Quantum multiparameter estimation involves estimating multiple parameters simultaneously and can be more precise than estimating them individually. Our interest here is to determine fundamental quantum limits to the achievable multiparameter estimation precision in the presence of noise. We present a lower bound to the estimation error covariance for a noisy initial probe state evolving via a noiseless quantum channel. We then present a lower bound to the estimation error covariance in the most general form for a noisy initial probe state evolving via a noisy quantum channel. We show conditions and accordingly measurements to attain these estimation precision limits for noisy systems. We see that the Heisenberg precision scaling of $1/N$ can be achieved with a probe comprising $N$ particles even in the presence of noise. In fact, some noise in the initial probe state or the quantum channel can serve as a feature rather than a bug, since the estimation precision scaling achievable in the presence of noise in the initial state or the channel in some situations is impossible in the absence of noise in the initial state or the channel. However, a lot of noise harms the quantum advantage achievable with $N$ parallel resources, and allows for a best precision scaling of $1/\sqrt{N}$. Moreover, the Heisenberg precision limit can be beaten with noise in the channel, and we present a super-Heisenberg precision limit with scaling of $1/N^2$ for optimal amount of noise in the channel, characterized by one-particle evolution operators. Further, using $\gamma$-particle evolution operators for the noisy channel, where $\gamma > 1$, the best precision scaling attainable is $1/N^{2\gamma}$, which is otherwise known to be only possible using $2\gamma$-particle evolution operators for a noiseless channel. Besides, we propose a fundamental correlations conservation law underlying the fabric of everything.

I. INTRODUCTION

Studying quantum multiparameter estimation has recently been of significant interest [1–14]. While quantum resources allow for surpassing measurement limits set by classical physics [15–17], it is important to consider fundamental measurement limits set by quantum mechanics. Although quantum estimation of a single parameter captures many scenarios [18], the practically more relevant problem of estimating multiple parameters simultaneously has started drawing more attention, mainly because unlike in quantum single-parameter estimation case, quantum measurements required to attain multiparameter bounds do not necessarily commute [5, 19, 21].

Multiparameter estimation using a pure (i.e. noiseless) probe state under unitary (i.e. noiseless) evolution has been studied, e.g. in Ref. [5]. This work, like most in the literature, used symmetric logarithmic derivatives (SLDs), as used by Helstrom [19], to define the quantum Fisher information matrix (QFIM) [22]. Then, the estimation error covariance (that is the multiparameter counterpart to the mean-squared estimation error in single parameter estimation) is lower-bounded by the inverse of the QFIM and the bound is called a quantum Cramér-Rao bound (QCRB) [23]. Such a QFIM for a probe with multiple particles under unitary evolution via one particle Hamiltonians [5, 23, 24] was shown to depend only on the one- and two-particle reduced density operators [24] of the probe state. However, when the initial probe state is mixed (i.e. noisy) but the quantum channel is unitary, even for single parameter estimation, only an upper bound to such an SLD-based QFIM (and therefore, a lower bound to the corresponding QCRB) can be explicitly established in general [25, 26]. Although noiseless quantum parameter estimation has been studied extensively and is well understood, it is important to study and better understand fundamental quantum estimation limits in more practical noisy situations [2, 22, 26, 47].

In this article, we present a multiparameter QCRB for a noisy initial state evolving unitarily, based on antisymmetric logarithmic derivatives (ALDs) [18, 49], that lend a convenient way to study noisy quantum metrology. Moreover, we use a similar ALD-approach to present an upper bound to the QFIM (like in Refs. [22, 26]) for the case of impure initial states under arbitrary evolution. That is, we consider a noisy quantum channel and a mixed initial probe state and define a quantum lower bound for the estimation error covariance in this general-case. Such bounds for an $N$-particle probe state depend on the one- and two-particle reduced density operators only, similar to the case of pure state evolving unitarily in Ref. [5]. We also provide conditions and accordingly measurements that allow to attain these bounds.

Our results here are fundamentally profound because of several reasons. Firstly, the tight bounds presented here are explicitly computable (e.g. in terms of the Kraus operators of a noisy channel), without any knowledge of the eigenvalues and the eigenvectors of the evolved probe state [24, 27] and are not known to be possible for these most general noisy cases using the conventional SLD-approach. A similar bound with SLDs was obtained for single parameter estimation earlier [26, 31, 50], but it was not considered tight being an upper bound to the
SLD QFI, and accordingly a tighter bound, linear in the number \( N \) of resources was considered. Secondly, our bounds are such that the quantum enhancement to the estimation precision is provided by the two-particle reduced density matrices of the probe state and the attainability of the quantum enhancement is determined solely by the one-particle reduced density matrices of the probe state, when the channel is characterized by one-particle evolution operators, even in the presence of noise, similar to the noiseless case from Ref. [3]. Thirdly, the results here suggest that the Heisenberg scaling of \( 1/N \) in the estimation precision, with \( N \) number of resources, is achievable even in the presence of noise. Moreover, some noise in the quantum channel or the initial probe state can act as a feature rather than a bug, since we see that there are situations when it is not possible to attain the Heisenberg limit in the absence of noise in the channel or the initial state, but it is possible in the presence of noise in the channel or the initial state. However, too much noise in the initial state or the channel harms the quantum advantage achievable with \( N \) parallel resources.

Furthermore, we show that the Heisenberg precision limit can be beaten with noise in the quantum channel. The best achievable precision limit for non-unitary channel is then determined by two-particle reduced density operators of the evolved probe state being maximally entangled and one-particle reduced density operators being maximally mixed, and corresponds to a precision scaling of \( 1/N^2 \), attained with one-particle evolution operators for the channel. Further, using \( \gamma \)-particle (instead of one-particle) evolution operators for a noisy channel, where \( \gamma > 1 \), the best precision scaling achievable is \( 1/N^{2\gamma} \), that is otherwise known as achievable with \( 2\gamma \)-particle evolution operators of a noiseless channel. Besides, we propose a spatiotemporal correlations conservation law, that may underlie the fabric of everything.

Before we proceed, it is important to explicitly point out why the non-standard ALD-approach instead of the standard SLD-approach is adopted in this paper. The way we choose the ALDs in this article, it turns out that the ALD-based QFIM is an upper bound to the standard SLD-based QFIM for the noiseless channel case. As already pointed out, such an upper bound to the SLD QFIM for single parameter estimation has been obtained earlier, but it was not considered a tight bound, since beating the SLD QFIM would mean that the Heisenberg limit can be beaten. However, we show here that such an upper bound to the SLD QFIM can be tight too, but the use of ALD-approach indicates that the Heisenberg limit is not beaten for the noiseless channel case. Thus, the QFIM obtained here for the noiseless channel case cannot be obtained using the SLD-approach and the corresponding equivalent bound obtained using SLDs would seem to beat the Heisenberg limit. Moreover, for the multiparameter noisy channel case considered here, the upper bound to the ALD QFIM we obtained cannot be obtained using the SLD-approach, since it would be an upper bound to the aforementioned upper bound to the SLD QFIM. We show that such an upper bound to the ALD QFIM can also be tight, implying that the Heisenberg limit can be beaten. It is unlikely that there exists some other logarithmic derivative for which the QFIM would be the upper bound to the ALD QFIM, suggesting that the Heisenberg limit is still not beaten.

II. MULTIPARAMETER QUANTUM CRAMÉR-RAO BOUND

An experiment for estimation of some unknown parameters corresponding to a quantum process involves three stages. First, a probe state is prepared in an initial state, comprising \( N \) number of resources, and evolves under the evolution operators of a noiseless channel. Besides, we show that the Heisenberg precision limit to the aforementioned upper bound to the SLD QFIM can also be tight, implying that the Heisenberg limit can be beaten. It is unlikely that there exists some other logarithmic derivative for which the QFIM would be the upper bound to the SLD QFIM, suggesting that the Heisenberg limit is still not beaten.

Before we proceed, it is important to explicitly point out why the non-standard ALD-approach instead of the standard SLD-approach is adopted in this paper. The way we choose the ALDs in this article, it turns out that the ALD-based QFIM is an upper bound to the standard SLD-based QFIM for the noiseless channel case. As already pointed out, such an upper bound to the SLD QFIM for single parameter estimation has been obtained earlier, but it was not considered a tight bound, since beating the SLD QFIM would mean that the Heisenberg limit can be beaten. However, we show here that such an upper bound to the SLD QFIM can be tight too, but the use of ALD-approach indicates that the Heisenberg limit is not beaten for the noiseless channel case. Thus, the QFIM obtained here for the noiseless channel case cannot be obtained using the SLD-approach and the corresponding equivalent bound obtained using SLDs would seem to beat the Heisenberg limit. Moreover, for the multiparameter noisy channel case considered here, the upper bound to the ALD QFIM we obtained cannot be obtained using the SLD-approach, since it would be an upper bound to the aforementioned upper bound to the SLD QFIM. We show that such an upper bound to the ALD QFIM can also be tight, implying that the Heisenberg limit can be beaten. It is unlikely that there exists some other logarithmic derivative for which the QFIM would be the upper bound to the ALD QFIM, suggesting that the Heisenberg limit is still not beaten.

II. MULTIPARAMETER QUANTUM CRAMÉR-RAO BOUND

An experiment for estimation of some unknown parameters corresponding to a quantum process involves three stages. First, a probe state is prepared in an initial state, comprising \( N \) number of resources, and evolves under the action of the quantum process. The second stage involves choosing a suitable measurement, applied to the evolved probe state. The final step involves associating, through an estimator, each experimental result with an estimation of the parameters [26]. The Heisenberg limit to the estimation precision is then the precision scaling of \( 1/N \).

Consider that a probe state \( \hat{\rho} \) acquires \( q \) number of parameters \( \hat{\theta} = [\theta_1 \theta_2 \ldots \theta_q]^T \) via a unitary transformation \( \hat{U}(\hat{\theta}) \), and we seek the best quantum strategy to estimate the parameters from the evolved probe state, \( \hat{\rho}(\hat{\theta}) = \hat{U}(\hat{\theta})\hat{\rho}\hat{U}^\dagger(\hat{\theta}) \). Let a measurement performed on the evolved state \( \hat{\rho}(\hat{\theta}) \) be given by some positive operator valued measure (POVM) \( \{\hat{P}_m\} \). The conditional probability to obtain the outcome \( m \) given the parameters have the value \( \theta \) is \( p(m|\theta) = \text{Tr}(\hat{P}_m\hat{\rho}(\theta)) \). The estimates \( \hat{\theta}(m) = [\hat{\theta}_1(m) \hat{\theta}_2(m) \ldots \hat{\theta}_q(m)]^T \) are unbiased if

\[
\sum_m p(m|\theta)\hat{\theta}_j(m) = \theta_j \quad \forall j.
\]

Then, the estimation error covariance is

\[
V[\hat{\theta}(m)] = \sum_m p(m|\theta) (\hat{\theta}(m) - \theta)(\hat{\theta}(m) - \theta)^T.
\]
Then, we have
\[ \nu V[\theta(m)] \geq [J_C(\theta)]^{-1} \geq [J_Q(\theta)]^{-1}, \] (7)
where, \( \hat{L}_k \) was taken to be Hermitian by Helstrom [19], in which case it is called the symmetric logarithmic derivative (SLD). In general, \( \hat{L}_k \) need not be Hermitian. We assume that \( \hat{L}_k \) is anti-Hermitian, such that \( \hat{L}_k \) is an SLD and an anti-Hermitian \( \hat{L}_k \) is an ALD [49]. Although Ref. [48] considered a different (Bayesian waveform-) estimation problem, [41] can be similarly proven here. See Appendix A.

Although the classical Cramér-Rao bound (i.e. the first inequality in (7)) can always be saturated, e.g. by a maximum likelihood estimator [51], the QCRB (i.e. the second inequality in (7)) for SLDs is not known to be attainable in general. We claim that an ALD-based QCRB of the form (4) can be saturated (i.e. attained), when the QFIM is not rank deficient and the expectation of the commutator of every pair of the ALDs vanishes, similar to the case of SLD-based QCRB [5, 52, 53]:

\[
\text{Tr} \left[ \left( \hat{L}_j \hat{L}_k - \hat{L}_k \hat{L}_j \right) \hat{\rho}(\theta) \right] = \text{Tr} \left( \left[ \hat{L}_j, \hat{L}_k \right] \hat{\rho}(\theta) \right) = 0. \quad (8)
\]

See Appendix A. The above condition is trivially true for single parameter estimation. Then, the set of POVMs of cardinality \( q+2 \), comprising the following \( q+1 \) elements,

\[
\hat{P}_b = \sqrt{\hat{\rho}(\theta)} = \hat{U}(\theta) \hat{\rho}(\theta) \hat{U}^\dagger(\theta),
\]

\[
\hat{P}_m = \frac{\partial \hat{\rho}(\theta)}{\partial \theta_m} \hat{U}(\theta) \hat{\rho}(\theta) \hat{U}^\dagger(\theta) + \hat{U}(\theta) \hat{\rho}(\theta) \frac{\partial \hat{U}^\dagger(\theta)}{\partial \theta_m} \forall m = 1, \ldots, q,
\]

along with one normalising element, saturates the QCRB (see Appendix A). For pure states \( |\psi\rangle \), the \( q+1 \) projectors,

\[
\hat{P}_b = \sqrt{\hat{\rho}(\theta)} = \hat{U}(\theta)|\psi\rangle\langle\psi|\hat{U}^\dagger(\theta),
\]

\[
\hat{P}_m = \frac{\partial \hat{\rho}(\theta)}{\partial \theta_m} |\psi\rangle\langle\psi| \frac{\partial \hat{U}^\dagger(\theta)}{\partial \theta_m} \forall m = 1, \ldots, q,
\]

along with one normalising element, saturates the QCRB. This follows from Refs. [1, 5] (see Appendix A).

III. THE QFIM FOR ONE-PARTICLE HAMILTONIANS

Let us now consider that the unitary evolution is \( \hat{U}(\theta) = e^{-i \hat{H}(\theta)} \) and that the probe state \( \hat{\rho} \) comprises \( N \) particles evolving under the one-particle Hamiltonian \( \hat{h}^{[n]} = \sum_{k=1}^q \theta_k \hat{h}_k^{[n]} \) for \( n = 1, \ldots, N \), such that [5]:

\[
\hat{H}(\theta) = \sum_{n=1}^N \hat{h}^{[n]} = \sum_{k=1}^q \theta_k \sum_{n=1}^N \hat{h}_k^{[n]} \equiv \sum_{k=1}^q \theta_k \hat{H}_k.
\] (11)

The generators \( \hat{H}_k \) are assumed to not depend on \( \theta \) and do not generally commute with each other. Then, as employed by Ref. [3], we have [54]:

\[
\frac{\partial \hat{U}(\theta)}{\partial \theta_k} = \frac{1}{i} \int_0^1 d\alpha e^{-i(1-\alpha)\hat{U}(\theta)\hat{h}(\theta)\hat{U}^\dagger(\theta)} e^{-i\alpha \hat{h}(\theta)}.
\] (12)

Then, we have

\[
\frac{\partial}{\partial \theta_k} \hat{\rho}(\theta) = \frac{\partial}{\partial \theta_k} \left( \hat{U}(\theta) \hat{\rho}(\theta) \hat{U}^\dagger(\theta) \right) = -i \left[ \hat{M}_k(\theta), \hat{\rho}(\theta) \right].
\] (13)

where

\[
\hat{M}_k(\theta) = i \frac{\partial \hat{U}(\theta)}{\partial \theta_k} \hat{U}^\dagger(\theta) = \hat{U}(\theta) \hat{A}_k(\theta) \hat{U}^\dagger(\theta),
\]

with \( \hat{A}_k(\theta) = \int_0^1 d\alpha e^{i\alpha \hat{H}(\theta)} \hat{H}_k e^{-i\alpha \hat{H}(\theta)} \). We choose the operator \( \hat{L}_k \) as the anti-Hermitian, \( \hat{L}_k = -2i \Delta \hat{M}_k \), where

\[
\Delta \hat{M}_k = \hat{M}_k(\theta) - \text{Tr} \left( \hat{M}_k(\theta) \hat{\rho}(\theta) \right).
\] (15)

The QFIM from (4) then takes the form:

\[
J^k_Q = 2 \text{Tr} \left[ (\Delta \hat{A}_k \Delta \hat{A}_k + \Delta \hat{A}_k \Delta \hat{A}_k) \hat{\rho} \right],
\]

where

\[
\Delta \hat{A}_k = \hat{A}_k(\theta) - \text{Tr} \left( \hat{A}_k(\theta) \hat{\rho} \right) = \sum_n \left( \hat{\rho}^{[n]} - \text{Tr} \left( \hat{\rho}^{[n]} \hat{b}^{[n]} \right) \right) = \sum_n \hat{c}^{[n]},
\]

with \( \hat{c}^{[n]} = \int_0^1 d\alpha e^{i\alpha \hat{h}^{[n]}} \hat{b}^{[n]} e^{-i\alpha \hat{h}^{[n]}} \). Thus, (10) becomes:

\[
J^k_Q = 2 \sum_n \text{Tr} \left[ \left( \hat{c}^{[n]}_{\hat{b}^{[n]}} + \hat{c}^{[n]}_{\hat{c}^{[n]}} \right) \hat{\rho}^{[n]} \right] + 2 \sum_{n \neq m} \text{Tr} \left[ \left( \hat{c}^{[n]}_{\hat{c}^{[m]}} + \hat{c}^{[m]}_{\hat{c}^{[n]}} \right) \hat{\rho}^{[n,m]} \right] = 2 \sum_n \text{Re} \left[ \text{Tr} \left( \hat{\rho}^{[n]} \hat{b}^{[n]} \right) - \text{Tr} \left( \hat{\rho}^{[n]} \hat{b}^{[n]} \right) \text{Tr} \left( \hat{\rho}^{[n]} \hat{b}^{[n]} \right) \right] + 2 \sum_{n \neq m} \text{Re} \left[ \text{Tr} \left( \hat{\rho}^{[n]} \hat{b}^{[m]} \right) \text{Tr} \left( \hat{\rho}^{[m]} \hat{b}^{[n]} \right) \right]
\]

\[
- \text{Tr} \left( \hat{\rho}^{[n]} \hat{b}^{[n]} \right) \text{Tr} \left( \hat{\rho}^{[m]} \hat{b}^{[m]} \right) = \sum_n J^k_Q^{[1]} \left( \hat{\rho}^{[n]} \right) + \sum_{n \neq m} J^k_Q^{[2]} \left( \hat{\rho}^{[n,m]} \right),
\]

where \( J^k_Q^{[1]} \) depends only on one-particle reduced density matrix on subsystem \( n \) and \( J^k_Q^{[2]} \) depends on two-particle reduced density matrix on subsystems \( n, m \).

We now restrict to permutationally invariant states [3], i.e. states that are invariant under any permutation of its constituents: \( \hat{\rho} = O_\pi \hat{\rho} O_\pi^\dagger \) for all possible \( \pi \), where \( O_\pi \) is the unitary operator for the permutation \( \pi \). Then,

\[
J^k_Q = N J^k_Q^{[1]} \left( \hat{\rho}^{[1]} \right) + N(N-1) J^k_Q^{[2]} \left( \hat{\rho}^{[1]}, \hat{\rho}^{[2]} \right),
\] (18)

where

\[
J^k_Q^{[1]} = 4 \text{Re} \left[ \text{Tr} \left( \hat{\rho}^{[1]} \hat{b}^{[n]} \right) - \text{Tr} \left( \hat{\rho}^{[1]} \hat{b}^{[n]} \right) \text{Tr} \left( \hat{\rho}^{[1]} \hat{b}^{[n]} \right) \right].
\]
only depends on the first order reduced density matrix, 
\[ J^{[1],2}_Q = 4\text{Re} \left[ \text{Tr} \left[ \hat{\rho}^{[2]} \left( b_j \otimes \hat{b}_k \right) \right] - \text{Tr} \left[ \hat{\rho}^{[1]} b_j \right] \text{Tr} \left[ \hat{\rho}^{[1]} \hat{b}_k \right] \right] \]
also depends on the second order reduced density matrix.

