Simulation of Random Variables under Rényi Divergence Measures of All Orders

Lei Yu and Vincent Y. F. Tan, Senior Member, IEEE

Abstract

The random variable simulation problem consists in using a $k$-dimensional i.i.d. random vector $X^k$ with distribution $P_X$ to simulate an $n$-dimensional i.i.d. random vector $Y^n$ so that its distribution is approximately $Q_Y^n$. In contrast to previous works, in this paper we consider the standard Rényi divergence and two variants of all orders to measure the level of approximation. These two variants are the max-Rényi divergence $D_{\alpha}^{\text{max}}(P, Q)$ and the sum-Rényi divergence $D_{\alpha}^+(P, Q)$. When $\alpha = \infty$, these two measures are strong because for any $\epsilon > 0$, $D_{\alpha}^{\text{max}}(P, Q) \leq \epsilon$ or $D_{\alpha}^+(P, Q) \leq \epsilon$ implies $e^{-\epsilon} \leq \frac{P(x)}{Q(x)} \leq e^\epsilon$ for all $x$. Under these Rényi divergence measures, we characterize the asymptotics of normalized divergences as well as the Rényi conversion rates. The latter is defined as the supremum of $\frac{\epsilon}{2} k$ such that the Rényi divergences vanish asymptotically. Our results show that when the Rényi parameter is in the interval $(0, 1)$, the Rényi conversion rates equal the ratio of the Shannon entropies $\frac{H(P_X)}{H(Q_Y)}$, which is consistent with traditional results in which the total variation measure was adopted. When the Rényi parameter is in the interval $(1, \infty)$, the Rényi conversion rates are, in general, smaller than $\frac{H(P_X)}{H(Q_Y)}$. When specialized to the case in which either $P_X$ or $Q_Y$ is uniform, the simulation problem reduces to the source resolvability and intrinsic randomness problems. The preceding results are used to characterize the asymptotics of Rényi divergences and the Rényi conversion rates for these two cases.

I. INTRODUCTION

How can we use a $k$-dimensional i.i.d. random vector $X^k$ with distribution $P_X$ to simulate an $n$-dimensional i.i.d. random vector $Y^n$ so that its distribution is approximately $Q_Y^n$? This is so-called random variable simulation problem or distribution approximation problem [1]. In [1] and [2], the total variation (TV) distance and the Bhattacharyya coefficient (the Rényi divergence of order $\frac{1}{2}$) were respectively used to measure the level of approximation. In these works, the asymptotic conversion rate was studied. This rate is defined as the supremum of $\frac{\epsilon}{2}$ such that the employed measure vanishes asymptotically as the dimensions $n$ and $k$ tend to infinity. For both the TV distance and the Bhattacharyya coefficient, the asymptotic (first-order) conversion rates are the same, and both equal to the ratio of the Shannon entropies $\frac{H(P_X)}{H(Q_Y)}$. Furthermore, in [2], Kumagai and Hayashi also investigated the asymptotic second order conversion rate. Note that by Pinsker’s inequality [3], the Bhattacharyya coefficient (the Rényi divergence of order $\frac{1}{2}$) is stronger than the TV distance, i.e., if the Bhattacharyya coefficient tends to 1 (or the Rényi divergence of order $\frac{1}{2}$ tends to 0), then the TV distance tends to 0. In this paper, we strengthen the TV distance and the Bhattacharyya coefficient by considering Rényi divergences of orders in $[0, \infty]$.

As two important special cases of the distribution approximation problem, the source resolvability and intrinsic randomness problems have been extensively studied in literature, e.g., [1], [4]–[9].

1) Resolvability: When $P_X$ is set to the Bernoulli distribution $\text{Bern}(\frac{1}{2})$, the distribution approximation problem reduces to the source resolvability problem, i.e., determining how much information is needed to simulate a random process so that it approximates a target output distribution. If the simulation is realized through a given channel, and we require that the channel output approximates a target output distribution, then we obtain the channel resolvability problem. These resolvability problems were first studied by Han and Verdú [4]. In [4], the total variation (TV) distance and the normalized relative entropy (Kullback-Leibler divergence) were used to measure the level of approximation. The resolvability problems with the unnormalized relative entropy were studied by Hayashi [5], [6]. Recently, Liu, Cuff, and Verdú [7] and Yu and Tan [8] extended the theory of resolvability by respectively using the so-called $E_\gamma$ metric with $\gamma \geq 1$ and various Rényi divergences of orders in $[0, 2] \cup \{\infty\}$ to measure the level of approximation. In this paper, we extend the results in [8] to the Rényi divergences of orders in $[0, \infty]$.

2) Intrinsic randomness: When $Q_Y$ is set to the Bernoulli distribution $\text{Bern}(\frac{1}{2})$, the distribution approximation problem reduces to the intrinsic randomness, i.e., determining the amount of randomness contained in a source [9]. Given an arbitrary general source $X = \{X^n\}_{n=1}^\infty$, we approximate, by using $X$, a uniform random number with as large a rate as possible. Vembu and Verdú [9] and Han [1] determined the supremum of achievable uniform random number generation rates by invoking the information spectrum method. In this paper, we extend the results in [9] to the family of Rényi divergence measures.

A. Main Contributions

Our main contributions are as follows:

1) For the distribution approximation problem, we use the standard Rényi divergences \( D_\alpha (P_{Y^n} \| Q_Y^n) \) and \( D_\alpha (Q_Y^n \| P_{Y^n}) \), as well as two variants, namely the max-Rényi divergence \( D_\alpha^{\max} (P, Q) \) and the sum-Rényi divergence \( D_\alpha^+ (P, Q) \), to measure the distance between the simulated and target output distributions. For these measures, we consider all orders in \( \alpha \in [0, \infty] \). We characterize the asymptotics of these Rényi divergences, as well as the Rényi conversion rates, which are defined as the supremum of \( \frac{1}{n} \) to guarantee that the Rényi divergences vanish asymptotically. Interestingly, when the Rényi parameter is in the interval \((0, 1]\) for the measure \( D_\alpha (P_{Y^n} \| Q_Y^n) \) and in \((0, 1) \) for the measures \( D_\alpha (Q_Y^n \| P_{Y^n}) \) and \( D_\alpha^{\max} (P_{Y^n}, Q_Y^n) \) (or \( D_\alpha^+ (P_{Y^n}, Q_Y^n) \)), the Rényi conversion rates are simply equal to the ratio of the Shannon entropies \( \frac{H(P_X)}{H(Q_X)} \). This is consistent with the existing results in [2] where the Rényi parameter is \( \frac{1}{2} \). In contrast if the Rényi parameter is in \((1, \infty] \) for the measure \( D_\alpha (P_{Y^n} \| Q_Y^n) \) and \([1, \infty] \) for the measures \( D_\alpha (Q_Y^n \| P_{Y^n}) \) and \( D_\alpha^{\max} (P_{Y^n}, Q_Y^n) \) (or \( D_\alpha^+ (P_{Y^n}, Q_Y^n) \)), the Rényi conversion rates are, in general, larger than \( \frac{H(P_X)}{H(Q_X)} \). It is worth noting that the obtained expressions for the asymptotics of Rényi divergences and the Rényi conversion rates involve Rényi entropies of all real orders, even including negative orders. To the best of our knowledge, this is the first time that an explicit operational interpretation of the Rényi entropies of negative orders is provided.

2) When specialized to the cases in which either \( P_X \) or \( Q_Y \) is uniform, the preceding results are used to derive results for the source resolvability and intrinsic randomness problems. These results extend the existing results in [1], [4], [8], [9], where the TV distance, the relative entropy, and the Rényi divergences of orders in \([0, 2]\) were used to measure the level of approximation.

B. Paper Outline

The rest of this paper is organized as follows. In Subsections I-C and I-D, we introduce several Rényi information quantities and use them to formulate the random variable simulation problem. In Section II, we present our main results on characterizing asymptotics of Rényi divergences and Rényi conversion rates. As consequences, in Sections III and IV, we apply our main results to the problems of Rényi source resolvability and Rényi intrinsic randomness. Finally, we conclude the paper in Section V. For seamless presentation of results, the proofs of all theorems and the notations involved in these proofs are deferred to the appendices.

C. Notations and Information Distance Measures

The set of probability measures on \( \mathcal{X} \) is denoted as \( \mathcal{P} (\mathcal{X}) \), and the set of conditional probability measures on \( \mathcal{Y} \) given a variable in \( \mathcal{X} \) is denoted as \( \mathcal{P} (\mathcal{Y}|\mathcal{X}) := \{ P_{Y|X} : P_{Y|X} (\cdot | x) \in \mathcal{P} (\mathcal{Y}), x \in \mathcal{X} \} \). For a distribution \( P_X \in \mathcal{P} (\mathcal{X}) \), the support of \( P_X \) is defined as \( \text{supp} (P_X) := \{ x \in \mathcal{X} : P_X (x) > 0 \} \).

We use \( T_{x^n}(x) := \frac{1}{n} \sum_{i=1}^{n} 1 \{ x_i = x \} \) to denote the type (empirical distribution) of a sequence \( x^n \), \( T_X \) and \( V_{Y|X} \) to respectively denote a type of sequences in \( \mathcal{X}^n \) and a conditional type of sequences in \( \mathcal{Y}^n \). For a type \( T_X \), the type class (set of sequences having the same type \( T_X \)) is denoted by \( T_{T_X} \). For a conditional type \( V_{Y|X} \) and a sequence \( x^n \), the V-shell of \( x^n \) (the set of \( y^n \) sequences having the same conditional type \( V_{Y|X} \) given \( x^n \)) is denoted by \( T_{V_{Y|X}} (x^n) \). The set of types of sequences in \( \mathcal{X}^n \) is denoted as

\[
\mathcal{P}^{(n)} (\mathcal{X}) := \{ T_{x^n} : x^n \in \mathcal{X}^n \},
\]

(1)

The set of conditional types of sequences in \( \mathcal{Y}^n \) given a sequence in \( \mathcal{X}^n \) with the type \( T_X \) is denoted as

\[
\mathcal{P}^{(n)} (\mathcal{Y}|T_X) := \{ V_{Y|X} \in \mathcal{P} (\mathcal{Y}|\mathcal{X}) : V_{Y|X} \times T_X \in \mathcal{P}^{(n)} (\mathcal{X} \times \mathcal{Y}) \}.
\]

(2)

For brevity, sometimes we use \( T (x, y) \) to denote the joint distributions \( T (x) V (y|x) \) or \( T (y) V (x|y) \).

The \( \epsilon \)-typical set of \( Q_X \) is denoted as

\[
T^{(n)}_\epsilon (Q_X) := \{ x^n \in \mathcal{X}^n : | T_{x^n} (x) - Q_X (x) | \leq \epsilon Q_X (x), \forall x \in \mathcal{X} \}.
\]

(3)

The conditionally \( \epsilon \)-typical set of \( Q_{XY} \) is denoted as

\[
T^{(n)}_\epsilon (Q_{XY}|x^n) := \{ y^n \in \mathcal{X}^n : (x^n, y^n) \in T^{(n)}_\epsilon (Q_{XY}) \}.
\]

(4)

For brevity, sometimes we write \( T^{(n)}_\epsilon (Q_X) \) and \( T^{(n)}_\epsilon (Q_{XY}|x^n) \) as \( T^{(n)}_\epsilon \) and \( T^{(n)}_\epsilon (x^n) \) respectively.
For a distribution $P_X \in \mathcal{P}(\mathcal{X})$, the Rényi entropy of order $\alpha \in (-\infty, 1) \cup (1, +\infty)$, is defined as
\[
H_\alpha(P_X) := \frac{1}{1 - \alpha} \log \sum_{x \in \text{supp}(P_X)} P_X(x)^\alpha,
\] (5)
and the Rényi entropy of order $\alpha = 1, -\infty, +\infty$ is defined as the limit by taking $\alpha \to 1, -\infty, +\infty$, respectively. It is known that for $\alpha = 1$, $H_1(P_X) = H(P_X) := -\sum_{x \in \text{supp}(P_X)} P_X(x) \log P_X(x)$, so the usual Shannon entropy $H(P_X)$ is a special (limiting) case of the Rényi entropy. Some properties of Rényi entropies of all real orders (including negative orders) can be found in a recent work [11], e.g., $H_\alpha(P_X)$ is monotonically decreasing in $\alpha$ throughout the real line, and $\frac{\alpha - 1}{\alpha} H_\alpha(P_X)$ is monotonically increasing in $\alpha$ on $(0, +\infty)$ and $(-\infty, 0)$.

For a distribution $P_X \in \mathcal{P}(\mathcal{X})$, the mode entropy is known as the cross (Shannon) entropy between Unif(supp($P_X$)) and $P_X$. For a distribution $P_X \in \mathcal{P}(\mathcal{X})$, the $\alpha$-tilted mode entropy is defined as
\[
H_\alpha^n(P_X) := -\sum_{x \in \text{supp}(P_X)} \frac{1}{\alpha} \log P_X(x).
\] (6)

The mode entropy is also known as the cross (Shannon) entropy between Unif(supp($P_X$)) and $P_X$. For a distribution $P_X \in \mathcal{P}(\mathcal{X})$, the $\alpha$-tilted mode entropy is defined as
\[
H_\alpha^n(P_X) := -\sum_{x \in \text{supp}(P_X)} \frac{P_X(x) \log P_X(x)}{\sum_{x \in \text{supp}(P_X)} P_X(x)}.
\] (7)

Obviously, $H_0^n(P_X) = H^n(P_X)$, and $H_1^n(P_X) = H_\alpha(P_X)$ for $\alpha \in \{0, 1, \infty\}$.

Fix distributions $P_X, Q_X \in \mathcal{P}(\mathcal{X})$. Then the Rényi divergence of order $0, 1, +\infty$ is defined as
\[
D_\alpha(P_X \| Q_X) := \frac{1}{\alpha - 1} \log \sum_{x \in \text{supp}(P_X)} P_X(x)^\alpha Q_X(x)^{1-\alpha},
\] (8)
and the Rényi divergence of order $\alpha = 0, 1, +\infty$ is defined as the limit by taking $\alpha \to 0, 1, +\infty$, respectively. It is known that for $\alpha = 1$, $D_1(P_X \| Q_X) = D(P_X \| Q_X) := \sum_{x \in \text{supp}(P_X)} P_X(x) \log \frac{P_X(x)}{Q_X(x)}$, so a special case of the Rényi divergence is the usual relative entropy $D(P_X \| Q_X)$.

We define the max-Rényi divergence as
\[
D_{\alpha}^\text{max}(P, Q) = \max \{ D_\alpha(P \| Q), D_\alpha(Q \| P) \},
\] (9)
and the sum-Rényi divergence as
\[
D_{\alpha}^+ (P, Q) = D_\alpha(P \| Q) + D_\alpha(Q \| P).
\] (10)

The sum-Rényi divergence reduces to Jefferies’s divergence $D(P \| Q) + D(Q \| P)$ [12] when the parameter $\alpha$ is set to 1. Observe that $D_{\alpha}^\text{max}(P, Q) \leq D_{\alpha}^+(P, Q) \leq 2D_{\alpha}^\text{max}(P, Q)$. Hence $D_{\alpha}^\text{max}(P, Q)$ is “equivalent” to $D_{\alpha}^+(P, Q)$ in the sense that for any sequences of distribution pairs $\{(P^{(n)}, Q^{(n)})\}_{n=1}^\infty$, $D_{\alpha}^\text{max}(P^{(n)}, Q^{(n)}) \to 0$ if and only if $D_{\alpha}^+(P^{(n)}, Q^{(n)}) \to 0$. Hence in this paper, we only consider the max-Rényi divergence. For $\alpha = \infty$,
\[
D_{\infty}(P, Q) = \sup_{x \in \mathcal{X}} |\log P(x) - \log Q(x)|
\] (11)
and
\[
= \sup_{A \subseteq \mathcal{X}} \left| \log P(A) - \log Q(A) \right|.
\] (12)

This expression is similar to the definition of TV distance, hence we term $D_{\infty}^\text{max}$ as the logarithmic variation distance.$^3$

**Lemma 1.** The following properties hold.

1) $D_{\infty}^\text{max}$ is a metric. Similarly, $D_{\alpha}^+$ is also a metric.

In the literature, the Rényi entropy was defined only for orders $\alpha \in [0, +\infty)$ [10], except for a recent work [11], but here we define it for orders $\alpha \in [-\infty, +\infty)$. This is due to the fact that our results involve Rényi entropies of all real orders, even including negative orders. Indeed, in the axiomatic definitions of Rényi entropy and Rényi divergence, Rényi restricted the parameter $\alpha \in (0, 1) \cup (1, +\infty)$ [10]. However, it is easy to verify that in [10], the postulates 1, 2, 3, 4, and 5 in the definition of Rényi entropy with $g_\alpha(x) = e^{(\alpha - 1)x}$ and the postulates 6, 7, 8, 9, and 10 in the definition of Rényi divergence with the same function $g_\alpha(x)$ are also satisfied when $\alpha \in (-\infty, 0)$. It is worth noting that the Rényi entropy for $\alpha \in (-\infty, 0)$ is always non-negative, but the Rényi divergence for $\alpha \in (-\infty, 0)$ is always non-positive. The Rényi divergence of negative orders was studied in [3]. Observe that $D_\alpha(P \| Q)(Q)^{\frac{\alpha}{\alpha - 1}}D_{\alpha}(Q \| P) = 0$ holds for $\alpha \in [-\infty, 0) \cup (0, 1) \cup (1, +\infty]$. Hence we only need to consider the divergences $D_\alpha(P \| Q)$ and $D_{\alpha}(Q \| P)$ with $\alpha \in [0, +\infty]$, since these divergences completely characterize the divergences $D_{\alpha}(P \| Q)$ and $D_{\alpha}(Q \| P)$ with $\alpha \in [-\infty, +\infty]$. Furthermore, it is also worth noting that the Rényi entropy is non-increasing and the Rényi divergence is non-decreasing in $\alpha$ for $\alpha \in [-\infty, +\infty]$ [3, 11].

$^3$Here the concept of "mode entropy" is consistent with the concept of "mode" in statistics. This is because, in statistics, the mode of a set of data values is the value that appears most often. On the other hand, for a product set $\text{supp}(P_X^n)$, the type class $T_X$ with type $T_X \approx \text{Unif}(\text{supp}(P_X^n))$ has more elements than any other type class, and under the product distribution $P_X^n$, the probability values of sequences in the type class $T_X$ is $e^{-nH^n(P_X)}$. Hence, under the product distribution $P_X^n$, the probability value $e^{-nH^n(P_X)}$ is the mode of the data values ($P_X^n(x^n) > 0 : x^n \in \mathcal{X}^n$).
2) \(D_{\infty}^{\max}(P, Q) \leq \epsilon \iff e^{-\epsilon} \leq \frac{P(x)}{Q(x)} \leq e^{\epsilon}, \forall x.\)

3) For any \(f, -D_{\infty}(Q \parallel P) \leq \log \frac{E_{P}(f(X))}{E_{Q}(f(X))} \leq D_{\infty}(P \parallel Q),\) hence \(D_{\infty}^{\max}(P, Q) \leq \epsilon \iff e^{-\epsilon} \leq \frac{E_{P}(f(X))}{E_{Q}(f(X))} \leq e^{\epsilon}.\)

4) \(D_{\infty}^{\max}(P|X, Q|X) = D_{\infty}^{\max}(P, Q|X).\)

The proof of this lemma is omitted.

