \in \mathcal{M} \),

where \( X \subseteq \mathbb{R}^n \) is a closed and convex set that encodes deterministic constraints on the decision variable \( x \), \( c \in \mathbb{R}^n \), \( \alpha \in (0, 1) \), and \( \mathcal{M} \subseteq P(\Xi) \), referred to as the ambiguity set, is a suitably defined family of probability distributions associated with the random variable \( \xi \). Without loss of generality, we assume that the constraint function \( F : \mathbb{R}^n \times \Xi \rightarrow \mathbb{R} \) is continuous in \( x \) for every \( \xi \).

In a DRC-CP, the probabilistic constraint is required to hold for every distribution in the ambiguity set \( \mathcal{M} \). In other words, \( \tilde{x} \in X \) is feasible to (8) if \( F(\tilde{x}, \xi) \leq 0 \) with probability at least \( 1 - \alpha \) for every distribution \( \mathcal{P} \) that lies in \( \mathcal{M} \). The distributionally robust chance constraint can equivalently be written as

\[
\inf_{\mathcal{P} \in \mathcal{M}} \mathbb{P}(F(x, \xi) \leq 0) \geq 1 - \alpha \iff \sup_{\mathcal{P} \in \mathcal{M}} \mathbb{P}(F(x, \xi) > 0) \leq \alpha.
\]

In this work our focus is on ambiguity sets defined using data. Let \( \{\hat{x}_i\}_{i=1}^N \) be a set of \( N \) samples available to the decision maker. Given this data and \( \theta > 0 \), the Wasserstein ambiguity set \( \mathcal{M}_\theta^0 \), defined in (7), is the set of all distributions that are within \( \theta > 0 \) distance to the empirical distribution \( \hat{P}_N \).

*Note that if \( F : \mathbb{R}^n \times \Xi \rightarrow \mathbb{R}^K \), then we can instead define \( F \) as the component-wise maximum of \( K \) constraints.*
The DRCCP defined for Wasserstein ambiguity sets then reads as
\[
\min \{ c^T x : x \in \hat{X}_{\text{DCP}} \}, \quad \text{where} \quad \hat{X}_{\text{DCP}} := \left\{ x \in X \mid \sup_{\xi \in \Xi} \mathbb{P}(F(x, \xi) > 0) \leq \alpha \right\}, \tag{9}
\]

Note that (9) involves optimization over a set of probability distributions. In order to get a handle on this infinite-dimensional optimization problem, in the remainder of the section, we provide exact reformulations of the DRCCP that involve optimization over finite dimensions.

**Assumption III.1.** (Regularity in uncertainty: I): For every \( x \in X \), the following properties are satisfied.
(i) The function \( \xi \mapsto F(x, \xi) \) is continuous on \( \Xi \).
(ii) Either \( \Xi \) is bounded or there exists \( \xi_0 \in \Xi \) such that
\[
\limsup_{d(\xi, \xi_0) \to \infty} \frac{F(x, \xi) - F(x, \xi_0)}{d^p(\xi, \xi_0)} < \infty. \tag{10}
\]
(iii) The set \( \text{cl}\{\xi \in \Xi : F(x, \xi) > 0\} \) is nonempty.

The condition (10) is met if \( F \) is bounded or \( \xi \mapsto F(x, \xi) \) is Lipschitz continuous for every \( x \in X \) with \( p = 1 \). The reformulations presented below were independently shown in [28] under the assumption that \( F \) is affine in \( \xi \) for every \( x \in X \). Here we establish that the results hold more generally.

**Theorem III.2.** (Exact reformulations of DRCCPs): Let Assumption III.1 hold. Then,
\[
\hat{X}_{\text{DCP}} = \left\{ x \in X \mid \exists \lambda \geq 0, \lambda^p + \frac{1}{N} \sum_{i=1}^{N} s_i \leq \alpha, s_i = \max\{1 - \lambda G(x, \hat{\xi}_i), 0\} \right\}, \tag{11}
\]
\[
= \left\{ x \in X \mid \frac{\theta^p}{\alpha} + \text{CVaR}_{\lambda}^\text{p}(-G(x, \xi)) \leq 0 \right\} \tag{12}
\]
where
\[
G(x, \hat{\xi}) = \inf_{\xi \in \hat{\text{cl}}\{\xi : F(x, \xi) > 0\}} d^p(\xi, \hat{\xi}). \tag{13}
\]

**Proof.** We first show that \( \hat{X}_{\text{DCP}} \) defined in (9) is equivalent to the set in the right-hand side of (11). We suppress the argument \( x \) from the functions \( F \) and \( G \) in the following computations as the arguments hold point wise for every \( x \in X \). We evaluate
\[
\sup_{\xi \in \Xi} \mathbb{P}(F(\xi) > 0) = \sup_{\xi \in \Xi} \mathbb{E}[\mathbb{1}_{\text{cl}(\xi : F(\xi) > 0)}] = \inf_{\lambda \geq 0} \lambda^p + \frac{1}{N} \sum_{i=1}^{N} \mathbb{1}_{\text{cl}(\xi : F(\xi) > 0)} - \lambda d^p(\xi, \hat{\xi}_i)), \tag{14}
\]
where the first equality follows from [24, Proposition 4], and the second equality is a consequence of the strong duality theorem (Theorem II.2).\footnote{Recall that Theorem II.2 requires the function within the expectation to be upper semicontinuous. Since the indicator function of an open set is lower semicontinuous, we replace it with its closure. This substitution is valid due to [24 Proposition 4].}

\[
= \max\{ \sup_{\xi \in \Xi} [1 - \lambda d^p(\xi, \hat{\xi}_i)], \sup_{\xi \in \Xi} -\lambda d^p(\xi, \hat{\xi}_i) \}
\]
\[
= \max\{1 - \lambda G(\hat{\xi}_i), \sup_{\xi \in \Xi} -\lambda d^p(\xi, \hat{\xi}_i) \},
\]
where \( G \) is defined in (13). Now, if \( \hat{\xi}_i \in \Xi_2 \), the second term is 0. On the other hand, if \( \xi_i \in \Xi_1, G(\xi_i) = 0 \) and the second term is nonpositive. Therefore, the maximum evaluates to 1. Accordingly, we have
\[
s_i = \max\{1 - \lambda G(\hat{\xi}_i), 0\}.
\]

Thus, \( \hat{X}_{\text{DCP}} \) is equivalently given by (11).

For the second reformulation, let \( \hat{X}_{\text{DCP}} \) denote the set given in (12). We first show that \( \hat{X}_{\text{DCP}} \subseteq \hat{X}_{\text{DCP}} \).

Let \( x \in \hat{X}_{\text{DCP}} \) as stated in (11). Note that we must have \( \lambda > 0 \). Suppose otherwise, and let \( \lambda = 0 \). Then, \( s_i = 1 \) for \( i \in [N] \), and consequently, we have \( \alpha > 1 \); a contradiction. Consequently, we can replace \( \lambda \) in (11) by \( 1 \alpha > 0 \), and obtain
\[
\frac{\theta^p}{\alpha} + \frac{1}{N} \sum_{i=1}^{N} \max\left\{1 - \frac{G(x, \xi_i)}{t}, 0\right\} \leq \alpha \tag{15}
\]
\[
\iff \frac{\theta^p}{\alpha} - t + \frac{1}{\alpha N} \sum_{i=1}^{N} \max\{-G(x, \xi_i) + t, 0\} \leq 0 \tag{16}
\]
\[
\iff \frac{\theta^p}{\alpha} + \text{CVaR}_{\lambda}^\text{p}(-G(x, \xi)) \leq 0
\]
following the definition of conditional value-at-risk [4]; note that we can replace \( t \) with \( -t \) without loss of generality since the infimum in (4) is over \( \mathbb{R} \). As a result, \( x \in \hat{X}_{\text{DCP}} \).