Then, similar observations can be made as were made in Ref. [3] for pure state. For example, if the probe state is a product state, i.e. \( \hat{\rho} = \bigotimes_{n=1}^{N} \hat{\rho}^{[n]} \), and permutation-invariant, then \( \hat{\rho}^{[2]} = \hat{\rho}^{[1]} \otimes \hat{\rho}^{[1]} \), such that \( J^{[1],2}_Q = 0 \), and so \( J^{[k]}_Q = N J^{[k],1}_Q \). This implies that quantum correlations necessary for achieving the Heisenberg scaling \( 1/N \), which is evidently attainable even when the initial probe state is mixed. However, if both \( \hat{\rho}^{[1]} \) and \( \hat{\rho}^{[2]} \) are maximally mixed, the Heisenberg scaling is lost, i.e. too much quantum correlations harm the quantum advantage in Ref. [5] for pure state. For example, if the probe state also depends on the second order reduced density matrix.

Moreover, from (9), the set of POVMs, comprising
\[ \tilde{P}_m = \frac{\partial \hat{\rho}(\theta)}{\partial \theta_m} = i \left[ M_m(\theta, \hat{\rho}(\theta)) \right] \quad \forall m = 1, \ldots, q, \] (19)
along with one element accounting for normalisation, saturates the QCRB for \( \tilde{P} \), provided we have \( \tilde{S} \), i.e. here
\[ 2 \text{Tr} \left[ \left( \Delta A_j \Delta A_k - \Delta A_k \Delta A_j \right) \hat{\rho} \right] = 0 \quad \forall j, k \]
\[ \Rightarrow 4 \text{Im} \text{Tr} \left[ \hat{\rho}^{[n]} b_j^{[n]} b_k^{[n]} \right] = 0 \]
\[ + 4 \text{Im} \text{Tr} \left[ \hat{\rho}^{[n]} (b_j^{[n]} \otimes b_k^{[n]}) \right] = 0 \] (20)
\[ \Rightarrow 4 \text{Im} \text{Tr} \left[ \hat{\rho}^{[n]} b_j^{[n]} b_k^{[n]} \right] = 0, \]
\[ \text{Tr} \left[ \hat{\rho}^{[n]} b_j^{[n]} \right] = 1. \] Hence, the attainability of the quantum enhancement to the estimation precision is determined solely by the one-particle reduced density matrices of the probe state.

IV. ESTIMATING A MAGNETIC FIELD IN THREE DIMENSIONS

Now consider the task of estimating the components of a magnetic field in three dimensions simultaneously using two-level systems. The Hamilton operator for this system is given by \( \hat{h} = \hat{\mu} \cdot \mathbf{B} = \sum_{k=1}^{3} \mu_k B_k \mathbf{b}_k = \sum_{k=1}^{3} (\mu/2) B_k \hat{b}_k = 2 \sum_{k=1}^{3} \theta_k \sigma_k \), where the magnetic moment \( \mu_k = \mu \sigma_k / 2 \) is proportional to the spin, \( \{ \sigma_k \} \) are the unnormalized Pauli operators, and \( \theta_k = \mu B_k / 2 \mathbf{2} \).

Start with a Greenberger-Horne-Zeilinger (GHZ) type pure state \( | \Phi_k \rangle = \left( | \Phi_+^{[N]} \rangle + | \Phi_-^{[N]} \rangle \right) / \sqrt{2} \), where \( | \Phi_\pm^{[N]} \rangle \) is the eigenvector of the Pauli operator \( \sigma_k \) corresponding to the eigenvalue \( \pm 1 \) \( (k = 1, 2, 3 \) corresponding to the \( X, Y, \) and \( Z \) directions). These states are permutation-invariant with first and second order reduced density matrices \( \hat{\rho}^{[1]}_k = \mathbf{1}_2/2 \) and \( \hat{\rho}^{[2]}_k = \left( | \phi_k^+ \rangle \langle \phi_k^+ | + | \phi_k^- \rangle \langle \phi_k^- | \right) / \sqrt{2} + \hat{\sigma}_k/2 \), respectively. This directly follows from the way it was shown in Ref. [3] for the pure state case. Hence, we consider the probe state to have marginals \( \hat{\rho}^{[1]}_k = \mathbf{1}_2/2 \) and \( \hat{\rho}^{[2]}_k \) as above and calculate the QFIM. We get
\[ J^{[k]}_Q = 2 \text{Tr} \left[ \hat{b}_j \hat{b}_k \right] \] (22)
and
\[ J^{[k],2}_Q = \frac{1}{3} \sum_{t=1}^{3} \text{Tr} \left[ \frac{1}{2} \left( \sum_{r=0}^{N-1} \hat{E}_t \sigma_t \hat{E}_r \otimes \sum_{s=0}^{N-1} \hat{E}_s \sigma_s \hat{E}_r \right) \left( \hat{b}_j \otimes \hat{b}_k \right) \right] \]
\[ = \frac{1}{3} \sum_{t=1}^{3} \text{Tr} \left[ \frac{1}{2} \left( \sum_{r=0}^{N-1} \hat{E}_t \sigma_t \hat{E}_r \right) \left( \sum_{s=0}^{N-1} \hat{E}_s \sigma_s \hat{E}_r \right) \right] \]
\[ = \frac{1}{3} \sum_{t=1}^{3} \text{Tr} \left[ \left( \frac{1}{2} \left( \sum_{r=0}^{N-1} \hat{E}_t \sigma_t \hat{E}_r \right) \hat{b}_j \hat{b}_k \right) \hat{E}_t \right] \]
\[ = \frac{2}{3} \sum_{t=1}^{3} \text{Tr} \left[ \hat{\sigma}_t \left( \frac{1}{2} \left( \sum_{r=0}^{N-1} \hat{E}_t \hat{b}_j \hat{E}_r \right) \right) \hat{b}_k \hat{E}_t \right] \]
\[ = \frac{2}{3} \sum_{t=1}^{3} \text{Tr} \left[ \hat{E}_t \hat{b}_j \hat{E}_t \hat{b}_k \hat{E}_t \right] \] (23)
Define \( \hat{f}_i = \sum_{r=0}^{l} \hat{E}_r \hat{b}_i \hat{E}_r \) and \( \hat{f}_k = \sum_{r=0}^{l} \hat{E}_r \hat{b}_k \hat{E}_r \). Also, let \( \xi = \sqrt{\theta_1^2 + \theta_2^2 + \theta_3^2}, \eta_k = \frac{\theta_k}{\sqrt{\theta_1^2 + \theta_2^2 + \theta_3^2}} \) for all \( k = 1, 2, 3 \) (corresponding to the \( X, Y \) and \( Z \) directions). Here, (22) is found to be (following Ref. [3]):
\[
J_{Q}^{j_1, j_2} = 4 \left[ (1 - \sin^2[\xi]) \eta_j \eta_k + \delta_{jk} \sin^2[\xi] \right],
\]
where \( \sin[\xi] = \sin[\xi]/\xi \). From (18), (24), (25), we get:
\[
J_{Q}^{j_k} = 4N \left[ (1 - \sin^2[\xi]) \eta_j \eta_k + \delta_{jk} \sin^2[\xi] \right] + \frac{2N(N-1)}{3} \text{Tr} \left[ \hat{f}_j \hat{f}_k \right],
\]
where the terms \( \text{Tr} \left[ \hat{f}_j \hat{f}_k \right] \) can be explicitly calculated.

Since some or all of the terms \( \text{Tr} \left[ \hat{b}_j \hat{b}_k \right] \) are non-zero, we can have the terms \( \text{Tr} \left[ \hat{f}_j \hat{f}_k \right] \) as non-zero, such that the scaling \( 1/N \) can be achieved, as the parallel scheme bound without ancillas from Ref. [53] can be tight even for \( \beta \neq 0 \). Even when \( \text{Tr} \left[ \hat{b}_j \hat{b}_k \right] = 0 \), the terms \( \text{Tr} \left[ \hat{f}_j \hat{f}_k \right] \) in general (i.e. when \( \hat{E}_0 \) and \( \hat{E}_1 \) need not be local dephasing operators), can be non-zero. This implies that it is possible to achieve the Heisenberg scaling with the presence of noise in the initial probe state, even when such a scaling cannot be achieved in the absence of noise in the initial state. This is because mixed separable states can be as nonclassical as entangled pure states [57]. Thus, noise in the initial probe state can act as a feature rather than a bug in attaining the Heisenberg limit. Note though that it is unlikely for all the terms \( \text{Tr} \left[ \hat{b}_j \hat{b}_k \right] \) to be zero, since that would mean that the QFIM \( J_Q \) is zero for the pure state case from Ref. [3]. However, even when some or all of the terms \( \text{Tr} \left[ \hat{b}_j \hat{b}_k \right] \) are non-zero, it may be possible for the terms \( \text{Tr} \left[ \hat{f}_j \hat{f}_k \right] \) to be such that the QFIM \( J_Q \) for the mixed state case considered here is larger than that for the pure state case from Ref. [3]. This is because mixed entangled states can be more nonclassical than pure entangled states [57]. Thus, noise in the initial probe state can allow for better estimation precision than the case of no noise in the initial state.

Although noise is known to reduce quantum correlations in a system in most cases [24, 58], noise can also introduce or increase quantum correlations in a system [59, 62]. For example, local dephasing considered in this section is a local unital noise [61], that mostly decreases quantum correlations. Instead, if local non-unital noise, such as local dissipation [62] as represented by the following single-particle Kraus operators [24], is used to obtain the initial mixed probe state from a classically correlated separable state, the mixed state so obtained can have quantum correlations, that may be activated into entanglement, allowing for better estimation precision [63, 66]:
\[
\hat{E}_0 = \begin{bmatrix} 1 & 0 \\ 0 & \sqrt{1-e^{-\kappa}} \end{bmatrix}, \quad \hat{E}_1 = \begin{bmatrix} 0 & e^{-\kappa} \\ 0 & 0 \end{bmatrix},
\]
where \( \kappa \) is a constant causing amplitude damping. This is why ancilla-assisted schemes of Ref. [31] yielded scaling better than that without ancillas for amplitude damping. Nonetheless, if \( \hat{\rho}^{[1]} = \hat{\rho}^{[1]} = \mathbb{I}_4/4 \), i.e. both \( \hat{\rho}^{[1]} \) and \( \hat{\rho}^{[2]} \) are maximally mixed, then \( \text{Tr} \left[ \hat{f}_j \hat{f}_k \right] = 0 \), since \( \sum_{k=1}^{3} \left( \sum_{r=0}^{l} \hat{E}_r \hat{\sigma}_r \hat{E}_r \hat{\sigma}_r \right) = 0 \), where \( \hat{\sigma}_r \) are non-zero, \( \eta = \frac{\sqrt{\theta_1^2 + \theta_2^2 + \theta_3^2}}{\sqrt{\theta_1^2 + \theta_2^2 + \theta_3^2}} \) for all \( r = 1, 2, 3 \). Therefore, the evolution is [22, 26]
\[
\hat{\rho}(\theta) = \sum_{l} \hat{\Pi}_l(\theta) \hat{\rho} \hat{\Pi}_l^\dagger(\theta),
\]
where \( \sum_{l} \hat{\Pi}_l^\dagger(\theta) \hat{\Pi}_l(\theta) = 1 \). Even when the transformation (27) is non-unitary, it may be described by a unitary evolution \( \hat{U}_{SB}(\theta) \) in a bigger space, comprising the system \( S \) and some vacuum state ancillary bath \( B \). The evolved state in \( S + B \) space is given by
\[
\hat{\rho}_{SB}(\theta) = \hat{U}_{SB}(\theta) \left( \hat{\rho} \otimes |0\rangle |0\rangle \right) \hat{U}_{SB}^\dagger(\theta) = \sum_{l,v} \hat{\Pi}_l(\theta) \hat{\rho} \hat{\Pi}_l^\dagger(\theta) \otimes |l\rangle \langle v|,
\]
Then, following from (13), (14), (15) for the noiseless \( S + B \) space, we get
\[
\frac{\partial}{\partial \theta_k} \hat{\rho}_{SB}(\theta) = -i \left( \hat{M}_k(\theta), \hat{\rho}_{SB}(\theta) \right) = \frac{1}{2} \left( \hat{L}_k \hat{\rho}_{SB}(\theta) + \hat{\rho}_{SB}(\theta) \hat{L}_k^\dagger \right),
\]
where \( \hat{M}_k(\theta) = i \frac{\partial \hat{U}_{SB}(\theta)}{\partial \theta_k} \hat{U}_{SB}^\dagger(\theta) \), and \( \hat{L}_k = -2i \Delta \hat{M}_k \) is anti-Hermitian, \( \Delta \hat{M}_k = \hat{M}_k(\theta) - \text{Tr} \left( \hat{M}_k(\theta) \hat{\rho}_{SB}(\theta) \right) \).
Then, the QFIM from (6) for \( \hat{\rho}_{SB}(\theta) \) takes the form:
\[
J_{Q}^{j_1, j_2} = 4 \text{Re} \left[ \text{Tr} \left( \hat{H}_{Q}^{j_1}(\theta) (\hat{\rho} \otimes |0\rangle |0\rangle) \right) - \text{Tr} \left( \hat{H}_{Q}^{j_2}(\theta) (\hat{\rho} \otimes |0\rangle |0\rangle) \right) \right],
\]
where
\[
\hat{H}_{Q}^{j_1}(\theta) = \frac{\partial \hat{U}_{SB}^\dagger(\theta)}{\partial \theta_j} \frac{\partial \hat{U}_{SB}(\theta)}{\partial \theta_k}, \quad \hat{H}_{Q}^{j_2}(\theta) = \frac{\partial \hat{U}_{SB}(\theta)}{\partial \theta_j} \frac{\partial \hat{U}_{SB}^\dagger(\theta)}{\partial \theta_k} \hat{U}_{SB}(\theta).
\]
However, when only the system $S$ is monitored but the bath $B$ is not monitored, we recover (27) by taking a partial trace with respect to $B$: $\text{Tr}_B(\hat{\rho}_{SB}(\Theta)) = \hat{\rho}(\Theta)$. Then, if we trace out the bath $B$ before having the traces in (23), we obtain an upper bound (like those obtained in Refs. 22, 26) to the QFIM in (1) for $\hat{\rho}(\Theta)$:

$$C_Q^{jk} = 4\text{Re} \left[ \text{Tr} \left( \hat{K}_1^{jk}(\Theta) \hat{\rho} \right) - \text{Tr} \left( \hat{K}_2^{jk}(\Theta) \hat{\rho} \right) \text{Tr} \left( \hat{K}_2^{jk}(\Theta) \hat{\rho} \right) \right],$$  

where

$$\hat{K}_1^{jk}(\Theta) = \sum_i \frac{\partial \hat{P}_i(\Theta)}{\partial \theta_j} \hat{P}_i(\Theta), \quad \hat{K}_2^{jk}(\Theta) = i \sum_i \frac{\partial \hat{P}_i(\Theta)}{\partial \theta_k} \hat{P}_i(\Theta),$$

such that

$$\hat{K}_1^{jk}(\Theta) \hat{\rho} = \text{Tr}_B \left[ \hat{H}_1^{jk}(\Theta) (\hat{\rho} \otimes |0\rangle \langle 0|) \right], \quad \hat{K}_2^{jk}(\Theta) \hat{\rho} = \text{Tr}_B \left[ \hat{H}_2^{jk}(\Theta) (\hat{\rho} \otimes |0\rangle \langle 0|) \right].$$

We prove in Appendix D that $C_Q$ from (29) is an upper bound to the QFIM $J_{Q}$ from (3) for $\hat{\rho}(\Theta)$.

One may compare these results with those in Ref. 22, where initially pure states in different modes were assumed to evolve independently. We made no such assumption and our initial state is mixed, and so our results are more general. Also, we consider estimation of multiple parameters, as opposed to single parameter estimation studied in Ref. 26. Our upper bound to the QFIM is relevant, since there are an infinitude of Kraus representations $\hat{P}_i(\Theta)$ of the channel that make the bound to equal the QFIM (26).

Now, we claim that (29) is saturated, when the following condition is satisfied:

$$\text{Im} \left[ \sum_i \text{Tr} \left\{ \left( \frac{\partial \hat{P}_i(\Theta)}{\partial \theta_j} \frac{\partial \hat{P}_i(\Theta)}{\partial \theta_k} \right) \hat{\rho} \right\} \right] = 0 \quad \forall j, k,$$

which is obtained from (8) for $S + B$ space, by tracing out $B$ (see Appendix C). That is, the bound (29) is saturated, when the expectation of the commutator of every pair of the derivatives of the channel Kraus operator and its adjoint vanishes. Clearly, when the above condition is satisfied, it is possible to attain the elusive Heisenberg limit even in the most general noisy estimation scenario. The above condition is trivially true for single parameter estimation.

Then, the set of POVMs of cardinality $q + 2$, comprising the following $q + 1$ elements,

$$\hat{P}_0 = \hat{\rho}(\Theta) = \sum_l \hat{P}_l(\Theta) \hat{P}_l^\dagger(\Theta),$$

$$\hat{P}_m = \frac{\partial \hat{\rho}(\Theta)}{\partial \theta_m} = \sum_l \left[ \frac{\partial \hat{P}_l(\Theta)}{\partial \theta_m} \hat{P}_l^\dagger(\Theta) \right] + \hat{P}_l(\Theta) \hat{P}_l^\dagger(\Theta) \frac{\partial \hat{P}_l(\Theta)}{\partial \theta_m} \forall m = 1, \ldots, q,$$

along with one element accounting for normalisation, saturates (29) (See Appendices III and IV).