D. Problem Formulation

We consider the distribution approximation problem, which can be described as follows. We are given a target “output” distribution \(Q_Y\) that we would like to simulate. At the same time, we are given a \(k\)-length sequence of a memoryless source \(X^k \sim P_X^k\). We would like to design a function \(f : X^k \to Y^n\) such that the distance, according to some divergence measure, of the simulated distribution \(P_Y^n\) with \(Y^n := f(X^k)\) and \(n\) independent copies of the target distribution \(Q_Y^n\) is minimized. Here we let \(n = [kR]\), where \(R\) is a fixed positive known number as the rate. We assume the alphabets \(X\) and \(Y\) are finite. We also assume \(P_X(x) > 0, \forall x \in X\) and \(Q_Y(y) > 0, \forall y \in Y\). There are now two fundamental questions associated to this simulation task: (i) as \(k \to \infty\), what is the asymptotic level of approximation as a function of \((R, P_X, Q_Y)\)? (ii) As \(k \to \infty\), what is the maximum rate \(R\) such that the discrepancy between the distribution \(P_Y^n\) and \(Q_Y^n\) tends to zero? In contrast to previous works on this problem [1], [2], here we employ Rényi divergences \(D_{\alpha}(P_Y^n || Q_Y^n), D_{\alpha}(Q_Y^n || P_Y^n),\) and \(D_{\alpha}^{\max}(P_Y^n, Q_Y^n)\) of all orders \(\alpha \in [0, \infty)\) to measure the discrepancy between \(P_Y^n\) and \(Q_Y^n\).

Furthermore, our results are summarized in Table I.

E. Mappings

The following two fundamental mappings, illustrated in Fig. 1, will be used in our constructions of the functions \(f : X^k \to Y^n\) described in Subsection I-D.

Consider two nonnegative measures \(P_X\) and \(Q_Y\), which could be unnormalized. Sort the elements in \(X\) as \(x_1, x_2, \ldots, x_{|X|}\) such that \(P_X(x_1) \geq P_X(x_2) \geq \ldots \geq P_X(x_{|X|}).\) Similarly, sort the elements in \(Y\) as \(y_1, y_2, \ldots, y_{|Y|}\) such that \(Q_Y(y_1) \geq Q_Y(y_2) \geq \ldots \geq Q_Y(y_{|Y|}).\) Now we list two mappings from \(X\) to \(Y\):

- **Mapping 1** (Inverse-Transform): If \(P_X\) and/or \(Q_Y\) are unnormalized, then normalize them first. Define \(G_X(i) := P_X(x_i) : i \leq i\) and \(G_X^{-1}(\theta) := \max \{ i \in N : G_X(i) \leq \theta \}.\) Similarly, for \(Q_Y\), we define \(G_Y(j) := Q_Y(y_i) : j \leq j\) and \(G_Y^{-1}(\theta) := \min \{ j \in N : G_Y(j) \leq \theta \}.\) Consider the following mapping. For each \(i \in [1 : |X|]\), \(x_i\) is mapped to \(y_j\) where \(j = G_Y^{-1}(G_X(i)\).\) The resulting distribution is denoted as \(P_Y.\) This mapping is illustrated in Fig. 1a. For such a mapping, the following properties hold:

1) If \(P_X(x_i) \geq Q_Y(y_j)\) where \(i := G_X^{-1}(G_Y(j)),\) then \(\{ i : G_X^{-1}(G_X(i)) = j \} \leq 1.\) Hence \(P_Y(y_j) \leq P_X(x_i).\)

2) If \(P_X(x_i) < Q_Y(y_j)\) where \(i := G_X^{-1}(G_Y(j)),\) then \(\{ i : G_X^{-1}(G_X(i)) = j \} \geq 1\) and

\[
\max \left\{ \frac{1}{2} Q_Y(y_j), Q_Y(y_j) - P_X(x_i) \right\} \leq P_Y(y_j) \leq Q_Y(y_j) + P_X(x_i). \tag{13}
\]

- **Mapping 2**: Denote \(k_m, m \in [1 : L]\) with \(k_L := |X|\) as a sequence of integers such that for \(m \in [1 : L - 1], \sum_{i=k_m-1+1}^{k_m} P_X(x_i) < Q_Y(y_m) \leq \sum_{i=k_m-1+1}^{k_m} P_X(x_i),\) and \(k_L = L + 1\) or \(k_{L-1} = L + 1\) or \(P_X(x_i) < Q_Y(y_L) \leq \sum_{i=k_L-1+1}^{k_L} P_X(x_i).\) Obviously \(L \leq |Y|\). For each \(m \in [1 : L]\), map \(x_{k_m-1+1}, \ldots, x_{k_m}\) to \(y_m.\) The resulting distribution is denoted as \(P_Y.\) This mapping is illustrated in Fig. 1b. For such a mapping, we have

\[
Q_Y(y_m) \leq P_Y(y_m) < Q_Y(y_m) + P_X(x_k)
\tag{14}
\]

for \(m \in [1 : L - 1],

\[
P_Y(y_m) < Q_Y(y_m) + P_X(x_k)
\tag{15}
\]

for \(m = L,\) and \(P_Y(y_m) = 0\) for \(m > L.\)

II. Rényi Distribution Approximation

A. Asymptotics of Rényi Divergences

We first characterize the asymptotics of Rényi divergences \(D_{\alpha}(P_Y^n || Q_Y^n), D_{\alpha}(Q_Y^n || P_Y^n),\) and \(D_{\alpha}^{\max}(P_Y^n, Q_Y^n)\), as shown by the following theorems.

**Theorem 1** (Asymptotics of \(\frac{1}{n} D_{\alpha}(P_Y^n || Q_Y^n)\)). For any \(\alpha \in [0, \infty),\) we have

\[
\lim_{n \to \infty} \frac{1}{n} \inf_{f} D_{\alpha}(P_Y^n || Q_Y^n)
= \sup_{t \in [0,1]} \left\{ \frac{t}{n} H^{\frac{1}{\alpha}}(Q_Y) - \frac{t}{R} H^{\frac{1}{\alpha}}(P_X) \right\}. \tag{16}
\]
TABLE I: Summary of results on asymptotics of Rényi divergences. Here \( a(t') \) and \( b(t') \) are defined in (19) and (20) respectively, and \( c(\alpha) := \frac{\alpha^{-1}}{\alpha} \) for \( \alpha \neq 0 \). For \( \alpha \in [0, 1] \cup \{ \infty \} \), Rényi conversion rates for unnormalized Rényi divergences are the same to those for normalized Rényi divergences. Furthermore, for \( \alpha \in (1, \infty) \), an achievable result on the Rényi conversion rate for unnormalized Rényi divergence \( D_\alpha(P_Y^n || Q_Y^n) \) is given in (26). All of our results summarized here are new, except that the Rényi conversion rates for the unnormalized Rényi divergence \( D_\alpha(P_Y^n || Q_Y^n) \) with \( \alpha \in (0, \frac{1}{2}] \) are implied by Kumagai and Hayashi [2] and Han [1].

**Theorem 2** (Asymptotics of \( \frac{1}{n} D_\alpha(Q_Y^n || P_Y^n) \)). For any \( \alpha \in [0, \infty] \), we have

\[
\lim_{n \to \infty} \frac{1}{n} \inf_{f} D_\alpha(Q_Y^n || P_Y^n) = \begin{cases} 
\infty, & \alpha \in [1, \infty] \ \text{and} \ R > \frac{H_0(P_X)}{H_0(Q_Y)} \\
\sup_{t \in (0, \infty)} \left\{ tH_{\frac{1}{1+\alpha}}(Q_Y) - \frac{\alpha}{\alpha} \frac{H_{\frac{1}{1+\alpha}}(P_X)}{H_{\frac{1}{1+\alpha}}(Q_Y)} \right\}, & \alpha \in [1, \infty] \ \text{and} \ R < \frac{H_0(P_X)}{H_0(Q_Y)} \\
\frac{1}{1-\alpha} \max_{t \in [0, 1]} \left\{ tH_{\frac{1}{1+\alpha}}(Q_Y) - \frac{\alpha}{\alpha} \frac{H_{\frac{1}{1+\alpha}}(P_X)}{H_{\frac{1}{1+\alpha}}(Q_Y)} \right\}, & \alpha \in (0, 1) \\
0, & \alpha = 0
\end{cases}
\]

(17)

**Theorem 3** (Asymptotics of \( \frac{1}{n} D_\alpha^{\max}(P_Y^n, Q_Y^n) \)). For any \( \alpha \in [0, \infty] \), we have

\[
\lim_{n \to \infty} \frac{1}{n} \inf_{f} D_\alpha^{\max}(P_Y^n, Q_Y^n) = \begin{cases} 
\infty, & \alpha \in [1, \infty] \ \text{and} \ R > \frac{H_0(P_X)}{H_0(Q_Y)} \\
\sup_{t \in (0, \infty)} \left\{ tH_{\frac{1}{1+\alpha}}(Q_Y) - \frac{\alpha}{\alpha} \frac{H_{\frac{1}{1+\alpha}}(P_X)}{H_{\frac{1}{1+\alpha}}(Q_Y)} \right\}, & \alpha \in [1, \infty] \ \text{and} \ R < \frac{H_0(P_X)}{H_0(Q_Y)} \\
\frac{1}{1-\alpha} \max_{t \in [0, 1]} \left\{ tH_{\frac{1}{1+\alpha}}(Q_Y) - \frac{\alpha}{\alpha} \frac{H_{\frac{1}{1+\alpha}}(P_X)}{H_{\frac{1}{1+\alpha}}(Q_Y)} \right\}, & \alpha \in (0, 1) \\
0, & \alpha = 0
\end{cases}
\]
Theorem 1, we first design a function $P$ after sorting the elements of $X$ into type classes, and design codes on the level of type classes. More specifically, for $X$-types on $\{1\}$ and $\{2\}$, respectively denote the resulting sequences $Q$ and $Q_Y$ and then a code

$$\begin{align*}
\alpha \in [1, \infty] \text{ and } R > \frac{H_0(P_X)}{H_0(Q_Y)} \\
\alpha < 1, \text{ and } R < \frac{H_0(P_X)}{H_0(Q_Y)} \\
\alpha = 1, \text{ and } R < \frac{H_0(P_X)}{H_0(Q_Y)} \\
\alpha = 0
\end{align*}$$

where

$$\begin{align*}
\alpha(t') = \left(\frac{\alpha}{1 - \alpha} - 1\right) t' + 1 \\
b(t') = \left(1 - \frac{\alpha}{1 - \alpha}\right) t' + \frac{\alpha}{1 - \alpha}
\end{align*}$$

Remark 1. For $\alpha \in [1, \infty]$ and $R = \frac{H_0(P_X)}{H_0(Q_Y)}$, the asymptotic behavior of $\frac{1}{n} \inf f D_\alpha(Q_Y^n \parallel P_Y^n)$ and $\frac{1}{n} \inf f D_\alpha^{max}(P_X^n, Q_Y^n)$ depends on how fast $\frac{1}{n}$ converges to $R$. In this paper, we set $n = [kR]$, i.e., the fastest case. For this case, $\frac{1}{n} \inf f D_\alpha(Q_Y^n \parallel P_Y^n) = \frac{1}{n} \inf f D_\alpha^{max}(P_X^n, Q_Y^n) = \infty$, if $kR \notin \mathbb{N}$; and $\frac{1}{n} \inf f D_\alpha(Q_Y^n \parallel P_Y^n) = \frac{1}{n} D_\alpha(\{Q_i\} \parallel \{P_i\})$ and $\frac{1}{n} \inf f D_\alpha^{max}(P_X^n, Q_Y^n) = \frac{1}{n} \max \{D_\alpha(\{P_i\} || \{Q_i\}), D_\alpha(\{Q_i\} || \{P_i\})\}$, if $kR \in \mathbb{N}$, where $\{P_i\}$ and $\{Q_i\}$ respectively denote the resulting sequences after sorting the elements of $P_X^n$ and $Q_Y^n$ in descending order.

The proofs of Theorems 1, 2, and 3 are provided in Appendices B, C, and D, respectively. For the achievability parts, we partition the sequences in $X^k$ and $Y^\infty$ into type classes, and design codes on the level of type classes. More specifically, for Figure 1, we first design a function $g : \mathcal{P}^k(X) \to \mathcal{P}^n(Y)$ that maps $k$-types on $X$ to $n$-types on $Y$; and then a code

Fig. 1: Illustrations of Mappings 1 and 2.
f induced by g is obtained by mapping the sequences in \( T_{X} \) to the sequences in \( T_{g(T_{X})} \) as uniformly as possible for all \( T_{X} \in P^{(k)}(\mathcal{X}) \), i.e., f maps approximately \( |T_{X}|/|T_{g(T_{X})}| \) sequences in \( T_{X} \) to each distinct sequence in \( T_{g(T_{X})} \). Here the optimal selection of the function g depends on s and requires careful analysis (the detail can be found in the proof). The intuition of designing such a code is given in the following. On one hand, observe that

\[
H \sup \{ \text{finite and also as small as possible, it is required that} \}
\]

\[
T \in \mathcal{X} \}
\]

\[
\frac{1}{n} D_{1+s}(P_{Y^n} \| Q_{Y}^{n})
\]

\[
= \frac{1}{ns} \log \left\{ \sum_{T_{Y}} \sum_{y^n \in T_{Y}} \left( \sum_{T_{X}} \sum_{x^n \in T_{X}} P_{X}^{k}(x^k) 1 \{ y^n = f(x^k) \} \right)^{1+s} Q_{Y}^{n}(y^n)^{-s} \right\}
\]

\[
= \frac{1}{ns} \log \left\{ \max_{T_{X}, T_{Y}} \sum_{y^n \in T_{Y}} \left( \sum_{x^n \in T_{X}} P_{X}^{k}(x^k) 1 \{ y^n = f(x^k) \} \right)^{1+s} Q_{Y}^{n}(y^n)^{-s} \right\} + o(1)
\]

where (22) follows since the number of n-types (or k-types) is only polynomial in n (or k). This means that for any code f, the asymptotics of \( \frac{1}{n} D_{1+s}(P_{Y^n} \| Q_{Y}^{n}) \) induced by f is only determined by restrictions of f on \( A(T_{X}, T_{Y}) := \{ x^n \in T_{X} : f(x^n) \in T_{Y} \} \) for different \( (T_{X}, T_{Y}) \). In other words, the performance of a code f only depends on its restrictions to those maps from \( A(T_{X}, T_{Y}) \) to \( T_{Y} \). On the other hand, \( P_{X}^{k}(x^k) \) and \( Q_{Y}^{n}(y^n) \) are uniform on \( T_{X} \) and \( T_{Y} \), respectively. Hence for different \( (T_{X}, T_{Y}) \), to make the objective function of (22) as small as possible, we need to map the sequences in \( A(T_{X}, T_{Y}) \) to the sequences in \( T_{Y} \) as uniformly as possible. Since \( \cup_{T_{Y}} A(T_{X}, T_{Y}) = T_{X} \) and the number of types \( T_{Y} \) is polynomial in n, for each \( T_{X} \), there is a dominant type \( T_{Y} = g(T_{X}) \) such that redefining f to satisfy \( \{ f(x^n), x^n \in T_{X} \} \subseteq T_{Y} \) with \( T_{Y} = g(T_{X}) \) does not affect the asymptotics of \( \frac{1}{n} D_{1+s}(P_{Y^n} \| Q_{Y}^{n}) \). Therefore, we only need to consider the codes consisting of a function g that maps k-types on \( \mathcal{X} \) to n-types on \( \mathcal{Y} \), and mappings that map sequences in \( T_{X} \) to sequences in \( T_{g(T_{X})} \) as uniformly as possible.

The achievability proof for Theorem 2 follows similar ideas. However, in contrast, to ensure that \( \frac{1}{n} \inf_{f} D_{\alpha}(Q_{Y}^{n} \| P_{Y^n}) \) is finite and also as small as possible, it is required that \( \sup \{ P_{Y^n} \} \sup \{ Q_{Y}^{n} \} \) and \( P_{Y^n}(y^n) \) should be as large as possible for all \( y^n \). On the other hand, observe that \( |P^{(n)}(\mathcal{Y})| \) is polynomial in n. Hence for each \( T_{X} \), we should partition \( T_{X} \) into \( |P^{(n)}(\mathcal{Y})| \) subsets with equal size, and for each \( T_{Y} \), map the sequences in each subset to the sequences in the set \( T_{Y} \) as uniformly as possible. Observe that for each \( T_{Y} \), there must exist a type \( T_{X} \) such that \( H(T_{X}) \geq H(T_{Y}) + o(1) \) (otherwise \( \frac{1}{n} \inf_{f} D_{\alpha}(Q_{Y}^{n} \| P_{Y^n}) = \infty \)) and moreover, similar to (22), the summation term is dominated by some type \( T_{X} \) such that \( H(T_{X}) \geq H(T_{Y}) + o(1) \). Hence without loss of any optimality, it suffices to consider the following mapping. For each \( T_{X} \) and \( \delta > 0 \), partition \( T_{X} \) into \( |\{ T_{Y} : H(T_{X}) \geq H(T_{Y}) + \delta \}| \) subsets with approximately same size. For each \( T_{Y} \) such that \( H(T_{X}) \geq H(T_{Y}) + \delta \), map the sequences in each subset to the sequences in the set \( T_{Y} \) as uniformly as possible.

The code used to prove the achievability part of Theorem 3 is a combination of the two codes above.

### B. Rényi Conversion Rates

As shown in the theorems above, when the code rate is large, the normalized Rényi divergences \( \frac{1}{n} D_{\alpha}(P_{Y^n} \| Q_{Y}^{n}) \), \( \frac{1}{n} D_{\alpha}(Q_{Y}^{n} \| P_{Y^n}) \), and \( \frac{1}{n} D_{\alpha}^{\text{max}}(P_{Y^n}, Q_{Y}^{n}) \) converge to a positive number; however when the code rate is small enough, the normalized Rényi divergences converge to zero. This threshold rate, termed the Rényi conversion rate, is important, since it represents the maximum possible rate under the condition that the distribution induced by the code approximates the target distribution arbitrarily well as \( n \to \infty \). We characterize the Rényi conversion rates for normalized and unnormalized \( D_{\alpha}(P_{Y^n} \| Q_{Y}^{n}) \), \( D_{\alpha}(Q_{Y}^{n} \| P_{Y^n}) \), and \( D_{\alpha}^{\text{max}}(P_{Y^n}, Q_{Y}^{n}) \) in the following theorems.