It remains to show \( \hat{X}_{\text{DCP}} \subseteq \hat{X}_{\text{DCP}} \). Let \( x \in \hat{X}_{\text{DCP}} \). Then,
\[
\frac{\theta^p}{\alpha} + \inf_{i \in \mathbb{R}} \left\{t + \frac{1}{\alpha N} \sum_{i=1}^{N} (-G(x, \xi_i) - t)\right\} \leq 0.
\]
From the third property of Assumption III.1, we have \( G(x, \xi_i) < \infty \) for \( i \in [N] \). As a result, we have \( t + \frac{1}{\alpha N} \sum_{i=1}^{N} (-G(x, \xi_i) - t) \to \infty \) as \( |t| \to \infty \). Accordingly, there exists \( \bar{t} \in \mathbb{R} \) such that
\[
\frac{\theta^p}{\alpha} + \bar{t} + \frac{1}{\alpha N} \sum_{i=1}^{N} (-G(x, \xi_i) - \bar{t}) \leq 0.
\]
Since \( G \) is nonnegative, we must have \( \bar{t} < 0 \). Consequently, we can define \( \lambda = -\frac{1}{\bar{t}} > 0 \), which implies \( x \in \hat{X}_{\text{DCP}} \) as stated in (11). Therefore, \( \hat{X}_{\text{DCP}} \subseteq \hat{X}_{\text{DCP}} \).
\]

**Remark III.3.** (Comparison with literature and intractability of DRCCPs): By leveraging the above reformulations, Xie derives several inner and outer approximations of the feasibility set \( \hat{X}_{\text{DCP}} \) for affine constraint functions in [28]. Nonetheless, those approximations involve the distance function \( G \) which makes the optimization problem computationally intractable. In fact, [27] establishes that DRCCPs under Wasserstein ambiguity sets [9] are strongly NP-Hard for affine constraint functions [27].

Therefore, we now focus on developing tractable approximations of DRCCPs. In the remainder of the paper, we focus on the convex CVaR approximation approach by [31] and provide tractable reformulations and algorithms for solving DRCCPs under the CVaR approximation.
IV. CVAR APPROXIMATION OF DRCCPs

Recall from our earlier discussion that the feasibility set of a (DR)CCP is nonconvex (except for restrictive special cases). When $F$ is convex in $x$, the convex conservative approximation approach of [31] provides a convex inner approximation of the feasibility set of the original (DR)CCP. In the remainder of the paper, we focus on the CVaR approximation (discussed in Section II-A) of the DRCCP (9) under the following assumptions.

**Assumption IV.1.** *(Regularity in uncertainty: II):* Let $\Xi \subseteq \mathbb{R}^m$. In addition, the function $F : \mathbb{R}^n \times \Xi \rightarrow \mathbb{R}$ has the following properties.

(i) $x \mapsto F(x, \xi)$ is convex on $X$ for every $\xi \in \Xi$.
(ii) For every $x \in X$, the function $\xi \mapsto F(x, \xi)$ is bounded and continuous on $\Xi$.

Note that the second property in the above assumption implies the first two properties of Assumption III.1.

Following our earlier discussion in Section II-A, the CVaR approximation of the DRCCP (9) is the program

$$\min \{ c^T x : x \in \tilde{X}_{\text{cvr}} \}, \quad \text{where} \quad \tilde{X}_{\text{cvr}} := \left\{ x \in X \mid \sup_{\xi \in \Xi} \inf_{p \in M_N^p} \left( F(x, \xi) + t_\alpha \right) \leq 0 \right\}. \tag{17}$$

Under Assumption IV.1, $\tilde{X}_{\text{cvr}}$ is convex. Furthermore, $\tilde{X}_{\text{cvr}} \subseteq \bar{X}_{\text{cvr}}$ following [31]. Our goal now is to obtain a convex reformulation of the DRCCP (17) (that does not involve supremum over distributions). We start with the following lemma where we show that the inf and the sup in the constraint of (17) can be interchanged. The proof is an application of the min-max theorem due to [33] stated as Theorem II.3 in Section II-B.

**Lemma IV.2.** *(Min-max equality for the constraint function):* Suppose Assumption IV.1 holds. Then for every $x \in X$, we have

$$\sup_{p \in M_N^p} \inf_{t \in \mathbb{R}} \mathbb{E}_p [(F(x, \xi) + t_\alpha)], \quad \text{where} \quad \inf_{t \in \mathbb{R}} \mathbb{E}_p [(F(x, \xi) + t_\alpha) - \lambda t_\alpha]. \tag{18}$$

**Proof.** We suppress the variable $x$ in the proof for better readability. We verify that the hypotheses of the min-max theorem (Theorem II.3) hold.

Drawing the parallelism in notation between our case and Theorem II.3, note that here $\mathbb{F}$ plays the role of both $T$ and $V$; $M_N^p$ that of $M$; and the function $g(t, \xi) := (F(\xi) + t_\alpha)$. Following Proposition II.4, $M_N^p$ is weakly compact.

Note that $g$ is continuous in $F$ as continuous. Furthermore, $F$ is bounded, for every $t \in \mathbb{R}$, the function $\xi \mapsto g(t, \xi)$ is bounded and $\sup_\xi E_p[g(t, \xi)] < \infty$. Finally, for every $\xi \in \Xi$, $t \mapsto g(t, \xi)$ is convex. Thus, to conclude the proof it remains to show that the infimum on the right-hand side of (18) is attained. Define the function

$$h(t) := \sup_{p \in M_N^p} \mathbb{E}_p [(F(\xi) + t_\alpha) - \lambda t_\alpha].$$

Note that for any $p \in M_N^p$, the function $t \mapsto \mathbb{E}_p [(F(\xi) + t_\alpha) - \lambda t_\alpha]$ is convex and real-valued. Since $h$ is supremum over a family of such functions, $h$ too is convex and real-valued. Hence, $h$ is continuous. Further note that $(F(\xi) + t_\alpha) - \lambda t_\alpha \rightarrow -\infty$ as $|t| \rightarrow \infty$. This fact along with boundedness of $F$ implies $h(t) \rightarrow -\infty$ as $|t| \rightarrow \infty$. Thus, $\inf_{t \in \mathbb{R}} h(t)$ exists, concluding the proof.

Next, using the min-max equality established above and the strong duality result of distributionally robust optimization presented in Section II-B we obtain the following convex reformulation of the CVaR approximation of DRCCP (17).

**Proposition IV.3.** *(Convex reformulation of (17):* Under Assumption IV.1, the CVaR approximation of the DRCCP problem under Wasserstein ambiguity set (17) is equivalent to the convex optimization problem

$$\begin{align*}
\min & \quad c^T x \\
\text{s.t.} & \quad \lambda t_\alpha + \sum_{i=1}^N s_i \leq t_\alpha, \\
& \quad s_i = (\sup_{\xi \in \Xi} [F(x, \xi) + t - \lambda t_\alpha(\xi, \hat{\xi}_i)]), \quad \forall i \in [N], \\
& \quad \lambda \geq 0, \quad t \in \mathbb{R}, \quad x \in X.
\end{align*} \tag{19}$$

**Proof.** We evaluate the constraint in (17) as

$$\begin{align*}
& \sup_{p \in M_N^p} \inf_{t \in \mathbb{R}} \mathbb{E}_p [(F(x, \xi) + t_\alpha) - \lambda t_\alpha] \\
& = \inf_{t \in \mathbb{R}} \sup_{p \in M_N^p} \mathbb{E}_p [(F(x, \xi) + t_\alpha) - \lambda t_\alpha] \\
& = \inf_{t \in \mathbb{R}, \lambda > 0} \left\{ \lambda t_\alpha + \sum_{i=1}^N s_i \leq t_\alpha, \\
& \quad s_i = \sup_{\xi \in \Xi} [(F(x, \xi) + t) - \lambda t_\alpha(\xi, \hat{\xi}_i)], \quad \forall i \in [N] \right\}. \tag{20}
\end{align*}$$