VI. UPPER BOUND TO THE QFIM FOR $N$ PARTICLES EVOLVING VIA NOISY CHANNEL

Consider that the probe comprising $N$ particles evolves not necessarily unitarily. Then, the QFIM (10) is unitary evolution of a probe comprising more than $N$ particles in $S + B$ space. The evolution of the probe comprising $N$ particles in $S$ space alone is described here by some unital Kraus operators $\hat{P}_i(\Theta) = \frac{1}{\sqrt{L}} e^{-iG_i(\Theta)}$, where $l = 1, \ldots, L$, $\sum_l \hat{P}_l(\Theta) \hat{P}_l^\dagger(\Theta) = \sum_l \hat{P}_l(\Theta) \hat{P}_l(\Theta) = 1$, and

$$G_i(\Theta) = \sum_{n=1}^{N} \pi_{i,n} \theta_k \sum_{n=1}^{N} \pi_{i,n}^* \equiv \sum_{k=1}^{q} \theta_k \hat{G}_{ik}.$$ (33)

The generators $\hat{G}_{ik}$ do not depend on $\Theta$ and do not generally commute with each other. Then, as in Section III

$$\frac{\partial \hat{P}_i(\Theta)}{\partial \theta_k} = \frac{-i}{L \sqrt{L}} \int_0^1 d\alpha e^{-i(1-\alpha)G_i(\Theta) - i\alpha G_i(\Theta)}.$$ (34)

So, $\text{Tr}_B \left[ \hat{M}_k(\Theta) \right] = i \sum_l \frac{\partial \hat{P}_l(\Theta)}{\partial \theta_k} \hat{P}_l^\dagger(\Theta) = \sum_l \hat{P}_l(\Theta) \hat{B}_{ik}(\Theta) \hat{P}_l^\dagger(\Theta)$, where $\hat{M}_k(\Theta)$ is from (13) for $S + B$ space, $\sum_l \hat{B}_{ik}(\Theta) = \text{Tr}_B \left[ \hat{A}_k(\Theta) \right] = \frac{1}{L} \sum_l \int_0^1 d\alpha e^{i\alpha G_i(\Theta)} \hat{G}_{ik} e^{-i\alpha G_i(\Theta)}$, since we have $\frac{\partial \hat{G}_i(\Theta)}{\partial \theta_k} = \hat{G}_{ik}$. Then, we have in $S + B$ space

$$\frac{\partial \hat{U}_{SB}(\Theta)}{\partial \theta_k} = \hat{A}_k(\Theta) \hat{U}_{SB}(\Theta) \hat{U}_{SB}(\Theta) \hat{A}_k(\Theta).$$ (35)

Tracing out the bath $B$, we get (see Appendix D to understand why an extra $1/L$ does not arise below):

$$\frac{i}{L} \sum_l \frac{\partial \hat{P}_l(\Theta)}{\partial \theta_k} \hat{P}_l(\Theta) = \sum_l \hat{B}_{ik}(\Theta) \hat{P}_l(\Theta) \hat{P}_l^\dagger(\Theta).$$ (36)

Again, tracing out the bath $B$, we get:

$$i \sum_l \frac{\partial \hat{P}_l(\Theta)}{\partial \theta_k} \hat{P}_l(\Theta) = - \sum_l \hat{B}_{ik}(\Theta) \hat{P}_l(\Theta) \hat{P}_l^\dagger(\Theta).$$ (37)
Then, we get the desired upper bound $C_Q$ to the QFIM from (15) as follows:

\[
C_Q^{j,k} = 4\text{Re} \left[ \text{Tr} \left( \sum_l \hat{B}_{lj}(\theta) \hat{B}_{lk}(\theta) \hat{\rho} \right) - \text{Tr} \left( \sum_p \hat{B}_{pj}(\theta) \hat{\rho} \right) \text{Tr} \left( \sum_r \hat{B}_{rk}(\theta) \hat{\rho} \right) \right],
\]

(39)

and

\[
\sum \hat{B}_{lj}(\theta) \hat{B}_{lk}(\theta) = 1. \text{ Also, here we have}
\]

\[
\sum_{l \neq m} \hat{B}_{lj}(\theta) \hat{B}_{lk}(\theta) = 1.
\]

Thus, (39) becomes:

\[
C_Q^{j,k} = 4 \sum_l \text{Re} \left[ \text{Tr} \left( \sum_n \hat{\rho}_{j,[n]} \hat{d}_{n,k} \hat{\rho}_{k,[n]} \right) - \text{Tr} \left( \sum_n \hat{\rho}_{j,[n]} \hat{d}_{n,j,n} \hat{\rho}_{k,[n]} \right) \right] - \text{Tr} \left[ \sum_n \hat{\rho}_{j,[n]} \hat{d}_{n,j,n} \hat{\rho}_{k,[n]} \right] - \text{Tr} \left[ \sum_n \hat{\rho}_{j,[n]} \hat{d}_{n,j,n} \hat{\rho}_{k,[n]} \right] + 4 \sum_{n \neq m} \text{Re} \left[ \text{Tr} \left( \sum_n \hat{\rho}_{j,[n]} \hat{d}_{n,m} \hat{\rho}_{k,[n]} \right) \right]
\]

\[
= C^{j,[1]}_Q (\hat{\rho}^{[1]}_j) + C^{j,[2]}_Q (\hat{\rho}^{[2]}_j),
\]

where $C^{j,[1]}_Q$ depends only on one-particle reduced density matrix on subsystem $n$ and $C^{j,[2]}_Q$ depends on two-particle reduced density matrix on subsystems $n, m$.

Further, if we restrict ourselves to only permutationally invariant states, the upper bound to the QFIM from (15) is as follows:

\[
C_Q^{j,k} = NC^{j,[1]}_Q (\hat{\rho}^{[1]}_j) + N(N-1)C^{j,[2]}_Q (\hat{\rho}^{[2]}_j), \quad (40)
\]

where

\[
C^{j,[1]}_Q = 4 \sum_{p,r} \text{Re} \left[ \text{Tr} \left( \hat{\rho}^{[1]}_j \hat{d}_{p,j} \hat{d}_{p,k} \right) - \text{Tr} \left( \hat{\rho}^{[1]}_j \hat{d}_{p,j} \right) \text{Tr} \left( \hat{\rho}^{[1]}_j \hat{d}_{r,k} \right) \right]
\]

only depends on the first order reduced density matrix,

\[
C^{j,[2]}_Q = 4 \sum_{p,r} \text{Re} \left[ \text{Tr} \left( \hat{\rho}^{[2]}_j \left( \hat{d}_{p,j} \otimes \hat{d}_{r,k} \right) \right) - \text{Tr} \left( \hat{\rho}^{[1]}_j \hat{d}_{p,j} \right) \text{Tr} \left( \hat{\rho}^{[1]}_j \hat{d}_{r,k} \right) \right]
\]

also depends on the second order reduced density matrix.

Clearly, when the two-particle reduced density matrix of the initial probe state is a product state, we get $C^{j,[2]}_Q = 0$. When both the one- and two-particle reduced density matrices of the initial probe state are maximally mixed, unitary noise cannot create quantum correlations from any classical correlation in the initial state [61]. Thus, a precision scaling of $1/N$ cannot be achieved, when there are no correlations or too much quantum correlations in the initial state, like in unitary channel case. Thus, any quantum enhancement to the estimation precision is provided by the two-particle reduced density matrices of the probe state.

Now, from (52), the set of POVMs comprising

\[
\hat{P}_0 = \hat{\rho} (\theta) = \sum_i \hat{\Pi}_i (\theta) \hat{\pi}_i (\theta),
\]

\[
\hat{P}_m = \frac{\partial \hat{\rho} (\theta)}{\partial \theta_m} = \sum_i \left[ \hat{\Pi}_i (\theta) \hat{B}_{im} (\theta) \hat{\rho} \hat{\Pi}_i^\dagger (\theta) \right] \quad \text{for } m = 1, \ldots, q,
\]

along with one element accounting for normalisation, saturates the upper bound (39) to the QFIM, provided we have (31), i.e. here

\[
4 \sum_l \text{Im} \left[ \text{Tr} \left( \hat{B}_{lj}(\theta) \hat{B}_{lk}(\theta) \hat{\rho} \right) \right] = 0 \quad \forall j, k
\]

\[
\Rightarrow 4 \sum_n \text{Im} \left[ \text{Tr} \left( \sum_l \hat{\rho}_{j,[n]} \hat{d}_{n,j,n} \hat{\rho}_{k,[n]} \right) \right] = 0
\]

\[
+ 4 \sum_{n \neq m} \sum_l \text{Im} \left[ \text{Tr} \left( \hat{\rho}_{j,[n]} \hat{d}_{n,j,m} \hat{\rho}_{k,[m]} \right) \right] = 0
\]

\[
= 4 \sum_n \text{Im} \left[ \text{Tr} \left( \sum_l \hat{\rho}_{j,[n]} \hat{d}_{n,j,n} \hat{\rho}_{k,[n]} \right) \right] = 0,
\]

since $\sum_{l \neq m} \text{Tr} \left( \hat{\rho}_{j,[n]} \hat{d}_{n,j,n} \hat{\rho}_{k,[n]} \right) \in \mathbb{R}$. Hence, the attainability of the quantum enhancement to the estimation precision is determined solely by the one-particle reduced density matrices of the probe state.

Consider the magnetic field example again here in the context of noisy channel. The same permutationally invariant mixed input probe state is used. Thus, the first and second order marginals are the same. Moreover, for the purposes of this example here, each Pauli operator $\hat{\sigma}_k$ for $k = 1, 2, 3$ (corresponding to $X$, $Y$ and $Z$ directions) can be split into a sum of two single particle Kraus operators as $\hat{\sigma}_k = \sum_{l=1}^3 \hat{\pi}_l$, so that $\hat{\pi}_1 = \sum_{k=1}^3 \hat{\theta}_k \hat{\pi}_l$, e.g.

\[
\begin{align*}
\hat{\sigma}_1 & = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}, \\
\hat{\sigma}_2 & = \begin{bmatrix} 0 & -i \\ i & 0 \end{bmatrix} = \begin{bmatrix} 0 & -i \\ i & 0 \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}, \\
\hat{\sigma}_3 & = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 0 & -1 \end{bmatrix}.
\end{align*}
\]

One can verify that such a decomposition for each Pauli operator $\hat{\sigma}_k$ satisfies $\sum \hat{\pi}_1 \hat{\pi}_k = \sum \hat{\pi}_l \hat{\pi}_1 \hat{\pi}_k = \hat{1}_2$. Then,

\[
\hat{d}_{lk} = \frac{1}{2} \int_0^1 da e^{ia \hat{\pi}_l \hat{\pi}_k e^{-ia \hat{\pi}_l}}.
\]

Then, we get:

\[
C_Q^{j,[1]} = 4 \sum_{l,p} \text{Re} \left[ 2 \text{Tr} \left( \hat{d}_{lj} \hat{d}_{lk} \right) - \text{Tr} \left( \hat{d}_{lj} \right) \text{Tr} \left( \hat{d}_{lk} \right) \right], \quad (45)
\]
that the Heisenberg scaling is lost and the covariance scaling of $1/J$ where all the quantities may be explicitly calculated.

Now, note that the first term $\hat{g}_{lj}$ is of $O(N)$ and the second term $\hat{g}_{lp}$ is of $O(N^2)$, as they involve $N$ and $N(N-1)/2$ terms, respectively. Then the term $\hat{g}_{lp}$ should be non-zero, implying that quantum correlations amongst the particles play a role in attaining the Heisenberg scaling of $1/N$. As observed earlier, if the probe state is a product state, i.e. $\hat{\rho} = \bigotimes_{n=1}^{N} \hat{\rho}^{[n]}$, then we have $\hat{\rho}^{[n,m]} = \hat{\rho}^{[n]} \otimes \hat{\rho}^{[m]}$, and consequently $\hat{g}_{lp} = 0$, such that the Heisenberg scaling is lost and the covariance scales as $1/\sqrt{N}$ at best. Also, if both $\hat{\rho}^{[n]}$ and $\hat{\rho}^{[m]}$ are not all zero, the terms $\text{Tr} [\hat{g}_{lj}\hat{g}_{pk}]$ can be such that $C_{Q}$ with noise in the initial probe state, such as by means of $\hat{E}_{0}$ and $\hat{E}_{1}$ for local dissipation, is larger than that without noise in the initial probe state, so that the estimation precision can be better with noise in the initial probe state than that without noise in the initial state.

We next consider the more general situation, where the noisy channel need not be necessarily unital, and illustrate that the presence of noise in the channel can actually serve as a feature rather than a bug, since even when the Heisenberg precision scaling cannot be achieved with a unitary channel, it is possible to attain the Heisenberg scaling, and in fact, even beat it with a noisy channel.

### VII. Noise in Channel as a Feature Rather Than a Bug

We now look at the utility of the presence of noise in a general channel in achieving or even beating the Heisenberg precision limit.

Consider first the case of a mixed probe state, comprising $N$ particles, evolving through a unitary channel, and that the $N$ particles of the probe undergo $N$ independent $\theta$-dependent unitary evolutions, i.e. the unitary operator of the channel is a product of $N$ independent unitary operators $\hat{U}(\theta) = \bigotimes_{n=1}^{N} \hat{U}_{(n)}(\theta)$.

Then, the QFIM takes the form as in (28) as follows:

$$J_{Q}^{[k]} = 4\text{Re} \sum_{n} \left[ \text{Tr} \left( \frac{\partial \hat{U}_{(n)}(\theta)}{\partial \theta} \frac{\partial \hat{U}_{(n)}(\theta)\hat{\rho}^{[n]}}{\partial \theta} \right) - \text{Tr} \left( i \frac{\partial \hat{U}_{(n)}(\theta)}{\partial \theta} \hat{U}_{(n)}(\theta) \hat{\rho}^{[n]} \right) \right]$$

$$+ 4\text{Re} \sum_{n \neq m} \left[ \text{Tr} \left( \frac{\partial \hat{U}_{(n)}(\theta)}{\partial \theta} \hat{U}_{(n)}(\theta) \otimes \hat{U}_{(m)}^{\dagger}(\theta) \frac{\partial \hat{U}_{(m)}(\theta)}{\partial \theta} \hat{\rho}^{[n,m]} \right) - \text{Tr} \left( i \frac{\partial \hat{U}_{(n)}(\theta)}{\partial \theta} \hat{U}_{(n)}(\theta) \hat{\rho}^{[n]} \right) \text{Tr} \left( i \frac{\partial \hat{U}_{(m)}^{\dagger}(\theta)}{\partial \theta} \hat{U}_{(m)}(\theta) \hat{\rho}^{[m]} \right) \right]$$

$$= J_{Q}^{[k,n]} + J_{Q}^{[k,n,m]}.$$
since $\hat{U}_{(n/m)}(\Omega)\hat{U}_{(n/m)}^\dagger(\Omega) = 1_2 \forall n,m$. Clearly, the attainability of the quantum enhancement to the estimation precision is determined solely by the one-particle reduced density matrices of the initial mixed probe state.

Next, consider the case of a mixed initial probe state, comprising $N$ particles, evolving through a noisy quantum channel, and that the $N$ particles of the initial probe state undergo $N$ independent $\theta$-dependent evolutions, i.e. the Kraus operator of the noisy quantum channel is a product of $N$ independent Kraus operators $\hat{\Pi}_l(\Theta) = \otimes_{n=1}^N \hat{\Pi}_{l,n}^{(n)}(\Theta)$, where we have $l = (l_1, l_2, \ldots, l_N)$.

Then, (29) takes the form:
\[
C_Q^{jk} = 4\text{Re} \sum_n \left[ \text{Tr} \left( \sum_{i_n} \frac{\partial \hat{\Pi}_{l,n}^{(n)}(\Theta)}{\partial \theta_j} \rho^{\otimes n} \right) - \text{Tr} \left( i \sum_{i_n} \frac{\partial \hat{\Pi}_{l,n}^{(n)}(\Theta)}{\partial \theta_k} \hat{\Pi}_{l,n}^{(n)}(\Theta) \rho^{\otimes n} \right) \right] \\
+ 4\text{Re} \sum_{n \neq m} \sum_{l_1, l_m} \left[ \text{Tr} \left( \frac{i \partial \hat{\Pi}_{l,n}^{(n)}(\Theta)}{\partial \theta_j} \hat{\Pi}_{l,n}^{(n)}(\Theta) \otimes \hat{\Pi}_{l,m}^{(m)}(\Theta) \frac{\partial \hat{\Pi}_{l,m}^{(m)}(\Theta)}{\partial \theta_k} \rho^{\otimes n,m} \right) \right] \\
- \text{Tr} \left( i \frac{\partial \hat{\Pi}_{l,n}^{(n)}(\Theta)}{\partial \theta_j} \hat{\Pi}_{l,n}^{(n)}(\Theta) \rho^{\otimes n} \right) \text{Tr} \left( i \frac{\partial \hat{\Pi}_{l,m}^{(m)}(\Theta)}{\partial \theta_k} \hat{\Pi}_{l,m}^{(m)}(\Theta) \rho^{\otimes n,m} \right) \\
= C_Q^{jk[n]} + C_Q^{jk[n,m]}.
\]

Again, note that the first term $C_Q^{jk[n]}$ is of $O(N)$ and the second term $C_Q^{jk[n,m]}$ is of $O(N^2)$, as they involve $N$ and $N(N-1)/2$ terms, respectively. Then, the term $C_Q^{jk[n,m]}$ should be non-zero, implying that quantum correlations amongst the particles play a role in attaining the Heisenberg scaling of $1/N$ or better. Now, if the initial probe state is separable but not a product state, then that leads to $C_Q^{jk[n,m]} \neq 0$. This is because, as noted earlier, although noise is widely known to reduce quantum correlations in a system in most cases, noise can also introduce or increase quantum correlations in a system, that may then be activated into entanglement. Even without quantum correlations between the particles of the initial probe state, an estimation precision scaling of $1/N$ or better can be achieved, when the initial probe state has classical correlations, that can be converted into quantum correlations by non-unital noise in the channel, unlike in cases of mixed state evolving unitarily or unitarily considered earlier. Moreover, even if both $\hat{\rho}^{\otimes n}$ and $\hat{\rho}^{\otimes n,m}$ are maximally mixed, we can get $C_Q^{jk[n,m]} \neq 0$, when non-unital noise in the channel creates quantum correlations from classical correlations, so the Heisenberg scaling of $1/N$ or better can be achieved. Thus, noise in the quantum channel can act as a feature rather than a bug, since we see that the estimation precision that can be achieved with a noisy channel in these situations is impossible with a noiseless unitary channel.

However, if there exists some Kraus representation $\hat{\Pi}_l(\Theta)$ of the quantum channel which renders $C_Q^{jk[n,m]} = 0$, then the covariance scales as $1/\sqrt{N}$ at best, even when the particles of the initial probe state are entangled. Extending the argument from Ref. [29] to the multiparameter case, the covariance also scales as $1/\sqrt{N}$ at most, even in the presence of feedback control. Thus, any quantum enhancement to the estimation precision is provided by the two-particle reduced density matrices of the initial probe state. The saturability condition (31) here becomes:
\[
4\text{Im} \sum_n \text{Tr} \left( \sum_{l_n} \frac{\partial \hat{\Pi}_{l,n}^{(n)}(\Theta)}{\partial \theta_j} \hat{\Pi}_{l,n}^{(n)}(\Theta) \rho^{\otimes n} \right) + 4\text{Im} \sum_{n \neq m} \sum_{l_1, l_m} \text{Tr} \left( \frac{i \partial \hat{\Pi}_{l,n}^{(n)}(\Theta)}{\partial \theta_j} \hat{\Pi}_{l,n}^{(n)}(\Theta) \otimes \hat{\Pi}_{l,m}^{(m)}(\Theta) \frac{\partial \hat{\Pi}_{l,m}^{(m)}(\Theta)}{\partial \theta_k} \rho^{\otimes n,m} \right) = 0
\]
\[
\Rightarrow 4\text{Im} \sum_n \text{Tr} \left( \sum_{l_n} \frac{\partial \hat{\Pi}_{l,n}^{(n)}(\Theta)}{\partial \theta_j} \hat{\Pi}_{l,n}^{(n)}(\Theta) \rho^{\otimes n} \right) = 0,
\]

since $\sum_{l_n/l_m} \hat{\Pi}_{l,n}^{(n/m)}(\Theta) \hat{\Pi}_{l,n}^{(n/m)}(\Theta) = 1_2 \forall n,m$. Clearly, the attainability of the quantum enhancement to the estimation precision is determined solely by the one-particle reduced density matrices of the probe state.
Clearly, if the final probe state is a product state, we get $C_Q^{k,[n,m]} = 0$, such that a scaling of $1/\sqrt{N}$ can be attained at best. This implies that noise in the channel should introduce quantum correlations between the particles of the probe state, in order to provide quantum advantage in achieving an estimation precision scaling of $1/N$ or better. Also, if both $\hat{\rho}^{[n]}(\theta)$ and $\hat{\rho}^{[n,m]}(\theta)$ are maximally mixed, there are only classical correlations in the two-particle reduced density matrix. This implies that a lot of noise in the channel can introduce too much quantum correlations between the particles of the probe state to render it only classically correlated.

Thus, some amount of noise in the quantum channel can act as a feature rather than a bug by introducing quantum correlations into the system, but excessive noise destroys the achievable quantum advantage with $N$ parallel resources.

**VIII. BEATING THE HEISENBERG LIMIT**

We show in Appendix I that unless the following condition is also satisfied by the channel Kraus operators:

$$\sum_\ell \frac{\partial \hat{\Pi}_\ell(\theta)}{\partial \theta_j} \hat{\Pi}_\ell^\dagger(\theta) = \sum_\ell \frac{\partial \hat{\Pi}_\ell(\theta)}{\partial \theta_k} \hat{\Pi}_\ell^\dagger(\theta) \hat{\rho} \Rightarrow \sum_\ell \hat{\Pi}_\ell(\theta) \hat{\Pi}_\ell^\dagger(\theta) = 1,$$

i.e. unless the channel is unital, any noise in the channel may beat the Heisenberg limit, when \(\{31\}\) is satisfied.