**Theorem 4** (Rényi Conversion Rate for \( D_{\alpha}(P_{Y^n} \| Q_{Y}^{n}) \)). For any \( \alpha \in [0, \infty) \),

\[
\sup \left\{ R : \frac{1}{n} D_{\alpha}(P_{Y^n} \| Q_{Y}^{n}) \to 0 \right\} = \begin{cases} \inf_{f \in (0,1)} \frac{H(f(P_{X}))}{H(f(Q_{Y}))}, & \alpha \in [1, \infty) \\ \frac{H(P_{X})}{H(Q_{Y})}, & \alpha = 0, \end{cases}
\]

For \( \alpha \in [0, 1) \cup \{ \infty \} \), we have

\[
\sup \left\{ R : \frac{1}{n} D_{\alpha}(P_{Y^n} \| Q_{Y}^{n}) \to 0 \right\} = \sup \left\{ R : \frac{1}{n} D_{\alpha}(P_{Y^n} \| Q_{Y}^{n}) \to 0 \right\}.
\]
For $\alpha \in [1, \infty]$, we have
\[
\sup \left\{ R : \frac{1}{n} D_\alpha(P_{Y^n} \| Q_{Y^n}) \rightarrow 0 \right\} \\
\geq \sup \left\{ R : D_\alpha(P_{Y^n} \| Q_{Y^n}) \rightarrow 0 \right\} \\
\geq \inf_{\epsilon \in (0, 1)} \frac{H_{\alpha - 1 + \frac{\epsilon}{1+\frac{\epsilon}{\alpha-1}}} (P_X)}{H_{\alpha - 1 + \frac{\epsilon}{1+\frac{\epsilon}{\alpha-1}}} (Q_Y)}.
\] (25)

(26)

Remark 2. The analogous result under the TV distance measure was first shown by Han [1]. Theorem 4 is an extension of [1] to the Rényi divergence of all orders $\alpha \in [0, \infty]$. Besides, the first-order and second-order rates, as well as the conversion rates of the quantum version, for the unnormalized Rényi divergence $D_\alpha(P_{Y^n} \| Q_{Y^n})$ with $\alpha = \frac{1}{2}$ were given by Kumagai and Hayashi [2]; and the corresponding moderate deviation of the quantum Rényi conversion rates with the same order was studied by Chubb, Tomamichel, and Korzekwa [14]. The result for the unnormalized Rényi divergence with $\alpha \in (0, \frac{1}{2})$ can be obtained by combining two observations: 1) the achievability for $D_{\frac{1}{2}} (P_{Y^n} \| Q_{Y^n})$ implies the achievability for $\alpha \in (0, \frac{1}{2})$; 2) by Pinsker’s inequality for Rényi divergence [3], the converse result for the TV distance measure [1] implies the converse for $\alpha \in (0, \frac{1}{2})$. Our results for orders $\alpha \in \{0\} \cup (\frac{1}{2}, \infty]$ are new.

Remark 3. $D_\alpha(P_{Y^n|x=x'} \| P_{Y^n|x=x'}) \leq \epsilon$ for all neighboring databases $x, x'$ is known as the $\epsilon$-Rényi differential privacy of order $\alpha$ [15], and the special case with $\alpha = 0$ is known as the $\epsilon$-differential privacy [16]. Here, $X$ represents public data and $Y$ represents private data. In the theorem above, this measure is applied to the random variable simulation problem, and we provide a “necessary and sufficient condition” for $\lim_{n \to \infty} \frac{1}{n} D_\alpha \leq \epsilon$ for any $\epsilon > 0$.

Theorem 5 (Rényi Conversion Rate for $D_\alpha(Q_{Y^n}\|P_{Y^n})$). For any $\alpha \in [0, \infty]$,
\[
\sup \left\{ R : \frac{1}{n} D_\alpha(Q_{Y^n} \| P_{Y^n}) \rightarrow 0 \right\} \\
\geq \inf_{\epsilon \in (0, 1)} \frac{H_{\alpha - 1 + \frac{\epsilon}{1+\frac{\epsilon}{\alpha-1}}} (P_X)}{H_{\alpha - 1 + \frac{\epsilon}{1+\frac{\epsilon}{\alpha-1}}} (Q_Y)}, \quad \alpha \in (1, \infty] \\
= \min \left\{ \frac{H(P_X)}{H(Q_Y)}, \frac{H_0(P_X)}{H_0(Q_Y)} \right\}, \quad \alpha = 1 \\
= \min \left\{ \frac{H(P_X)}{H(Q_Y)}, \frac{H_0(P_X)}{H_0(Q_Y)} \right\}, \quad \alpha \in (0, 1) \\
\geq \alpha = 0.
\] (27)

For $\alpha \in [0, 1] \cup \{\infty\}$, we have
\[
\sup \left\{ R : D_\alpha(Q_{Y^n} \| P_{Y^n}) \rightarrow 0 \right\} \\
= \sup \left\{ R : \frac{1}{n} D_\alpha(Q_{Y^n} \| P_{Y^n}) \rightarrow 0 \right\}.
\] (28)

Remark 4. Our results for all orders $\alpha \in [0, \infty]$ are new.

Theorem 6 (Rényi Conversion Rate for $D_{\alpha}^{\max}(P_{Y^n}, Q_{Y^n})$). For $\alpha \in [0, \infty]$, we have
\[
\sup \left\{ R : \frac{1}{n} D_{\alpha}^{\max}(P_{Y^n}, Q_{Y^n}) \rightarrow 0 \right\} \\
= \min \left\{ \frac{H(P_X)}{H(Q_Y)}, \frac{H_0(P_X)}{H_0(Q_Y)} \right\}, \quad \alpha \in (1, \infty] \\
= \min \left\{ \frac{H(P_X)}{H(Q_Y)}, \frac{H_0(P_X)}{H_0(Q_Y)} \right\}, \quad \alpha = 1 \\
= \min \left\{ \frac{H(P_X)}{H(Q_Y)}, \frac{H_0(P_X)}{H_0(Q_Y)} \right\}, \quad \alpha \in (0, 1) \\
\geq \alpha = 0.
\] (29)

For $\alpha \in [0, 1] \cup \{\infty\}$, we have
\[
\sup \left\{ R : D_{\alpha}^{\max}(P_{Y^n}, Q_{Y^n}) \rightarrow 0 \right\} \\
= \sup \left\{ R : \frac{1}{n} D_{\alpha}^{\max}(P_{Y^n}, Q_{Y^n}) \rightarrow 0 \right\}.
\] (30)

Remark 5. Note that for $\alpha \in (1, \infty]$, (29) involves an infimum taken over $(\frac{\epsilon}{\alpha-1}, \infty)$, and hence it is in general smaller than the minimum of (23) and (27).

Remark 6. For $\alpha = \infty$, the Rényi conversion rate in (29) is $\min_{\beta \in [-\infty, \infty]} \frac{H_\beta(P_X)}{H_\beta(Q_Y)}$. Consider $R = 1$. Then this theorem implies that $P_X$ can approximate $Q_Y$ in the sense that $\frac{1}{n} D_{\infty}^{\max}(P_{Y^n}, Q_{Y^n}) \rightarrow 0$ or $D_{\infty}^{\max}(P_{Y^n}, Q_{Y^n}) \rightarrow 0$, if $H_\beta(P_X) > H_\beta(Q_Y)$.
for all $\beta \in [-\infty, \infty]$, and only if $H_\beta(P_X) \geq H_\beta(Q_Y)$ for all $\beta \in [-\infty, \infty]$. This also implies the statement 1) of [17, Proposition III.3], since if $H_\beta(P_X) < H_\beta(Q_Y)$ for some $\beta \in [-\infty, \infty]$, then approximate simulation (under the measure $D_{max}^\infty$) is impossible, and hence exact simulation is also impossible.

Remark 7. Note that $D_{max}^\infty$ is an extremely strong distance measure. Theorem 6 states that the Rényi conversion rate (the maximum possible rate under the condition $D_{max}^\infty(P_Y^n, Q_Y^n) \to 0$) is finite. That is to say, as the dimension tends to infinity, it is always possible to achieve $D_{max}^\infty(P_Y^n, Q_Y^n) \to 0$, even though $D_{max}^\infty$ is extremely strong. However, in our recent work [17, Proposition III.4], we showed that for some special pairs of distributions, it is impossible to achieve $D_{max}^\infty(P_Y^n, Q_Y^n) = 0$ for finite $n$, i.e., the exact simulation cannot be obtained for finite-dimensional product of distributions.

Remark 8. The condition $D_{max}^\infty(P, Q) \leq \epsilon$ is called $(\epsilon, 0)$-closeness, and was used to measure privacy in [13]. In Theorem 6, we provide a “necessary and sufficient condition” for $\lim_{n \to \infty} D_{max}^\infty(P_Y^n, Q_Y^n) \leq \epsilon$ or $\lim_{n \to \infty} \frac{1}{n} D_{max}^\infty(P_Y^n, Q_Y^n) \leq \epsilon$ for any $\epsilon > 0$. $D_{max}^\infty(P, Q)$ is a very strong measure, hence it can be taken as a secrecy measure for a secrecy system when secrecy stronger than the usual notion of strong secrecy is required. Our result can be applied to this case. Furthermore, $D_{max}^\infty(P, Q)$ is also related to $\epsilon$-information privacy, which is defined as $D_{max}^\infty(P_{XY}, P_Y) \leq \epsilon$ where $X$ and $Y$ represent public and private datum respectively [18].

The proofs of Theorems 4, 5, and 6 are provided in Appendices E, F, and G, respectively. The Rényi conversion rates for normalized $D_{\alpha}(P_Y^n || Q_Y^n)$, $D_{\alpha}(Q_Y^n || P_Y^n)$, and $D_{max}^\infty(P_Y^n, Q_Y^n)$ respectively follow from Theorems 1, 2, and 3. Obviously, the unnormalized Rényi conversion rates are lower bounded by the normalized ones. We believe such lower bounds are tight. However, we do not know how to construct an efficient coding scheme for the case $\alpha \in (1, \infty)$. Hence for the measure $D_{\alpha}(P_Y^n || Q_Y^n)$, we consider a relatively simple scheme — the inverse-transform scheme, which is described in Subsection I-E and illustrated in Fig. 1a. Another reason for using the inverse-transform scheme is that such a scheme is optimal (which results in zero divergences) when the source distribution $P_X$ is continuous [19, Proposition 1]. Hence we believe it should work well for discrete source distributions. For $\delta > 0$, define $B_1 := \{y^n : Q_Y^n(y^n) \geq e^{-n(H(Q_Y)+\delta)}\}$. To ensure $D_{\alpha}(P_Y^n || Q_Y^n) \to 0$, we only need to simulate a truncated version $Q_Y^n(y^n) := Q_Y^n(y^n) 1\{y^n \in B_1\}$ of $Q_Y^n$. This is because, on one hand, for any function $f : \mathcal{X}^k \to \mathcal{B}_1$ with output $Y^n = f(X^n)$,

$$D_{\alpha}(P_Y^n || Q_Y^n) = \frac{1}{\alpha - 1} \log \sum_{y^n \in A} P_Y^n(y^n) \left( \frac{P_Y^n(y^n)}{Q_Y^n(y^n)} \right)^{\alpha - 1}$$

and on the other hand, observe that $Q_Y^n(B_1) \to 1$ as $n \to \infty$. That is to say, if a function $f$ is a “good” simulator for $\tilde{Q}_Y^n$ in the sense that $D_{\alpha}(P_Y^n || Q_Y^n) \to 0$, then it must be also “good” for $Q_Y^n$ in the same sense. The reason why we consider simulating $\tilde{Q}_Y^n$ rather than simulating $Q_Y^n$ directly, is that by doing this, the influence of the behavior of $(Q_Y^n(y^n) : y^n \in \mathcal{Y}^n\setminus B_1)$ on the value of $D_{\alpha}(P_Y^n || Q_Y^n)$ is removed. For such a simulation, all sequences $x^n$ are mapped to the sequences $y^n$ in $B_1$. Hence in general, a code $f : \mathcal{X}^k \to \mathcal{B}_1$ induces a smaller $D_{\alpha}(P_Y^n || Q_Y^n)$ than a code $f : \mathcal{X}^k \to \mathcal{Y}^n$. By using the inverse-transform scheme, we derive an upper bound for $\alpha \in [1, \infty)$, which is tight for $\alpha = 1$ or $\infty$. This is because that to ensure $D_{\alpha}(P_Y^n || Q_Y^n) \to 0$, it is required that $\frac{P_Y^n(y^n)}{Q_Y^n(y^n)} \leq 1 + o(1)$ for all $y^n \in \mathcal{Y}^n$ when $\alpha = \infty$, and $\frac{P_Y^n(y^n)}{Q_Y^n(y^n)} = 1 + o(1)$ for all $y^n$ in a high probability set of $Q_Y^n$ when $\alpha = 1$.

Similar ideas also apply to the cases with measures $D_{\alpha}(Q_Y^n || P_Y^n)$ and $D_{max}^\infty(P_Y^n, Q_Y^n)$. However, for $\alpha = 1$, differently from the case $D_{\alpha}(P_Y^n || Q_Y^n)$ to ensure $D_{\alpha}(Q_Y^n || P_Y^n) \to 0$ or $D_{max}^\infty(P_Y^n, Q_Y^n) \to 0$, it is required not only that $\frac{Q_Y^n(y^n)}{P_Y^n(y^n)} = 1 + o(1)$ for all $y^n$ in a high probability set of $Q_Y^n$, but also that $P_Y^n(y^n) > 0$ for all $y^n \in \mathcal{Y}^n$ (otherwise, $D_{\alpha}(Q_Y^n || P_Y^n) = D_{max}^\infty(P_Y^n, Q_Y^n) = \infty$). Observe that there exists a code such that $P_Y^n(y^n) > 0$ for all $y^n \in \mathcal{Y}^n$ if and only if $|\mathcal{X}^k| \geq |\mathcal{Y}^n|$, i.e., $\frac{1}{n} \leq \frac{\log(|\mathcal{Y}^n|)}{\log(|\mathcal{X}^k|)}$ appears in (27) and (29) for $\alpha = 1$.

For $\alpha = \infty$ and for the measure $D_{\alpha}(Q_Y^n || P_Y^n)$, in contrast to the case $D_{\alpha}(P_Y^n || Q_Y^n)$, here the sequences in $B_2 := \{y^n : e^{-nH(Q_Y)} \leq Q_Y^n(y^n) \leq e^{-n(H(Q_Y) + \delta)}\}$, instead of those in $B_1$, are dominant. That is to say, the influence of $(Q_Y^n(y^n) : y^n \in \mathcal{Y}^n\setminus B_2)$ on the value of $D_{\alpha}(Q_Y^n || P_Y^n)$ can be removed. However, for the measure $D_{max}^\infty(P_Y^n, Q_Y^n)$, the influence of $Q_Y^n(y^n), y^n \in \mathcal{Y}^n$ cannot be removed anymore. That is, all the sequences in $\mathcal{Y}^n$ are dominant.

In summary, for $\alpha = \infty$, the conversion rates are determined by the (part of or all of) exponents of information spectrums of $P_X$ and $Q_Y$, and on the other hand, the exponents of information spectrums are determined by the Rényi entropies (see Lemmas 9 and 11; more specifically, the infinity order cases in Theorems 4, 5, and 6 respectively correspond to (84), (86), as well as, (84) and (85)). Hence the conversion rates are determined by Rényi entropies. This is the reason why the conversion rates are expressed as functions of Rényi entropies. However, for $\alpha = 1$, the conversion rates are related to the limits of
Fig. 2: Illustration of the Rényi conversion rates under normalized divergences in Theorems 4, 5, and 6 for $P_X = \text{Bern}(0.3)$ and $Q_Y = \text{Bern}(0.1)$ (top) and for $P_X = \text{Bern}(0.1)$ and $Q_Y = \text{Bern}(0.3)$ (bottom).

information spectrums of $P_X^k$ and $Q_Y^n$, and do not depend on how fast the information spectrums converge. Hence they are only functions of Rényi entropies with orders 1 and 0.

Theorems 4, 5, and 6 are illustrated in Fig. 2.

III. SPECIAL CASE 1: RÉNYI SOURCE RESOLVABILITY

If we set $P_X$ to the Bernoulli distribution $\text{Bern}\left(\frac{1}{2}\right)$, then the distribution approximation problem reduces to the source resolvability problem, i.e., simulating a memoryless source whose distribution is approximately subject to a target distribution $Q_Y$, using a uniform random variable $M_n$ that is uniformly distributed over $\mathcal{M}_n := [1 : M]$ with $M := \lfloor e^{nR} \rfloor$. The rate $R$ here
measures are respectively characterized in the following corollaries. These results follow from Theorems 1, 2, and 3 by setting $A$. Asymptotics of Rényi Divergences

We consider the Rényi divergences $D_\alpha(P_Y^n || Q_Y^n)$, $D_\alpha(Q_Y^n || P_Y^n)$, and $D_\alpha^{max}(P_Y^n, Q_Y^n)$. The asymptotic behaviors of these measures are respectively characterized in the following corollaries. These results follow from Theorems 1, 2, and 3 by setting $P_X = \text{Bern}(\frac{1}{2})$.

**Corollary 1** (Asymptotics of $\frac{1}{n}D_\alpha(P_Y^n || Q_Y^n)$). For any $\alpha \in [0, \infty]$, we have

$$
\lim_{n \to \infty} \frac{1}{n} \inf_f D_\alpha(P_Y^n || Q_Y^n) = \sup_{t \in [0,1]} \left\{ tH_{\tilde{R}}(Q_Y) - t\tilde{R} \right\}.
$$

**Remark 9.** This result for $\alpha \in [0, 2]$ was shown by our previous work [8]. Hence our results here for $\alpha \in (2, \infty]$ are new.

**Corollary 2** (Asymptotics of $\frac{1}{n}D_\alpha(Q_Y^n || P_Y^n)$). For any $\alpha \in [0, \infty]$, we have

$$
\lim_{n \to \infty} \frac{1}{n} \inf_f D_\alpha(Q_Y^n || P_Y^n) = \begin{cases} 
\infty, & \alpha \in [1, \infty] \text{ and } \tilde{R} < H_0(Q_Y) \\
0, & \alpha \in [1, \infty] \text{ and } \tilde{R} > H_0(Q_Y) \\
\frac{\alpha}{1-\alpha} \sup_{t \in [0,1]} \left\{ tH_{\tilde{R}}(Q_Y) - t\tilde{R} \right\}, & \alpha \in (0, 1) \\
0, & \alpha = 0
\end{cases}
$$

**Corollary 3** (Asymptotics of $\frac{1}{n}D_\alpha^{max}(P_Y^n, Q_Y^n)$). For any $\alpha \in [0, \infty]$, we have

$$
\lim_{n \to \infty} \frac{1}{n} \inf_f D_\alpha^{max}(P_Y^n, Q_Y^n) = \begin{cases} 
\infty, & \alpha \in [1, \infty] \text{ and } \tilde{R} < H_0(Q_Y) \\
\sup_{t \in [\frac{\alpha}{1-\alpha}, \infty]} \left\{ tH_{\tilde{R}}(Q_Y) - t\tilde{R} \right\}, & \alpha \in (1, \infty] \text{ and } \tilde{R} > H_0(Q_Y) \\
0, & \alpha = 1 \text{ and } \tilde{R} > H_0(Q_Y) \\
\max \left\{ \frac{\alpha}{1-\alpha}, 1 \right\} \sup_{t \in [0,1]} \left\{ tH_{\tilde{R}}(Q_Y) - t\tilde{R} \right\}, & \alpha \in (0, 1) \\
\sup_{t \in [0,1]} \left\{ tH_{\tilde{R}}(Q_Y) - t\tilde{R} \right\}, & \alpha = 0
\end{cases}
$$

**B. Rényi Source Resolvability**

As shown in the theorems above, when the code rate is small, the normalized Rényi divergences $\frac{1}{n}D_\alpha(P_Y^n || Q_Y^n)$, $\frac{1}{n}D_\alpha(Q_Y^n || P_Y^n)$, and $\frac{1}{n}D_\alpha^{max}(P_Y^n, Q_Y^n)$ converge to a positive number; however when the code rate is large enough, the normalized Rényi divergences converge to zero. The threshold rate, named Rényi resolvability, represents the minimum rate needed to ensure the distribution induced by the code well approximates the target distribution. We characterize the Rényi resolvabilities in the following theorems. The Rényi resolvabilities for normalized divergences of all orders and the Rényi resolvabilities for unnormalized divergences of orders in $[0, 1] \cup \{ \infty \}$ are direct consequences of Theorems 4, 5, and 6. Hence we only need focus on the cases for unnormalized divergences of orders in $(1, \infty)$. Furthermore, the converse parts for these cases follow from the fact the unnormalized divergences are stronger than the normalized versions. Hence we only prove the achievability parts for unnormalized divergences of orders in $(1, \infty)$. These proofs are provided in Appendices H, I, and J, respectively.