The first equality follows from Lemma IV.2. The second equality is a consequence of the strong duality result in Theorem II.2. Note that since $F$ is bounded, the second property of Assumption III.1 holds (including when $\Xi$ is not bounded). Furthermore, the infimum over $\lambda \geq 0$ is attained following Theorem II.2 and the infimum over $t \in \mathbb{R}$ is also attained from the proof of Lemma IV.2. Therefore, $\tilde{X}_{\text{cvr}}$ is equivalent to the set

$$\Pi_x \left\{ x \in X, \lambda \geq 0, \begin{bmatrix} x \in X, \\ \lambda \geq 0, \\ s_i = \sup_{\xi \in \Xi} [(F(x, \xi) + t) - \lambda t_\alpha(\xi, \hat{\xi}_i)] \end{bmatrix}, \text{where} \begin{bmatrix} x \in X, \\ \lambda \geq 0, \\ s_i = \sup_{\xi \in \Xi} [(F(x, \xi) + t) - \lambda t_\alpha(\xi, \hat{\xi}_i)] \end{bmatrix}, \text{where} \begin{bmatrix} x \in X, \\ \lambda \geq 0, \\ s_i = \sup_{\xi \in \Xi} [(F(x, \xi) + t - \lambda t_\alpha(\xi, \hat{\xi}_i))] \end{bmatrix} \right\}, \tag{21}$$

where $\Pi_x$ gives the $x$-component of the argument.

Now observe that for a given $(x, \lambda, t) \in [N]$, $s_i = \max_{\xi \in \Xi_1} \sup_{\xi \in \Xi_2} [F(x, \xi) + t - \lambda t_\alpha(\xi, \hat{\xi}_i)]$, where $\Xi_1 = \{ \xi \in \Xi : F(x, \xi) + t \geq 0 \}$, and $\Xi_2 = \Xi \setminus \Xi_1$. We distinguish between the following two cases.

Suppose $\hat{\xi}_i \in \Xi_1$. Then, $s_i - \lambda t_\alpha(\xi, \hat{\xi}_i) < 0$ and $\sup_{\xi \in \Xi_1} F(x, \xi) + t - \lambda t_\alpha(\xi, \hat{\xi}_i) = \sup_{\xi \in \Xi_2} \tilde{F}(x, \xi) + t - \lambda t_\alpha(\xi, \hat{\xi}_i) > 0$.
On the other hand, if \( \tilde{\xi} \in \Xi_2 \), we have
\[
\sup_{\xi \in \Xi_2} - \lambda d^p(\xi, \hat{\xi}_i) = 0 > \sup_{\xi \in \Xi_2} F(x, \xi) + t - \lambda d^p(\xi, \hat{\xi}_i).
\]
In both cases, we have
\[
s_i = \max \{ \sup_{\xi \in \Xi} [F(x, \xi) + t - \lambda d^p(\xi, \hat{\xi}_i)], 0 \}.
\]
This concludes the proof.

The above result shows that the CVaR approximation of DRCCPs under Wasserstein ambiguity sets can be reformulated as a convex optimization problem. However, the constraints involving \( s_i \) in (19) involve supremum operators. In the remainder of the paper, we develop tractable reformulations and algorithms to solve (19) under suitable assumptions on the constraint function \( F \).

### A. Tractable reformulation when \( F \) is affine in uncertainty

We now present a tractable reformulation (19) when \( F \) is piecewise maximum of a set of functions that are affine in \( \xi \). The analysis is inspired by a similar reformulation in \([25]\).

Let the ambiguity set \( \mathcal{M}_b \) be defined using the 1-Wasserstein metric and \( d \) is the standard Euclidean distance. Then, the DRCCP (19) is equivalent to the following tractable convex optimization problem
\[
\min_{x \in X, t \in \mathbb{R}, \lambda \geq 0} c^T x
\]
\[
s.t. \lambda \theta + \frac{1}{N} \sum_{i=1}^{N} s_i \leq t \alpha, \]
\[
(b_k(x) + t + (a_k(x) - C^T \eta_{ik})^\top \tilde{\xi}_i + \eta_{ik}^\top h)_+ \leq s_i, \quad \eta_{ik} \geq 0, \quad \forall k \in [K],
\]
and the inequalities involving \( s_i \) and \( \eta_{ik} \) hold for every \( i \in [N] \) and \( k \in [K] \).

**Proof.** Following Proposition IV.3 and (19), we focus on reformulating the constraints involving the auxiliary variables \( s_i, i \in [N] \). In particular, for piecewise maximum of affine functions, we have
\[
s_i = \sup_{\xi \in \Xi} \max_{k \in [K]} \{ a_k(x) \}^\top \xi + b_k(x) + t - \lambda \| \xi - \hat{\xi}_i \|_1 \}
\]
\[
= \max_{k \in [K]} \left( b_k(x) + t + \sup_{\xi \in \Xi} \{ a_k(x) \}^\top \xi - \lambda \| \xi - \hat{\xi}_i \|_1 \} \right)_+, \forall k \in [K].
\]
The second equality interchanges the sup and the max. We now compute
\[
\sup_{\xi \in \Xi} \{ a_k(x) \}^\top \xi - \lambda \| \xi - \hat{\xi}_i \|_1 \}
\]
\[
= \sup_{\xi \in \Xi} \{ a_k(x) \}^\top \xi - \lambda \| \xi - \hat{\xi}_i \|_1 \} + \inf_{\xi \in \Xi} \{ a_k(x) \}^\top \xi - \lambda \| \xi - \hat{\xi}_i \|_1 \}
\]
\[
= \inf_{\xi \in \Xi} \{ a_k(x) \}^\top \xi + \sup_{\xi \in \Xi} \{ a_k(x) \}^\top \xi - \lambda \| \xi - \hat{\xi}_i \|_1 \}
\]
\[
= \inf_{\xi \in \Xi} \{ a_k(x) \}^\top \xi + \sup_{\xi \in \Xi} \{ a_k(x) \}^\top \xi - \lambda \| \xi - \hat{\xi}_i \|_1 \}
\]
\[
= \inf_{\xi \in \Xi} \{ a_k(x) \}^\top \xi + \sup_{\xi \in \Xi} \{ a_k(x) \}^\top \xi - \lambda \| \xi - \hat{\xi}_i \|_1 \}
\]
\[
= \inf_{\xi \in \Xi} \{ a_k(x) \}^\top \xi + \sup_{\xi \in \Xi} \{ a_k(x) \}^\top \xi - \lambda \| \xi - \hat{\xi}_i \|_1 \}
\]
Here, (a) uses the definition of the norm, (b) follows by interchanging the supremums, and (c) writes the dual form of the inner linear program using the definition of \( \Xi = \{ \xi \in \mathbb{R}^m \mid C \xi \leq h \} \). Substituting (23) in (22), we obtain
\[
s_i \geq \left( b_k(x) + t + \sup_{\eta_{ik} \geq 0} \left( (a_k(x) - C^T \eta_{ik})^\top \tilde{\xi}_i + \eta_{ik}^\top h \right)_+ \right), \forall k \in [K],
\]
where the inequalities hold for every \( k \in [K] \). This completes the proof.

**Remark IV.5.** When \( \Xi = \mathbb{R}^m \), we recover the reformulations in \([28], [29]\) by setting \( C = 0 \), \( h = 0 \), and \( \eta = 0 \) in (22). In addition, \([28], [29]\) showed that when \( \Xi = \mathbb{R}^m \) and \( N \alpha \leq 1 \), the CVaR approximation is exact, i.e., \( \hat{X}_{\text{DRCCP}} = \hat{X}_{\text{CDECP}} \).