However, since the Heisenberg limit is not ultimate, e.g. see Refs. [68–81], although this has sparked some controversy [82–84], now the question is what is the fundamental ultimate quantum limit to the achievable estimation precision in the presence of optimal amount of noise in a non-unitary quantum channel. In other words, what should the quantity $C_Q$ look like when the precision achievable is maximum in a non-unitary channel. It is fairly easy to see that for optimal quantity of noise in the channel, the two-particle reduced density operators of the evolved probe state should be a maximally entangled mixed state (MEMS) [89] and the one-particle reduced density operators of the evolved probe state should be a maximally mixed state [90]. Therefore, we must have the reduced density operators of the evolved probe state as: $\hat{\rho}^{[n]}(\theta) = 1/2$ and $\hat{\rho}^{[n,m]}(\theta) \neq \hat{\rho}^{[n]}(\theta) \otimes \hat{\rho}^{[m]}(\theta)$.

Then, the fundamental quantum limit to the achievable estimation precision in a noisy channel is given by:
where we have used the subscript "SH" to denote 'super-Heisenberg' fundamental quantum estimation precision limit. The set of POVMs from (32) then saturates this ultimate limit. Note that a maximally discordant mixed state (MDMS) need not be maximally entangled [91]. In fact, it can be not entangled at all, but then it can be at best as nonclassical as (and not more nonclassical than) a maximally entangled pure state [57], and therefore, cannot allow to beat the Heisenberg limit.

Note, however, that in order for entanglement to be activated from the quantum correlations in the probe state, multi-particle unitary maps (such as CNOT gates) are required [57, 66], if there was no entanglement in the initial probe state already or any entanglement in the initial probe state vanishes even if leaving the probe state maximally discordant. The Kraus representation of the channel is non-unique and is invariant under arbitrary unitary maps and so the above equations are invariant under addition of such unitary maps. But unless the quantum correlations are activated into entanglement, the above best estimation precision cannot be achieved. Thus, the active ancilla-assisted scheme from Ref. [31] can be strictly better than the passive ancilla-assisted scheme, since mixed entangled states can be more nonclassical than mixed separable states [57]. Note that a unitary operator is also a Kraus operator, and an identity operator is trivially unitary.

Now, without the additional unitary maps, that can activate entanglement from quantum correlations in the probe state, the best estimation precision limit is determined by the two-particle reduced density matrices of the evolved probe state being separable and maximally discordant (MDMS) [91], i.e. the two-particle reduced density matrices having maximal dissonance [92]. Therefore, we must have $\hat{\rho}_{MDMS}^{[n,m]}(\theta) \neq \hat{\rho}^{[n]}(\theta) \otimes \hat{\rho}^{[m]}(\theta)$, and then the fundamental limit is given by:

\[
J_{SH}^{[k]} = 4 \text{Re} \sum_n \left[ \text{Tr} \left( \sum_{l_n} \hat{\Pi}_{l_n}^{(n)}(\theta) \frac{\partial \hat{\Pi}_{l_n}^{(n)}(\theta)}{\partial \theta_j} \frac{\partial \hat{\Pi}_{l_n}^{(n)}(\theta)}{\partial \theta_k} \hat{\Pi}_{l_n}^{(n)}(\theta) \rho^{[n]}(\theta) \right) \right. \\
- \text{Tr} \left( i \sum_{l_{n1}} \hat{\Pi}_{l_{n1}}^{(n)}(\theta) \frac{\partial \hat{\Pi}_{l_{n1}}^{(n)}(\theta)}{\partial \theta_j} \hat{\rho}^{[n]}(\theta) \right) \text{Tr} \left( i \sum_{l_{n2}} \hat{\Pi}_{l_{n2}}^{(n)}(\theta) \frac{\partial \hat{\Pi}_{l_{n2}}^{(n)}(\theta)}{\partial \theta_k} \hat{\rho}^{[n]}(\theta) \right) \\
+ 4 \text{Re} \sum_{n \neq m, l_n, l_m} \left[ \text{Tr} \left( \hat{\Pi}_{l_n}^{(n)}(\theta) \frac{\partial \hat{\Pi}_{l_n}^{(n)}(\theta)}{\partial \theta_j} \frac{\partial \hat{\Pi}_{l_n}^{(n)}(\theta)}{\partial \theta_k} \hat{\Pi}_{l_n}^{(n)}(\theta) \rho_{MDMS}^{[n,m]}(\theta) \right) \right. \\
- \text{Tr} \left( i \hat{\Pi}_{l_n}^{(n)}(\theta) \frac{\partial \hat{\Pi}_{l_n}^{(n)}(\theta)}{\partial \theta_j} \hat{\rho}^{[n]}(\theta) \right) \text{Tr} \left( i \hat{\Pi}_{l_m}^{(m)}(\theta) \frac{\partial \hat{\Pi}_{l_m}^{(m)}(\theta)}{\partial \theta_k} \hat{\rho}^{[m]}(\theta) \right) \right] = J_{Q}^{[k]} + J_{Q}^{[k,[n,m]]},
\]

which corresponds to a precision scaling of $1/N$ for maximal pairwise quantum correlations, without entanglement, amongst the final probe particles [69], since mixed separable states can be as nonclassical as entangled pure states [57]. Since the best estimation precision achievable with quantum correlations without entanglement coincides with and does not beat the Heisenberg limit, we used the subscript "Q" above.

Next, with the additional unitary maps and entanglement activated from the quantum correlations in the probe state, since the super-Heisenberg limit is obtained for the two-particle reduced density operators of the evolved probe state being maximally entangled and the one-particle reduced density operators being maximally mixed, the super-Heisenberg limit corresponds to a precision scaling of $1/N^2$ for maximal pairwise quantum correlations including entanglement amongst the final probe particles [72]. This is because mixed entangled bipartite
states can be twice as nonclassical as maximally entangled bipartite pure states [57].

Note that the precision scaling that could be achieved, e.g. in Ref. [72], using two-particle Hamiltonians for a unitary channel, is achieved using one-particle Kraus operators for a noisy channel here, i.e. local noise inducing quantum correlations including entanglement amongst the two particles [61, 62]. Notice that we did not get precision scaling better than $1/N$ when we studied the unitary channel case in this paper, since we considered only one-particle Hamiltonians. If we further considered $\gamma$-particle (instead of one-particle) Kraus operators for the noisy channel case here, with $\gamma > 1$, each set of Kraus operators can generate quantum correlations including entanglement induced by a common bath amongst the $\gamma$ particles [59, 60]. Then, the best super-Heisenberg precision scaling of $1/N^22^N$ may be attained, that is known to be only attainable using $2\gamma$-particle Hamiltonians for a unitary channel. For example, using three-particle Kraus operators for a noisy channel, the best precision scaling of $1/N^3$ can be achieved, that is otherwise known to be possible with six-particle Hamiltonians for a unitary channel. This is again because mixed entangled states can be twice as nonclassical as pure entangled states [57].

Considering again one-particle Kraus operators for the noisy channel, although the quantum Cramér-Rao bound (QCRB) can be beaten in the system space, the QCRB for the enlarged system plus bath space, for which the evolution is unitary, is not beaten. This also holds for multi-particle Kraus operators for the channel, where entanglement is induced by common baths. This implies that the estimation in the system space alone is not unbiased, when the QCRB, and therefore, the Heisenberg limit are beaten [22, 83]. However, when the estimation involving measurements beats the QCRB, and therefore, the Heisenberg limit, it does not violate Robertson’s generalized formulation of Heisenberg’s uncertainty relation [23, 24, 93], that does not include the measurement process. Note that the QCRB can be derived from the general Heisenberg’s uncertainty relation, upon considering that the estimator is unbiased [23]. Thus, beating the QCRB implies that the estimator bias is no longer zero (also see Appendix A1, but does not violate the general Heisenberg’s uncertainty principle. Nonetheless, without including measurements, it is noteworthy that entanglement amongst the particles of a state allows for lower bounds for the dispersions of non-commuting observables than that furnished by the traditional Heisenberg’s uncertainty relation, originally derived for one particle [94].

Finally, note that the super-Heisenberg limit will not necessarily be strictly less than the Heisenberg limit, such as when there are quantum correlations without entanglement in the evolved probe state. Moreover, if the two-particle reduced density matrices of the initial probe state are already maximally entangled, the super-Heisenberg limit will equal the Heisenberg limit. This is because it is only entanglement generated in the channel, i.e. in the evolution stage, that can contribute to a precision scaling better than the Heisenberg limit, and entanglement in the preparation and measurement stages are inessential [70]. Furthermore, the Heisenberg limit is not beaten, when the Kraus operators of the channel satisfy the condition [47]. When the QCRB and the Heisenberg limit are not beaten, the estimator in the $S$ space alone will be unbiased. Otherwise, when they are beaten, the estimator in the $S$ space alone will be biased and may be of limited interest in practice.

The upper bound [20] to the QFIM reduces to the following actual QFIM, when [47] is satisfied:

$$J_Q^{jk} = 4\text{Re} \sum_n \left[ \text{Tr} \left( \sum_{l_n} \frac{\partial \hat{\Pi}^{(n)}_{l_n}}{\partial \theta_j} \frac{\partial \hat{\Pi}^{(n)}_{l_n}}{\partial \theta_k} \hat{\rho}^{[n]} \right) - \text{Tr} \left( \sum_{l_{n_1}} \frac{\partial \hat{\Pi}^{(n_1)}_{l_{n_1}}}{\partial \theta_j} \hat{\Pi}^{(n_1)}_{l_{n_1}} \hat{\rho}^{[n_1]} \right) \text{Tr} \left( \sum_{l_{n_2}} \frac{\partial \hat{\Pi}^{(n_2)}_{l_{n_2}}}{\partial \theta_k} \hat{\rho}^{[n_2]} \right) \right] $$

$$+ 4\text{Re} \sum_{n \neq m} \left[ \text{Tr} \left( \frac{\partial \hat{\Pi}^{(n)}_{l_n}}{\partial \theta_j} \hat{\Pi}^{(m)}_{l_m} \right) \frac{\partial \hat{\Pi}^{(m)}_{l_m}}{\partial \theta_k} \hat{\rho}^{[n]} \right) \text{Tr} \left( \frac{\partial \hat{\Pi}^{(m)}_{l_m}}{\partial \theta_j} \hat{\Pi}^{(n)}_{l_n} \right) \hat{\rho}^{[m]} \right] $$

$$- \text{Tr} \left( \frac{\partial \hat{\Pi}^{(n)}_{l_n}}{\partial \theta_j} \hat{\Pi}^{(m)}_{l_m} \right) \frac{\partial \hat{\Pi}^{(m)}_{l_m}}{\partial \theta_k} \hat{\rho}^{[n]} \right) \text{Tr} \left( \frac{\partial \hat{\Pi}^{(m)}_{l_m}}{\partial \theta_j} \hat{\Pi}^{(n)}_{l_n} \right) \hat{\rho}^{[m]} \right] \right] = J_Q^{[n]} + J_Q^{[m]}.$$
the evolved state will not be maximally mixed. Thus, it may be possible to beat the Heisenberg limit with non-unital channels, and the estimator would be biased when the Heisenberg limit is beaten.

Moreover, the fact that dissonance is more robust to decoherence than entanglement suggests that it is more probable to attain the Heisenberg limit with a mixed state input than a pure entangled state input to a unital channel. In fact, it may not be possible at all to attain the Heisenberg limit with an input pure entangled state because of entanglement sudden death. Furthermore, since dissonance can grow and give rise to entanglement in the presence of dissipation, it is more probable to attain or surpass the Heisenberg limit with a mixed state input than a pure entangled state input to a non-unital channel. In fact, it is never possible to attain or surpass the Heisenberg limit with an input pure entangled state because of no initial classical correlations and entanglement sudden death. On the other hand, the fact that entanglement is the intrinsic and minimal discord capturing nonlocal quantum correlations, as opposed to dissonance, which is the extrinsic discord capturing local quantum correlations that cannot be shared, is the reason why the Heisenberg limit can be surpassed only when entanglement and not just dissonance is generated in a non-unital channel fed with an input mixed probe state.

In summary, it may appear that noisy quantum states or channels may require the same or less resources to achieve as much as noiseless quantum states or channels, by exploiting additional resources from the environment. That is why, the overall resources required by the noisy cases in the enlarged noiseless system plus bath space are the same as those known to be required by the noiseless cases in the system space alone. However, any channel can be expressed by Kraus operators, which has the same effect as performing a measurement and discarding the result. To have a measurement on a pure state that is the same as the measurement of the pure state after noise, one would just need to have a POVM that combines the POVM elements used for the mixed state with the Kraus operators of the channel, without requiring any extra resource. Thus, a precision scaling of $1/N^{2\gamma}$ can, in principle, be achieved with a pure initial probe state evolving through a unitary channel, described by $\gamma$-particle Hamiltonians, by using a POVM, that combines the POVM elements used here with the $\gamma$-particle Kraus operators of the noisy channel considered here. But using entangling measurements with our noisy channel, it is possible to obtain even better precision scaling, so the noisy case is still superior.

Nonetheless, although it may likewise seem that it should be possible too to achieve a precision scaling of $1/N^{2\gamma}$ with a pure initial probe state evolving through the noisy channel, described by $\gamma$-particle Kraus operators, by using a POVM, obtained by combining the POVM elements used here with the Kraus operators used to prepare the initial mixed probe state from the pure state, that is not true even if the initial pure probe state is maximally entangled and/or if the channel is non-unital. This is because of no initial classical or quantum correlations in the probe state and sudden death of any entanglement in the probe state caused by the noise in the channel, as discussed earlier. This is the distinct important advantage, unique to mixed state metrology.

IX. CORRELATIONS CONSERVATION LAW

It would be interesting to further extend these results to the general relativistic context, since the author anticipates that this can resolve the cosmological constant problem. This is because it may indicate that dark energy, allowing for antigravity and the expansion of the universe at an accelerating rate, may indeed arise from entanglement of quantum vacuum fluctuations, mediated by the vacuum fluctuations of an environment, constituting what is dark matter. This is similar to entanglement induced by common baths considered in our work. Also, while bosonic entanglement degrades, fermionic entanglement in an inertial frame can be generated by measurements on vacuum by an accelerating observer, due to Unruh ‘channel’, which has an effect of non-unital ‘environmental noise’. This is similar to local non-unital noise considered in our work converting classical correlations in the initial state to quantum correlations, which is effected by the acceleration of the measuring observer here, followed by conversion of the quantum correlations to entanglement, which is effected by the nonunitary measurement (unitary in the enlarged space of both observers) performed by the accelerating observer here. Note that owing to projective measurements used here, the output entangled state in an inertial frame is pure, and all correlations, classical and quantum, end up becoming entanglement, leaving no other correlations in the final state. Clearly, the environment required in the (only known) two scenarios combined, of quantum noise inducing entanglement considered in our work, causing the Heisenberg limit to be beaten, amounts to about half or less the size of the actual noisy system, comparable to the known proportion of matter and dark energy in the universe.

Since only about half as memory (dark and normal matter combined) is available as the system (dark energy) with quantum correlations, undetectable and rather observed as vacuum by an observer in a noninertial frame, beating of the Heisenberg limit by such an observer with
quantum memory using measurements coupled to the system allows for negative entropy and violation of Landauer’s erasure principle [107], in turn, allowing for violation of Heisenberg’s uncertainty principle and the second law of thermodynamics [108, 109]. This implies that the energy conservation law is violated too, giving rise to antigravity and the observed cosmic acceleration [110]. However, the fact that the Heisenberg limit may not be beaten in the enlarged noiseless system plus environment space [88] (the entire universe) may imply that these principles or laws, including the second law of thermodynamics [111], appear to be violated only locally by the observer, but are not violated globally. Thus, a likely possibility is that the expansion of the universe may not be accelerating at all, and merely appears so to an observer on earth. Similarly, all effects observed locally from earth indicating existence of antimatter in dark matter may not be global effects. Nonetheless, an extension of our results should allow to account for the known value of the cosmological constant as observed locally from earth. But a global cosmic non-acceleration in space seems unlikely.

Another more likely possibility is that the universe is indeed expanding at an accelerating rate but only spatially, and the overall spacetime of the universe may not be expanding at an accelerating rate, nor at a decelerating rate, and in fact, not even expanding at all. In other words, the universe may be ‘shrinking’ at as much an accelerating rate temporally (along the time dimension) as it is expanding at an accelerating rate spatially. Time slows down in the presence of gravity, as we know already [112], and must become faster in the presence of antigravity. The author suggests that time is flowing forward because space is expanding. Since space is expanding at an accelerating rate, time is flowing forward at an increasingly faster rate. Thus, more time is going out of existence, as more space is coming into existence. This may sound exactly opposite to what is believed. However, just like gravity is not a downward pull by earth and is rather an accelerating upward push by earth’s surface, the arrow of time is not increasing time and is rather decreasing time. Consider the example of daylight savings time. When one wakes up at 8:30 am and finds the time is rather 9:30 am, i.e. the time moved forward, time is rather lost, and not less time is gained. Similarly, when one wakes up at 9:30 am and finds the time is rather 8:30 am, i.e. the time moved backward, time is rather gained, and not more time is lost. The universe may have comprised zero space and all time at its beginning, what is referred to as a ‘singularity’ [101], and as space expanded, time kept shrinking. The universe would likely end with all space and zero time (since time would stop, space cannot expand any further), what is referred to as the ‘heat death’ of the universe [101].

Let us now discuss what likely causes this. As Seth Lloyd had said, the arrow of time is an arrow of increasing (spatial) correlations [113, 117]. Thus, as time moves forward, space expands and spatial correlations are created, as much as temporal correlations are destroyed. So, the arrow of time is also the arrow of decreasing temporal correlations. By spatial correlations, we imply ‘space-like’ correlations, and by temporal correlations, we imply ‘time-like’ correlations [116, 118]. Time moves backward as spatial correlations are destroyed and as much temporal correlations are created. Note how temporal correlation got destroyed and converted into spatial correlation with forward passage of time in Ref. [113]. However, everywhere we make measurements, say, on the qubits of a two-qubit (spatially) entangled state to destroy the entanglement, the fact that the measurement results (even if they are made at different distant instants of time) are correlated is caused by temporal entanglement among the qubits being created. The apparent superluminal communication between the spatially separated qubits, as if one instantly knows what measurement has been performed on the other, known as the EPR paradox [119], is due to momentary backward flow of time for the pair. The universe may have started with no spatial correlations and all temporal correlations. As spatial correlations increased, temporal correlations kept decreasing. The universe would likely end with all spatial correlations and no temporal correlations.

The author suggests that for any closed system - quantum, classical, astronomical or cosmological - the total spacetime is constant, since the total spatiotemporal correlations is constant. This is because measurement on an EPR pair simply recreates the temporal correlation between the pair, that already existed between the pair and was killed by the process of creating the spatially correlated pair. This may likely be easily verified in a lab. Such a fundamental correlations conservation law, e.g. see Ref. [120], may explain all fundamental physical laws, paradoxes, mysteries, etc. All that exist or do not exist are and because of correlations. In fact, a similar thing was done by the authors of Ref. [117], where they killed a temporal entanglement between past and future in the process of creating the spatial entanglement, only to recreate the temporal entanglement by measuring the spatial entanglement, but they seem to not have inferred a correlations conservation principle. Some fundamental implications of correlations conservation are discussed:

1. **Infinity may not exist:** Notice that we said that the universe started with zero space and ‘all’ (and not infinite) time, i.e. zero spatial correlations and all temporal correlations. That is because the total number of correlations of the universe is finite. And no number larger than the total spatiotemporal correlations of the universe makes sense for anything. Infinity is some humongously large but finite number that we don’t know. If we know when the universe started (~13.8 billion years ago) and we could know the remaining age of the universe, that should indicate what infinity is.