**Theorem 7** (Rényi Resolvability). For any $\alpha \in [0, \infty]$, we have

$$
\inf \left\{ \tilde{R} : \frac{1}{n}D_\alpha(P_Y^n || Q_Y^n) \to 0 \right\} = \inf \left\{ \tilde{R} : D_\alpha(P_Y^n || Q_Y^n) \to 0 \right\} = H(Q_Y).
$$
Remark 10. The case $\alpha = 1$ and the normalized divergence (i.e., the normalized relative entropy case) was first shown by Han and Verdú [4]. The case $\alpha = 1$ and the unnormalized divergence (i.e., the unnormalized relative entropy case) has been shown in other works, such as those by Hayashi [5], [6] and Han, Endo, and Sasaki [20]. In fact, Theorem 7 is implied by our previous work on Rényi channel resolvability [8] by setting the channel to be the identity channel.

**Theorem 8** (Rényi Resolvability). For any $\alpha \in [0, \infty]$, we have

$$\inf \left\{ \tilde{R} : \frac{1}{n} D_{\alpha}(Q_Y^n || P_Y^n) \to 0 \right\} = \inf \left\{ \tilde{R} : D_{\alpha}(Q_Y^n || P_Y^n) \to 0 \right\} = \begin{cases} H_0(Q_Y), & \alpha \in [1, \infty] \\ H(Q_Y), & \alpha \in (0, 1) \\ 0, & \alpha = 0 \end{cases}$$

(38)

Remark 11. The results in Theorem 8 for all orders $\alpha \in [0, \infty]$ are new.

**Theorem 9** (Rényi Resolvability). For any $\alpha \in [0, \infty]$, we have

$$\inf \left\{ \tilde{R} : \frac{1}{n} D_{\alpha}^{\max}(P_Y^n, Q_Y^n) \to 0 \right\} = \inf \left\{ \tilde{R} : D_{\alpha}^{\max}(P_Y^n, Q_Y^n) \to 0 \right\} = \begin{cases} H_{1-\alpha}(Q_Y), & \alpha \in [1, \infty] \\ H(Q_Y), & \alpha \in [0, 1) \end{cases}$$

(39)

Remark 12. For special cases $\alpha = 1, \infty$, the Rényi resolvabilities are respectively equal to $H_{-\infty}(Q_Y) = -\log \min_y Q_Y(y)$ and $H_0(Q_Y) = \log |\text{supp}(Q_Y)|$.

Remark 13. To the best of our knowledge, we are the first to give an explicit operational interpretation of Rényi entropies of negative orders as Rényi resolvabilities. In [11], [21], Rényi entropies of negative orders were used to lower bound the probability of error for hypothesis testing.

Theorems 7, 8, and 9 are illustrated in Fig. 3.
IV. SPECIAL CASE 2: RÉNYI INTRINSIC RANDOMNESS

If we set $Q_Y$ to the Bernoulli distribution $\text{Bern}(\frac{1}{2})$, then the distribution approximation problem reduces to the intrinsic randomness problem, which can be seen as a “dual” problem of the source resolvability problem. Consider simulating a uniform random variable $M_n$ that is uniformly distributed over $\mathcal{M}_n := \{1 : M\}$ with $M := e^{n\hat{R}}$ using a memoryless source $X^n \sim P^Y_X$. The rate $\hat{R}$ here is approximately equal to $\log$ 2 times the rate $R$ in Section II with $Q_Y$ set to $\text{Bern}(\frac{1}{2})$. Given the distribution $P_X$, we wish to maximize the rate $\hat{R}$ such that the distribution of $M_n := f(X^n)$ forms a good approximation to the target distribution $Q_{M_n} := \text{Unif}[1 : M]$.

A. Asymptotics of Rényi Divergences

We consider the Rényi divergences $D_\alpha(P_{M_n} || Q_{M_n}), D_\alpha(Q_{M_n} || P_{M_n})$, and $D^\max_\alpha(P_{M_n}, Q_{M_n})$. The asymptotics of these measures are respectively characterized in the following corollaries. These results respectively follow from Theorems 1, 2, and 3 by setting $Q_Y = \text{Bern}(\frac{1}{2})$.

**Corollary 4** (Asymptotics of $\frac{1}{n} D_\alpha(P_{M_n} || Q_{M_n})$). For any $\alpha \in [0, \infty]$, we have

$$
\lim_{n \to \infty} \frac{1}{n} \inf_{\hat{f}} D_\alpha(P_{M_n} || Q_{M_n}) = \begin{cases} 
\left[ \hat{R} - H_\alpha(P_X) \right]^+, & \alpha \in \{0\} \cup [1, \infty] \\
\max_{t \in [0, 1]} \left\{ t\hat{R} - tH_\frac{1}{1+\alpha}(P_X) \right\}, & \alpha \in (0, 1) 
\end{cases}
$$

(40)

**Remark 14.** The case $\alpha \in [0, 2]$ was shown by Hayashi and Tan [22]. Hence our results for $\alpha \in (2, \infty]$ are new.

**Corollary 5** (Asymptotics of $\frac{1}{n} D_\alpha(Q_{M_n} || P_{M_n})$). For any $\alpha \in [0, \infty]$, we have

$$
\lim_{n \to \infty} \frac{1}{n} \inf_{\hat{f}} D_\alpha(Q_{M_n} || P_{M_n}) = \begin{cases} 
\sup_{t \in [0, \infty]} \left\{ t\hat{R} - tH_\frac{1}{1+\alpha}(P_X) \right\}, & \alpha \in [1, \infty] \\
\frac{\alpha}{1+\alpha} \max_{t \in [0, 1]} \left\{ t\hat{R} - tH_\frac{1}{1+\alpha}(P_X) \right\}, & \alpha \in (0, 1) \\
0, & \alpha = 0 
\end{cases}
$$

(41)

**Remark 15.** If $\hat{R} > H_0(P_X)$, then $\lim_{n \to \infty} \frac{1}{n} \inf_{\hat{f}} D_\alpha(Q_{M_n} || P_{M_n}) = \infty, \alpha \in [1, \infty]$.

**Corollary 6** (Asymptotics of $\frac{1}{n} D^\max_\alpha(P_{Y^n}, Q^\alpha_Y)$). For any $\alpha \in [0, \infty]$, we have

$$
\lim_{n \to \infty} \frac{1}{n} \inf_{\hat{f}} D^\max_\alpha(P_{Y^n}, Q^\alpha_Y) = \begin{cases} 
\max \left\{ \left[ \hat{R} - H_\alpha(P_X) \right]^+, \sup_{t \in [0, \infty]} \left\{ t\hat{R} - tH_\frac{1}{1+\alpha}(P_X) \right\} \right\}, & \alpha \in [1, \infty] \\
\max_{t \in [0, 1]} \max_{t' \in [0, 1]} \left\{ t\hat{R} - tH_\frac{1}{1+\alpha}(P_X) \right\}, & \alpha \in (0, 1) \\
\left[ \hat{R} - H_0(P_X) \right]^+, & \alpha = 0 
\end{cases}
$$

(42)

where $a(t')$ and $b(t')$ are defined in (19) and (20).

B. Rényi Intrinsic Randomness

As shown in the theorems above, when the rate is large, the normalized Rényi divergences $\frac{1}{n} D_\alpha(P_{M_n} || Q_{M_n}), \frac{1}{n} D_\alpha(Q_{M_n} || P_{M_n})$, and $\frac{1}{n} D^\max_\alpha(P_{M_n}, Q_{M_n})$ converge to a positive number; however when the rate is small enough, the normalized Rényi divergences converge to zero. The threshold rate, named Rényi intrinsic randomness, represents the maximum possible rate to satisfy that the distribution induced by a code well approximates the target uniform distribution. We characterize the Rényi intrinsic randomness in the following theorems. The Rényi intrinsic randomness for normalized divergences of all orders and the Rényi intrinsic randomness for unnormalized divergences of orders in $[0, 1] \cup \{\infty\}$ are direct consequences of Theorems 4, 5, and 6. Hence we only need focus on the cases for unnormalized divergences of orders in $(1, \infty)$. Furthermore, the converse parts for these cases follow from the fact the unnormalized divergences are stronger than the normalized versions. Hence we only prove the achievability parts. The proofs are provided in Appendices K, L, and M, respectively.
Theorem 10 (Rényi Intrinsic Randomness). For any $\alpha \in [0, \infty]$, we have
\[
\sup \left\{ \hat{R} : \frac{1}{n} D_\alpha(P_{\mathcal{M}_n} \| Q_{\mathcal{M}_n}) \to 0 \right\} = \sup \left\{ \hat{R} : D_\alpha(P_{\mathcal{M}_n} \| Q_{\mathcal{M}_n}) \to 0 \right\} = \begin{cases} H_{\alpha}(P_X) & \alpha \in \{0\} \cup [1, \infty], \\ H(P_X) & \alpha \in (0, 1) \end{cases}.
\]

Remark 16. The case $\alpha = 1$ and the normalized divergence (i.e., the normalized relative entropy case) was shown in [1]. The case $\alpha = 1$ and the unnormalized divergence (i.e., the unnormalized relative entropy case) was shown by Hayashi [23]. The result for the unnormalized Rényi divergence with $\alpha \in (0, 1)$ can be obtained by combining two observations: 1) the achievability for $D(P_{Y^n} \| Q_Y^n)$ implies the achievability for this case; 2) by Pinsker’s inequality [3], the result under the TV distance measure [1] implies the converse for $\alpha \in (0, 1)$. The case $\alpha \in [0, 2]$ was shown by Hayashi and Tan [22]. Hence our results for $\alpha \in (2, \infty]$ are new.

Theorem 11 (Rényi Intrinsic Randomness). For any $\alpha \in [0, \infty]$, we have
\[
\sup \left\{ \hat{R} : \frac{1}{n} D_\alpha(Q_{\mathcal{M}_n} \| P_{\mathcal{M}_n}) \to 0 \right\} = \sup \left\{ \hat{R} : D_\alpha(Q_{\mathcal{M}_n} \| P_{\mathcal{M}_n}) \to 0 \right\} = \begin{cases} H(P_X), & \alpha \in (0, \infty] \\ \infty, & \alpha = 0 \end{cases}
\]

Remark 17. The case $\alpha = 1$ was shown by Hayashi [23]. Our results for all orders $\alpha \in [0, 1) \cup (1, \infty]$ are new.

Theorem 12 (Rényi Intrinsic Randomness). For any $\alpha \in [0, \infty]$, we have
\[
\sup \left\{ \hat{R} : \frac{1}{n} D_\alpha^{\max}(P_{\mathcal{M}_n}, Q_{\mathcal{M}_n}) \to 0 \right\} = \sup \left\{ \hat{R} : D_\alpha^{\max}(P_{\mathcal{M}_n}, Q_{\mathcal{M}_n}) \to 0 \right\} = \begin{cases} H_{\alpha}(P_X), & \alpha \in \{0\} \cup [1, \infty] \\ H(P_X), & \alpha \in (0, 1) \end{cases}
\]

Theorems 10, 11, and 12 are illustrated in Fig. 4.

V. CONCLUDING REMARKS

In this paper, we studied generalized versions of random variable simulation problem or distribution approximation problem, in which the (normalized or unnormalized) standard Rényi divergence and max- or sum-Rényi divergence of orders in $[0, \infty]$ are used to measure the level of approximation. As special cases, the source resolvability problem and the intrinsic randomness problem were studied as well.

Our results on the distribution approximation problem extend those by Han [1] and by Kumagai and Hayashi [2], as we consider Rényi divergences with all orders in $[0, \infty]$ instead of the TV distance or the special case with order $\frac{1}{2}$. Similarly, our source resolvability results extend those by Han and Verdú [4], by Hayashi [5], [6], and by Yu and Tan [8] for the source resolvability case, and our intrinsic randomness results extend those by Vembu and Verdú [9], by Han [1], and by Hayashi and Tan [22].

A. Open Problem

In Theorems 4, 5, and 6, we completely characterized the Rényi conversion rates only for $\alpha \in [0, 1] \cup \{\infty\}$. But the cases for $\alpha \in (1, \infty)$ are still open. We believe that analogous to the case $\alpha \in [0, 1] \cup \{\infty\}$, the unnormalized version of Rényi conversion rate for $\alpha \in (1, \infty)$ is also equal to the corresponding normalized version with the same $\alpha$.

B. Applications

Similar to other results concerning simulation of random variables, our results can be applied to the analysis of Monte Carlo methods, randomized algorithms (or random coding), and cryptography. In the following we apply our results to information-theoretic security. To illustrate this point, we consider the Shannon cipher system with a guessing wiretapper that was studied in [24]. In the Shannon cipher system, the sender and the legitimate receiver share a secret key $K_n \sim \text{Unif} [1 : e^{nR}]$, and they want...
to communicate a source $X^n \sim P^n_X$ with zero-error (using a variable-length code $M_n = f(X^n, K_n)$ and $X^n = f^{-1}(M_n, K_n)$) from the sender to the legitimate receiver through a public noiseless channel with sufficiently large capacity. However, the cryptogram $M_n$ is overheard by a wiretapper, who has a test mechanism by which s/he can identify whether any given candidate message $\hat{X}_n$ is the true message. Upon the code $f$ used by the sender and legitimate receiver and the received cryptogram $Y^n$, the wiretapper conducts an optimal sequential guessing strategy, i.e., an ordered list of guesses $\mathcal{L}(m) := \{\hat{x}^1_n(m), \hat{x}^2_n(m), \ldots\}$ with $\hat{x}^i_n(m)$ corresponding to the $i$-th largest probability value of $P_{X^n|M_n}(\cdot|m)$ for any given $M_n = m$. It is obvious that such a guessing scheme based on maximizing the posterior probability minimizes the expectation or positive-order moments of the number of guesses. Let the random variable $G(X^n|M_n)$ denote the number of guesses of the wiretapper until identification of the true message. Then for $\rho > 0$, the $\rho$-th moment of $G(X^n|M_n)$ can be also expressed as

$$
\mathbb{E}[G(X^n|M_n)^\rho] = \inf_{\{\mathcal{L}(m)\}} \sum_{i=1}^{\infty} i^\rho \cdot \mathbb{P}\{\mathcal{L}(M_n)_i = X^n\},
$$

where $\mathcal{L}(M_n)_i$ denotes the $i$-th element of $\mathcal{L}(M_n)$. For $\rho > 0$, the guessing exponents are defined as

$$
E^+(R, \rho) := \limsup_{n \to \infty} \frac{1}{n} \log \mathbb{E}[G(X^n|M_n)^\rho]
$$

and

$$
E^-(R, \rho) := \liminf_{n \to \infty} \frac{1}{n} \log \mathbb{E}[G(X^n|M_n)^\rho].
$$

Then Merhav and Arikan \cite{MerhavArikan02} showed that

$$
E^+(R, \rho) = E^-(R, \rho) = E(R, \rho) := \max_{Q_X} \{\rho \min_{R} \{H(Q_X, R) - D(Q_X \| P_X)\}\}.
$$

Now we consider a variant of this problem. Suppose the secret key $K_n$ is replaced by a memoryless source $Y^n \sim P^n_Y$. Correspondingly, denote the guessing exponents for this case as $\tilde{E}^+(P_Y, \rho)$ and $\tilde{E}^-(P_Y, \rho)$. Next, we apply our results to this new problem.

For the achievability part, we use $Y^n$ to simulate a key $K_n \sim Q_{K_n} := \text{Unif}[1 : e^{nR}]$ by our simulation code $K_n = g(Y^n)$. Assume $P_{K_n}$ is the key distribution induced by a generator $K_n = g(Y^n)$. Then Corollary 4 implies that $\inf_{\rho} \frac{1}{n} D_\infty(Q_{K_n} \| P_{K_n}) \leq \sup_{t \in [0, \infty)} \left\{ tR - tH_{\tilde{t}}(P_Y) \right\}$. Furthermore, for any $f$ and any $\{\mathcal{L}(m)\}$, if

$$
\frac{1}{n} \log \mathbb{E}_{P_{K_n}} \mathbb{E}_{Q_X} [\sum_{i=1}^{\infty} i^\rho \cdot 1 \{ \mathcal{L}(f(X^n, K_n))\}_i = X^n] \geq \frac{1}{n} D_{\infty}(Q_{K_n} \| P_{K_n}).
$$

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{fig4.png}
\caption{Illustration of the R\'enyi intrinsic randomness in Theorems 10, 11, and 12 for $P_X = \text{Bern}(0.1)$.}
\end{figure}
On the other hand, (49) implies

$$\lim_{n \to \infty} \sup_{f} \frac{1}{n} \log \inf_{\{L(m)\}} E_{Q_{K_n}} P_R^E \left[ \sum_{i=1}^{\infty} i^p \cdot 1 \{ L(f(X^n, K_n)) \}_{i} = X^n \right] = E(R, \rho). \quad (51)$$

Hence the guessing exponent functions are bounded as follows.

$$\sup_{R \geq 0} \left\{ E(R, \rho) - \sup_{t \in [0,\infty)} \left\{ tR - tH_{\frac{1}{t+1}}(P_Y) \right\} \right\} \leq \tilde{E}^- (P_Y, \rho) \leq \tilde{E}^+ (P_Y, \rho). \quad (52)$$

For the converse part, we use a key $K_n \sim Q_{K_n} := \text{Unif} \left[ 1 : e^{nR} \right]$ to simulate a memoryless source $Y^n \sim P^n_Y$ by our simulation code $Y^n = g(K_n)$. Similarly, by our Corollary 1, we obtain the following converse result.

$$\tilde{E}^- (P_Y, \rho) \leq \tilde{E}^+ (P_Y, \rho) \leq E(H_0(P_Y), \rho). \quad (53)$$

When $P_X$ is uniform, the bounds in (52) and (53) coincide, and they reduce to the result in (49). However, in general, the bounds in (52) and (53) do not coincide. Furthermore, it is worth noting that the analysis here also applies to variants of any information-theoretic security problem in which a key (uniform random variable) is replaced with a memoryless source, as long as the objective of the problem is to minimize or maximize the same expectation.

The results derived in this paper can be also applied to the information-theoretic security problems with the information leakage measured by Rényi divergences. Recently, in [25], Theorem 7 has been used to establish the equivalence between bounds in (52) and (53) do not coincide. Furthermore, it is worth noting that the analysis here also applies to variants of any information-theoretic security problem in which a key (uniform random variable) is replaced with a memoryless source, as long as the objective of the problem is to minimize or maximize the same expectation.

Remark 18. We have
\[
\lim_{n \to \infty} \min_{P_X \in \mathcal{P}(\mathcal{X}^n)} \max_{P_Y \in \mathcal{P}(\mathcal{Y}^n)} f(P_X^{(n)} P_Y^{(n)}) = \lim_{n \to \infty} \min_{P_X \in \mathcal{P}(\mathcal{X}^n)} \max_{P_Y \in \mathcal{P}(\mathcal{Y}^n)} f(P_X^{(n)} P_Y^{(n)})
\] (56)
if either one of the limits above exists.

We also need the following lemmas. Lemmas 4, 6, 7, and 8 follow from basic inequalities and basic properties (continuity, monotonicity, and convexity) of functions. To save space, the proofs are omitted.

Lemma 4. Assume \( f(z) \) and \( g(z) \) are continuous functions defined on a compact set \( Z \subseteq \mathbb{R}^n \) for some positive integer \( n \). Define \( h(t) := \min_{z \in Z; g(z) \leq t} f(z) \). Then \( h(t) \) is a also continuous function.