In the following section, we present a primal-dual algorithm to solve CVaR approximation of DRCCPs when the constraint function is concave in uncertainty.

### V. Constraint Function Concave in Uncertainty

Here we aim to develop an algorithm to solve the convex inner approximation of the DRCCP (19) under the assumption that \( F \) is concave in \( \xi \). The roadblock in solving (19) is the supremum operator present in the constraint that makes implementing first- or second-order methods almost impossible. To construct the algorithm, we first identify a convex-concave function whose saddle points are in one-to-one correspondence with the primal-dual optimizers of (19) and then implement first-order methods to find such saddle points. The steps involved in determining the convex-concave function are similar to those used in \([35]\).

**Assumption V.1.** (Zero-duality gap): The duality gap between the primal and the dual optimization problems for (19) is zero. In addition, \( X \) and \( \Xi \) are compact.

Unless stated otherwise, the results in this section hold under Assumption IV.1 and V.1. The next result provides a sufficient condition that ensures that the duality gap is zero for the problem (19).
Lemma V.2. (Robust feasibility implies zero-duality gap): If the optimal value of the optimization problem (19) is finite and there exists \(x \in X\) such that \(F(x, \xi) \leq -\delta < 0\) for all \(\xi \in \Xi\), then the problem (19) admits zero duality gap.

Proof. The duality gap is zero if there exists \((x, t, \lambda) \in X \times \mathbb{R} \times \mathbb{R}_{\geq 0}\) such that the inequalities in (19) are satisfied strictly [36, Chapter 6]. To this end, fix \(x = \bar{x}, \lambda = 0\), and \(t \in \delta / \alpha\). For this choice, we have

\[
\frac{1}{N} \sum_{i=1}^{N} \sup_{\xi \in \Xi} (F(x, \xi) + t) + t \alpha = \sup_{\xi \in \Xi} (F(x, \xi) + t) + t \alpha \\
\leq (-\delta + t) + t \alpha < 0,
\]

Here, (a) follows from the assumption that \(\sup_{\xi \in \Xi} F(x, \xi) \leq -\delta\) and (b) follows from the choice of \(t\). Consequently, the inequalities in (19) are satisfied strictly. □

We construct the convex-concave function, whose saddle points will be our object of interest. Following (20), we define the Lagrangian of the problem (19) in a compact form as

\[
L(x, t, \lambda, \eta) = ct \bar{x} + \eta (\lambda \theta p + \frac{1}{N} \sum_{i=1}^{N} \sup_{\xi \in \Xi} ([F(x, \xi) + t] + t \alpha - \lambda d^p(\xi, \bar{\xi}))
\]

where \(\eta \in \mathbb{R}_{\geq 0}\) is the Lagrange multiplier for the inequality constraint. Under Assumption (17), the following min-max inequality holds for the Lagrangian

\[
\inf_{x \in X, \eta \geq 0} \sup_{t \in \mathbb{R}, \lambda \geq 0} L(x, t, \lambda, \eta) = \sup_{\eta \geq 0, t \in \mathbb{R}, \lambda \geq 0} \inf_{x \in X, \lambda \geq 0} L(x, t, \lambda, \eta).
\]

Note that the set of supremum operators in the Lagrangian can be extracted out to write \(L\) as

\[
L(x, t, \lambda, \eta) = \sup_{\xi \in \Xi} \tilde{L}(x, t, \lambda, \eta, \{\xi_i\}),
\]

where \(\{\xi_i\}\) stands for \((\xi_i)_{i=1}^{N}\) and the function \(\tilde{L}\) is

\[
\tilde{L}(x, t, \lambda, \eta, \{\xi_i\}) := ct \bar{x} + \eta (\lambda \theta p + \frac{1}{N} \sum_{i=1}^{N} (F(x, \xi_i) + t) + t \alpha - \lambda d^p(\xi_i, \bar{\xi_i})).
\]

The function \(\tilde{L}\) is convex-concave and locally Lipschitz. Substituting (26) in (25), we get

\[
\inf_{x \in X, t \in \mathbb{R}, \lambda \geq 0} \sup_{\eta \geq 0} \sup_{\xi \in \Xi} \tilde{L}(x, t, \lambda, \eta, \{\xi_i\}) = \sup_{\eta \geq 0} \inf_{x \in X, t \in \mathbb{R}, \lambda \geq 0} \sup_{\xi \in \Xi} \tilde{L}(x, t, \lambda, \eta, \{\xi_i\}).
\]

If the inner inf and sup operators can be exchanged in the right-hand side of the above equation, then min-max equality will hold for \(\tilde{L}\), consequently, saddle points of \(\tilde{L}\) exist which will correspond to the optimizers of (19). The next result shows that the operators can in fact be interchanged.

Lemma V.3. (The inf-sup interchange in \(\tilde{L}\)): Let Assumption (17) and (17) hold. Then, for any \(\tilde{\eta} \geq 0\), we have

\[
\inf_{\eta \geq 0} \sup_{x \in X, t \in \mathbb{R}, \lambda \geq 0} \tilde{L}(x, t, \lambda, \eta, \{\xi_i\}) = \sup_{\eta \geq 0, \xi \in \Xi} \inf_{x \in X, t \in \mathbb{R}, \lambda \geq 0} \tilde{L}(x, t, \lambda, \eta, \{\xi_i\}).
\]

Since \(\tilde{L}\) is convex-concave and real-valued, the equality (31) implies saddle points of \(\tilde{L}\) exists [37, Lemma 36.2]. Further, along with (25), one can show that the saddle points of \(L\) and \(\tilde{L}\) have a one-to-one correspondence, leading to the following.

Proof. Note that if \(\tilde{\eta} = 0\), then (29) holds trivially. Now let \(\tilde{\eta} > 0\). For this case, we will use [37, Theorem 37.3 & 37.6] which states that the equality (29) holds if the following two conditions are satisfied

(a) the set of functions \(\{\xi_i\} \mapsto \tilde{L}(x, t, \lambda, \eta, \{\xi_i\}) | (x, t, \lambda) \in (X \times \mathbb{R} \times \mathbb{R}_{\geq 0})\) do not have a common direction of recession in the domain \(\Xi\),

(b) the set of functions \(\{x, t, \lambda\} \mapsto \tilde{L}(x, t, \lambda, \eta, \{\xi_i\}) | \{\xi_i\} \in \Xi\) do not have a common direction of recession in \(X \times \mathbb{R} \times \mathbb{R}_{\geq 0}\).

Condition (a) is true as \(F\) is bounded. To show (b), pick \(\tilde{\xi_i} = \xi_i\) for all \(i \in [N]\). Then, the resulting function is

\[
(x, t, \lambda) \mapsto \tilde{L}(x, t, \lambda, \eta, \{\xi_i\}) = ct \bar{x} + \eta (\lambda \theta p + \frac{1}{N} \sum_{i=1}^{N} (F(x, \tilde{\xi}_i) + t) + t \alpha - \lambda d^p(\tilde{\xi}_i, \bar{\xi}_i))
\]

\[
\inf_{\eta \geq 0} \sup_{x \in X, t \in \mathbb{R}, \lambda \geq 0} \tilde{L}(x, t, \lambda, \eta, \{\xi_i\})
\]

Thus, we will show that there is no direction of recession for the above function. Note that since \(F\) is bounded, the term *1 is bounded below. Further, the term *2 is lower bounded as this term is continuous in \(t\) and tends to \(+\infty\) as \(|t| \to +\infty\). Finally, the term *3 is bounded below as \(\eta \theta p \geq 0\). Thus, we conclude that (30) is lower bounded over the domain of interest \(X \times \mathbb{R} \times \mathbb{R}_{\geq 0}\). For the sake of contradiction, assume there exists a direction of recession \(\gamma = (\gamma_x, \gamma_r, \gamma_{\lambda}) \in \mathbb{R}^d \times \mathbb{R} \times \mathbb{R}\) for the function in (30). Since \(X\) is bounded, \(\gamma_x = 0\). Further, the domain satisfying \(\lambda \geq 0\) implies that \(\gamma_{\lambda}\) is nonnegative. On the other hand, along a positive \(\gamma\), the above function goes to \(+\infty\). Hence, \(\gamma_{\lambda} = 0\). Finally, \(\gamma_t = 0\) as the function is unbounded as \(|t| \to +\infty\). This implies that \(\gamma = 0\) and there is no direction of recession for (30). □