2. **Nonunitarity may not exist globally:** Measurements are nonunitary only spatially, i.e. locally, and must be unitary in spacetime, i.e. globally, be-
cause a measurement converts a spatial correlation into a temporal correlation, just like every operation that converts a temporal correlation into a spatial correlation in a closed system is unitary. A single qubit superposition state is also a spatial correlation of its classical basis states, and will have temporal correlations with itself upon measurement. Thus, even if the spatial wave function is collapsed by a measurement, the spatiotemporal wave function never collapses and is only modified by the measurement. That is why Unruh effect is nonunitary locally, but unitary globally. Measurements appear nonunitary due to the arrow of time.

3. **Causality may not exist globally**: We see that past events cause future events, because the arrow of time is the arrow of increasing spatial correlations. But everytime a spatial correlation is converted into a temporal correlation, the arrow of time is momentarily reversed in that system (and space in that system gets shrinked along the reversed arrow of time), implying that a future event caused a past event. All events already existed, since all time existed, at the inception of the universe, and events are nothing but manifestation of temporal correlations, all of which existed when the universe started. With the arrow of time, past is going out of existence, causing future, that is only what exists now.

4. **Continuity may not exist globally**: It is only discreteness that exists, because number of correlations is discrete. Whatever is continuous in space is discontinuous in time, and whatever is continuous in time is discontinuous in space. Space or time cannot expand or shrink unless they are quantized. Spacetime is quantum but it does not expand or shrink because if space expands, time decreases, i.e. moves forward, and if space shrinks, time increases, i.e. moves backward.

5. **Classicality may not exist globally**: It is only quantumness that exists in spacetime. All that are classical in space must be quantum in time, and all that are classical in time must be quantum in space. This is because all spatial classical correlations must be quantum in time and all temporal classical correlations must be quantum in space. This is so since we saw that classical states cannot allow to attain the Heisenberg limit in a closed system, which in spacetime should be Heisenberg limited and not standard quantum limited.

6. **Locality may not exist globally**: It is only nonlocality that exists in spacetime. Whatever is local in space must be nonlocal in time, and whatever is local in time must be nonlocal in space. This is because all local spatial correlations (classical, dissonance) must be nonlocal in time, and all local temporal correlations must be nonlocal in space (entanglement). This is so since we saw that local correlations cannot allow to beat the Heisenberg limit along space or time in a closed system, which otherwise in spacetime cannot expand in space or shrink in time. So, to be precise, the arrow of time is the arrow of increasing nonlocal spatial correlations and reducing nonlocal temporal correlations.

7. **Nonlinearity may not exist globally**: It is only linearity that exists in spacetime. Whatever is nonlinear in space or time must be linear in spacetime, since quantum mechanics is linear and spacetime is quantum, for which total correlations is conserved in a closed system. For example, see Ref. [120].

Thus, there needs to be a temporal correction to be made to, that may entirely cancel out, the cosmological constant globally (in both spatial and temporal senses). Now, if the universe was zero space and all time (temporal entanglement) at the start and will be all space (spatial entanglement) and zero time at the end, a temporal entanglement is ‘empty space’ (spatial vacuum) and a spatial entanglement is ‘empty time’ (temporal vacuum). That is, matter is nothing but spatial correlations and quantum vacuum is nothing but temporal entanglement. That is why Ref. [117] could extract temporal entanglement from quantum vacuum. That is also why entanglement in an inertial frame is seen as vacuum by a noninertial observer [103,106]. That is also why a spatial entanglement like an EPR pair has an instantaneous relationship. What we see as undetected in the universe are temporal entanglement (dark energy), or spatial correlations that appear timelike from our frame of reference (dark matter). An extension of our work to the relativistic context should allow to cancel out the cosmological constant, when temporal correlations are also considered.

Moreover, for supersymmetry [122] to hold in the Standard Model [123] for the universe (without which the universe must expand/shrink globally in spacetime), either the bosons behave the way fermions should behave and fermions behave the way bosons should behave along time, or there are more likely other particles, say temporal bosons (shadow fermions) as many as there are spatial fermions and temporal fermions (shadow bosons) as many as there are spatial bosons (such shadow particles may constitute dark matter), so that the total number of bosons are the same as fermions in the universe. A cosmic temporal accelerating contraction and spatial accelerating expansion may then be attributed to temporal entanglement between such particles. Any region in spacetime having higher density of spatial correlations expands faster in space and shrinks faster in time curving the spacetime in a way that it exerts gravity in its surrounding region, where spatial correlations are created at a slower rate, so that space expands and time moves forward at a slower rate. Similarly, any region having much lower density of spatial correlations, with respect to our inertial frame, expands much slower in space and shrinks much slower in time curving the spacetime in a way that
it exerts much lower gravity in its surrounding region, where time slows down very little. Such a region would be timelike correlated with respect to our inertial frame, so that it would appear as vacuum, would behave like antimatter, and constitutes what is dark matter. Likewise, any region in spacetime having only temporal correlations and no spatial correlation, does not have any space or time moving in it. Temporal correlations in it are converted extremely slowly to spatial correlations, that are then released to its surrounding region, where antigravity is exerted, since spatial correlations are created at a much faster rate, so that space expands and time moves forward at a much faster rate. Such a region would again appear as vacuum and is what constitutes dark energy. Thus, although the space of the universe is expanding at an accelerating rate, the dark energy is relatively constant, since space or time is not expanding or shrinking within it. By contrast, a black hole [113] has no temporal correlation, and so again space does not expand and time does not move within it, such that even light cannot transmit through it. It resembles the end of the universe and exerts extreme gravity even if hardly expanding, since spatial correlations are created, space expands and time moves forward extremely slowly near it, so that it sucks matter, i.e. spatial correlations, over time to expand in space extremely slowly.

Furthermore, the fact that dark energy is ‘energy’ suggests that energy corresponds to the temporal component and mass corresponds to the spatial component of a spatiotemporal correlation. This implies that a spatiotemporal correlation becomes more ‘mass’-ive by absorbing energy, i.e. energy is converted into mass, as it becomes more spacelike, which accounts for the expansion of the earth and its gravity, for example. This also suggests that when measurements are performed on an EPR pair, which is a nonlocal spatial correlation, to convert it into a nonlocal temporal correlation, mass is converted into energy. Similarly, a region in spacetime that has, or appear to a noninertial observer to have, all timelike correlations will appear to behave like having negative mass [124]. On the other hand, a black hole has all mass and no energy, resembling a black body in thermal equilibrium, since it has all spatial correlations and does not have any temporal component of correlations left in it. This is why any spatial component of correlations in its vicinity (event horizon) gets sucked or absorbed into it, leaving the temporal component emitted as radiation. This also explains why fundamental bosons but not fermions can be massless [125], since bosonic but not fermionic spatial correlations can be destroyed completely in spacetime, which is also why fermions but not bosons obey Pauli exclusion principle [126]. Thus, the conservation of spatiotemporal correlations also accounts for the mass-energy conservation of a closed system [127].

Finally, the fact that energy corresponds to the temporal component and mass corresponds to the spatial component of correlations suggests that the fundamental force carrier bosons [128], i.e. W and Z bosons, gluons, photons or gravitons, carry force because of temporal correlations amongst them, and the fundamental matter particles [123], i.e. fermions (quarks and leptons), and composite particles, such as hadrons, cannot be massless because of non-diminishing spatial correlations amongst fermions that cannot exist in vacuum. Force carrying bosons either do not exist or are massless in vacuum because of no spatial component of correlations that can exist in vacuum. They acquire mass, owing to Higgs boson [128], since a Higgs boson imparts spatial correlations amongst the force carrier particles, such that the force carriers in a medium have non-zero mass and speed lower than that of light in vacuum. Photons and gluons are known to not interact with a Higgs field, but they can no longer be ‘free’ particles in a medium, owing to inevitable spatial correlations amongst them when not in vacuum, and therefore, they acquire non-zero mass and slow down in the medium. The W and Z bosons are massive, owing to strong spatial correlations, because of which they have weak temporal correlations so that they mediate a weak force. On the other hand, gluons are massless and mediate a strong force, owing to strong temporal correlations. Photons and gravitons too mediate non-diminishing forces, owing to strong temporal correlations, that get weakened when not in vacuum. Hence, electroweak symmetry breaking, CP violation, non-zero neutrino mass, or coupling non-unification [123], all arise from the correlations conservation law. Also, vibrational energy like heat or sound is mediated by the quasiparticles phonons, that are massless in vacuum, but acquire negative mass in a medium [129], as temporal correlations get created amongst them from existing spatial correlations in the medium, which is why heat or sound travels faster in denser fluid by acquiring more negative mass. Thus, it is apt to state that a theory of everything [130] can be developed based on the correlations conservation law. The reader is reminded that by a spatial or temporal correlation in this section, we meant ‘spacelike’ or ‘timelike’ correlation in general, unless where it is evident that a purely spatial or temporal correlation is implied.

Before concluding, we discuss a couple of examples where this may be useful. Noise is vibrational energy (that travel in longitudinal waves), like heat or sound, mediated by phonons having negative mass. Whenever non-vibrational energy (that travel in transverse waves), like light, wind or water, is converted into (positive) mass, it inevitably ‘dissipates’ vibrational energy into the environment, e.g. causing global warming [131]. Likewise, whenever mass ‘decoheres’ into energy, it inevitably sucks noise from the environment, causing the reverse of global warming. In other words, (non-unital) dissipation causes global warming and (unital) decoherence can reverse it. To stress on why that may not be negligible, it is impossible to generate vibrational energy (negative mass) without consuming non-vibrational energy (positive mass), and it is impossible to generate non-vibrational energy (positive mass) without consuming vibrational energy (negative mass), which follow...
from the fundamental conservation law of mass. More explicitly, excess vibrational energy in the environment will inevitably force the (open) system to generate non-vibrational energy, like uncontrolled melting of polar ice, rise of sea-levels, floods, hurricanes, etc. Instead, if we generate more and more non-vibrational energy in a controlled manner to meet our energy needs, it will suck environmental vibrational energy, allowing to curb global warming. That is, if we can produce more non-vibrational energies than we can consume, it will inevitably have negative net vibrational energies released to the environment by humans. Also, one may likely explain and/or understand metabolism, consciousness, Darwinian evolution, etc. using this law \[132\]. All life forms, including single-cell organisms, maintain non-zero cellular energy and so, negative entropy \[133, 134\], that starts increasing at and after death. If a wooden chair has no life, even if the wood came from a living tree, the wood essentially became all cellular mass (i.e. no energy at cell level). However, these are out of the current scope of the paper and the author, and are best left for specialists in respective disciplines to explore. We summarize the various physical processes and quantities discussed in this section by a schematic diagram in Fig. 1, where we also depict that decoherence (i.e. measurement) of a system triggers the quantum to classical transition of the system in space \[135\] (and classical to quantum transition in time) and is caused by increasing friction in the classical world in space \[136\], while dissipation causes decreasing friction in the quantum world in space \[137\].

\section*{X. CONCLUSION}

We studied fundamental quantum limits in noisy quantum multiparameter estimation using a quantum Fisher information matrix (QFIM) defined in terms of antisymmetric logarithmic derivatives (ALDs), that lend a convenient way to study noisy metrology. We presented a QFIM for multiparameter estimation using a mixed probe state evolving unitarily. We then considered a mixed state evolving via a noisy channel, and presented an upper bound to the QFIM for this general-most case. We found that the bounds are such that the quantum enhancement in the estimation precision is provided by the two-particle reduced density matrices and the attainability of the quantum enhancement is solely determined by the one-particle reduced density matrices of the initial probe state, when the channel is described by one-particle evolution operators. We showed conditions and accordingly measurements to saturate these explicitly computable bounds (e.g. in terms of the Kraus op-
erators of the channel), not known to exist with conventional symmetric logarithmic derivatives (SLDs) for these general-most cases. We saw that the Heisenberg limit can be achieved even in these most general noisy cases.

Moreover, for the most part of the past century since the inception of quantum physics, weird quantum phenomena, such as superposition and entanglement, were perceived as bugs, until the 80s when the scientists started to exploit them as features [138]. Today, the biggest hurdle to quantum technologies, e.g. in building a scalable quantum computer, is noise. The results here suggest that some noise in the initial probe state or the quantum channel can actually serve as a feature rather than a bug, because we saw that the achievable estimation precision scaling in the presence of noise is not possible in the absence of any noise in the initial probe state or the quantum channel. Noise in the initial probe state or the channel provides with a quantum advantage by introducing quantum correlations into the system. However, too much noise in the initial probe state or the channel is detrimental, since it introduces too much quantum correlations into the system, and, in turn, harms the quantum advantage achievable with $N$ parallel resources.

Furthermore, we found that it is possible to beat the Heisenberg limit by exploiting the noise in the quantum channel. The fundamental super-Heisenberg precision limit for non-unitary channel is then determined by two-particle reduced density operators of the evolved probe state being maximally entangled and one-particle reduced density operators being maximally mixed, and corresponds to a precision scaling of $1/N^2$, achieved with one-particle Kraus operators. Further, using $\gamma$-particle (instead of one-particle) Kraus operators for a noisy channel, where $\gamma > 1$, the best scaling of $1/N^{2\gamma}$ can be attained, that is known to be only possible with $2\gamma$-particle Hamiltonians for a noiseless channel. Such a precision scaling can be achieved with an initial pure or mixed probe state evolving through a unitary channel without requiring additional resources, but not with an initial pure probe state evolving through a noisy channel.

These results may be experimentally demonstrated, as part of future work, with more practically implementable measurements that may exist than those presented in this work. Also, as discussed, extending these results to the general relativistic context may resolve the cosmological constant problem. In particular, we proposed a spatiotemporal correlations conservation law, having fundamental implications, that may explain all fundamental physical laws, paradoxes, mysteries, etc., since all that exist or do not exist are and because of correlations. Such a correlations conservation law suggests that while the universe is expanding at an accelerating rate in space, it may be shrinking in time at an equally accelerating rate. All fundamental particles and forces of nature exist the way they do due to the correlations conservation law, which may, therefore, be used to develop a comprehensive and consistent theory of everything.

The author thanks Christos Gagatsos, Dominic Brandford, Animesh Datta, Ranjith Nair, Mankei Tsang, Andy Chia, Pieter Kok, Rafał Demkowicz-Dobrzański, Dominic Berry, Pragya Shukla, Rahul Gupta, Anindya Banerji, Sai Vinjanampathy and Jamie Friel for stimulating discussions in relation to this work.

Appendix A: Proof for $\nu V \left[ \hat{\theta}(m) \right] \geq [J_C(\theta)]^{-1} \geq [J_Q(\theta)]^{-1}$

Here, we prove the following quantum Cramér-Rao inequality, as claimed in Section III.

$$\nu V \left[ \hat{\theta}(m) \right] \geq [J_C(\theta)]^{-1} \geq [J_Q(\theta)]^{-1}, \quad (A1)$$

where $\nu$ is the number of times the experiment is repeated,

$$V \left[ \hat{\theta}(m) \right] = \sum_{m} p(m|\theta) \left( \hat{\theta}(m) - \theta \right) \left( \hat{\theta}(m) - \theta \right)^T =: \Sigma \quad (A2)$$

is the estimation error covariance,

$$J_C^{jk} = \sum_{m} \frac{1}{p(m|\theta)} \frac{\partial}{\partial \theta_j} p(m|\theta) \frac{\partial}{\partial \theta_k} p(m|\theta) \quad (A3)$$

is the classical Fisher information matrix (FIM), and

$$J_Q^{jk} = \frac{1}{2} \text{Tr} \left[ \left( \hat{L_j} \hat{L_k} + \hat{L_k} \hat{L_j} \right) \hat{\rho}(\theta) \right] \quad (A4)$$

is the quantum Fisher information matrix (QFIM), with the operators $\hat{L_k}$ satisfying

$$\frac{1}{2} \left( \hat{L_k} \hat{\rho}(\theta) + \hat{\rho}(\theta) \hat{L_k}^\dagger \right) = \frac{\partial}{\partial \theta_k} \hat{\rho}(\theta). \quad (A5)$$

The proof is adapted from Ref. [48] for frequentist multiparameter estimation problem here.

The estimates $\hat{\theta}(m) = [ \hat{\theta}_1(m) \quad \hat{\theta}_2(m) \quad \ldots \quad \hat{\theta}_q(m) ]^T$ of the parameters $\theta = [ \theta_1 \quad \theta_2 \quad \ldots \quad \theta_q ]^T$ are unbiased, if

$$\sum_{m} p(m|\theta) \hat{\theta}_j(m) = \theta_j \quad \forall j. \quad (A6)$$
where \( p(m|\theta) = \text{Tr} \left( \hat{P}_m \hat{\rho}(\theta) \right) \) is the conditional probability to obtain the outcome \( m \) from a measurement performed on the evolved probe state \( \hat{\rho}(\theta) \) via a positive operator valued measure (POVM) \( \{ \hat{P}_m \} \), given that the parameters have the value \( \theta \). Differentiating (A6) with respect to \( \theta_k \), we get

\[
\delta_{jk} = \sum_m \left( \hat{\theta}_j(m) - \theta_j \right) \frac{\partial p(m|\theta)}{\partial \theta_k} = \text{Re} \sum_m \left( \hat{\theta}_j(m) - \theta_j \right) \text{Tr} \left[ \hat{P}_m \hat{L}_k \hat{\rho}(\theta) \right].
\]

(A7)

Then, following Ref. [48], since \( \nu \geq 1 \), we get:

\[
\nu^T \mathbf{u} = \sum_j u_j v_j \leq A^T B, \quad \nu^T \mathbf{w} = \sum_k w_k \leq \text{Re} \left[ \text{Tr} \left( C^T D \right) \right],
\]

(A8)

where \( \mathbf{u}, \mathbf{v}, \mathbf{w} \) are arbitrary real column vectors, and

\[
A^T = \sum_k v_k \frac{\partial p(m|\theta)}{\partial \theta_k} \frac{1}{\sqrt{p(m|\theta)}}, \quad B = \sum_j u_j \left( \hat{\theta}_j(m) - \theta_j \right) \sqrt{\nu \sqrt{p(m|\theta)}},
\]

\[
C^i = \sum_l \nu \sqrt{\text{Tr} \left[ \hat{P}_m \hat{L}_l \hat{\rho}(\theta) \right]}, \quad D = \sum_j u_j \left( \hat{\theta}_j(m) - \theta_j \right) \sqrt{\nu \sqrt{\hat{\rho}(\theta)}} \sqrt{\hat{P}_m}.
\]

(A9)

We assume that \( \nu^T \mathbf{u} \) and \( \nu^T \mathbf{w} \) are positive, which are valid assumptions given how we set these later. Then,

\[
\left( \nu^T \mathbf{u} \right)^2 \leq (A^T B)^2 \leq (A^T A) (B^T B), \quad \left( \nu^T \mathbf{w} \right)^2 \leq \left| \text{Tr} \left( C^T D \right) \right|^2 \leq \text{Tr} \left( C^T C \right) \text{Tr} \left( D^T D \right),
\]

(A10)

where the second inequalities in both lines are Schwarz inequalities.

Now, note that \( A^T A = \nu^T J_C v \), where \( J_C \) is a real, symmetric and positive semidefinite classical Fisher information matrix (FIM) as defined in (A3), \( \text{Tr} \left( C^T C \right) = \nu^T Q \mathbf{w} \), where \( Q \) is a real, symmetric and positive semidefinite quantum Fisher information matrix (QFIM) as defined in (A4), and \( B^T B = \text{Tr} \left( D^T D \right) = \nu^T \Sigma u \), where \( \nu \Sigma \) is the estimation error covariance matrix as defined in (A2). Substituting these in (A10), we find that

\[
\left( \nu^T J_C v \right) \left( \nu^T \Sigma u \right) \geq \left( \nu^T \mathbf{u} \right) \left( u^T v \right), \quad \left( \nu^T J_Q w \right) \left( \nu^T \Sigma u \right) \geq \left( \nu^T \mathbf{u} \right) \left( u^T w \right).
\]

(A11)

Setting \( \nu = J_C^{-1} \mathbf{u} \) implies that

\[
\nu^T \left( \Sigma - J_C^{-1} \right) \mathbf{u} \geq 0,
\]

(A12)

for arbitrary real vectors \( \mathbf{u} \). Since \( \Sigma - J_C^{-1} \) is real and symmetric, this implies that \( \Sigma - J_C^{-1} \) is positive semidefinite. Also, setting \( \mathbf{w} = J_Q^{-1} \mathbf{u} \) implies that

\[
\nu^T \left( \Sigma - J_Q^{-1} \right) \mathbf{u} \geq 0.
\]

(A13)

Since \( \Sigma - J_Q^{-1} \) is real and symmetric, this implies that \( \Sigma - J_Q^{-1} \) is positive semidefinite.