Lemma 5. \([26, \text{Problem 4.15(f)}]\) Assume \( \{a_i\} \) are non-negative real numbers. Then for \( p \geq 1 \), we have
\[
\sum_i a_i^p \leq \left( \sum_i a_i \right)^p,
\] (57)
and for \( 0 < p \leq 1 \), we have
\[
\sum_i a_i^p \geq \left( \sum_i a_i \right)^p.
\] (58)

Lemma 6.
\[
(1 + x)^s \leq 1 + sx^s, \quad x \geq 0, 0 \leq s \leq 1,
\] (59)
\[
(1 + x)^s \leq 1 + sx + x^s, \quad x \geq 0, 1 \leq s \leq 2,
\] (60)
\[
(1 + x)^s \leq 1 + s(2^{s-1} - 1)x + x^s, \quad 0 \leq x \leq 1, s \geq 2.
\] (61)

Lemma 7. Assume \( \sum_{i=1}^n b_i = m \). Then we have that for \( \beta \leq 0 \) or \( \beta \geq 1 \), \( \frac{1}{n} \sum_{i=1}^n b_i^\beta \geq (\frac{m}{n})^\beta \); for \( 0 < \beta < 1 \), \( \frac{1}{n} \sum_{i=1}^n b_i^\beta \leq (\frac{m}{n})^\beta \). Moreover, if \( m < n \) and \( b_i \in \{0\} \cup \mathbb{N} \), we have that for \( \beta \leq 0 \) or \( \beta \geq 1 \), \( \frac{1}{n} \sum_{i=1}^n b_i^\beta \geq \frac{m}{n} \); for \( 0 < \beta < 1 \), \( \frac{1}{n} \sum_{i=1}^n b_i^\beta \leq \frac{m}{n} \).

Lemma 8. For any \( a \geq 0 \) and any \( b \),
\[
\sup_{\tilde{P}_X \in \mathcal{P}(\mathcal{X})} \left\{ aH(\tilde{P}_X) + b\sum_x \tilde{P}_X(x) \log P_X(x) \right\} = (a-b) H_\frac{a}{a+b}(P_X).
\] (62)

For any \( a \leq 0 \) and any \( b \),
\[
\inf_{\tilde{P}_X \in \mathcal{P}(\mathcal{X})} \left\{ aH(\tilde{P}_X) + b\sum_x \tilde{P}_X(x) \log P_X(x) \right\} = (a-b) H_\frac{a}{a+b}(P_X).
\] (63)

B. Exponents of Information Spectrum

Since exponents of information spectrum are important in our proofs of the results in this paper, they will be introduced in the following. Furthermore, as fundamental information-theoretic quantities, investigating exponents of information spectrum are of independent interest.

For a general distribution \( P_{X^n} \), define \( F_{P_{X^n}}(j) := P_{X^n} \left( x^n : -\frac{1}{n} \log P_{X^n}(x^n) < j \right) \) and \( F_{P_{X^n}}^{-1}(\theta) := \sup \{ j : F_{P_{X^n}}(j) \leq \theta \} \). Now consider a product distribution \( P_{X^n} \) with \( P_X \) defined on a finite set \( \mathcal{X} \). Define the exponents of information spectrum for distribution \( P_X \) as
\[
E_{P_X}(j) := \lim_{n \to \infty} -\frac{1}{n} \log F_{P_X}(j),
\] (64)
\[
\tilde{E}_{P_X}(j) := \lim_{n \to \infty} -\frac{1}{n} \log (1 - F_{P_X}(j)).
\] (65)
Or simply, define the exponent of information spectrum for distribution \( P_X \) as
\[
\tilde{E}_{P_X}(j) := \max \left\{ E_{P_X}(j), \tilde{E}_{P_X}(j) \right\}.
\] (66)
Since for each \( j \geq 0 \), either \( E_{P_X}(j) \) or \( \tilde{E}_{P_X}(j) \) can be positive (the other one must be zero), the exponent \( \tilde{E}_{P_X}(j) \) contains all the information about the exponent pair \( \left( E_{P_X}(j), \tilde{E}_{P_X}(j) \right) \). Moreover, the inverse functions of \( E_{P_X}(j) \) and \( \tilde{E}_{P_X}(j) \) are denoted as \( E_{P_X}^{-1}(\omega) \) and \( \tilde{E}_{P_X}^{-1}(\omega) \). Then we have the following lemmas. Observe that if \( P_X \) is uniform, then \( \tilde{E}_{P_X}(j) = +\infty \) for all \( j \). Hence, in the following, we exclude this trivial case.
**Lemma 9** (Exponents of Information Spectrum). Assume $P_X$ is not uniform. For $j > H_\infty(P_X)$,

$$E_{P_X}(j) = \min_{\tilde{P}_X : \sum_x \tilde{P}_X(x) \log P_X(x) \leq j} D(\tilde{P}_X \| P_X)$$

(67)

and for $0 \leq j \leq H_\infty(P_X)$,

$$\tilde{E}_{P_X}(j) = \min_{\tilde{P}_X : \sum_x \tilde{P}_X(x) \log P_X(x) \geq j} D(\tilde{P}_X \| P_X)$$

(69)

For $0 \leq \omega < H_\infty(P_X)$,

$$E_{P_X}^{-1}(\omega) = \max_{\tilde{P}_X : D(\tilde{P}_X \| P_X) \leq \omega} \sum_x \tilde{P}_X(x) \log P_X(x)$$

(71)

and for $0 \leq \omega \leq H_\infty(P_X)$,

$$\tilde{E}_{P_X}^{-1}(\omega) = \max_{\tilde{P}_X : D(\tilde{P}_X \| P_X) \leq \omega} \sum_x \tilde{P}_X(x) \log P_X(x)$$

(73)

Moreover, $E_{P_X}(j)$, $\tilde{E}_{P_X}(j)$, $E_{P_X}^{-1}(\omega)$, and $\tilde{E}_{P_X}^{-1}(\omega)$ are continuous on the intervals mentioned above.

**Remark 19.** We can use $E_{P_X}(j)$, $\tilde{E}_{P_X}(j)$, $E_{P_X}^{-1}(\omega)$, and $\tilde{E}_{P_X}^{-1}(\omega)$ to rewrite $F_{P_X}(j)$, $1 - F_{P_X}(j)$, $F_{P_X}^{-1}(\theta)$, and $F_{P_X}^{-1}(1 - \theta)$ as follows:

$$F_{P_X}(j) = e^{-n(\log j + o(1))}$$

(75)

$$1 - F_{P_X}(j) = e^{-n(\tilde{E}_{P_X}(j) + o(1))}$$

(76)

$$F_{P_X}^{-1}(\theta) = E_{P_X}^{-1}(1 - \frac{1}{n} \log \theta - o(1))$$

(77)

$$F_{P_X}^{-1}(1 - \theta) = \tilde{E}_{P_X}^{-1}(1 - \frac{1}{n} \log \theta - o(1))$$

(78)

where the first two equalities follow from the definitions of $E_{P_X}(j)$ and $\tilde{E}_{P_X}(j)$, and the last two follow since

$$F_{P_X}^{-1}(\theta) = \sup \left\{ j : F_{P_X}(j) \leq \theta \right\}$$

(79)

$$= \sup \left\{ j : e^{-n(\log j + o(1))} \leq \theta \right\}$$

(80)

$$= \sup \left\{ j : E_{P_X}(j) \geq \frac{1}{n} \log \theta - o(1) \right\}$$

(81)

$$= E_{P_X}^{-1}(\frac{1}{n} \log \theta - o(1))$$

(82)

and similarly for $F_{P_X}^{-1}(1 - \theta)$.

**Lemma 9** follows by large deviation theory [27], and it holds not only for finite alphabets, but also for countably infinite or continuous alphabets. Note that $tH_{1-t}(P_X) = \log E[e^{-t \log P_X(x)}]$ is the logarithmic moment generating function with respect to the self-information $- \log P_X(x)$, and (68) and (70) are the Fenchel–Legendre transform of $tH_{1-t}(P_X)$. Furthermore, by [27, Lemma 2.2.31], $tH_{1-t}(P_X)$ is convex in $t \in \mathbb{R}$.

**Lemma 10.** $\tilde{E}_{P_X}(j)$ can be expressed as the following parametric representation with $\alpha \in [-\infty, \infty]$.

$$\begin{align*}
\tilde{E}_{P_X} = D \left( \frac{t P_X}{\sum_x P_X(x)} \| P_X \right).
\end{align*}$$

Specialized to the case $\alpha = 0$, it reduces to that

$$\tilde{E}_{P_X}(H^n(P_X)) = \tilde{E}_{P_X}(H^n(P_X)) = D(\text{Unif}(\mathcal{X}) \| P_X).$$

(83)
Hence for all \( t \in [0,1] \),
\[
\max_{t \in [0,1]} \left\{ -\frac{t}{R} H_{1-t}(P_X) + t j \right\} = \max_{t \in [0,\infty]} \left\{ -\frac{t}{R} H_{1-t}(P_X) + t j \right\}.
\]
Hence for \( j \in \frac{1}{R}[H(P_X), H^u(P_X)] \),
\[
\max_{t \in [0,\infty]} \left\{ -\frac{t}{R} H_{1-t}(P_X) + t j \right\} < \max_{t \in [0,1]} \left\{ -t H_{1-t}(Q_Y) + t j \right\} \leq \max_{t \in [0,\infty]} \left\{ -t H_{1-t}(Q_Y) + t j \right\},
\]

**Proof:** Here we only provide a proof for the equivalence in (86). Other equivalences can be proven similarly.

**Lemma 11 (Comparison of Exponents). Assume both \( P_X \) and \( Q_Y \) are not uniform. Then we have**

\[
\begin{align*}
\frac{1}{R} E_{P_X}(R_j) &> E_{Q_Y}(j), \forall j \in \frac{1}{R} [H_\infty(P_X), H(P_X)] \quad \Leftrightarrow \quad R < \min_{t \in [0,1]} \frac{H_t(P_X)}{H_t(Q_Y)}; \\
\frac{1}{R} \tilde{E}_{P_X}(R_j) &< \tilde{E}_{Q_Y}(j), \forall j \in \frac{1}{R} [H(P_X), H_{-\infty}(P_X)] \quad \Leftrightarrow \quad R < \min_{t \in [-\infty,0]} \frac{H_t(P_X)}{H_t(Q_Y)}. 
\end{align*}
\]

Furthermore, the equivalences in (85) can be divided into the following two parts:

\[
\begin{align*}
\left\{ \frac{1}{R} \tilde{E}_{P_X}(R_j) < \tilde{E}_{Q_Y}(j), \forall j \in \frac{1}{R} [H(P_X), H^u(P_X)] \right\} &\quad \Leftrightarrow \quad R < \min_{t \in [0,1]} \frac{H_t(P_X)}{H_t(Q_Y)}; \\
\left\{ \frac{1}{R} \tilde{E}_{P_X}(R_j) < \tilde{E}_{Q_Y}(j), \forall j \in \frac{1}{R} [H^u(P_X), H_{-\infty}(P_X)] \right\} &\quad \Leftrightarrow \quad R < \min_{t \in [-\infty,0]} \frac{H_t(P_X)}{H_t(Q_Y)}. 
\end{align*}
\]

In addition, the equivalences in (84)-(87) also hold if all the “<” are replaced with “\(<\)".
which, by Lemma 9, implies the LHS of (86).

Proof of “$$\Rightarrow$$”: The LHS of (86) implies for $$j \in \frac{1}{R}[H(P_X), H^n(P_X)],$$

$$\max_{t \in [0, \infty)} \left\{ -\frac{t}{R} H_{1-t}(P_X) + t j \right\} \leq \max_{t \in [0, \infty)} \left\{ -t H_{1-t}(Q_Y) + t j \right\}, \tag{92}$$

By setting $$j = \frac{1}{R} H(P_X),$$ we have $$\frac{1}{R} H(P_X) > H(Q_Y).$$

On the other hand, given $$j \in [H(Q_Y), H_{-\infty}(Q_Y)],$$ the maximum in the RHS of (92) is attained at $$g^{-1}(j)$$ which is a value $$t$$ satisfying $$j = g(t) := \frac{d}{dt} (t H_{1-t}(Q_Y)) = -\frac{1}{R} \sum_{x \in X} Q_1^{-1}(y) \sum_{y \in Y} Q_Y^{-1}(y) \log Q_Y(y).$$ Here $$g(t)$$ is an increasing function since $$t H_{1-t}(Q_Y)$$ is convex. Hence for $$j$$ running from $$H(Q_Y)$$ to $$\frac{1}{R} H^n(P_X),$$ $$g^{-1}(j)$$ runs from 0 to $$t_0,$$ where $$t_0$$ is the solution to $$\frac{1}{R} H^n(P_X) = g(t_0).$$ Observe $$g^{-1}(j)$$ is continuous. Hence for each $$t' \in [0, t_0],$$ we can find a $$j' \in [H(Q_Y), \frac{1}{R} H^n(P_X)]$$ such that $$g^{-1}(j') = t'.$$ For such $$(j', t'),$$ we have

$$-t' H_{1-t'}(Q_Y) + t' j' = \max_{t \in [0, \infty)} \left\{ -t H_{1-t}(Q_Y) + t j' \right\} \geq -\frac{t'}{R} H_{1-t'}(P_X) + t' j'. \tag{95}$$

That is, for $$t' \in [0, t_0],$$

$$RH_{1-t'}(Q_Y) < H_{1-t'}(P_X). \tag{96}$$

If $$t_0 < 1,$$ then $$\frac{1}{R} H^n(P_X) < H^n(Q_Y).$$ The derivative of $$\hat{E}_{Q_Y}(j)$$ is $$g^{-1}(j)$$ at $$j,$$ where $$g(t)$$ is defined above. For $$j \in [\frac{1}{R} H^n(P_X), H^n(Q_Y)],$$ $$g^{-1}(j) \in [t_0, 1].$$ Observe that $$\hat{E}_{Q_Y}(j)$$ and $$\frac{1}{R} \hat{E}_{P_X}(R_j)$$ are convex, and $$-H_0(Q_Y) + j$$ and $$-\frac{1}{R} H_0(P_X) + j$$ are respectively the tangent lines of $$\hat{E}_{Q_Y}(j)$$ at $$j_0 = H^n(Q_Y)$$ and $$\frac{1}{R} \hat{E}_{P_X}(R_j)$$ at $$j_0 = \frac{1}{R} H^n(P_X).$$ Hence combining with the assumption $$R < \frac{1}{R} H_0(P_X),$$ we have $$\hat{E}_{Q_Y}(j) \geq -H_0(Q_Y) + j > -\frac{1}{R} H_0(P_X) + j.$$ Moreover, we also have that tangent lines of $$\frac{1}{R} \hat{E}_{P_X}(R_j)$$ at $$j_0 < \frac{1}{R} H^n(P_X)$$ (with slope $$t' < 1$$) are below the line $$-\frac{1}{R} H_0(P_X) + j$$ for $$j > \frac{1}{R} H^n(P_X).$$

For $$t' \in [0, 1],$$ denote $$j' = g(t').$$ Then by the analysis above, for such $$(j', t'),$$ we have

$$-t' H_{1-t'}(Q_Y) + t' j' = \hat{E}_{Q_Y}(j') \geq -\frac{1}{R} H_0(P_X) + j' \geq -\frac{t'}{R} H_{1-t'}(P_X) + t' j'. \tag{99}$$

Hence for $$t' \in [t_0, 1],$$ (96) also holds.

For a distribution $$P_X,$$ define the exponent of information spectrum in an interval $$[j_1, j_2]$$ as

$$E_{P_X}(j_1, j_2) := \lim_{n \to \infty} -\frac{1}{n} \log \frac{F_{P_X}^n(j_1, j_2)}{F_{P_X}^n(j_2, j_2)}, \tag{100}$$

where $$F_{P_X}^n(j_1, j_2) := \frac{P_X^n}{n} (x^n : -\frac{1}{n} \log P_X^n(\{x^n\}) \in [j_1, j_2]).$$

**Lemma 12** (Exponent of Information Spectrum in an Interval). Assume $$P_X$$ is not uniform. Then for $$j_1 < j_2,$$ we have

$$E_{P_X}(j_1, j_2) = \begin{cases} E_{P_X}(j_2), & H_\infty(P_X) \leq j_1 < j_2 \leq H(P_X) \\ \hat{E}_{P_X}(j_1), & H(P_X) \leq j_1 < j_2 \leq H_{-\infty}(P_X) \\ 0, & H_\infty(P_X) \leq j_1 \leq H(P_X) \leq j_2 \leq H_{-\infty}(P_X) \end{cases}. \tag{101}$$

Lemma 12 follows directly from Lemma 9, and the proof is omitted.

**Appendix B**

**Proof of Theorem 1**

In the following, we only consider the case of $$R = 1.$$ For the general case, we can obtain the result by setting $$Q_Y$$ to the product distribution $$Q_Y^R$$, if $$R$$ is an integer; otherwise, set $$P_X$$ to $$P_X^{k_0}$$ and $$Q_Y$$ to $$Q_Y^{n_0},$$ where $$k_0$$ and $$n_0$$ are co-prime and $$R = \frac{n_0}{k_0}.$$

**Achievability:** Assume $$g : \mathcal{P}^{(n)}(X) \to \mathcal{P}^{(n)}(Y)$$ is a function that maps $$n$$-types on $$X$$ to $$n$$-types on $$Y.$$ A code $$f$$ induced by $$g$$ is obtained by mapping the sequences in $$T_X$$ to the sequences in $$T_{g(T_X)}$$ as uniformly as possible for all $$T_X \in \mathcal{P}^{(n)}(X).$$
That is, \( f \) maps \( \left\lfloor |\mathcal{T}_X|/|\mathcal{T}_{g(T_X)}| \right\rfloor \) or \( \left\lceil |\mathcal{T}_X|/|\mathcal{T}_{g(T_X)}| \right\rceil \) sequences in \( \mathcal{T}_X \) to each sequence in \( \mathcal{T}_{g(T_X)} \). For this code \( f \), and for \( \alpha = 1 + s > 1 \), we have

\[
\frac{1}{n} D_{1+s}(P_{Y^n} \| Q_Y^n) = \frac{1}{n_s} \log \sum_{y^n} P_{Y^n}(y^n)^{1+s} Q_Y^n(y^n)^{-s}
\]

\[
= \frac{1}{n_s} \log \sum_{T_Y} \sum_{y^n \in T_Y} \left( \sum_{T_X \in g^{-1}((T_Y))} \sum_{x^n \in T_X} P_X^n(x^n) \mathbb{1} \{ y^n = f(x^n) \} \right)^{1+s} Q_Y^n(y^n)^{-s}
\]

\[
\leq \frac{1}{n_s} \log \sum_{T_Y} \sum_{y^n \in T_Y} \left( \sum_{T_X \in g^{-1}((T_Y))} \varphi_1(T_X, T_Y) + \varphi_2(y^n, T_X, T_Y) \right)^{1+s} e^{-n_s \mathbb{E}_Y \log Q_Y(y)},
\]

where

\[\varphi_1(T_X, T_Y) := e^{n \mathbb{E}_X T_X(x) \log P_X(x)} \left( \frac{|\mathcal{T}_X|}{|\mathcal{T}_Y|} \right) \mathbb{1} \{ |\mathcal{T}_X| \geq |\mathcal{T}_Y| \},\]

\[\varphi_2(y^n, T_X, T_Y) := e^{n \mathbb{E}_X T_X(x) \log P_X(x)} \mathbb{1} \{ y^n \in f(T_X) \} \mathbb{1} \{ |\mathcal{T}_X| < |\mathcal{T}_Y| \},\]

and (104) follows from the construction of the code \( f \).