Following above result, we use (29) in the right-hand side of (28) to obtain

\[
\inf_{\eta \geq 0, \{\xi_i\} \in \Xi} \sup_{x \in X, t \in \mathbb{R}, \lambda \geq 0} \tilde{L}(x, t, \lambda, \eta, \{\xi_i\})
\]

Since \(\tilde{L}\) is convex-concave and real-valued, the equality (31) implies saddle points of \(\tilde{L}\) exists [37, Lemma 36.2]. Further, along with (25), one can show that the saddle points of \(L\) and \(\tilde{L}\) have a one-to-one correspondence, leading to the following.
To arrive at the contradiction, we will show that the constraint in \( \hat{L} \) is nonempty and the following holds:

(i) If \((\hat{x}, \hat{t}, \hat{\lambda}, \hat{\eta}, \{\xi_i\})\) is a saddle point of \( \hat{L} \), then \((\hat{x}, \hat{t}, \hat{\lambda}, \hat{\eta}, \{\xi_i\})\) is a primal-dual optimizer of \( (19) \).

(ii) If \((\bar{x}, \bar{t}, \lambda, \bar{\eta})\) is a primal-dual optimizer of \( (19) \), then there exists \( \{\tilde{\xi}_i\} \in \Xi^N \) such that \((\bar{x}, \bar{t}, \lambda, \bar{\eta}, \{\tilde{\xi}_i\})\) is a saddle point of \( \hat{L} \).

Here, saddle points of \( \hat{L} \) satisfy the saddle property over the domain \((X \times R \times R_{\geq 0}) \times (R_{\geq 0} \times \Xi^N)\).

As a consequence of the above result, finding primal-dual optimizers of \( (19) \) is equivalent to finding the saddle points of \( \hat{L} \). To this end, we employ a primal-dual update algorithm. The convergence of this scheme relies on the fact that the primal-dual optimizers are contained in a compact set, which is characterized below.

**Lemma V.5.** (Optimizers of \( (19) \) belong to a compact set): Let Assumption IV.1 and V.1 hold. Then, the (primal) optimizers of \( (19) \) belong to the set \( X \times [0, t^M] \times [0, \lambda^M] \), where

\[
\begin{align*}
t^M &:= \frac{1}{1 - \alpha} \sup_{x \in X, \xi \in \Xi} -F(x, \xi), \\
\lambda^M &:= \frac{\alpha}{\theta^p(1 - \alpha)} \sup_{x \in X, \xi \in \Xi} -F(x, \xi).
\end{align*}
\]

Further, let \((\bar{x}, \bar{t}, \bar{\lambda})\) be a feasible point of \( (19) \) that satisfies the constraint strictly. That is,

\[
\gamma := \bar{\lambda}^p + \frac{1}{N} \sup_{\xi \in \Xi} (\bar{F}(\bar{x}, \xi) + \bar{t}) - \bar{\lambda} \geq 0.
\]

Then, the dual optimizers of \( (19) \) lie in the set \([0, \eta^M]\), where

\[
\eta^M := \frac{1}{|\gamma|} \left(c^T \bar{x} + \bar{\eta} \lambda^M \alpha - \inf_{x \in X} c^T x\right),
\]

and \(\bar{\eta} > 0\) is any arbitrary value.

**Proof.** (Bound on the primal optimizers:) Let \((x^*, t^*, \lambda^*)\) be an optimizer of \( (19) \). By definition, \(x^* \in X\). For the sake of contradiction, assume \(t^* \notin [0, t^M]\). Note that for each \(i \in [N]\), \(\sup_{\xi \in \Xi} (F(x, \xi) + t^*) - \lambda \geq 0\). The other possibility is \(t^* > t^M\). Since \(\alpha < 1\), we have \(t^M > \sup_{x \in X, \xi \in \Xi} -F(x, \xi)\) which implies that \(t^* > -F(x, \xi), \forall x \in X, \xi \in \Xi\).

Using this fact, we deduce that

\[
(F(x, \xi) + t^*) = F(x, \xi) + t^*, \quad \forall x \in X, \xi \in \Xi.
\]

To arrive at the contradiction, we will show that the constraint in \( (19) \) is violated for such a choice of \(t^*\). Note that

\[
\lambda^p \geq \lambda^p - t^* \alpha + \frac{1}{N} \sum_{i=1}^{N} \sup_{\xi \in \Xi} (F(x^*, \xi) + t^*) - \lambda \geq 0.
\]

where in (a) we lower bound the supremum in each \(i\)-th term by substituting \(\xi \in \Xi\). From (31), we conclude that \(t^* \notin [0, t^M]\). To show that \(\lambda^p - t^* \alpha \leq 0\) implying \(\lambda \leq t^* \alpha \). The bound on \(\lambda^p\) then follows by using the bound on \(t^*\).

**Bound on the dual optimizers:** Consider any \(\bar{\eta} > 0\). From (31) Lemma 4.1, the dual optimum \(\eta^*\) satisfies

\[
0 \leq \eta^* \leq \frac{1}{|\gamma|} \left(c^T x - q(\xi)\right),
\]

where \(q\) is the dual function.

\[
\eta \mapsto q(\eta) = \inf_{x \in X} \{F(x, t, \lambda, \eta) \mid x \in X, t \in R, \lambda \in R_{\geq 0}\}.
\]

Next we show that for any \(\bar{\eta} > 0\), the following inequality holds which concludes the proof

\[
q(\bar{\eta}) \geq -\bar{\eta} \lambda^p \alpha + \inf_{x \in X} c^T x.
\]

Note that

\[
q(\bar{\eta}) \geq \inf_{x \in X} c^T x + \bar{\eta} \left(\inf_{x \in X, t \in R, \lambda \in R_{\geq 0}} (\lambda \theta^p - t \alpha) + \sum_{i=1}^{N} \sup_{\xi \in \Xi} (F(x, \xi) + t) - \lambda \theta^p (\xi, \tilde{\xi}_i)\right)
\]

As shown in the previous steps of the proof, if \(t \notin [0, t^M]\) or \(\lambda \notin [0, \lambda^M]\), there does not exist any \(x\) such that the constraint in \( (19) \) is met. Whereas we do know that the problem is feasible. Therefore, on the right-hand side of the above inequality we can restrict the domain and infer the following inequalities

\[
q(\bar{\eta}) \geq \frac{\inf_{x \in X} c^T x + \bar{\eta} \left(\inf_{x \in X, t \in [0, t^M], \lambda \in [0, \lambda^M]} (\lambda \theta^p - t \alpha + \sum_{i=1}^{N} \sup_{\xi \in \Xi} (F(x, \xi) + t) - \lambda \theta^p (\xi, \tilde{\xi}_i)\right)\right)}{\lambda \theta^p}
\]

Above, inequality (a) uses the facts that \(\inf\) of a sum of functions is lower bounded by the sum of the \(\inf\). Inequality (b) uses the nonnegativity of the term with the projection.
Once we have identified the set in which the primal-dual optimizers of (19) lie, we can search for the saddle-points of \( \tilde{L} \) over the set \( \mathcal{F}_P \times \mathcal{F}_D \), where

\[
\mathcal{F}_P := X \times [0, t^M] \times [0, \lambda^M], \\
\mathcal{F}_D := [0, \eta^M] \times \mathbb{R}^N,
\]
in order to solve (19). To this end, we write the following primal-dual update scheme

\[
P_{k+1} \in \Pi_{\mathcal{F}_P}(P_k - \zeta_k \partial_P \tilde{L}(P_k, D_k)), \quad (34a) \\
D_{k+1} \in \Pi_{\mathcal{F}_D}(D_k + \zeta_k \partial_D \tilde{L}(P_k, D_k)), \quad (34b)
\]
where \( \zeta_k \) is the stepsize at the \( k \)-th iteration, \( P \) represents the variables \( (x, t, \lambda) \), and \( D \) represents \( (\eta, \xi) \). The notation \( \partial_P \tilde{L} \) and \( \partial_D \tilde{L} \) stand for generalized gradients of \( \tilde{L} \) with respect to variables \( P \) and \( D \), respectively. The operator \( \Pi \) is the euclidean projection of a point onto a set. Next, we will analyze the convergence properties of (34). The exposition uses techniques presented in [38] and [39].