We now take \( \mathbf{v} = \mathbf{w} \). Then, we have

\[
\nu^T \mathbf{u} \leq A^T B = \text{Re} \left[ \text{Tr} \left( C^T D \right) \right] \Rightarrow \left( \nu^T \mathbf{u} \right) \left( u^T \mathbf{v} \right) \leq \left| \text{Tr} \left( C^T D \right) \right|^2 \leq \text{Tr} \left( C^T C \right) \text{Tr} \left( D^T D \right) = \left( \nu^T J_Q \mathbf{v} \right) \left( \nu^T \Sigma u \right). \quad (A14)
\]

Then, again setting \( \nu = J_C^{-1} \mathbf{u} \) imply that

\[
\left( \nu^T J_C^{-1} \mathbf{u} \right) \left( \nu^T J_C^{-1} \mathbf{u} \right) \leq \left( \nu^T J_C^{-1} J_Q J_C^{-1} \mathbf{u} \right) \left( \nu^T \Sigma u \right).
\]

(A15)

Now, since \( \nu^T \left( \Sigma - J_C^{-1} \right) \mathbf{u} \geq 0 \), we get from above

\[
\nu^T J_C^{-1} \mathbf{u} \leq \nu^T J_C^{-1} J_Q J_C^{-1} \mathbf{u} \Rightarrow J_C^{-1} \leq J_C^{-1} J_Q J_C^{-1} \Rightarrow \nu^T \geq \nu^T.
\]

(A16)

Thus, we have (A1).
Appendix B: Saturability of ALD-based QCRB

Here, we prove that an ALD-based QCRB can be saturated when the expectation of the commutator of the ALDs vanishes, as claimed in Section II

\[ \text{Tr} \left( \left( \hat{L}_j \hat{L}_k - \hat{L}_k \hat{L}_j \right) \hat{\rho}(\theta) \right) = \text{Tr} \left( \left[ \hat{L}_j, \hat{L}_k \right] \hat{\rho}(\theta) \right) = 0, \]

(B1)

where the operators \( \hat{L}_k \) are anti-Hermitian. The proof presented here is directly adapted from Ref. [53] for ALDs, and relies on the fact that it is enough to show that the QFIM bound is equivalent to the Holevo bound when (B1) is satisfied, because the Holevo bound is a tighter bound, known to be asymptotically saturable.

Given that the operators \( \hat{L}_k \) are anti-Hermitian and satisfy

\[ \frac{1}{2} \left( \hat{L}_k \hat{\rho}(\theta) - \hat{\rho}(\theta) \hat{L}_k \right) = \frac{\partial}{\partial \theta_k} \hat{\rho}(\theta), \]

(B2)

and the QFIM \( J_Q \) is given by (A4), then (A1) implies that for a given cost matrix \( G \), the estimation cost is bounded by

\[ \text{tr} \left( G \nu V [\hat{\theta}(m)] \right) \geq \text{tr} \left( G J_Q^{-1} \right), \]

(B3)

where \( \text{tr} \) denotes the trace of a matrix in distinction from \( \text{Tr} \) for an operator. Then, the achievable estimation uncertainty is lower-bounded by the Holevo Cramér-Rao bound [53, 139]:

\[ \text{tr} \left( G \nu V [\hat{\theta}(m)] \right) \geq \min_{\{\hat{X}_j\}} \{ \text{tr} (G \text{Re} W) + ||G \text{Im} W||_1 \}, \]

(B4)

where \( || \cdot ||_1 \) is the operator trace norm, the elements of the matrix \( W \) are [139]

\[ W_{jk} = \text{Tr} \left( \hat{X}_j^\dagger \hat{X}_k \hat{\rho}(\theta) \right), \]

(B5)

and the minimization is performed over the operators \( \hat{X}_j \) satisfying

\[ \frac{1}{2} \text{Tr} \left( \left( \hat{X}_j^\dagger \hat{L}_k + \hat{L}_k \hat{X}_j \right) \hat{\rho}(\theta) \right) = \delta_{jk}. \]

(B6)

In our case, the operators \( \hat{X}_j \) are also anti-Hermitian. The bound (B4) is stronger than the bound (B3), the right hand side of which can be rewritten in the form [53]:

\[ \text{tr} \left( G J_Q^{-1} \right) = \min_{\{\hat{X}_j\}} \{ \text{tr} (G \text{Re} W) \}. \]

(B7)

Then, the solution to the minimization problem in (B7) is [53]

\[ \hat{X}_j = \sum_k (G^{-1} \Lambda)_{jk} \hat{L}_k = \sum_k (J_Q^{-1})_{jk} \hat{L}_k, \]

(B8)

where \( \Lambda \) is a matrix of Lagrange multipliers, chosen so that \( G^{-1} \Lambda J_Q = \mathbb{1} \).

Now, the cost matrix \( G \) and the QFIM \( J_Q \) are assumed to be strictly positive. Firstly, we assume that (B1) holds for all \( j, k \). We saw that the optimal \( \hat{X}_j = \sum_k (J_Q^{-1})_{jk} \hat{L}_k \) are linear combinations of \( \hat{L}_j \). This implies that

\[ \text{Tr} \left( \left[ \hat{X}_j, \hat{X}_k \right] \hat{\rho}(\theta) \right) = 0 \]

for all \( j, k \). Hence, the same set of \( \hat{X}_j \) minimizes the Holevo bound, since it makes the second term in (B4) to equal zero. Thus, (B1) is a sufficient condition for saturating the ALD-based QCRB corresponding to the QFIM (A4).

Secondly, we assume that the Holevo bound coincides with the QFIM bound, and so for the \( \hat{X}_j \) that minimize both (B3) and (B4), the second term in (B4) must equal zero. Since \( G \) is strictly positive, the matrix \( \text{Im} W \) must be zero and hence

\[ \text{Tr} \left( \left[ \hat{X}_j, \hat{X}_k \right] \hat{\rho}(\theta) \right) = 0 \]

for all \( j, k \). However, the \( \hat{X}_j \) that minimizes (B3) is \( \hat{X}_j = \sum_k (J_Q^{-1})_{jk} \hat{L}_k \).

Inverting this formula, we get \( \hat{L}_j = \sum_k (J_Q^{-1})_{jk} \hat{X}_k \). Hence, (B1) holds for all \( j, k \) and is also a necessary condition for saturating the ALD-based QCRB corresponding to the QFIM (A4).
Appendix C: The states $\hat{\rho}^N$ are permutationally invariant

Here, we show that the first order and second order reduced density matrices are as claimed in Section XV for the magnetic field example.

First, considering the $N = 2$ case:

$$\hat{\rho}^{N=2} = \frac{1}{2} \left[ \hat{E}_{00}^{\otimes 2} |\phi_k^+, \phi_k^+\rangle \langle \phi_k^+, \phi_k^+| + \hat{E}_{10}^{\otimes 2} |\phi_k^-, \phi_k^-\rangle \langle \phi_k^-, \phi_k^-| + (\hat{E}_0 \otimes \hat{E}_1)|\phi_k^+, \phi_k^+\rangle \langle \phi_k^+, \phi_k^+| \right]$$

Then, tracing out the second qubit, we get:

$$\text{Tr}_2 [\hat{\rho}^{N=2}] = \frac{1}{2} \left[ \hat{E}_0 |\phi_k^+\rangle \langle \phi_k^+| \hat{E}_0 |\phi_k^+\rangle \langle \phi_k^+| + \hat{E}_0 |\phi_k^+\rangle \langle \phi_k^+| \hat{E}_0 |\phi_k^+\rangle \langle \phi_k^+| + \hat{E}_0 |\phi_k^+\rangle \langle \phi_k^+| \hat{E}_0 |\phi_k^+\rangle \langle \phi_k^+| \right]$$

(C2)
Similarly, considering the $N = 3$ case, and then tracing out the third qubit, we get:

$$
\text{Tr}_3 \left[ \hat{\rho}_k^{N=3} \right] = \frac{1}{2} \left[ \hat{E}_0^{\otimes 2} \langle \phi_k^+, \phi_k^\dagger | \langle \phi_k^+, \phi_k^\dagger | \hat{E}_0^{\otimes 2} + (\hat{E}_0 \otimes \hat{E}_1)| \phi_k^+, \phi_k^\dagger | \hat{E}_0 \otimes \hat{E}_1 \right] \\
+ (\hat{E}_1 \otimes \hat{E}_0)| \phi_k^+, \phi_k^\dagger | \langle \phi_k^+, \phi_k^\dagger | \hat{E}_1 \otimes \hat{E}_0 \rangle + \hat{E}_0^{\otimes 2} \langle \phi_k^+, \phi_k^\dagger | \hat{E}_0 \otimes \hat{E}_1 | \phi_k^+, \phi_k^\dagger \rangle \\
+ \hat{E}_0^{\otimes 2} \langle \phi_k^-, \phi_k^\dagger | \langle \phi_k^-, \phi_k^\dagger | \hat{E}_0 \otimes \hat{E}_1 \rangle \\
+ (\hat{E}_1 \otimes \hat{E}_0)| \phi_k^-, \phi_k^\dagger | \langle \phi_k^-, \phi_k^\dagger | \hat{E}_1 \otimes \hat{E}_0 \rangle + \hat{E}_1^{\otimes 2} \langle \phi_k^-, \phi_k^\dagger | \hat{E}_1 \otimes \hat{E}_0 | \phi_k^-, \phi_k^\dagger \rangle \\
= \frac{1}{2} \left[ \hat{E}_0^{\otimes 2} (\langle \phi_k^+, \phi_k^\dagger | \langle \phi_k^+, \phi_k^\dagger | + | \phi_k^-, \phi_k^\dagger | \langle \phi_k^-, \phi_k^\dagger | ) \hat{E}_0^{\otimes 2} \right] \\
+ (\hat{E}_0 \otimes \hat{E}_1) \left( \langle \phi_k^+, \phi_k^\dagger | \langle \phi_k^+, \phi_k^\dagger | + | \phi_k^-, \phi_k^\dagger | \langle \phi_k^-, \phi_k^\dagger | \right) (\hat{E}_0 \otimes \hat{E}_1) \\
+ (\hat{E}_1 \otimes \hat{E}_0) \left( \langle \phi_k^+, \phi_k^\dagger | \langle \phi_k^+, \phi_k^\dagger | + | \phi_k^-, \phi_k^\dagger | \langle \phi_k^-, \phi_k^\dagger | \right) (\hat{E}_1 \otimes \hat{E}_0) \\
+ \hat{E}_1^{\otimes 2} \left( \langle \phi_k^+, \phi_k^\dagger | \langle \phi_k^+, \phi_k^\dagger | + | \phi_k^-, \phi_k^\dagger | \langle \phi_k^-, \phi_k^\dagger | \right) \hat{E}_1^{\otimes 2} \right]
$$

and so on.

**Appendix D: Proof for $C_Q(\theta) \geq J_Q(\theta)$**

Here, we prove that the quantity $C_Q(\theta)$ is indeed an upper bound to the quantity $J_Q(\theta)$ for the evolved probe state $\hat{\rho}(\theta)$, as claimed in Section [V]. Consider the following relationship of the Bures fidelity with the quantum Fisher information matrix (QFIM), where the QFIM is real, symmetric and positive semidefinite but more general and not necessarily composed of symmetric logarithmic derivatives (SLDs):

$$
F(\hat{\rho}(\theta), \hat{\rho}(\theta + \epsilon)) = 1 - \frac{1}{4} \sum_{j,k} \epsilon_j \epsilon_k \text{Tr} \left[ \frac{\hat{L}_j \hat{L}_k + \hat{L}_k \hat{L}_j}{2} \hat{\rho}(\theta) \right],
$$

where $\theta$ is assumed to be the actual value of the vector of unknown parameters, $\epsilon$ is an infinitesimal increment in $\theta$, and $0 \leq F(\hat{\rho}_1, \hat{\rho}_2) = \text{Tr} \left( \sqrt{\sqrt{\hat{\rho}_1} \hat{\rho}_2 \sqrt{\hat{\rho}_1}} \right) \leq 1$ is the Bures fidelity between two given states $\hat{\rho}_1$ and $\hat{\rho}_2$. [20, 22, 24, 140, 142].

Here, (D1) holds, when the operators $\hat{L}_k$ are not necessarily Hermitian and satisfy:

$$
\frac{1}{2} \left( \hat{L}_k \hat{\rho}(\theta) + \hat{\rho}(\theta) \hat{L}_k \right) = \frac{\partial \hat{\rho}(\theta)}{\partial \theta_k}.
$$

This can be seen as follows. When the operators $\hat{L}_k$ are Hermitian, such that $\hat{L}_k^\dagger = \hat{L}_k$, as is the convention, the Bures metric $d_B$ and Bures distance $D_B$ are defined and related to the fidelity $F$ for infinitesimal $\epsilon$ as follows [28, 140]:

$$
d_B^2 (\hat{\rho}(\theta), \hat{\rho}(\theta + \epsilon)) = D_B^2 (\hat{\rho}(\theta), \hat{\rho}(\theta + \epsilon)) = 2 [1 - F(\hat{\rho}(\theta), \hat{\rho}(\theta + \epsilon))] = \frac{1}{2} \sum_{j,k} \epsilon_j \epsilon_k \text{Tr} \left[ \frac{\hat{L}_j \hat{L}_k + \hat{L}_k \hat{L}_j}{2} \hat{\rho}(\theta) \right],
$$

where $\hat{L}_k$ are the SLDs satisfying:

$$
\frac{1}{2} \left( \hat{L}_k \hat{\rho}(\theta) + \hat{\rho}(\theta) \hat{L}_k \right) = \frac{\partial \hat{\rho}(\theta)}{\partial \theta_k}.
$$

However, if the operators $\hat{L}_k$ are not necessarily Hermitian and rather satisfy (D2), then (D3) becomes:

$$
d_B^2 (\hat{\rho}(\theta), \hat{\rho}(\theta + \epsilon)) = D_B^2 (\hat{\rho}(\theta), \hat{\rho}(\theta + \epsilon)) = 2 [1 - F(\hat{\rho}(\theta), \hat{\rho}(\theta + \epsilon))] = \frac{1}{2} \sum_{j,k} \epsilon_j \epsilon_k \text{Tr} \left[ \frac{\hat{L}_j^\dagger \hat{L}_k + \hat{L}_k^\dagger \hat{L}_j}{2} \hat{\rho}(\theta) \right].
$$
Then, clearly (D11) is obtained from the above.

We must comment here that there is a lot of inconsistency in the literature about the relationship between $d_B$, $D_B$ and $F$. We here used the relationship originally presented in Ref. 140.

Now, for our case in this paper, the operators $\hat{L}_k$ are anti-symmetric logarithmic derivatives (ALDs), such that $\hat{L}_k = -\hat{L}_k$. We have from (D11):

$$F(\hat{\rho}(\theta), \hat{\rho}(\theta + \epsilon)) = 1 - \frac{1}{4} \sum_{j,k} \epsilon_j \epsilon_k C^j_k(\theta).$$

(D6)

Now, since fidelity is non-decreasing with respect to partial trace (See Refs. 24, 141, 143, 144, for example), we have:

$$F(\hat{\rho}(\theta), \hat{\rho}(\theta + \epsilon)) = F(\operatorname{Tr}_B[\hat{\rho}_{SB}(\theta)], \operatorname{Tr}_B[\hat{\rho}_{SB}(\theta + \epsilon)]) \geq F(\hat{\rho}_{SB}(\theta), \hat{\rho}_{SB}(\theta + \epsilon)) = 1 - \frac{1}{4} \sum_{j,k} \epsilon_j \epsilon_k C^j_k(\theta).$$

(D7)

Clearly, from (D6) and (D7), we have (like in Ref. 22):

$$C_Q(\theta) \geq J_Q(\theta).$$

(D8)

An alternative argument for (D8) to hold is that the quantum Fisher information (for both single and multiparameter cases) is an operator monotone function, non-increasing with respect to partial trace 31, 145, noting that the partial trace is a completely positive and trace-preserving map from $S + B$ space to $S$ space.

Note that, even though we did not explicitly invoke Uhlmann’s theorem here, the inequality in (D7) is the monotonicity property of fidelity and is a consequence of Uhlmann’s theorem. Thus, extending the argument from Ref. 20 to the multiparameter case, the equality in (D8) is achieved by minimizing $C_Q(\theta)$ over all Kraus representations of the quantum channel. Hence, there are an infinitude of Kraus representations of the channel that lead to $C_Q(\theta) = J_Q(\theta)$.

Appendix E: POVM to attain QCRB for Pure State Input via Unitary Channel

Here, we prove that, as claimed in Section III, the set of POVMs $\{\hat{P}_{m1}\}$ of cardinality $q + 2$, comprising the following $q + 1$ elements,

$$\hat{P}_0 = \hat{\rho}(\theta) = \hat{U}(\theta)|\psi\rangle\langle\psi|\hat{U}^\dagger(\theta), \quad \hat{P}_m = \frac{\partial \hat{U}(\theta)}{\partial \theta_m}|\psi\rangle\langle\psi|\frac{\partial \hat{U}^\dagger(\theta)}{\partial \theta_m} \quad \forall m = 1, \ldots, q,$$

(E1)

together with one element $\hat{P}_q = \hat{P}_{q+1} := |\phi_n\rangle\langle\phi_n|$ that accounts for the normalisation, saturates the ALD-based QCRB, provided (D11) is satisfied for every pair of ALDs.

The proof is adapted from Ref. 4, noting that for pure state and unitary channel our ALD-based QCRB coincides with the SLD-based QCRB, and it is enough to demonstrate that using the set of POVMs $\{\hat{P}_{m1}\}$ the quantum Fisher information matrix (QFIM) equals the classical Fisher information matrix (FIM), when (B1) is satisfied. The set of POVMs must be complete, i.e. $\sum_{m=1}^{q+1} \hat{P}_{m1} = 1$.

Consider that the initial probe state is $\hat{\rho} = |\psi\rangle\langle\psi|$. Then, we use the short notations

$$|\psi_\theta\rangle = \hat{U}(\theta)|\psi\rangle, \quad |\partial_{\theta_k} \psi_\theta\rangle = \frac{\partial}{\partial \theta_k} |\psi_\theta\rangle = \frac{\partial \hat{U}(\theta)}{\partial \theta_k} |\psi\rangle.$$

(E2)

The elements of the quantum Fisher information matrix (QFIM) are given by 4, 3

$$J^j_k = 4\Re \left[ \langle \partial_{\theta_j} \psi_\theta | \partial_{\theta_k} \psi_\theta \rangle - \langle \partial_{\theta_j} \psi_\theta | \psi_\theta \rangle \langle \psi_\theta | \partial_{\theta_k} \psi_\theta \rangle \right].$$

(E3)

The elements of the corresponding classical Fisher information matrix (FIM) $J_C$ are given by 4

$$J^j_k = \sum_{m=0}^{q+1} \frac{\partial_{\theta_j} p(m|\theta) \partial_{\theta_k} p(m|\theta)}{p(m|\theta)} = \sum_m 4\Re \left[ \langle \partial_{\theta_j} \psi_\theta | \hat{P}_m | \psi_\theta \rangle \right] \Re \left[ \langle \psi_\theta | \hat{P}_m | \partial_{\theta_k} \psi_\theta \rangle \right].$$

(E4)

The component of the FIM corresponding to the POVM element $\hat{P}_0 = |\psi_\theta\rangle\langle\psi_\theta|$ is

$$4\Re \left[ \langle \partial_{\theta_j} \psi_\theta | \psi_\theta \rangle \right] \Re \left[ |\psi_\theta\rangle \langle \partial_{\theta_k} \psi_\theta | \psi_\theta \rangle \right] = 0.$$
The above quantity vanishes because $\text{Re} \left[ (\partial_{\theta_k}\psi_\theta | \psi_\theta) \right] = 0$ for any parameter $\theta_k$. Next, the component of the FIM corresponding to the POVM element $\hat{P}_n = \hat{P}_{q+1} = |\phi_n\rangle \langle \phi_n|$ is

$$4\text{Re} \left[ (\partial_{\theta_k}\psi_\theta | \hat{P}_n | \psi_\theta) \right] \text{Re} \left[ (\psi_\theta | \hat{P}_n | \partial_{\theta_k}\psi_\theta) \right] = 4\text{Re} \left[ (\partial_{\theta_k}\psi_\theta | \phi_n) \langle \phi_n | \partial_{\theta_k}\psi_\theta \rangle \right],$$

(E6)

since $\langle \psi_\theta | \hat{P}_n | \psi_\theta \rangle$ is, by definition, real.