Observe that

\[\varphi_1(T_X, T_Y) \leq 2 \tilde{\varphi}_1(T_X, T_Y) := 2 e^{n \mathbb{E}_X T_X(x) \log P_X(x)} \left( \frac{|\mathcal{T}_X|}{|\mathcal{T}_Y|} \right) \mathbb{1} \{ |\mathcal{T}_X| \geq |\mathcal{T}_Y| \}.\]

Hence

\[
\frac{1}{n} D_{1+s}(P_{Y^n} \| Q_Y^n) \leq \frac{1}{n_s} \log \sum_{T_Y} \sum_{y^n \in T_Y} \left( \sum_{T_X \in g^{-1}((T_Y))} \tilde{\varphi}_1(T_X, T_Y) + \varphi_2(y^n, T_X, T_Y) \right)^{1+s} e^{-n_s \mathbb{E}_Y \log Q_Y(y)} + \frac{1}{n_s} \log 2^{1+s}
\]

\[
\leq \frac{1}{n_s} \log \sum_{T_Y} \sum_{y^n \in T_Y} \left( \sum_{T_X \in g^{-1}((T_Y))} \left( e^{n(1+s) \mathbb{E}_X T_X(x) \log P_X(x)} \mathbb{1} \{ |\mathcal{T}_X| \geq |\mathcal{T}_Y| \} \right) + e^{n(1+s) \mathbb{E}_X T_X(x) \log P_X(x)} \mathbb{1} \{ |\mathcal{T}_X| < |\mathcal{T}_Y| \} \right) e^{-n_s \mathbb{E}_Y \log Q_Y(y)} + o(1)
\]

\[
= \frac{1}{n_s} \log \max_{T_Y} \max_{T_X \in g^{-1}((T_Y))} \left( e^{-n(1+s) D(T_X \| P_X) - n_s H(T_X)} \mathbb{1} \{ |\mathcal{T}_X| \geq |\mathcal{T}_Y| \} + e^{n(1+s) \mathbb{E}_X T_X(x) \log P_X(x) + n_s H(T_X)} \mathbb{1} \{ |\mathcal{T}_X| < |\mathcal{T}_Y| \} \right) e^{-n_s \mathbb{E}_Y \log Q_Y(y)} + o(1)
\]

\[
= \frac{1}{s} \max_{T_X} \left\{ - (1 + s) D(T_X \| P_X) + s D(T_X \| Q_Y) + s (H(T_Y) - H(T_X)) \right\} \mathbb{1} \{ |\mathcal{T}_X| = |\mathcal{T}_{g(T_X)}| \} + o(1),
\]

where in (109), the sum operation \( \sum_{T_X \in g^{-1}((T_Y))} \) is taken outside the \( (\cdot)^{1+s} \) since by the fact that the number of \( n \)-types \( T_X \) is polynomial in \( n \), we have

\[
\left( \sum_{T_X \in g^{-1}((T_Y))} \tilde{\varphi}_1(T_X, T_Y) + \varphi_2(y^n, T_X, T_Y) \right)^{1+s} e^{-n_s \mathbb{E}_Y \log Q_Y(y)}
\]

\[
= \max_{T_X \in g^{-1}((T_Y))} \left( \tilde{\varphi}_1(T_X, T_Y) + \varphi_2(y^n, T_X, T_Y) \right)^{1+s} e^{-n_s \mathbb{E}_Y \log Q_Y(y)} + o(1)
\]

\[
= \sum_{T_X \in g^{-1}((T_Y))} \left( \tilde{\varphi}_1(T_X, T_Y) + \varphi_2(y^n, T_X, T_Y) \right)^{1+s} e^{-n_s \mathbb{E}_Y \log Q_Y(y)} + o(1);
\]

and (112) also follows from the fact that the number of \( n \)-types \( T_X \) (or \( T_Y \)) is polynomial in \( n \).
For each $T_X$, choose $g(T_X)$ as the $T_Y$ that minimizes the expression in (115). Then we obtain

$$\limsup_{n \to \infty} \frac{1}{n} D_{1+s}(P_Y \| Q_Y^n)$$

$$\leq \limsup_{n \to \infty} \max_{T_X} \min_{T_Y} \left\{ -\frac{1+s}{s} D(T_X \| P_X) + D(T_Y \| Q_Y) + [H(T_Y) - H(T_X)]^+ \right\}$$

$$= \max_{\tilde{P}_X \in \mathcal{P}(X)} \min_{\tilde{P}_Y \in \mathcal{P}(Y)} \max_{t \in [0,1]} \left\{ -\frac{1+s}{s} D(\tilde{P}_X \| P_X) + D(\tilde{P}_Y \| Q_Y) + t \left( H(\tilde{P}_Y) - H(\tilde{P}_X) \right) \right\}$$

$$= \max_{\tilde{P}_X \in \mathcal{P}(X)} \max_{t \in [0,1]} \min_{\tilde{P}_Y \in \mathcal{P}(Y)} \left\{ tH(\tilde{P}_Y) - \frac{1+s}{s} D(\tilde{P}_X \| P_X) - tH(\tilde{P}_X) \right\}$$

$$= \max_{t \in [0,1]} \left\{ tH(\tilde{P}_Y) - \frac{1+s}{s} D(\tilde{P}_X \| P_X) - tH(\tilde{P}_X) \right\},$$

where (119) follows from Lemma 3, the swapping of min and max in (121) follows from the fact that the objective function is convex and concave in $P_Y$ and $t$ respectively, $P_Y$ resides in a compact, convex set (the probability simplex) and $t$ resides in a convex set $[0,1]$ (Sion’s minimax theorem [28]); and (122) and (123) follow from Lemma 8.

For $\alpha = 1+s \in (0,1)$, similar to (115), we can show that

$$\limsup_{n \to \infty} \frac{1}{n} D_{1+s}(P_Y \| Q_Y^n)$$

$$\leq \max_{T_X} \left\{ -\frac{1}{s} D(T_X \| P_X) + sD(T_Y \| Q_Y) + s \left[ H(T_Y) - H(T_X) \right]^+ \right\}_{T_Y=g(T_X)}.$$  

For each $T_X$, choose $g(T_X)$ as the $T_Y$ that maximizes the expression in (124). Then similarly we obtain that

$$\limsup_{n \to \infty} \frac{1}{n} D_{1+s}(P_Y \| Q_Y^n)$$

$$\leq \limsup_{n \to \infty} \min_{T_Y} \max_{T_X} \left\{ -\frac{1+s}{s} D(T_X \| P_X) + sD(T_Y \| Q_Y) + s \left[ H(T_Y) - H(T_X) \right]^+ \right\}$$

$$= \min_{\tilde{P}_X \in \mathcal{P}(X)} \max_{\tilde{P}_Y \in \mathcal{P}(Y)} \min_{t \in [0,1]} \left\{ \frac{1+s}{s} D(\tilde{P}_X \| P_X) + D(\tilde{P}_Y \| Q_Y) + t \left( H(\tilde{P}_Y) - H(\tilde{P}_X) \right) \right\}$$

$$= \min_{t \in [0,1]} \max_{\tilde{P}_X \in \mathcal{P}(X)} \min_{\tilde{P}_Y \in \mathcal{P}(Y)} \left\{ \frac{1+s}{s} D(\tilde{P}_X \| P_X) + D(\tilde{P}_Y \| Q_Y) + t \left( H(\tilde{P}_Y) - H(\tilde{P}_X) \right) \right\}$$

$$= \max_{t \in [0,1]} \left\{ tH(\tilde{P}_Y) - \frac{1+s}{s} D(\tilde{P}_X \| P_X) - tH(\tilde{P}_X) \right\},$$

where (126) follows from Lemma 3 (Note that here $s < 0$).

**Converse:** Consider an optimal function $f : \mathcal{X}^k \to \mathcal{Y}^m$ attaining the minimum of $\frac{1}{n} D_{1+s}(P_Y \| Q_Y^n)$. Since $|\mathcal{P}(\mathcal{Y})| \leq (n+1)^{|\mathcal{Y}|}$, by the pigeonhole principle, we have that for every $T_X$, there exists a type $T_Y = g(T_X)$ such that at least $\frac{1}{(n+1)^{|\mathcal{Y}|}} |T_Y|$ sequences in $T_X$ are mapped through $f$ to the sequences in $T_Y$. Hence for such $T_Y = g(T_X)$, we have

$$\sum_{y^n \in T_Y} |f^{-1}(\{y^n\})| \cap T_X = |f^{-1}(T_Y) \cap T_X| \geq \frac{1}{(n+1)^{|\mathcal{Y}|}} |T_X|.$$

For $s > 0$, we have

$$\frac{1}{n} D_{1+s}(P_Y \| Q_Y^n) = \frac{1}{ns} \log \sum_{T_Y} \sum_{y^n \in T_Y} \left( \sum_{T_X} \sum_{x^n \in T_X} P_X^n(x^n) \mathbb{1}_{\{y^n = f(x^n)\}} \right)^{1+s} Q_Y^n(y^n)^{-s}$$

$$\geq \frac{1}{ns} \log \sum_{T_Y} \sum_{y^n \in T_Y} \left( \max_{T_X} \sum_{x^n \in T_X} P_X^n(x^n) \mathbb{1}_{\{y^n = f(x^n)\}} \right)^{1+s} Q_Y^n(y^n)^{-s}$$

$$\geq \frac{1}{ns} \log \max_{T_X} \sum_{T_Y} \sum_{y^n \in T_Y} \left( \sum_{x^n \in T_X} P_X^n(x^n) \mathbb{1}_{\{y^n = f(x^n)\}} \right)^{1+s} Q_Y^n(y^n)^{-s}.$$
\[ \geq \frac{1}{n^s} \log_{T_X} \left( \sum_{y^n \in T_{Y'}} \left( \sum_{x^n \in T_{X'}} P_X^n(x^n) \mathbb{1} \{ y^n = f(x^n) \} \right)^{1+s} Q_Y^n(y^n)^{-s} \right)_{T_Y = g(T_X)} \]

\[ = \frac{1}{n^s} \log_{T_X} \left( e^{n(1+s) \sum_s T_X(x) \log P_X(x) - ns \sum_s T_Y(y) \log Q_Y(y)} \sum_{y^n \in T_{Y'}} |f^{-1}(\{y^n\}) \cap T_{TX}|^{1+s} \right)_{T_Y = g(T_X)} \] (134)

By Lemma 7,

\[ \sum_{y^n \in T_{Y'}} |f^{-1}(\{y^n\}) \cap T_{TX}|^{1+s} \]

\[ \geq |T_{TY}| \left( \frac{1}{(n+1)^s} \frac{|T_{TX}|}{|T_{TY}|} \right)^{1+s} 1\{|T_{TX}| \geq |T_{TY}| \} + |T_{TX}| 1\{|T_{TX}| < |T_{TY}| \} \] (135)

\[ \geq e^{(1+s)nH(T_X) - snH(T_Y)} 1\{|T_{TX}| \geq |T_{TY}| \} + e^{nH(T_X)} 1\{|T_{TX}| < |T_{TY}| \} \] (136)

Therefore,

\[ \frac{1}{n} D_{1+s}(P_Y^n \| Q_Y^n) \geq \frac{1}{n^s} \log_{T_X} \left( e^{n(1+s) \sum_s T_X(x) \log P_X(x) - ns \sum_s T_Y(y) \log Q_Y(y)} \times \left( e^{(1+s)nH(T_X) - snH(T_Y)} 1\{|T_{TX}| \geq |T_{TY}| \} + e^{nH(T_X)} 1\{|T_{TX}| < |T_{TY}| \} \right) \right)_{T_Y = g(T_X)} + o(1) \]

\[ = \frac{1}{s} \max_{T_X} \left\{ - (1+s) D(T_X \| P_X) + s D(T_Y \| Q_Y) + s [H(T_Y) - H(T_X)]^+ \right\}_{T_Y = g(T_X)} + o(1) \] (137)

\[ \geq \max_{T_X} \min_{T_Y} \left\{ \frac{1}{s} \left( - 1 + s \right) D(T_X \| P_X) + D(T_Y \| Q_Y) + [H(T_Y) - H(T_X)]^+ \right\} + o(1) \] (138)

\[ = \max_{t \in [0,1]} \left\{ t H \frac{1}{s} (Q_Y) - t H \frac{1+s}{s+n+s} (P_X) \right\} + o(1), \] (140)

where (140) follows from the derivations in (119)-(123).

For \( s < 0 \), following derivations similar to (130)-(138), we have

\[ \frac{1}{n} D_{1+s}(P_Y^n \| Q_Y^n) \geq \frac{1}{s} \max_{T_X} \left\{ - (1+s) D(T_X \| P_X) + s D(T_Y \| Q_Y) + s [H(T_Y) - H(T_X)]^+ \right\}_{T_Y = g(T_X)} + o(1) \] (141)

\[ \geq \min_{T_X} \max_{T_Y} \left\{ - \frac{1}{s} \left( 1 + s \right) D(T_X \| P_X) + D(T_Y \| Q_Y) + [H(T_Y) - H(T_X)]^+ \right\} + o(1) \] (142)

\[ = \max_{t \in [0,1]} \left\{ t H \frac{1}{s} (Q_Y) - t H \frac{1+s}{s+n+s} (P_X) \right\} + o(1), \] (143)

where (143) follows from the derivations in (125)-(129).

**Appendix C**

**Proof of Theorem 2**

Similar to the proof in Appendix B, we only prove the case of \( R = 1 \).

**Achievability:** By the equality \( D_{\alpha}(Q \| P) = \frac{\alpha}{\alpha - \alpha} D_{1-\alpha}(P \| Q) \) for \( \alpha \in (0,1) \), the case \( \alpha \in (0,1) \) has been proven in Theorem 1, so here we only need to consider the case \( \alpha > 1 \).

We consider the following mapping. For each \( T_X \), partition \( T_{TX} \) into \( a_{TX} = |\{ T_Y : H(T_X) \geq H(T_Y) + \delta \}| \) subsets with size \( \left[ \frac{|T_Y|}{a_{TX}} \right] \) or \( \left[ \frac{|T_Y|}{a_{TX}} \right] \). For each \( T_Y \) such that \( H(T_X) \geq H(T_Y) + \delta \), map the sequences in each subset to the sequences in the set \( T_{TY} \) as uniformly as possible, such that \( \left[ \frac{|T_Y|}{a_{TX}} \right] / |T_{TY}| \) or \( \left[ \frac{|T_Y|}{a_{TX}} \right] / |T_{TY}| \) (for subsets with size \( \left[ \frac{|T_Y|}{a_{TX}} \right] \)) or \( \left[ \frac{|T_Y|}{a_{TX}} \right] / |T_{TY}| \) or \( \left[ \frac{|T_Y|}{a_{TX}} \right] / |T_{TY}| \) (for subsets with size \( \left[ \frac{|T_Y|}{a_{TX}} \right] \)).

If there is no such \( T_Y \), then map the sequences in \( T_{TX} \) into any sequences in \( \mathcal{Y}^n \).
For this code and for $s > 0$, we have

$$
\frac{1}{n} D_{1+s}(Q^X \parallel P_Y^n)
= \frac{1}{ns} \log \sum_{y^n} Q^X_n(y^n)^{1+s} P_Y^n(y^n)^{-s}
= \frac{1}{ns} \log \sum_{T_Y} \sum_{y^n \in T_Y} \left( \sum_{T_X} \sum_{x^n \in T_X} P^n_X(x^n) 1 \{ y^n = f(x^n) \} \right) Q^X_n(y^n)^{1+s}
\leq \frac{1}{ns} \log \sum_{T_Y} \sum_{y^n \in T_Y} \left( \sum_{T_X: H(T_X) \geq H(T_Y) + \delta} e^{n \sum_x T_X(x) \log P_X(x) \left( \frac{|T_X|}{nT_Y} - 1 \right)} \right)^{-s} Q^X_n(y^n)^{1+s}
\leq \frac{1}{ns} \log \sum_{T_Y} \sum_{y^n \in T_Y} \left( \sum_{T_X: H(T_X) \geq H(T_Y) + \delta} e^{n \sum_x T_X(x) \log P_X(x) \left( e^{n(H(T_X) - H(T_Y) + o(1))} - 2 \right)} \right)^{-s} e^{(1+s)n \sum_x T_Y(y) \log Q_Y(y)}
\leq \frac{1}{ns} \log \sum_{T_Y} \sum_{y^n \in T_Y} \left( \sum_{T_X: H(T_X) \geq H(T_Y) + \delta} e^{-nD(T_X \parallel P_X) - nH(T_Y) + o(1)} \left( 2 - 2e^{-n(\delta + o(1))} \right) \right)^{-s} e^{(1+s)n \sum_x T_Y(y) \log Q_Y(y)}
= \frac{1}{ns} \log \sum_{T_Y} \sum_{y^n \in T_Y} \left( \sum_{T_X: H(T_X) \geq H(T_Y) + \delta} e^{-nD(T_X \parallel P_X) - nH(T_Y)} \right)^{-s} e^{(1+s)n \sum_x T_Y(y) \log Q_Y(y) + o(1)}
\leq \frac{1}{ns} \log \max_{T_Y} \min_{T_X: H(T_X) \geq H(T_Y) + \delta} \left\{ D(T_X \parallel P_X) - \frac{1+s}{s} D(T_Y \parallel Q_Y) \right\} + o(1)
= \max_{\tilde{P}_Y \in P(Y)} \min_{\tilde{P}_X \in P(X): H(\tilde{P}_X) \geq H(\tilde{P}_Y) + \delta} \left\{ D(\tilde{P}_X \parallel P_X) - \frac{1+s}{s} D(\tilde{P}_Y \parallel Q_Y) \right\} + o(1),
$$

where (150) follows from the fact that the number of $n$-types $T_X$ is polynomial in $n$. Therefore,

$$
\limsup_{n \to \infty} \frac{1}{n} D_{1+s}(Q^X \parallel P_Y^n)
\leq \max_{\tilde{P}_Y \in P(Y)} \min_{\tilde{P}_X \in P(X): H(\tilde{P}_X) \geq H(\tilde{P}_Y) + \delta} \left\{ D(\tilde{P}_X \parallel P_X) - \frac{1+s}{s} D(\tilde{P}_Y \parallel Q_Y) \right\}.
$$

Since $\delta > 0$ is arbitrary,

$$
\limsupinf_{n \to \infty} \frac{1}{n} D_{1+s}(Q^X \parallel P_Y^n)
\leq \max_{\tilde{P}_Y \in P(Y)} \min_{\tilde{P}_X \in P(X): H(\tilde{P}_X) \geq H(\tilde{P}_Y)} \left\{ D(\tilde{P}_X \parallel P_X) - \frac{1+s}{s} D(\tilde{P}_Y \parallel Q_Y) \right\}
= \max_{\tilde{P}_Y \in P(Y)} \max_{t \in [0, \infty]} \min_{\tilde{P}_X \in P(X)} D(\tilde{P}_X \parallel P_X) - \frac{1+s}{s} D(\tilde{P}_Y \parallel Q_Y) + t \left( H(\tilde{P}_Y) - H(\tilde{P}_X) \right)
= \max_{t \in [0, \infty]} \max_{\tilde{P}_Y \in P(Y)} \min_{\tilde{P}_X \in P(X)} \left\{ t H_{1+s}^{\frac{1}{1+s}}(Q_Y) - t H_{1+s}^{\frac{1}{1+s}}(P_X) \right\}.
$$
Converse: For $s > 0$, we have
\[
\frac{1}{n} D_{1+s} (Q^n_Y \| P_Y^n) = \frac{1}{ns} \log \sum_{y^n} Q^n_Y (y^n)^{1+s} P_Y^n (y^n)^{-s} 
\]
\[
= \frac{1}{ns} \log \sum_{T_Y} \sum_{y^n \in T_Y} \left( \sum_{T_X} \sum_{x^n \in T_X} P^n_X (x^n) 1 \{ y^n = f(x^n) \} \right)^{-s} e^{(1+s)n \sum_T y^n \log Q(y)} 
\]
\[
\geq \frac{1}{ns} \log \sum_{T_Y} \sum_{y^n \in T_Y \setminus \cup_{T_X : H(T_X) < H(T_Y) - \delta} f(T_X)} \left( \sum_{T_X} \sum_{x^n \in T_X} P^n_X (x^n) 1 \{ y^n = f(x^n) \} \right)^{-s} 
\times e^{(1+s)n \sum_T y^n \log Q(y)} 
\]
\[
= \frac{1}{ns} \log \sum_{T_Y} \sum_{y^n \in T_Y \setminus \cup_{T_X : H(T_X) < H(T_Y) - \delta} f(T_X)} \left( \sum_{T_X : H(T_X) \geq H(T_Y) - \delta} \sum_{x^n \in T_X} P^n_X (x^n) 1 \{ y^n = f(x^n) \} \right)^{-s} 
\times e^{(1+s)n \sum_T y^n \log Q(y)}. 
\]