**Proposition V.6. (Convergence of the primal-dual scheme):** Let Assumptions [IV.7] and [V.7] hold. Assume that for the primal-dual scheme (34), the sequence of stepizes \( \{\zeta_k\}_{k=0}^{\infty} \) satisfies the doubling rule. That is, we divide the nonnegative integers into epochs \( m = 0, 1, 2, \ldots \) where each epoch \( m \) has \( 2^m \) time steps, namely, \( s = 2^m, 2^m + 1, \ldots, 2^{m+1} - 1 \), and the stepsize is constant in each epoch, specifically, \( \zeta_s = \frac{1}{\sqrt{2^m}} \). In a compact way,

\[
\zeta_s = \frac{1}{\sqrt{2^m}}, \quad \text{for } s \in [2^m, 2^{m+1} - 1] \cap \mathbb{N}.
\]

Let \((P^*, D^*) = (x^*, t^*, \lambda^*, \eta^* {\xi^*})\) be a saddle point of \( \tilde{L} \). Let the ergodic sums be defined as

\[
P_{k}^{av} := \frac{1}{k} \sum_{i=0}^{k-1} P_i, \quad \text{and} \quad D_{k}^{av} := \frac{1}{k} \sum_{i=1}^{k-1} D_i,
\]
for all \( k \in \mathbb{N} \), where \((P_0, D_0) \in \mathcal{F}_P \times \mathcal{F}_D \) is the initial point and \( \{(P_i, D_i)\}_{i=1}^{\infty} \) are iterates generated by (34). Then,

\[
\tilde{L}(P_k^{av}, D_k^{av}) - \tilde{L}(P^*, D^*) \approx O(1/\sqrt{k}).
\]

**Proof.** Observe that the sequence \( \{(P_k, D_k)\}_{k=0}^{\infty} \) and the saddle point \((P^*, D^*)\) belong to the set \( \mathcal{F}_P \times \mathcal{F}_D \). Since for any \( k \in \mathbb{N} \), points \( P_k^{av} \) and \( D_k^{av} \) are convex combinations of points in the said sequence, they too belong to \( \mathcal{F}_P \) and \( \mathcal{F}_D \), respectively. By compactness of \( \mathcal{F}_P \) and \( \mathcal{F}_D \), there exist constants \( M_P, M_D > 0 \) such that

\[
\|\tilde{P} - \bar{P}\| \leq M_P \quad \forall \bar{P}, \tilde{P} \in \mathcal{F}_P, \\
\|\tilde{D} - \bar{D}\| \leq M_D \quad \forall \bar{D}, \tilde{D} \in \mathcal{F}_D.
\]

Further, since \( \tilde{L} \) is locally Lipschitz, there exists constant \( M_L > 0 \) that bounds the subgradient of \( \tilde{L} \) on \( \mathcal{F}_P \times \mathcal{F}_D \), that is,

\[
\|\partial_P \tilde{L}(P, D)\| \leq M_L, \quad \|\partial_D \tilde{L}(P, D)\| \leq M_L,
\]
for all \((P, D) \in \mathcal{F}_P \times \mathcal{F}_D \). In the above inequality, allowing a slight abuse of notation, we denote the magnitude of the maximum norm element of \( \partial_P \tilde{L}(P, D) \) by \( \|\partial_P \tilde{L}(P, D)\| \) (similar notation follows for \( \partial_D \tilde{L} \)).

Given the sequence \( \{(P_k, D_k)\}_{k=0}^{\infty} \), we define the sequence \( \{(P_m^e, D_m^e)\}_{m=0}^{\infty} \) that represents the iterates at the end of each epoch. Recall that an epoch \( m \) contains \( 2^m \) iterates \( s = 2^m, \ldots, 2^{m+1} - 1 \). Specifically, we define

\[
P_m^e := P_{2^m+1}, \quad D_m^e := D_{2^m+1}, \quad \forall m \in \mathbb{N}.
\]

From the proof of [38] Lemma 3.2], for any \( k \in \mathbb{N} \) and any \( P \in \mathcal{F}_P \), the following holds

\[
\tilde{L}(P_k, D_k) - \tilde{L}(P, D_k) \leq \frac{1}{2\zeta_k} \bigg( \|P_k - P\|^2 - \|P_{k+1} - P\|^2 \bigg) + \frac{\zeta_k M_L^2}{2}. \quad (35)
\]

To obtain this inequality one uses the definition of the dynamics and bound on the subgradients, see also [38] Lemma 3.1 for more details. Now consider some \( k \in \mathbb{N} \) and add (35) for \( k = 0, \ldots, k-1 \). This gives

\[
\sum_{k=0}^{k-1} \left( \tilde{L}(P_k, D_k) - \tilde{L}(P, D_k) \right) \leq \sum_{k=0}^{k-1} \left( \frac{1}{2\zeta_k} \left( \|P_k - P\|^2 - \|P_{k+1} - P\|^2 \right) + \frac{\zeta_k M_L^2}{2} \right). \quad (36)
\]

Let \( \tilde{m} \) be the epoch such that \( 2^{\tilde{m}} \leq k - 1 \leq 2^{\tilde{m}+1} - 1 \). By assumption, stepizes follow the doubling rule, that is, the stepsize is constant \( 1/\sqrt{2^\tilde{m}} \) in each epoch \( m = 0, \ldots, \tilde{m} \). Using this fact in (36) gives

\[
\sum_{k=0}^{k-1} \left( \tilde{L}(P_k, D_k) - \tilde{L}(P, D_k) \right) \leq \sum_{m=0}^{\tilde{m}} \left( \frac{\sqrt{2^m}}{2} \left( \|P_m^e - P\|^2 - \|P_{m+1}^e - P\|^2 \right) + \frac{M_L^2}{2} \right) \leq \sum_{m=0}^{\tilde{m}} \left( \frac{\sqrt{2^m}}{2} \right) \sum_{m=0}^{\tilde{m}} \sqrt{2^m} = \frac{M_P^2 + M_D^2}{2} \sqrt{\frac{2^{2\tilde{m}+1} - 2}{2}}. \quad (37)
\]

Note that \( 2^{2\tilde{m}+1} \geq 2k \) by definition of the epoch \( \tilde{m} \). This inequality along with the previous one gives

\[
\sum_{k=0}^{k-1} \left( \tilde{L}(P_k, D_k) - \tilde{L}(P, D_k) \right) \leq \frac{M_P^2 + M_D^2}{2} \sqrt{k}. \quad (38)
\]

From concavity of \( \tilde{L} \) in \( D \), we have \( \tilde{L}(P, D_{k+1}^{av}) \geq \frac{1}{k} \sum_{k=0}^{k-1} \tilde{L}(P, D_k) \). Using this inequality in (38) gives

\[
\sum_{k=0}^{k-1} \left( \tilde{L}(P_k, D_k) - k \tilde{L}(P_{k+1}^{av}, D) \right) \leq \frac{M_P^2 + M_D^2}{2} \sqrt{k}. \quad (38)
\]