The remaining components $\hat{P}_k$ for $k = 1, \ldots, q$ may be similarly computed, and we get

$$J^R_{C} = 4 \sum_{m=1}^{q} \text{Re} \left[ (\partial_{\theta_k}\psi_\theta | \partial_{\theta_m}\psi_\theta) (\partial_{\theta_m}\psi_\theta | \partial_{\theta_k}\psi_\theta) \right] + 4\text{Re} \left[ (\partial_{\theta_k}\psi_\theta | \phi_n) \langle \phi_n | \partial_{\theta_k}\psi_\theta \rangle \right].$$

(E7)

Now, note that, for the completeness of the set of POVMs, we require

$$\sum_{m=1}^{q} (\partial_{\theta_m}\psi_\theta) (\partial_{\theta_m}\psi_\theta) + |\phi_n\rangle \langle \phi_n | = 1 - |\psi_\theta\rangle \langle \psi_\theta |.$$

(E8)

Substituting (E8) in (E7), we get

$$J^R_{C} = 4 \text{Re} \left[ (\partial_{\theta_k}\psi_\theta) (\partial_{\theta_k}\psi_\theta) - (\partial_{\theta_k}\psi_\theta | \psi_\theta) \langle \psi_\theta | \partial_{\theta_k}\psi_\theta \rangle \right] = J^R_{Q}.$$

(E9)

Appendix F: POVM to attain QCRB for Mixed State Input via Unitary Channel

Here, we prove that, as claimed in Section III, the set of POVMs $\{\hat{P}_{m2}\}$ of cardinality $q+2$, comprising the following $q+1$ elements,

$$\hat{P}_0 = \hat{\rho} (= \hat{U}(\theta)\hat{\rho}\hat{U}^\dagger(\theta)), \quad \hat{P}_m = \frac{\partial \hat{\rho}(\theta)}{\partial \theta_m} = \left[ \frac{\partial \hat{U}(\theta)}{\partial \theta_m} \hat{\rho}\hat{U}^\dagger(\theta) + \hat{U}(\theta) \hat{\rho} \frac{\partial \hat{U}^\dagger(\theta)}{\partial \theta_m} \right], \quad \forall m = 1, \ldots, q,$$

(F1)

together with one element $\hat{P}_n = \hat{P}_{q+1}$ that accounts for the normalisation, saturates the ALD-based QCRB, provided (B1) is satisfied for every pair of ALDs.

The elements of the QFIM with $\hat{\rho}_\theta := \hat{\rho}(\theta)$ and $\hat{U}_\theta := \hat{U}(\theta)$ are:

$$J^R_{Q} = \frac{1}{2} \text{Tr} \left[ \left( \hat{L}_k^\dagger \hat{L}_k + \hat{L}_k^\dagger \hat{L}_k \right) \hat{\rho}_\theta \right] = 4\text{Re} \left[ \text{Tr} \left( \hat{U}_\theta \partial_{\theta_k}\hat{U}_\theta^\dagger \partial_{\theta_k}\hat{U}_\theta \hat{U}_\theta \hat{\rho}_\theta \right) + \text{Tr} \left( \hat{U}_\theta \partial_{\theta_k}\hat{U}_\theta^\dagger \hat{U}_\theta \partial_{\theta_k}\hat{\rho}_\theta \right) \right],$$

(F2)

where we used $\hat{L}_k = 2 \left( \partial_{\theta_k}\hat{U}_\theta \hat{U}_\theta^\dagger - \text{Tr} \left( \partial_{\theta_k}\hat{U}_\theta \hat{U}_\theta^\dagger \right) \right)$ (as taken in Sections III and V), that satisfy:

$$2\partial_{\theta_k}\hat{\rho}_\theta = \hat{L}_k \hat{\rho}_\theta + \hat{\rho}_\theta \hat{L}_k^\dagger, \quad \hat{L}_k^\dagger = -\hat{L}_k,$$

(F3)

noting that $\hat{U}_\theta \partial_{\theta_k}\hat{U}_\theta^\dagger = -\partial_{\theta_k}\hat{U}_\theta \hat{U}_\theta^\dagger$, arising from $\hat{U}_\theta \hat{U}_\theta^\dagger = 1$ upon differentiating both sides with respect to $\theta_k$.

Also, the elements of the FIM $J^R_C$, as defined in (A3), are:

$$J^R_{C} = \sum_{m} \frac{1}{p(m(\theta))} \frac{\partial}{\partial \theta_j} p(m(\theta)) \frac{\partial}{\partial \theta_k} p(m(\theta)) = \sum_{m} \frac{1}{\text{Tr} \left( \hat{P}_m \hat{\rho}_\theta \right)} \frac{\partial}{\partial \theta_j} \text{Tr} \left( \hat{P}_m \hat{\rho}_\theta \right) \frac{\partial}{\partial \theta_k} \text{Tr} \left( \hat{P}_m \hat{\rho}_\theta \right).$$

(F4)

Consider that we are interested in saturating the bound at a specific point $\theta_*$ in the space of $\theta$, as in Ref. 4. Then, (E8) here becomes:

$$\frac{\text{Tr} \left( \partial_{\theta_k}\hat{\rho}_\theta \partial_{\theta_k}\hat{\rho}_\theta \right) \text{Tr} \left( \partial_{\theta_k}\hat{\rho}_\theta \partial_{\theta_k}\hat{\rho}_\theta \right)}{\text{Tr} \left( \hat{\rho}_\theta \right)} = 0,$$

(F5)

where $\text{Tr} \left( \partial_{\theta_k}\hat{\rho}_\theta \partial_{\theta_k}\hat{\rho}_\theta \right) = 0$ for any parameter $\theta_k$, as an extension of Refs. 4, 23. This can be seen as follows. Given that $\hat{\rho}_\theta$ is not necessarily pure, we must have $\text{Tr} \left( \partial_{\theta_k}\hat{\rho}_\theta \partial_{\theta_k}\hat{\rho}_\theta \right) \leq 0$, arising upon differentiation with respect to $\theta_j$ from $\text{Tr} \left( \hat{\rho}_\theta \right) \leq 1$, for which $\text{Tr} \left( \hat{\rho}_\theta \right)$ is clearly non-decreasing. However, since $\partial_{\theta_k}\hat{\rho}_\theta$ is a POVM element, we must have $\text{Tr} \left( \partial_{\theta_k}\hat{\rho}_\theta \partial_{\theta_k}\hat{\rho}_\theta \right) = (\partial_{\theta_k}\hat{\rho}_\theta) = p(\theta_*), \partial_{\theta_k}\hat{\rho}_\theta = p(\theta_*)$, which being a probability cannot be negative. Here, $\langle \cdot \rangle$ denotes expectation.
with respect to $\hat{\rho}_{\theta_s}$. Hence, we must have $\text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \hat{\rho}_{\theta_s}) = 0$. For example, when the state $\hat{\rho}_{\theta_s}$ is maximally mixed, i.e. $\hat{\rho}_{\theta_s} = \mathbb{1}_d/d$, where $d$ is the dimension of the Hilbert space upon which the state $\hat{\rho}_{\theta_s}$ is defined, we have $\text{Tr}(\hat{\rho}_{\theta_s}^2) = 1/d$, and consequently, $\text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \hat{\rho}_{\theta_s}) = 0$. On the other hand, if $\hat{\rho}_{\theta_s}$ is pure, we must have $\text{Tr}(\hat{\rho}_{\theta_s}^2) = 1$, and consequently, $\text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \hat{\rho}_{\theta_s}) = 0$ again.

Next, proceeding in a manner similar to Ref. [4], for the terms of the FIM for $m = 1, \ldots, q$, we take $\hat{\rho}_\theta = \hat{\rho}_{\theta_s} + \delta \theta \partial_\theta \hat{\rho}_{\theta_s}$. Clearly, $\text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \partial_\theta \hat{\rho}_{\theta_s}) = 0$ (even for $j = m$), arising from $\text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \hat{\rho}_{\theta_s}) = 0$ upon differentiating both sides with respect to $\theta_m$, and noting that $\text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \hat{\rho}_{\theta_s} \hat{\rho}_{\theta_s}) = (\partial_\theta \hat{\rho}_{\theta_s} \hat{\rho}_{\theta_s}) = 0$, since $\partial_\theta \hat{\rho}_{\theta_s} = 0$. In general, we must have $\text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \hat{\rho}_{\theta_s}) = 0$, for $m = 0, 1, \ldots, q + 1$. Thus, we have $\text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \partial_\theta \hat{\rho}_{\theta_s}) = \delta \theta \text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \partial_\theta \hat{\rho}_{\theta_s})$, and $\text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \partial_\theta \hat{\rho}_{\theta_s}) = \delta \theta \text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \partial_\theta \hat{\rho}_{\theta_s})$. Then, we get

$$\sum_{m=1}^q \frac{\delta \theta^2 \text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \partial_\theta \hat{\rho}_{\theta_s}) \text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \partial_\theta \hat{\rho}_{\theta_s}) \text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \partial_\theta \hat{\rho}_{\theta_s})}{\delta \theta^2 \text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \partial_\theta \hat{\rho}_{\theta_s}) \text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \partial_\theta \hat{\rho}_{\theta_s})} = \sum_{m=1}^q \frac{\text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \partial_\theta \hat{\rho}_{\theta_s}) \text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \partial_\theta \hat{\rho}_{\theta_s}) \text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \partial_\theta \hat{\rho}_{\theta_s})}{\text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \partial_\theta \hat{\rho}_{\theta_s}) \text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \partial_\theta \hat{\rho}_{\theta_s})}$$

which we denote by $F6$.

since the limiting expression for the elements of the FIM at the point $\theta_s$ should be independent of the direction in which the state is expanded to calculate the above $[4]$, such that we can choose $r = j = k$ for our convenience. Also, we get

$$\frac{\text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \dot{\hat{P}}_{q+1}) \text{Tr}(\hat{P}_{q+1} \dot{\hat{P}}_{q+1})}{\text{Tr}(\hat{P}_{q+1} \dot{\hat{P}}_{q+1})} = \frac{\text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \dot{\hat{P}}_{q+1}) \text{Tr}(\hat{P}_{q+1} \dot{\hat{P}}_{q+1})}{\text{Tr}(\dot{\hat{P}}_{q+1} \dot{\hat{P}}_{q+1})} = 0$$

which we denote by $F7$.

Thus, $F7$ here becomes:

$$J_{Ck}^j = \sum_{m=1}^q \text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \dot{\hat{P}}_m) = -\text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \dot{\hat{P}}_m) = -\sum_{m=1}^q \text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \dot{\hat{P}}_m)$$

where the second equality arises from $\text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \dot{\hat{P}}_m) = 0$ upon differentiating both sides with respect to $\theta_k$.

Furthermore, $F8$ here becomes:

$$\sum_{m=1}^q \partial_\theta \hat{\rho}_{\theta_s} = \mathbb{1} - \hat{\rho}_{\theta_s} - \dot{\hat{P}}_{q+1}$$

which we denote by $F9$.

Then, $F9$ here becomes

$$J_{Ck}^j = -\text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \dot{\hat{P}}_m) - \text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \dot{\hat{P}}_m) + \text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \dot{\hat{P}}_m) = -\text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \dot{\hat{P}}_m)$$

where the second equality arises from $\text{Tr}(\dot{\hat{P}}_m) = 0$ upon differentiating both sides with respect to $\theta_k$, and that $\text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \dot{\hat{P}}_m) = 0$ upon differentiating both sides with respect to $\theta_k$, and that $\text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \dot{\hat{P}}_m) = 0$ upon differentiating both sides with respect to $\theta_k$. Also, $\text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \dot{\hat{P}}_m) = 0$, since $\text{Tr}(\partial_\theta \hat{\rho}_{\theta_s} \dot{\hat{P}}_m) = 0$.

Note that $\text{Tr}(\hat{\rho}_{\theta_s} \dot{\hat{P}}_m) = 0$, for $m = 1, \ldots, q$, but $\text{Tr}(\hat{\rho}_{\theta_s} \dot{\hat{P}}_m) \geq 0$, such that

$$\sum_{m=1}^q \text{Tr}(\hat{\rho}_{\theta_s} \dot{\hat{P}}_m) = 0 \Rightarrow \text{Tr}(\hat{\rho}_{\theta_s} - \dot{\hat{P}}_{q+1}) = 0 \Rightarrow \text{Tr}(\hat{\rho}_{\theta_s}^2) = 1 - \text{Tr}(\hat{\rho}_{\theta_s} \dot{\hat{P}}_{q+1}) \leq 0,$$
where the equality holds, when \( \text{Tr} \left( \hat{\rho}_\theta \hat{P}_{q+1} \right) = 0 \), and consequently, \( \hat{\rho}_\theta \) is pure. However, we have from above that
\[
\text{Tr} \left( \hat{\rho}_\theta \hat{P}_{q+1} \right) = p(q + 1)\theta_s = 1 - \text{Tr} \left( \hat{\rho}_\theta^2 \right),
\]
which upon differentiation with respect to \( \theta_j \) yields
\[
\text{Tr} \left( \frac{\partial}{\partial \theta_j} \hat{\rho}_\theta \hat{P}_{q+1} \right) = -2\text{Tr} \left( \frac{\partial}{\partial \theta_j} \hat{\rho}_\theta \hat{\rho}_\theta \right) = 0.
\]
Clearly, from (G9), upon differentiating both sides with respect to \( \theta_j \), multiplying both sides by \( \hat{\rho}_\theta \), which is positive definite, and then taking trace of both sides, we get
\[
\text{Tr} \left[ \frac{\partial}{\partial \theta_j} \hat{P}_\theta \hat{P}_{q+1} \right] = -\text{Tr} \left( \frac{\partial}{\partial \theta_j} \hat{\rho}_\theta \hat{\rho}_\theta \right) - \sum_{m=1}^q \text{Tr} \left( \frac{\partial}{\partial \theta_j} \hat{\rho}_\theta \hat{\rho}_\theta \hat{\rho}_\theta \right) = 0.
\]
Thus, we indeed have \( \text{Tr} \left( \hat{\rho}_\theta \hat{P}_{q+1} \hat{\rho}_\theta \right) = 0 \), as used earlier.

**Appendix G: Condition to saturate Upper Bound to QFIM**

Here, we prove that, as claimed in Section V, the following is a necessary and sufficient condition
\[
\text{Im} \left[ \sum_j \text{Tr} \left( \left( \frac{\partial \hat{\Pi}^i_j(\theta)}{\partial \theta_j} \hat{\Pi}^i_j(\theta) \right) \hat{\rho} \right) \right] = 0 \quad \forall j, k \quad \text{(G1)}
\]
for the following upper bound to the ALD-based QFIM to be saturated:
\[
C_{Q}^{jk} = 4\text{Re} \left[ \text{Tr} \left( \sum_j \frac{\partial \hat{\Pi}^i_j(\theta)}{\partial \theta_j} \frac{\partial \hat{\Pi}^j_i(\theta)}{\partial \theta_k} \hat{\rho} \right) + \text{Tr} \left( \sum_p \frac{\partial \hat{\Pi}^i_p(\theta)}{\partial \theta_j} \hat{\Pi}^j_p(\theta) \hat{\rho} \right) \text{Tr} \left( \sum_r \frac{\partial \hat{\Pi}^i_r(\theta)}{\partial \theta_k} \hat{\Pi}^j_r(\theta) \hat{\rho} \right) \right]. \quad \text{(G2)}
\]
Consider that our initial probe state is pure, i.e. \( \hat{\rho} = |\psi\rangle \langle \psi| \). Then, the unitary evolution \( \hat{U}_{SB}(\theta) \) in the \( S + B \) space can be considered equivalent to the output impure state \( \sum_j \hat{\Pi}^i_j(\theta)|\psi\rangle \langle \psi| \hat{\Pi}^i_j(\theta) \) of the noisy channel in the system \( S \) space, subsequently purified by extending the \( S \) space, introducing ancillas \( B \). For the sake of clarity, we use the notation \( \hat{U}_{SB}(\theta) := \hat{U}_{SB}(\theta) \) here, in distinction from \( \hat{U}_{SB}(\theta) \). The overall output is then a pure state denoted as \( \hat{\rho}_{SB} = |\psi^{S+B}\rangle \langle \psi^{S+B}| \). Then, the QCRB (A1) in the \( S + B \) space can be saturated, when (B1) leading here to
\[
\text{Im} \left[ \text{Tr} \left( \left( \frac{\partial \hat{\Pi}^i_j(\theta)}{\partial \theta_j} \hat{\Pi}^i_j(\theta) \right) |\psi\rangle \langle \psi| \hat{\Pi}^i_j(\theta) \right) \right] = 0 \quad \text{(G3)}
\]
is satisfied, where \( |0_B\rangle \) is a vacuum state ancillary bath. Tracing out \( B \) in (G3), we get (G1) as a necessary condition for the set of POVMs \( \{ \hat{P}_{n2} \} \) to result in (H6) (See Appendix H), since the operators \( \frac{\partial \hat{\Pi}^i_j(\theta)}{\partial \theta_j} \) do not act on \( B \).

Next, we assume that the initial probe state \( \hat{\rho} \) is not pure. It can be purified by extending the system \( S \) space, introducing ancillas \( S' \). Then, (G1) can be applied to the pure state \( |\psi^{S+S'}\rangle \) in the initial enlarged \( S + S' \) space. Since the operators \( \frac{\partial \hat{\Pi}^i_j(\theta)}{\partial \theta_j} \) do not act on \( S' \), we get (G1) again as a necessary condition for the set of POVMs \( \{ \hat{P}_{n3} \} \) to result in (H3) (See Appendix H).

Now, considering that the initial probe state is not pure, it can be purified by extending the initial system \( S \) space by introducing ancillas \( S' \). Then, since the operators \( \frac{\partial \hat{\Pi}^i_j(\theta)}{\partial \theta_j} \) do not act on \( S' \), (G1) saturating (C2) in the \( S \) space implies that (G3) saturates the QCRB (A1) in the \( S + B \) space. Thus, (G1) is a sufficient condition for the set of POVMs \( \{ \hat{P}_{n2} \} \) to result in (H6).

Now, considering that the initial probe state is not pure, it can be purified by extending the initial system \( S \) space by introducing ancillas \( S' \). Then, since the operators \( \frac{\partial \hat{\Pi}^i_j(\theta)}{\partial \theta_j} \) do not act on \( S' \), (G1) saturating (C2) in the \( S \) space implies that (G3) saturates the QCRB (A1) in the \( S + B + S' \) space, with \( \hat{U}_{SB}(\theta) \) replaced by \( \hat{U}^{(S+B+S')}_{SB}(\theta) \) and \( |\psi\rangle \) replaced by \( |\psi^{S+S'}\rangle \). Thus, we again get (G1) as a sufficient condition for the set of POVMs \( \{ \hat{P}_{n3} \} \) to result in (H3).