Observe that
\[
A := \sum_{y^n \in T_Y \setminus \cup_{T_X : H(T_X) < H(T_Y) - \delta} f(T_X)} \sum_{T_X : H(T_X) \geq H(T_Y) - \delta} \sum_{x^n \in T_X} P^n_X (x^n) 1 \{ y^n = f(x^n) \} 
\]
\[
\leq \sum_{T_X : H(T_X) \geq H(T_Y) - \delta} \sum_{x^n \in T_X} P^n_X (x^n) 
\]
\[
= \sum_{T_X : H(T_X) \geq H(T_Y) - \delta} e^{-n D(T_X \| P_X)} 
\]
\[
= e^{-n D(T_Y \| P_Y)}. 
\]

and
\[
N := \left| T_Y \setminus \bigcup_{T_X : H(T_X) < H(T_Y) - \delta} f(T_X) \right| 
\]
\[
\geq e^{nH(T_Y)} - \sum_{T_X : H(T_X) < H(T_Y) - \delta} e^{nH(T_X)} 
\]
\[
\geq e^{nH(T_Y)} - \max_{T_X : H(T_X) < H(T_Y) - \delta} e^{nH(T_X)} 
\]
\[
= e^{nH(T_Y)} - e^{n(H(T_Y) - \delta)} 
\]
\[
= e^{nH(T_Y)}. 
\]

Hence by Lemma 7 with the identifications $\beta = -s$, $m = A$, $n = N$, and $b_i = \sum_{T_X : H(T_X) \geq H(T_Y) - \delta} \sum_{x^n \in T_X} P^n_X (x^n) 1 \{ y^n = f(x^n) \}$, we have
\[
\frac{1}{n} D_{1+s} (Q^n_Y \| P_Y^n) \geq \frac{1}{ns} \log \sum_{T_Y} N \left( \frac{A}{N} \right)^{-s} e^{(1+s)n \sum_T y^n \log Q(y)} 
\]
\[
\geq \frac{1}{ns} \log \sum_{T_Y} e^{nH(T_Y)} \left( \sum_{T_X : H(T_X) \geq H(T_Y) - \delta} e^{-n D(T_X \| P_X) - n H(T_Y)} \right)^{-s} e^{(1+s)n \sum_T y^n \log Q(y) + o(1)} 
\]
\[
= \frac{1}{ns} \log \sum_{T_Y} e^{nH(T_Y)} \left( \max_{T_X : H(T_X) \geq H(T_Y) - \delta} e^{-n D(T_X \| P_X) - n H(T_Y)} \right)^{-s} e^{(1+s)n \sum_T y^n \log Q(y) + o(1)} 
\]
\[
= \frac{1}{ns} \log \max_{T_Y} \min_{T_X : H(T_X) \geq H(T_Y) - \delta} e^{nD(T_X \| P_X) + (1+s)n D(T_X \| P_X) - n H(T_Y)} e^{(1+s)n \sum_T y^n \log Q(y) + o(1)} 
\]
and analogous to (151), we can prove that

\begin{equation}
\max_{T_y} \min_{T_x \in H(T_y) \geq H(T_y) - \delta} \left\{ D(T_X \Vert P_X) - \frac{1+s}{s} D(T_Y \Vert Q_Y) \right\} + o(1) 
\end{equation}

\begin{equation}
= \max_{\tilde{P}_y \in P(Y)} \min_{\tilde{P}_x \in P(X) \cap H(\tilde{P}_x) \geq H(\tilde{P}_y) - \delta} \left\{ D(\tilde{P}_X \Vert P_X) - \frac{1+s}{s} D(\tilde{P}_Y \Vert Q_Y) \right\} + o(1).
\end{equation}

Since \( \delta > 0 \) is arbitrary, letting \( \delta \to 0 \) we have

\begin{equation}
\liminf_{n \to \infty} \frac{1}{n} D_{1+s}(Q^n_Y \Vert P^n_Y) \geq \max_{T_y} \min_{T_x \in g^{-1}(\{T_y\})} \left\{ D(\tilde{P}_X \Vert P_X) - \frac{1+s}{s} D(\tilde{P}_Y \Vert Q_Y) \right\}
\end{equation}

\begin{equation}
= \max_{i \in [0,1]} tH_{1+s} \left( \frac{1}{1+s} \right)(Q) - tH_{1+s} \left( \frac{1}{1+s} \right)(P),
\end{equation}

where (179) follows from the derivation (154)-(158).

**APPENDIX D**

**PROOF OF THEOREM 3**

In the following, we only prove the case of \( R = 1 \). In addition, we only prove the case \( \alpha = 1+s > 1 \). Other cases can be proven by similar proof techniques.

**Achievability:** Given two type-to-type functions \( g_1 : \mathcal{P}^{(n)}(\mathcal{X}) \to \mathcal{P}^{(n)}(\mathcal{Y}), g_2 : \mathcal{P}^{(n)}(\mathcal{Y}) \to \mathcal{P}^{(n)}(\mathcal{X}) \), we consider a mapping \( g \) that maps a set \( \{T_X\} \) of \( n \)-types on \( \mathcal{X} \) to the set \( g_1(\{T_X\}) \cup g_2^{-1}(\{T_X\}) \) of \( n \)-types on \( \mathcal{Y} \), i.e., \( g(\{T_X\}) = g_1(\{T_X\}) \cup g_2^{-1}(\{T_X\}) \). We design \( g_2 \) such that it satisfies \( H(g_2(T_y)) \geq H(T_y) + \delta, \forall T_y \).

For each \( T_X \), denote \( \alpha_{T_X} = |g(\{T_X\})| \). Partition \( T_{T_X} \) into \( \alpha_{T_X} \) subsets with size \( \left\lfloor \frac{\tau_{T_X}}{\alpha_{T_X}} \right\rfloor \) or \( \left\lceil \frac{\tau_{T_X}}{\alpha_{T_X}} \right\rceil \), and for each \( T_Y \in g(\{T_X\}) \), map the sequences in each subset to the sequences in the set \( T_{T_Y} \), as uniformly as possible: \( \left\lfloor \frac{\tau_{T_X}}{\alpha_{T_X}} \right\rfloor / \left\lfloor \tau_{T_Y} \right\rfloor \) (for subsets with size \( \left\lfloor \frac{\tau_{T_X}}{\alpha_{T_X}} \right\rfloor \)) or \( \left\lfloor \frac{\tau_{T_X}}{\alpha_{T_X}} \right\rceil / \left\lfloor \tau_{T_Y} \right\rceil \) (for subsets with size \( \left\lceil \frac{\tau_{T_X}}{\alpha_{T_X}} \right\rceil \)).

For this code, and for \( \alpha = 1+s > 1 \), analogous to (114), we can prove that

\begin{equation}
\frac{1}{n} D_{1+s}(P^n_Y \Vert Q^n_Y) \leq \max_{T_y} \min_{T_x \in g^{-1}(\{T_y\})} \left\{ \frac{1+s}{s} D(T_X \Vert P_X) + D(T_Y \Vert Q_Y) + (H(T_Y) - H(T_X)) 1 \{ H(T_X) < H(T_Y) \} \right\} + o(1)
\end{equation}

and analogous to (151), we can prove that

\begin{equation}
\frac{1}{n} D_{1+s}(Q^n_Y \Vert P^n_Y) \leq \max_{T_y} \min_{T_x \in g^{-1}(\{T_y\}) \cap H(T_X) \geq H(T_Y) + \delta} \left\{ D(T_X \Vert P_X) - \frac{1+s}{s} D(T_Y \Vert Q_Y) \right\} + o(1).
\end{equation}

Therefore,

\begin{equation}
\frac{1}{n} D_{1+s}(P^n_Y, Q^n_Y) \leq \max_{T_y} \min_{T_x \in g^{-1}(\{T_y\}) \cap H(T_X) \geq H(T_Y) + \delta} \left\{ D(T_X \Vert P_X) - \frac{1+s}{s} D(T_Y \Vert Q_Y) \right\} + o(1) \tag{182}
\end{equation}

\begin{equation}
\leq \max_{T_y} \min_{T_x \in g^{-1}(\{T_y\}) \cap H(T_X) \geq H(T_Y) + \delta} \left\{ D(T_X \Vert P_X) - \frac{1+s}{s} D(T_Y \Vert Q_Y) \right\} \left\vert_{T_X = g_2(T_Y)} \right. + o(1)
\end{equation}

\begin{equation}
= \max_{T_y} \min_{T_X \in g^{-1}(\{T_y\}) \cap H(T_X) \geq H(T_Y) + \delta} \left\{ \frac{1+s}{s} D(T_X \Vert P_X) + D(T_Y \Vert Q_Y) + (H(T_Y) - H(T_X)) 1 \{ H(T_X) < H(T_Y) \} \right\} + o(1)
\end{equation}

\begin{equation}
\max_{T_y} \min_{T_X \in g^{-1}(\{T_y\}) \cap H(T_X) \geq H(T_Y) + \delta} \left\{ D(T_X \Vert P_X) - \frac{1+s}{s} D(T_Y \Vert Q_Y) \right\} + o(1)
\end{equation}

\begin{equation}
\max_{T_Y} \min_{T_X \in g^{-1}(\{T_Y\}) \cap H(T_X) \geq H(T_Y) + \delta} \left\{ \frac{1+s}{s} D(T_X \Vert P_X) + D(T_Y \Vert Q_Y) + (H(T_Y) - H(T_X)) 1 \{ H(T_X) < H(T_Y) \} \right\} + o(1)
\end{equation}

\begin{equation}
= \max_{T_Y} \min_{T_X \in g^{-1}(\{T_Y\}) \cap H(T_X) \geq H(T_Y) + \delta} \left\{ \frac{1+s}{s} D(T_X \Vert P_X) + D(T_Y \Vert Q_Y) \right\} \left\vert_{T_X = g_2(T_Y)} \right. + o(1)
\end{equation}
\[
D(T_X \parallel P_X) - \frac{1+s}{s} D(T_Y \parallel Q_Y) \bigg|_{T_X = g_2(T_Y)} \bigg) + o(1).
\] (184)

Choose the function \( g_1(T_X) \) as the function \( g(T_X) \) given in Appendix B. Then as shown in Appendix B, we have
\[
\min_{T_Y} \max_{T_X \in g_1^{-1}(T_Y)} - \frac{1+s}{s} D(T_X \parallel P_X) + D(T_Y \parallel Q_Y) + (H(T_Y) - H(T_X)) \mathbb{1} \{ H(T_X) < H(T_Y) \}
\leq \max_{t \in [0,1]} \left\{ tH_{\frac{1}{1+t}}(Q_Y) - tH_{\frac{1+s}{1+s+t}}(P_X) \right\} + o(1). \tag{185}
\]

For each \( T_Y \), choose \( g_2(T_Y) \) as a \( T_X \) that satisfies \( H(T_X) \geq H(T_Y) + \delta \) and at the same time minimizes
\[
\max \left\{ - \frac{1+s}{s} D(T_X \parallel P_X) + D(T_Y \parallel Q_Y) \right\}. \tag{186}
\]

Then we obtain that
\[
\frac{1}{n} \frac{1}{n} D_{\alpha_{\max}}(P_{Y^n}, Q_{Y^n})
\leq \max_{t \in [0,1]} \left\{ tH_{\frac{1}{1+t}}(Q_Y) - tH_{\frac{1+s}{1+s+t}}(P_X) \right\} + o(1),
\max_{T_Y} \min_{T_X : H(T_X) \geq H(T_Y) + \delta} \max \left\{ - \frac{1+s}{s} D(T_X \parallel P_X) + D(T_Y \parallel Q_Y) \right\}
\leq \max_{t \in [0,1]} \left\{ tH_{\frac{1}{1+t}}(Q_Y) - tH_{\frac{1+s}{1+s+t}}(P_X) \right\} + o(1),
\max_{\tilde{P}_Y \in \mathcal{P}(Y)} \max_{\tilde{P}_X \in \mathcal{P}(X); H(\tilde{P}_X) \geq H(\tilde{P}_Y)} \max \left\{ - \frac{1+s}{s} D(\tilde{P}_X \parallel P_X) + D(\tilde{P}_Y \parallel Q_Y) \right\}
\leq \max_{t \in [0,1]} \left\{ tH_{\frac{1}{1+t}}(Q_Y) - tH_{\frac{1+s}{1+s+t}}(P_X) \right\},
\max_{\tilde{P}_Y \in \mathcal{P}(Y)} \max_{\tilde{P}_X \in \mathcal{P}(X); H(\tilde{P}_X) \geq H(\tilde{P}_Y)} \left\{ \frac{1+s}{s} D(\tilde{P}_X \parallel P_X) \right\}
\leq \max_{t \in [0,1]} \left\{ tH_{\frac{1}{1+t}}(Q_Y) - tH_{\frac{1+s}{1+s+t}}(P_X) \right\}.
\] (187)

Since \( \delta > 0 \) is arbitrary and all the functions in (188) are continuous, we have
\[
\lim_{n \to \infty} \sup_{n} \frac{1}{n} D_{\alpha_{\max}}(P_{Y^n}, Q_{Y^n})
\leq \max_{t \in [0,1]} \left\{ tH_{\frac{1}{1+t}}(Q_Y) - tH_{\frac{1+s}{1+s+t}}(P_X) \right\},
\]
\[
\max_{\tilde{P}_Y \in \mathcal{P}(Y)} \max_{\tilde{P}_X \in \mathcal{P}(X); H(\tilde{P}_X) \geq H(\tilde{P}_Y)} \left\{ \frac{1+s}{s} D(\tilde{P}_X \parallel P_X) \right\}
\leq \max_{t \in [0,1]} \left\{ tH_{\frac{1}{1+t}}(Q_Y) - tH_{\frac{1+s}{1+s+t}}(P_X) \right\},
\max_{t \in [0,1]} \left\{ \frac{1+s}{s} (1+t) H_{\frac{1+s}{1+s+t}}(Q_Y) - \frac{1+s}{s} (1+t) H_{\frac{1+s}{1+s+t}}(P_X) \right\},
\max_{t \in [0,1]} \left\{ tRH_{\frac{1+s}{1+s+t}}(Q_Y) - tH_{\frac{1+s}{1+s+t}}(P_X) \right\}
\leq \max_{t \in [0,1]} \left\{ tH_{\frac{1}{1+t}}(Q_Y) - tH_{\frac{1+s}{1+s+t}}(P_X) \right\},
\] (189)
\[\text{(190)}\]
\[\text{(191)}\]

\[
\max_{t \in [1/\alpha, \infty]} \left\{ tH_{1/\alpha}^{\max}(Q_Y) - tH_{1/\alpha}^{\min}(P_X) \right\} \quad (192)
\]

\[
\max_{t \in [0, \infty]} \left\{ tRH_{1/\alpha}^{\max}(Q_Y) - tH_{1/\alpha}^{\min}(P_X) \right\} = \max_{t \in [0, 1]} \left\{ tH_{1/\alpha}^{\max}(Q_Y) - tH_{1/\alpha}^{\min}(P_X) \right\} \quad (193)
\]

\[
\max_{t \in [0, 1]} \left\{ tH_{1/\alpha}^{\max}(Q_Y) - tH_{1/\alpha}^{\min}(P_X) \right\} \quad (194)
\]

Converse: By the converse part of Theorem 1, we have

\[
\lim_{n \to \infty} \frac{1}{n} D_{\alpha}^{\max}(P_{Y^n}, Q_Y^n) \geq \max_{t \in [0, 1]} \left\{ tH_{1/\alpha}^{\max}(Q_Y) - tH_{1/\alpha}^{\min}(P_X) \right\} \quad (195)
\]

Next we prove

\[
\lim_{n \to \infty} \frac{1}{n} D_{\alpha}^{\max}(P_{Y^n}, Q_Y^n) \geq \max_{t \in [0, \infty]} \left\{ tH_{1/\alpha}^{\max}(Q_Y) - tH_{1/\alpha}^{\min}(P_X) \right\} \quad (196)
\]

For \( s > 0 \), we have

\[
\frac{1}{n} D_{1+s}(Q_Y^n \parallel P_{Y^n}) = \frac{1}{ns} \log \sum_{y^n} Q_Y^n(y^n)^{1+s} P_{Y^n}(y^n)^{-s} \quad (197)
\]

\[
\geq \frac{1}{ns} \log \sum_{y^n} \sum_{x^n \in \mathcal{T}_{Y^n}} \left( \sum_{x^n \in \mathcal{T}_{Y^n}} P_X^n(x^n) \right)^s e^{(1+s)n \sum_y T_Y(y) \log Q_Y(y)} \quad (198)
\]

\[
\geq \frac{1}{ns} \log \sum_{y^n \in \mathcal{T}_{Y^n} \setminus \mathcal{U}_{T_X}(H(T_X) < H(T_Y) - \delta)} \left( \sum_{x^n \in \mathcal{T}_{Y^n}} P_X^n(x^n) \right)^s e^{(1+s)n \sum_y T_Y(y) \log Q_Y(y)} \quad (199)
\]

\[
\geq \frac{1}{ns} \log \sum_{y^n \in \mathcal{T}_{Y^n} \setminus \mathcal{U}_{T_X}(H(T_X) < H(T_Y) - \delta)} \left( \sum_{x^n \in \mathcal{T}_{Y^n}} P_X^n(x^n) \right)^s e^{(1+s)n \sum_y T_Y(y) \log Q_Y(y)} \quad (200)
\]

Same as (166) and (171), we have

\[
N := \left| \mathcal{T}_{Y^n} \setminus \bigcup_{T_X : H(T_X) < H(T_Y) - \delta} f(T_{Y^n}) \right| \quad (201)
\]

\[
\geq e^{n H(T_Y)} \quad (202)
\]

and

\[
A := \sum_{y^n \in \mathcal{T}_{Y^n} \setminus \mathcal{U}_{T_X}(H(T_X) < H(T_Y) - \delta)} \sum_{x^n \in \mathcal{T}_{Y^n}} \sum_{T_X : H(T_X) \geq H(T_Y) - \delta} P_X^n(x^n) \left\{ y^n = f(x^n) \right\} \quad (203)
\]

\[
\leq e^{-n H(T_Y) - \delta} \max_{T_X : H(T_X) \geq H(T_Y) - \delta} e^{-n D(T_X \parallel P_X)} \quad (204)
\]

Furthermore, \( A \) can be lower bounded as follows.

\[
A \geq \min_{T_X : H(T_X) \geq H(T_Y) - \delta} e^{n \sum_x T_X(x) \log P_X(x)} \quad (205)
\]

\[
\geq e^{n H(T_Y)} \min_{T_X : H(T_X) \geq H(T_Y) - \delta} e^{n \sum_x T_X(x) \log P_X(x)} \quad (206)
\]
Define $r := -\frac{1}{n} \log A$. Then

$$
\min_{T_X: H(T_X) \geq H(T_Y) - \delta} D(T_X \| P_X) \leq r \leq -H(T_Y) - \min_{T_X: H(T_X) \geq H(T_Y) - \delta} \sum_x T_X(x) \log P_X(x). \tag{207}
$$