Similarly, for the variable \( D \) one can follow the same steps to obtain

\[
\sum_{k=1}^{k-1} \left( \tilde{L}(P_k, D_k) - k \tilde{L}(P_{k+1}^{av}, D) \right) \geq - \frac{M_P^2 + M_D^2}{2} \sqrt{k}. \quad (39)
\]
Substituting $P$ with $P^*$ in (38) and $D$ with $D^*$ in (39), we get
\[
\sum_{k=1}^{k-1} \tilde{L}(P_k, D_k) - k \tilde{L}(P^*, D^*) \leq \frac{M_p^2 + M_d^2}{2 - \sqrt{2}} \sqrt{k},
\]
and
\[
\sum_{k=1}^{k-1} \tilde{L}(P_k, D_k) - k \tilde{L}(P^*, D^*) \geq -\frac{M_p^2 + M_d^2}{2 - \sqrt{2}} \sqrt{k}.
\]
Using then the saddle point property \( \tilde{L}(P^*, D^*) \leq \tilde{L}(P, D^*) \) we obtain
\[
\sum_{k=1}^{k-1} \tilde{L}(P_k, D_k) - k \tilde{L}(P^*, D^*) \leq \frac{M_p^2 + M_d^2}{2 - \sqrt{2}} \sqrt{k},
\]
and
\[
\sum_{k=1}^{k-1} \tilde{L}(P_k, D_k) - k \tilde{L}(P^*, D^*) \geq -\frac{M_p^2 + M_d^2}{2 - \sqrt{2}} \sqrt{k}.
\]
Now substituting $P$ with $P_{k-1}^{\text{av}}$ in (38) and $D$ with $D_{k-1}^{\text{av}}$ in (39), we get
\[
\sum_{k=1}^{k-1} \tilde{L}(P_k, D_k) - k \tilde{L}(P_{k-1}^{\text{av}}, D_{k-1}^{\text{av}}) \leq \frac{M_p^2 + M_d^2}{2 - \sqrt{2}} \sqrt{k},
\]
and
\[
\sum_{k=1}^{k-1} \tilde{L}(P_k, D_k) - k \tilde{L}(P_{k-1}^{\text{av}}, D_{k-1}^{\text{av}}) \geq -\frac{M_p^2 + M_d^2}{2 - \sqrt{2}} \sqrt{k}.
\]
Multiplying (41b) with $-1$ and adding to (40a) gives
\[
k(\tilde{L}(P_{k-1}^{\text{av}}, D_{k-1}^{\text{av}}) - \tilde{L}(P^*, D^*)) \leq \frac{M_p^2 + M_d^2 + 2M_L^2}{2 - \sqrt{2}} \sqrt{k}.
\]
Similarly multiplying (41a) with $-1$ and adding to (40b) gives
\[
k(\tilde{L}(P_{k-1}^{\text{av}}, D_{k-1}^{\text{av}}) - \tilde{L}(P^*, D^*)) \geq -\frac{M_p^2 + M_d^2 + 2M_L^2}{2 - \sqrt{2}} \sqrt{k}.
\]
This completes the proof.

Having established the convergence of the primal-dual algorithm for concave constraint functions, we next focus on the case where $F$ is convex in both $x$ and $\xi$.

VI. CONSTRAINT FUNCTION CONVEX IN UNCERTAINTY

We now consider the case where the function $\xi \mapsto F(x, \xi)$ is convex for every $x \in X$. For this class of functions, unlike the case dealt in the previous section, the supremum present in the definition of the constraint set of (19) are nonconvex in nature. Specifically, each supremum constitutes maximizing a difference of convex functions. Therefore, solving the CVaR approximation of the DRCCP (19) for this class of functions is quite challenging. As an alternative, in this section, we will first provide an inner convex approximation of the feasibility set of the CVaR approximation of the DRCCP which is computable using standard convex optimization tools. Later we will compare this inner convex approximation set with two other feasibility sets obtained from other data-driven approaches for CCPs. Unless stated otherwise, we consider $\Xi \subseteq \mathbb{R}^m$ and the 1-Wasserstein distance in this section, i.e., $p = 1$. We now state the following assumptions on the constraint function $F$.

**Assumption VI.1. (Lipschitz in uncertainty):** For every $x \in X$, the function $\xi \mapsto F(x, \xi)$ is convex. Moreover, there exists a convex function $L_F : X \to \mathbb{R}_{\geq 0}$, such that $\xi \mapsto F(x, \xi)$ is Lipschitz continuous with constant $L_F(x)$.

Recall from Lemma [VI.2] that the feasibility set of the CVaR approximation of DRCCP (17) is
\[
\bar{X}_{\text{CDCP}} := \left\{ x \in X \right| \inf_{t \in \mathbb{R}} \sup_{F \in P \in \mathcal{M}_N^p} [E_F[(F(x, \xi) + t)_+ + t\alpha] \leq 0 \right\}.
\]
We now show that the following set is a subset of $\bar{X}_{\text{CDCP}}$.
\[
\bar{X}_{\text{CDCP}}^\infty := \left\{ x \in X \right| \theta L_F(x) + \inf_{t \in \mathbb{R}} \frac{1}{N} \sum_{i=1}^{N} (F(x, \hat{\xi}_i) + t)_+ - t\alpha \leq 0 \right\}.
\]

**Lemma VI.2. (Inner approximation of $\bar{X}_{\text{CDCP}}$):** Let Assumptions [VI.1] and [VI.1] hold. Then, $\bar{X}_{\text{CDCP}}^\infty \subseteq \bar{X}_{\text{CDCP}}$ and these sets are equal when $\Xi = \mathbb{R}^m$.

**Proof.** Suppose $x \in \bar{X}_{\text{CDCP}}$. Recall from the proof of Lemma [VI.2] that for each $i \in [N]$, $(F(x, \hat{\xi}_i) + t)_+ - t\alpha \to \infty$ as $|t| \to \infty$. Therefore, fixing $\tilde{t}$, the infimum present in the inequality defining $\bar{X}_{\text{CDCP}}^\infty$ is attained. That is, there exists $t \in \mathbb{R}$ satisfying
\[
\theta L_F(x) + \frac{1}{N} \sum_{i=1}^{N} (F(x, \hat{\xi}_i) + t)_+ - t\alpha \leq 0.
\]
Further, $t$ should be positive as otherwise the above inequality will not hold. Note that under Assumption [VI.1], $\xi \mapsto (F(x, \xi) + t)_+ - t\alpha$ is convex and Lipschitz continuous with constant $L_F(x)$. Therefore, we get
\[
\inf_{t \in \mathbb{R}} \sup_{F \in \mathcal{M}_N^p} [E_F[(F(x, \xi) + t)_+ + t\alpha] \leq \sup_{F \in \mathcal{M}_N^p} [E_F[(F(x, \xi) + t)_+] - t\alpha]
\]
\[
\leq \theta L_F(x) + \frac{1}{N} \sum_{i=1}^{N} (F(x, \hat{\xi}_i) + t)_+ - t\alpha,
\]
where the last inequality is due to Theorem 6.3 and Proposition 6.5 of [23]. From (42) and (43) we conclude that $x \in \bar{X}_{\text{CDCP}}$. The equality is due to the fact that when $\Xi = \mathbb{R}^m$, the inequality (43) becomes an equality.

**Remark VI.3.** Note that Lipschitz continuity of $\xi \mapsto F(x, \xi)$ is a sufficient condition for [23, Theorem 6.3], and consequently, Lemma [VI.2] holds for a more general class of functions. However, we henceforth focus on the Lipschitz continuous case to have better clarity of exposition.