**Appendix H: POVM to attain QFIM Upper Bound for Pure State Input via Noisy Channel**

Here, we prove that, as claimed in Section V, the set of POVMs \( \{ \hat{P}_{n2} \} \) of cardinality \( q + 2 \), comprising the following \( q + 1 \) elements,
\[
\hat{P}_0 = \hat{\rho}(\theta) = \sum_i \hat{\Pi}_i(\theta)|\psi\rangle \langle \psi| \hat{\Pi}_i(\theta), \quad \hat{P}_m = \frac{\partial \hat{\rho}(\theta)}{\partial \theta_m} = \sum_i \left( \frac{\partial \hat{\Pi}_i(\theta)}{\partial \theta_m} |\psi\rangle \langle \psi| \hat{\Pi}_i(\theta) + \hat{\Pi}_i(\theta)|\psi\rangle \langle \psi| \frac{\partial \hat{\Pi}_i(\theta)}{\partial \theta_m} \right) \quad \forall m = 1, \ldots, q. \quad \text{(H1)}
\]
together with one element accounting for normalisation, saturates $\mathcal{C}_2$, provided $\mathcal{G}_1$ is satisfied.

We again consider initial pure state $\hat{\rho} = |\psi\rangle\langle\psi|$, and the unitary evolution in the $S + B$ space, $\hat{U}^{(S+B)}$ here, in distinction from $\hat{U}_{SB}(\theta)$ used in Section 4.

Then, the elements of the QFIM, as in $\mathcal{F}_2$, in terms of the initial pure state $|\psi\rangle$ here are

$$J^{(S+B)}_Q = 4\text{Re} \left[ \text{Tr} \left( \partial_\theta \hat{U}_\theta^{(S+B)} \hat{\Pi}_{\theta_B} \hat{\Pi}_\theta \langle \psi \rangle \langle \psi \rangle \langle \psi \rangle \langle \psi \rangle \right) \right],$$

where $|0_B\rangle$ is a vacuum state ancillary bath.

Tracing out $B$ from above, we get the upper bound $\mathcal{C}_2$ to the QFIM in terms of the initial pure state $|\psi\rangle$ in the $S$ space:

$$C^{(S)}_Q = 4\text{Re} \left[ \text{Tr} \left( \sum_p \partial_\theta \hat{\Pi}_\theta \partial_\theta \hat{\Pi}_\theta \langle \psi \rangle \langle \psi \rangle \right) \right],$$

where we used the short notations $\hat{\Pi}_\theta = \hat{\Pi}_\theta(\theta)$ and $\partial_\theta \hat{\Pi}_\theta = \partial_\theta \hat{\Pi}_\theta(\theta)$.

Now, since the operators, $\hat{\Pi}_\theta$ and $\partial_\theta \hat{\Pi}_\theta$, do not act on $B$, when $\mathcal{G}_1$ is satisfied, the bound $C_Q$ is the actual QFIM $J_Q$ in the $S$ space, with the set of POVMs $\{\hat{P}_n\}$ saturating the corresponding QCRB for unital channel (see Appendix 3).

Also, the elements of the FIM $J_C$, as defined in $\mathcal{A}_3$, are again as in $\mathcal{F}_2$. Consider again that we are interested in saturating the bound at a specific point $\theta_s$ in the space of $\theta$, as in Ref. [11]. Then, $\mathcal{F}_6$ and $\mathcal{F}_7$ remain the same. But, $\mathcal{F}_7$ becomes

$$\frac{\text{Tr} \left( \partial_\theta \hat{\rho}_{\theta s} | \Phi_n \rangle \langle \Phi_n | \right)}{\text{Tr} \left( | \Phi_n \rangle \langle \Phi_n | \right)} = 0.$$

since $\langle \Phi_n | \partial_\theta \hat{\rho}_{\theta s} | \Phi_n \rangle = 0$. Here, we used the normalising element $| \Phi_n \rangle \langle \Phi_n |$, in distinction from $| \phi_n \rangle \langle \phi_n |$ used in $\mathcal{E}_6$. Then, $\mathcal{E}_9$ remains the same. But, $\mathcal{E}_9$ here becomes:

$$\sum_{m=1}^q \partial_\theta \hat{\rho}_{\theta s} = 1 - \hat{\rho}_{\theta s} = | \Phi_n \rangle \langle \Phi_n |.$$

Then, $\mathcal{E}_10$ here becomes

$$J^{(S)}_C = -\text{Tr} \left( \partial_\theta \partial_\theta \hat{\rho}_{\theta s} \right) - \text{Tr} \left( \partial_\theta \hat{\rho}_{\theta s} \partial_\theta \hat{\rho}_{\theta s} \right) + \text{Tr} \left( \partial_\theta \partial_\theta \hat{\rho}_{\theta s} | \Phi_n \rangle \langle \Phi_n | \right)$$

noting that $\langle \psi | \hat{O} | \psi \rangle$ is, by definition, real for some operator $\hat{O}$. Here, we used the fact that $\sum_l \partial_\theta \hat{\Pi}_\theta \partial_\theta \hat{\Pi}_\theta = -\sum_l \hat{\Pi}_\theta \partial_\theta \hat{\Pi}_\theta$, arising from $\sum_l \hat{\Pi}_\theta \partial_\theta \hat{\Pi}_\theta = 1$ upon differentiating both sides with respect to $\theta_k$, and that $\sum_l \partial_\theta \hat{\Pi}_\theta \hat{\Pi}_\theta \langle \psi \rangle \langle \psi \rangle = -\sum_l \partial_\theta \hat{\Pi}_\theta \hat{\Pi}_\theta \langle \psi \rangle \langle \psi \rangle$, arising from $\partial_\theta \hat{\Pi}_\theta = 1$ upon differentiating both sides with respect to $\theta_k$ and that $\theta_j$. Also, $\text{Tr} \left( \partial_\theta \partial_\theta \hat{\rho}_{\theta s} | \Phi_n \rangle \langle \Phi_n | \right) = \langle \Phi_n | \partial_\theta \partial_\theta \hat{\rho}_{\theta s} | \Phi_n \rangle = 0$, since $\langle \Phi_n | \partial_\theta \partial_\theta \hat{\rho}_{\theta s} | \Phi_n \rangle = 0$. Thus, $\text{Tr} \left( \partial_\theta \partial_\theta \hat{\rho}_{\theta s} | \Phi_n \rangle \langle \Phi_n | \right) = 0$.
Appendix I: POVM to attain QFIM Upper Bound for Mixed State Input via Noisy Channel

Here, we prove that, as claimed in Section VI the set of POVMs \( \{ \hat{P}_{n3} \} \) of cardinality \( q + 2 \), comprising the following \( q + 1 \) elements,

\[
\hat{P}_0 = \hat{\rho}(\theta) = \sum_l \hat{\Pi}_l(\theta) \hat{\Pi}^\dagger_l(\theta), \quad \hat{P}_m = \frac{\partial \hat{\rho}(\theta)}{\partial \theta_m} = \sum_l \left[ \frac{\partial \hat{\Pi}_l(\theta)}{\partial \theta_m} \hat{\Pi}^\dagger_l(\theta) + \hat{\Pi}_l(\theta) \frac{\partial \hat{\Pi}^\dagger_l(\theta)}{\partial \theta_m} \right] \quad \forall m = 1, \ldots, q, \quad (11)
\]

together with one element accounting for normalisation, saturates (G2), provided (G1) is satisfied.

Consider that the initial probe state \( \hat{\rho} \) is impure. It can be purified by extending the system \( S' \), introducing ancillas \( S' \). Then, proceeding in a similar manner as in the previous section for the pure state \( |\psi^{S+S'}\rangle \) in the initial enlarged \( S + S' \) space, the upper bound (G2) to the QFIM in terms of the initial state \( \hat{\rho} \) in the \( S \) space is given by

\[
C_Q^{jk} = 4 \text{Re} \left[ \text{Tr} \left( \sum_l \partial_{\theta_l} \hat{\Pi}^\dagger_{q_l} \partial_{\theta_q} \hat{\Pi}_{q_l} \hat{\rho} \right) + \text{Tr} \left( \sum_p \partial_{\theta_p} \hat{\Pi}^\dagger_{q_p} \hat{\Pi}_{q_p} \hat{\rho} \right) \text{Tr} \left( \sum_r \partial_{\theta_r} \hat{\Pi}^\dagger_{q_r} \hat{\Pi}_{q_r} \hat{\rho} \right) \right], \quad (12)
\]

since the operators, \( \hat{\Pi}_{q_l} \) and \( \partial_{\theta_q} \hat{\Pi}_{q_l} \) do not act on \( S' \). Moreover, when (G1) is satisfied, the bound \( C_Q \) is the actual QFIM \( J_Q \) in the \( S \) space, with the set of POVMs \( \{ \hat{P}_{n3} \} \) saturating the corresponding QCRB for unital channel (see Appendix J).

Also, again the elements of the FIM \( J_C \), as defined in (A8), are as in (A4). Consider again that we are interested in saturating the bound at a specific point \( \theta_s \) in the space of \( \theta \), as in Ref. [4]. Then, (E5), (F6), (F7), (F8), (F9) remain the same, with the normalising element again being \( \hat{P}_{q+1} \). But, (F10), which was (H6) in the last section, becomes:

\[
J_C^{jk} = 4 \text{Re} \left[ \text{Tr} \left( \sum_l \partial_{\theta_l} \hat{\Pi}^\dagger_{q_l} \partial_{\theta_q} \hat{\Pi}_{q_l} \hat{\rho} \right) + \text{Tr} \left( \sum_p \partial_{\theta_p} \hat{\Pi}^\dagger_{q_p} \hat{\Pi}_{q_p} \hat{\rho} \right) \text{Tr} \left( \sum_r \partial_{\theta_r} \hat{\Pi}^\dagger_{q_r} \hat{\Pi}_{q_r} \hat{\rho} \right) \right] = C_Q^{jk}, \quad (13)
\]

which is as in (12).

Appendix J: Noise in Channel can allow to beat the Heisenberg Limit

Here, we prove that noise in the quantum channel can allow to beat the Heisenberg precision limit, as claimed in Section VII when the following condition is satisfied by the Kraus operators \( \hat{\Pi}_{\theta_l} = \hat{\Pi}(\theta) \) of the quantum channel:

\[
\text{Im} \left[ \sum_l \text{Tr} \left\{ \left( \partial_{\theta_l} \hat{\Pi}^\dagger_{\theta_l} \partial_{\theta_q} \hat{\Pi}_{\theta_l} \right) \hat{\rho} \right\} \right] = 0, \quad \forall j, k. \quad (J1)
\]

We have

\[
\hat{\rho}_\theta = \sum_l \hat{\Pi}_{\theta_l} \hat{\rho} \hat{\Pi}^\dagger_{\theta_l} \Rightarrow \partial_{\theta_q} \hat{\rho}_\theta = \sum_l \left[ \partial_{\theta_q} \hat{\Pi}_{\theta_l} \hat{\rho} \hat{\Pi}^\dagger_{\theta_l} + \hat{\Pi}_{\theta_l} \hat{\rho} \partial_{\theta_q} \hat{\Pi}^\dagger_{\theta_l} \right]. \quad (J2)
\]

Next, (J11) saturates an ALD-based QCRB, corresponding to:

\[
\partial_{\theta_q} \hat{\rho}_\theta = \frac{1}{2} \left[ \hat{O}_k \hat{\rho} + \hat{\rho} \hat{O}_k^\dagger \right] = \sum_l \left[ \partial_{\theta_q} \hat{\Pi}_{\theta_l} \hat{\rho} + \hat{\rho} \partial_{\theta_q} \hat{\Pi}^\dagger_{\theta_l} \right], \quad (J3)
\]

where the ALDs are chosen to be:

\[
\hat{O}_k = 2 \sum_l \partial_{\theta_q} \hat{\Pi}_{\theta_l}. \quad (J4)
\]

Note that the choice of ALD need not be unique. Our purpose here is that it is enough to find one instance where the Heisenberg limit can be beaten. Also, strictly speaking, the above is not a valid ALD, since it is not a function of the probe state, hence our choice of the ALDs in the main text. Moreover, (J3) is expressed in terms of the initial probe state and not the evolved probe state. However, for the purposes of our proof here, it suffices to consider the above for simplicity without loss of generality.
We start with assuming that when (J11) is satisfied, the upper bound (G2) to the QFIM equals the actual QFIM. In other words, the corresponding lower bound to the Heisenberg limit equals the Heisenberg limit, when (J11) is satisfied, which is possible, when we have:

\[
\sum_l \left[ \partial_{\theta_l} \Pi_{\theta_l} \hat{\rho} \, \Pi_{\theta_l}^\dagger + \hat{\Pi}_{\theta_l} \hat{\rho} \partial_{\theta_l} \Pi_{\theta_l}^\dagger \right] = \sum_l \left[ \partial_{\theta_l} \hat{\Pi}_{\theta_l} \hat{\rho} + \hat{\rho} \partial_{\theta_l} \hat{\Pi}_{\theta_l}^\dagger \right], \tag{J5}
\]

following from (J12) and (J3). Now, the above is possible only when the following condition is satisfied:

\[
\sum_l \partial_{\theta_l} \Pi_{\theta_l} \hat{\rho} \hat{\Pi}_{\theta_l}^\dagger = \sum_l \partial_{\theta_l} \hat{\Pi}_{\theta_l} \hat{\rho}
\Rightarrow \text{Tr} \left( \sum_l \partial_{\theta_l} \Pi_{\theta_l} \hat{\rho} \hat{\Pi}_{\theta_l}^\dagger \right) = \text{Tr} \left( \sum_l \partial_{\theta_l} \hat{\Pi}_{\theta_l} \hat{\rho} \right)
\Rightarrow \text{Tr} \left( \sum_l \hat{\Pi}_{\theta_l}^\dagger \partial_{\theta_l} \hat{\Pi}_{\theta_l} \hat{\rho} \right) = \text{Tr} \left( \sum_l \partial_{\theta_l} \hat{\Pi}_{\theta_l} \hat{\rho} \right)
\Rightarrow \text{Tr} \left( \sum_l \partial_{\theta_l} \hat{\Pi}_{\theta_l} \hat{\rho} \right) = \sum_l \text{Tr} \left[ \left( \partial_{\theta_l} \hat{\Pi}_{\theta_l} \right) \hat{\rho} \right],
\tag{J6}
\]

which is possible when we have \( \sum_l \hat{\Pi}_{\theta_l} \hat{\Pi}_{\theta_l}^\dagger = \mathbb{1} \), i.e. when the channel is unital. Thus, for unital channels the upper bound (G2) to the QFIM equals the actual QFIM. In the \( S \) space, by tracing out the bath \( B \), this is equivalent to the saturability condition (J1).

The fact that the channel indeed needs to be unital for the last line in (J6) to hold may not be evident without an extra summation index. Let us, therefore, reconfirm this.

First, note that (J7) saturates an ALD-based QCRB, corresponding to:

\[
\partial_{\theta_l} \hat{\rho} = \frac{1}{2} \left[ \hat{L}_l \hat{\rho} + \hat{\rho} \hat{L}_l \right] = \sum_l \left[ \hat{\Pi}_{\theta_l} \partial_{\theta_l} \hat{\Pi}_{\theta_l} \hat{\rho} + \hat{\rho} \partial_{\theta_l} \hat{\Pi}_{\theta_l} \hat{\Pi}_{\theta_l}^\dagger \right],
\tag{J8}
\]

where the ALDs are chosen to be:

\[
\hat{L}_l = 2 \sum_l \hat{\Pi}_{\theta_l} \partial_{\theta_l} \hat{\Pi}_{\theta_l}.
\tag{J9}
\]

Now, in terms of the evolved probe state \( \hat{\rho} = \hat{\rho}(\theta) \), the condition (J11) becomes:

\[
\text{Im} \left[ \sum_l \text{Tr} \left\{ \left( \hat{\Pi}_{\theta_l} \partial_{\theta_l} \hat{\Pi}_{\theta_l} \right) \hat{\rho} \right\} \right] = 0, \quad \forall \, j, k.
\tag{J10}
\]

This is obtained from the saturability condition corresponding to \( \hat{\rho}^{(S+B)} \) in the \( S + B \) space, by tracing out the bath \( B \). And this is equivalent to the saturability condition (J11).

Next, (J10) saturates an ALD-based QCRB, corresponding to:

\[
\partial_{\theta_l} \hat{\rho} = \frac{1}{2} \left[ \hat{Q}_l \hat{\rho} + \hat{\rho} \hat{Q}_l^\dagger \right] = \sum_l \left[ \partial_{\theta_l} \hat{\Pi}_{\theta_l} \hat{\Pi}_{\theta_l} \hat{\rho} + \hat{\rho} \hat{\Pi}_{\theta_l} \partial_{\theta_l} \hat{\Pi}_{\theta_l} \right],
\tag{J11}
\]

where the ALDs are chosen to be:

\[
\hat{Q}_l = 2 \sum_l \partial_{\theta_l} \hat{\Pi}_{\theta_l} \hat{\Pi}_{\theta_l}.
\tag{J12}
\]
Then, (J5) holds, when the following holds:

$$\sum_l \left[ \hat{\Pi}^\dagger_l \partial_{\theta_k} \hat{\Pi}_{\theta_l} \hat{\rho} + \hat{\rho} \partial_{\theta_k} \hat{\Pi}^\dagger_l \hat{\Pi}_{\theta_l} \right] = \sum_l \left[ \partial_{\theta_k} \hat{\Pi}^\dagger_{\theta_l} \hat{\Pi}^\dagger_{\theta_l} \hat{\rho}_{\theta_l} + \hat{\rho}_{\theta_l} \hat{\Pi}^\dagger_{\theta_l} \partial_{\theta_k} \hat{\Pi}^\dagger_{\theta_l} \right],$$

(J13)

that follows from (J8) and (J11).

Now, let us consider both $\hat{\rho}$ and $\hat{\rho}_{\theta}$ to be maximally mixed. Then, (J13) becomes:

$$\sum_l \left[ \hat{\Pi}^\dagger_l \partial_{\theta_k} \hat{\Pi}_{\theta_l} \hat{\rho} + \hat{\rho} \partial_{\theta_k} \hat{\Pi}^\dagger_l \hat{\Pi}_{\theta_l} \right] = \sum_l \left[ \partial_{\theta_k} \hat{\Pi}^\dagger_{\theta_l} \hat{\Pi}^\dagger_{\theta_l} \hat{\rho}_{\theta_l} + \hat{\rho}_{\theta_l} \hat{\Pi}^\dagger_{\theta_l} \partial_{\theta_k} \hat{\Pi}^\dagger_{\theta_l} \right],$$

(J14)

$$\Rightarrow \sum_l \partial_{\theta_k} \left[ \hat{\Pi}^\dagger_l \hat{\Pi}_{\theta_l} \right] = \sum_l \partial_{\theta_k} \left[ \hat{\Pi}^\dagger_{\theta_l} \hat{\Pi}^\dagger_{\theta_l} \right]$$

$$\Rightarrow 1 = \sum_l \hat{\Pi}_{\theta_l} \hat{\Pi}^\dagger_{\theta_l} \Rightarrow \sum_l \hat{\Pi}^\dagger_{\theta_l} \hat{\Pi}_{\theta_l} = 1,$$

where the last line follows from the previous line without an additional constant, since we must also have:

$$\hat{\rho}_{\theta} = \sum_l \hat{\Pi}_{\theta_l} \hat{\rho} \hat{\Pi}^\dagger_{\theta_l} \Rightarrow 1 = \sum_l \hat{\Pi}_{\theta_l} \hat{\Pi}^\dagger_{\theta_l},$$

(J15)

when both $\hat{\rho}$ and $\hat{\rho}_{\theta}$ are maximally mixed. Indeed, both the initial and evolved probe states can be maximally mixed, only if the noisy channel is unital. Thus, the channel indeed needs to be unital for (J13), and therefore, (J6) to hold.