Due to Lemma [VI.2], instead of minimizing the objective over $\bar{X}_{\text{CDCP}}$, which is difficult as stated earlier, one could perform the minimization over $\bar{X}_{\text{CDCP}}^\infty$. The later problem is easier to deal with and the obtained solution will be feasible with respect to $\bar{X}_{\text{CDCP}}$. Consequently, the optimal value will provide an upper bound on the cost.

In the remainder of the section, we will focus our attention on comparing the set $\bar{X}_{\text{CDCP}}^\infty$ with the feasibility set of other
Proposition VI.4. (Superset of $\hat{X}_{\text{SCP}}$): Let Assumptions [IV.7] and [VI.7] hold. Assume $L_F$ is constant over $X$. Then, $\hat{X}_{\text{SCP}} \subseteq \hat{X}_{\text{SCP}}$ with
\[
\delta = \alpha - \frac{\theta L_F}{t^*} \quad \text{and} \quad t^* = \sup_{x \in X} - F(x, \xi).
\]
Proof. Let $\bar{x} \in \hat{X}_{\text{SCP}}$ and $J^N := \{ i \in [N] | F(\hat{x}, \xi_i) > 0 \}$, i.e., $J^N$ is the set of indices of samples that violate the constraint $F(\hat{x}, \xi) \leq 0$. By the definition of $\hat{X}_{\text{SCP}},$
\[
L_F \theta + \inf_{t \in \mathbb{R}} \frac{1}{N} \sum_{i=1}^{N} (F(\hat{x}, \xi_i) + t)_+ - t \alpha \leq 0
\]

Next we compare $\hat{X}_{\text{SCP}}$ with the feasibility set of the scenario program [12]. In contrast with the sample approximation approach, such a comparison for the scenario program is not independent of the samples. To circumvent this issue, we first carry out the comparison with the feasibility of a “robust” scenario program. Given $\delta \geq 0$ and samples $\{\xi_i\}_{i=1}^N$, define
\[
\hat{X}_{\text{SCP}}, \delta := \{ x \in X \mid F(x, \hat{\xi}) + \delta \leq 0, i \in N \}.
\]
Note that the feasibility set of the scenario program is $\hat{X}_{\text{SCP}, 0}$ and for any $\delta > 0$, $\hat{X}_{\text{SCP}, \delta} \subseteq \hat{X}_{\text{SCP}, 0}$. The next result shows that the feasibility set of the “robust” scenario program is contained in the set $\hat{X}_{\text{SCP}}$.

Proposition VI.5. (Subset of $\hat{X}_{\text{SCP}}$): Let Assumptions [IV.7] and [VI.7] hold. Assume $L_F$ is constant over $X$. Then, $\hat{X}_{\text{SCP}} \subseteq \hat{X}_{\text{SCP}, 0}$ with $\delta = \frac{\theta L_F}{\alpha}$.

Proof. Let $\bar{x} \in \hat{X}_{\text{SCP}, \delta}$ with $\delta = \frac{\theta L_F}{\alpha}$. By definition, $F(\bar{x}, \hat{\xi}) + \delta \leq 0$ for all $i \in [N]$. Using this fact, we get
\[
L_F \theta + \frac{1}{N} \sum_{i=1}^{N} (F(\bar{x}, \hat{\xi}) + t)_+ - t \alpha \
\leq L_F \theta + \frac{1}{N} \sum_{i=1}^{N} \left( F(\hat{x}, \xi_i) + \frac{\theta L_F}{\alpha} \right)_+ - L_F \theta = 0.
\]
The inequality holds as we have picked $t = \delta$ and removed the infimum operator. Thus, we conclude that $\bar{x} \in \hat{X}_{\text{SCP}}$. 

The following equation summarizes the comparisons obtained so far. For $\delta_1 = \frac{\theta L_F}{\alpha}$ and $\delta_2 = \alpha - \frac{\theta L_F}{t^*}$, we have

Note that the feasibility set of the scenario program is $\hat{X}_{\text{SCP}, 0}$ and for any $\delta > 0$, $\hat{X}_{\text{SCP}, \delta} \subseteq \hat{X}_{\text{SCP}, 0}$. The next result shows that the feasibility set of the “robust” scenario program is contained in the set $\hat{X}_{\text{SCP}}$.

Remark VI.6. Independent of our work, [23] showed the above relationships between the feasibility sets $\hat{X}_{\text{SCP}}$ and $\hat{X}_{\text{SCP}, \delta}$ when the constraint function is affine in $x$ and $\xi$. We show that above comparison holds more generally when the constraint function is convex in both $x$ and $\xi$.

We conclude this section with the following ex-post comparison of the feasibility sets $\hat{X}_{\text{SCP}, 0}$ and $\hat{X}_{\text{SCP}}$.

Proposition VI.7. (Ex-post comparison of $\hat{X}_{\text{SCP}}$ and $\hat{X}_{\text{SCP}, 0}$): Let Assumptions [IV.7] and [VI.7] hold. Assume $L_F$ is constant over $X$. Let $x \in \hat{X}_{\text{SCP}, 0}$. Define $J_x := \{ i \in [N] | F(x, \xi_i) = 0 \}$ and $\gamma_x := \min_{i \in [N] \setminus J_x} (-F(x, \xi_i))$. If $\theta \leq \frac{\gamma_x}{\frac{1}{N}} (\alpha - \frac{\theta L_F}{t^*})$, then $x \in \hat{X}_{\text{SCP}}$.

Proof. Let $t = \gamma_x$. Then, for $i \in [N] \setminus J_x$, $F(x, \xi_i) + \gamma_x \leq 0$. Therefore,
\[
L_F \theta + \frac{1}{N} \sum_{i=1}^{N} (F(\bar{x}, \hat{\xi}) + \gamma_x)_+ - \gamma_x \alpha \
= L_F \theta - \gamma_x \alpha + \frac{1}{N} \sum_{i \in J_x} \gamma_x = L_F \theta - \gamma_x \alpha + \frac{\left| J_x \right|}{N} \gamma_x \leq 0.
\]
Thus, we deduce that $x \in \tilde{X}_{\text{CRRCP}}$.

As a consequence of the above result, for a given optimal solution $x^* \in X$ of the scenario program, if $\frac{\alpha - \theta^*}{\gamma} > 0$, we can choose the radius of the Wasserstein ambiguity set $\theta$ to be sufficiently small such that the optimal solution of the DRCCP with the feasibility set $\tilde{X}_{\text{CRRCP}}$ has a smaller value compared to the scenario program.

VII. CONCLUSION

We studied distributionally robust chance constrained optimization problems under Wasserstein ambiguity sets defined as the set of all distributions that are close to the empirical distribution constructed from data/samples. We presented a convex reformulation of the program when the original chance constraint is replaced by its convex CVaR counterpart. We then showed the tractability of the convex reformulation for constraint functions affine in uncertainty. Furthermore, we presented a primal-dual algorithm and proved its convergence to the optimal value of the CVaR approximation of DRCCP for constraint functions concave in uncertainty. Finally, for constraint functions convex in uncertainty, we compared the feasibility sets of DRCCP and its approximations with those of the scenario and sample approximation approaches.

Thus, our paper establishes the algorithmic foundations for computing data-driven solutions of DRCCPs. In subsequent works, we will build upon our results to design distributionally robust controllers for stochastic systems under uncertainty. In addition, we will explore online optimization approaches for DRCCPs, and investigate their relevance for stochastic model predictive control problems. A rigorous comparison of DRCCPs and the scenario approach vis-a-vis finite sample guarantees and asymptotic convergence of optimal solution also remain as challenging open problems.

ACKNOWLEDGEMENT

We thank Prof. Shabbir Ahmed and Prof. Weijun Xie for pointing out an error in an earlier version of this work as well as pointers to certain relevant papers. We thank Prof. Peyman Mohajerin Esfahani for helpful discussions.