Hence by Lemma 7, we have

$$
\frac{1}{n} D_{1+s}(Q_Y^n \| P_{Y^n}) \geq \frac{1}{n^s} \log \sum_{T_Y} N \left( \frac{A}{N} \right)^{-s} e^{(1+s)n \sum_y T_Y(y) \log Q_Y(y)} \tag{208}
$$

$$
= \frac{1}{n^s} \log \sum_{T_Y} e^{(1+s)n H(T_Y)} A^{-s} e^{(1+s)n \sum_y T_Y(y) \log Q_Y(y)} + o(1) \tag{209}
$$

$$
= \frac{1}{n^s} \log \sum_{T_Y} A^{-s} e^{-(1+s)D(T_Y \| Q_Y)} + o(1) \tag{210}
$$

$$
= \max_{T_Y} \left\{ r - \frac{1 + s}{s} D(T_Y \| Q_Y) \right\} + o(1). \tag{211}
$$

On the other hand,

$$
\frac{1}{n} D_{1+s}(P_{Y^n} \| Q_Y^n) \geq \frac{1}{n^s} \log \sum_{T_Y} \sum_{y^n \in T_Y} \left( \sum_{T_X: x^n \in T_X} P_X^n(x^n) 1 \{ y^n = f(x^n) \} \right)^{1+s} \tag{212}
$$

$$
\geq \frac{1}{n^s} \log \sum_{T_Y} \sum_{y^n \in T_Y \setminus \bigcup_{T_X: H(T_X) < H(T_Y) - \delta} f(T_X)} \left( \sum_{T_X: x^n \in T_X} P_X^n(x^n) 1 \{ y^n = f(x^n) \} \right)^{1+s} \tag{213}
$$

$$
= \frac{1}{n^s} \log \sum_{T_Y} \sum_{y^n \in T_Y \setminus \bigcup_{T_X: H(T_X) < H(T_Y) - \delta} f(T_X)} \left( \sum_{T_X: H(T_X) \geq H(T_Y) - \delta} \sum_{x^n \in T_X} P_X^n(x^n) 1 \{ y^n = f(x^n) \} \right)^{1+s} \tag{214}
$$

$$
\geq \frac{1}{n^s} \log \sum_{T_Y} N \left( \frac{A}{N} \right)^{1+s} Q_Y^n(y^n)^{-s} \tag{215}
$$

$$
= \frac{1}{n^s} \log \sum_{T_Y} e^{-sn H(T_Y)} A^{1+s} e^{-sn \sum_y T_Y(y) \log Q_Y(y)} + o(1) \tag{216}
$$

$$
= \frac{1}{n^s} \log \sum_{T_Y} A^{1+s} e^{ns D(T_Y \| Q_Y)} + o(1) \tag{217}
$$

$$
= \max_{T_Y} \left\{ D(T_Y \| Q_Y) - \frac{1 + s}{s} r \right\} + o(1). \tag{218}
$$

Combining (211) and (218), we have

$$
\frac{1}{n} D_{1+s}^{\max}(P_{Y^n}, Q_Y^n) \geq \max_{T_Y} \left\{ \max \left\{ D(T_Y \| Q_Y) - \frac{1 + s}{s} r, r - \frac{1 + s}{s} D(T_Y \| Q_Y) \right\} \right\} + o(1) \tag{219}
$$

$$
\geq \max_{T_Y} \left\{ r - \min_{T_X: H(T_X) \geq H(T_Y) - \delta} D(T_X \| P_X) \leq r \leq \min_{T_X: H(T_X) \geq H(T_Y) - \delta} \sum_x T_X(x) \log P_X(x) \right\} + o(1). \tag{220}
$$
Since $\delta > 0$ is arbitrary and all the functions involved in (220) are continuous, letting $\delta \to 0$ we have

$$
\liminf_{n \to \infty} \frac{1}{n} D_{\alpha}^\max(P_{Y^n}, Q_Y^n) \\
\geq \max_{\tilde{P}_Y \in \mathcal{P}(Y)} \left\{ \min_{r : \min_{P_X \in \mathcal{P}(X)} H(P_X) \geq H(\tilde{P}_Y), \min_{\tilde{P}_X \in \mathcal{P}(X)} H(\tilde{P}_X) \geq H(\tilde{P}_Y) + \min_{P_X \in \mathcal{P}(X)} \sum_x \tilde{P}_X(x) \log P_X(x)} \right. \\
\left. \max \left\{ D(\tilde{P}_Y \| Q_Y) - \frac{1}{s} \frac{1}{r} D(\tilde{P}_Y \| Q_Y) \right\} \right\} \\
= \max_{\tilde{P}_Y \in \mathcal{P}(Y)} \left\{ \min_{r : \min_{t \in [0, \infty]} t H(\tilde{P}_Y) \leq r \leq \min_{t \in [0, \infty]} (1+t) H(\tilde{P}_Y) - (1+t) H(\tilde{P}_Y)} \left( \min_{t \in [0, \infty]} t H(\tilde{P}_Y) - t H_{\frac{1}{1+t}} (P_X) \right) \left( \frac{1+s}{s} D(\tilde{P}_Y \| Q_Y) \right) \right\} (221)
$$

$$
= \max_{t \in [0, \infty]} \left\{ \min_{t \in [0, \infty]} t H(\tilde{P}_Y) - t H_{\frac{1}{1+t}} (P_X), \max_{t \in [0, \infty]} t H_{\frac{1}{1+t}} (Q_Y) - t H_{\frac{1}{1+t}} (P_X) \right\} (222)
$$

$$
= \max_{t \in [\frac{1}{2}, \infty]} \left\{ t H_{\frac{1}{1+t}} (Q_Y) - t H_{\frac{1}{1+t}} (P_X), \max_{t \in [0, \infty]} t H_{\frac{1}{1+t}} (Q_Y) - t H_{\frac{1}{1+t}} (P_X) \right\} (223)
$$

$$
= \max_{t \in [0, \infty]} \left\{ \frac{1+s}{s} D(\tilde{P}_Y \| Q_Y) - \frac{1+s}{s} D(\tilde{P}_Y \| Q_Y) \right\} (224)
$$

$$
= \max_{t \in [0, \infty]} \left\{ \frac{1+s}{s} (1+t) H_{\frac{1}{1+t}} (Q_Y) - \frac{1+s}{s} (1+t) H_{\frac{1}{1+t}} (P_X), \max_{t \in [0, \infty]} t H_{\frac{1}{1+t}} (Q_Y) - t H_{\frac{1}{1+t}} (P_X) \right\} (225)
$$

**APPENDIX E**

**PROOF OF THEOREM 4**

The equality in (23) follows from Theorem 1. For (24), the case $\alpha = 0$ can be proven easily. The converse parts for the cases $\alpha \in (0, 1) \cup \{ \infty \}$ follow from (23). The achievability parts for $\alpha \in [1, \infty)$ follow from (26). The achievability parts for $\alpha \in (0, 1)$ are implied by the achievability part for $\alpha = 1$, since the conversion rates for these cases are all equal to $\frac{H(P_X)}{H(Q_Y)}$. Hence here we only need to prove (26).

Define $\mathcal{A} := \{ y^n : Q_Y^n(y^n) \geq e^{-n H(Q_Y) + \delta} \}$ for $\delta > 0$. Define $\tilde{Q}_Y^n(y^n) := \frac{Q_Y^n(y^n)}{Q_Y^n(y^n) \in \mathcal{A}}1 \{ y^n \in \mathcal{A} \}$. Use Mapping 1 given in Appendix E to map the sequences in $\mathcal{A}^k$ to the sequences in $\mathcal{A}$, where the distributions $P_X$ and $Q_Y$ respectively replace by $P_X^k$ and $\tilde{Q}_Y^n$. That is, for each $i \in [1 : |X|^k]$, $x_i^k$ is mapped to $y_i^n$ where $j = G_Y^{-1}(G_X(i))$. Hence the following properties hold:

1. If $P_X^k(x_i^k) \geq \tilde{Q}_Y^n(y_i^n)$ where $i := G_Y^{-1}(G_X(j))$, then $\{ i : G_Y^{-1}(G_X(i)) = j \} \leq 1$. Hence $P_Y^n(y^n) \leq P_X^k(x_i^k)$.
2. If $P_X^k(x_i^k) < \tilde{Q}_Y^n(y_i^n)$ where $i := G_Y^{-1}(G_X(j))$, then $\{ i : G_Y^{-1}(G_X(i)) = j \} \geq 1$ and

$$
\frac{1}{2} \tilde{Q}_Y^n(y_i^n) \leq P_Y^n(y^n) \leq \tilde{Q}_Y^n(y_i^n) + P_X^k(x_i^k).
$$

3. $P_Y^n(y^n) = 0$ for $y^n \notin \mathcal{A}$.

For brevity, we denote $i(y^n) := G_Y^{-1}(G_X(j))$ where $j$ is the index of $y^n$, and denote $j(x_i^k) := G_Y^{-1}(G_X(i))$ where $i$ is the index of $x_i^k$.

For this code, and for $0 \leq s \leq 1$, we have

$$
D_{1+s}(P_Y^n \| Q_Y^n) \\
= \frac{1}{s} \log \sum_{y^n} P_Y^n(y^n)^{1+s} Q_Y^n(y^n)^{-s} \\
\leq \frac{1}{s} \log \sum_{y^n} P_Y^n(y^n) \left( P_X^k(x_i^k(y_i^n)) \right)^s \left( P_X(x_i^k(y_i^n)) \right) \\
\leq \frac{1}{s} \log \sum_{y^n} P_Y^n(y^n) \left( P_X^k(x_i^k(y_i^n)) \right)^s \left( P_X(x_i^k(y_i^n)) \right) \\
+ \tilde{Q}_Y^n(y_i^n)^s \left( 1 + \frac{P_X^k(x_i^k(y_i^n))}{\tilde{Q}_Y^n(y_i^n)} \right)^s \\
= \frac{1}{s} \log \sum_{y^n} P_Y^n(y^n) \left( P_X^k(x_i^k(y_i^n)) \right)^s \left( P_X(x_i^k(y_i^n)) \right) \\
+ \tilde{Q}_Y^n(y_i^n)^s \left( 1 + \frac{P_X^k(x_i^k(y_i^n))}{\tilde{Q}_Y^n(y_i^n)} \right)^s \\
= \frac{1}{s} \log \sum_{y^n} P_Y^n(y^n) \left( P_X^k(x_i^k(y_i^n)) \right)^s \left( P_X(x_i^k(y_i^n)) \right) \\
+ \tilde{Q}_Y^n(y_i^n)^s \left( 1 + \frac{P_X^k(x_i^k(y_i^n))}{\tilde{Q}_Y^n(y_i^n)} \right)^s
$$

\[ \leq \frac{1}{s} \log \sum_{y^n} P_{Y^n}(y^n) \left( P_{X^n}(x^n_{i(y^n)}) \right) \sum_{y^n} P_{Y^n}(y^n) \left( P_{X^n}(x^n_{i(y^n)}) \right) \left( \frac{P_{X^n}(x^n_{i(y^n)})}{Q_{Y^n}(y^n)} \right)^s \]

\[ + \bar{Q}_{Y^n}(y^n)^s \left( 1 + \left( \frac{P_{X^n}(x^n_{i(y^n)})}{Q_{Y^n}(y^n)} \right)^s \right) \left( \frac{P_{X^n}(x^n_{i(y^n)})}{Q_{Y^n}(y^n)} \right)^s \]

\[ = \frac{1}{s} \log Q^n_{Y^n}(A)^{-s} \sum_{y^n} P_{Y^n}(y^n) \left( \frac{P_{X^n}(x^n_{i(y^n)})}{Q_{Y^n}(y^n)} \right)^s + 1 \left( \frac{P_{X^n}(x^n_{i(y^n)})}{Q_{Y^n}(y^n)} \right)^s \]

\[ \leq \frac{1}{s} \log Q^n_{Y^n}(A)^{-s} \sum_{y^n} P_{Y^n}(y^n) \left( \frac{P_{X^n}(x^n_{i(y^n)})}{Q_{Y^n}(y^n)} \right)^s + 1 \]

\[ \leq - \log Q^n_{Y^n}(A) + \frac{1}{s} Q^n_{Y^n}(A)^{-s} \sum_{y^n} P_{Y^n}(y^n) \left( \frac{P_{X^n}(x^n_{i(y^n)})}{Q_{Y^n}(y^n)} \right)^s \]

(230)

where (230) follows from Lemma 6. To show \( D_{1+s}(P_{Y^n}||Q^n_{Y^n}) \to 0 \), we only need to show both terms in (233) converge to zero. Obviously, the first term converges to zero since \( Q^n_{Y^n}(A) \to 1 \). Next we focus on the second term.

\[ \sum_{y^n} P_{Y^n}(y^n) \left( \frac{P_{X^n}(x^n_{i(y^n)})}{Q_{Y^n}(y^n)} \right)^s \]

\[ \leq \sum_{y^n} P_{Y^n}(y^n) \left( P_{X^n}(x^n_{i(y^n)}) \geq \bar{Q}_{Y^n}(y^n) \right) + \left( \bar{Q}_{Y^n}(y^n) + P_{X^n}(x^n_{i(y^n)}) \right) \left( \frac{P_{X^n}(x^n_{i(y^n)})}{Q_{Y^n}(y^n)} \right)^s \]

\[ \leq \sum_{y^n} P_{Y^n}(y^n) \left( P_{X^n}(x^n_{i(y^n)}) \geq \bar{Q}_{Y^n}(y^n) \right) + 2 \bar{Q}_{Y^n}(y^n) \left( P_{X^n}(x^n_{i(y^n)}) < \bar{Q}_{Y^n}(y^n) \right) \left( \frac{P_{X^n}(x^n_{i(y^n)})}{Q_{Y^n}(y^n)} \right)^s \]

(234)

\[ \leq \sum_{x^n} P_{X^n}(x^n) \left( \frac{P_{X^n}(x^n)}{Q_{Y^n}(y^n)} \right)^s \left( P_{X^n}(x^n) \geq \bar{Q}_{Y^n}(y^n) \right) \]

\[ + 2 \sum_{j=1}^{|A|} \sum_{x^n \in B_j} P_{X^n}(x^n) \bar{Q}_{Y^n}(y^n) \left( \frac{P_{X^n}(x^n)}{Q_{Y^n}(y^n)} \right)^s \left( P_{X^n}(x^n) < \bar{Q}_{Y^n}(y^n) \right) \]

\[ \leq \sum_{x^n} P_{X^n}(x^n) \left( \frac{P_{X^n}(x^n)}{Q_{Y^n}(y^n)} \right)^s \left( P_{X^n}(x^n) \geq \bar{Q}_{Y^n}(y^n) \right) \]

\[ + 4 \sum_{x^n} P_{X^n}(x^n) \left( \frac{P_{X^n}(x^n)}{Q_{Y^n}(y^n)} \right)^s \left( P_{X^n}(x^n) < \bar{Q}_{Y^n}(y^n) \right) \]

(236)

where \( B_j \) denotes the set of \( x^n \) that are mapped to \( y^n_j \), (236) follows since \( P_{X^n}(x^n_{i(y^n)}) \leq P_{X^n}(x^n) \) for all \( x^n \) that are mapped to \( y^n \), and (237) follows since

\[ \sum_{x^n \in B_j} \frac{P_{X^n}(x^n)}{\bar{Q}_{Y^n}(y^n_j)} \left( \frac{P_{X^n}(x^n)}{Q_{Y^n}(y^n_j)} \right)^s \]

\[ = \sum_{x^n \in B_j} P_{X^n}(x^n) \bar{Q}_{Y^n}(y^n_j) \left( \frac{P_{X^n}(x^n)}{Q_{Y^n}(y^n_j)} \right)^s \]

\[ \leq \sum_{x^n \in B_j} \frac{1}{2} \bar{Q}_{Y^n}(y^n_j) \left( \frac{P_{X^n}(x^n)}{Q_{Y^n}(y^n_j)} \right)^s \]

\[ = 2 \sum_{x^n \in B_j} P_{X^n}(x^n) \left( \frac{P_{X^n}(x^n)}{Q_{Y^n}(y^n_j)} \right)^s \]

(239)

(240)

Next we prove \( \sum_{x^n} P_{X^n}(x^n) \left( \frac{P_{X^n}(x^n)}{Q_{Y^n}(y^n_j)} \right)^s \to 0 \).
Based on the notations defined in Appendix A-B, and using Lemma 9, we have

\[ Q^n_i(y^n_{G_X(i)}) = Q^n_i(y^n_{G^{(1)}_X (G_X(i))}) \] (242)

\[ \geq F^{-1}_Q(F^{-1}_P(x) \log P(x) + o(1)) \] (243)

\[ = e^{-n \log (e^{-k(E_{P_X}(-1/2 \log P(X(x_k)))) + o(1))} \] (244)

\[ = e^{-n \log (e^{-k(E_{P_X}(-1/2 \log P(X(x_k)))) + o(1))} \] (245)

\[ = \exp \left\{ -n \max_{t \in [0, \infty]} \left\{ h_1^{1+t}(Q_Y) - \frac{k}{t} \max_{t' \in [0, \infty]} \left\{ t'H_1^{1+t'}(P_X) + \frac{t'}{R} \log P(x^{(k)}_{x}) \right\} + o(1) \right\} \right\} \] (246)

where \( i \) in (242) denotes the index of \( x^n \) in the sequence \( x^n_1, x^n_2, \ldots, x^n_{|x^n|} \).

Therefore,

\[ \limsup_{n \to \infty} \frac{1}{n} \log \sum_{x^n} P^n_X(x^n) \left( \frac{P^n_X(x^n)}{Q^n_i(y^n_{G_X(i)})} \right)^s \] (247)

\[ \leq \limsup_{n \to \infty} \frac{1}{n} \log \sum_{x^n} \sum_{T_X} \sum_{x \in T_X} e^{\log \max_{t' \in [0, \infty]} \left\{ t'H_1^{1+t'}(P_X) + \frac{t'}{R} \log P(x^{(k)}_{x}) \right\} + o(1)} \] (248)

\[ = \limsup_{n \to \infty} \max_{T_X} \frac{k}{n} \left( H(T_X) + (1 + s) \sum_x T_X(x) \log P_X(x) \right) \] (249)

\[ + s \max_{t \in [0, \infty]} \left\{ H_1^{1+t}(Q_Y) - t \max_{t' \in [0, \infty]} \left\{ t'H_1^{1+t'}(P_X) + \frac{t'}{R} \log P(x^{(k)}_{x}) \right\} + o(1) \right\} \] (250)

\[ \leq \max_{t \in [0, \infty]} \min_{t' \in [0, \infty]} \max_{P_X \in P(X)} \frac{1}{R} \left( H(P_X) + (1 + s) \sum_x P_X(x) \log P_X(x) \right) \] (251)

\[ + s \left\{ H_1^{1+t}(Q_Y) - t \max_{t' \in [0, \infty]} \left\{ t'H_1^{1+t'}(P_X) + \frac{t'}{R} \log P_X(x^n) \right\} \right\} \] (252)

\[ = \max_{t \in [0, \infty]} \min_{t' \in [0, \infty]} \frac{C + s H_1^{1+t}(P_X) + sH_1^{1+t}(Q_Y) - \frac{sH_1^{1+t}(P_X)}{H^{1+t}}(H_1^{1+t}(P_X) - H_1^{1+t+t}(P_X)) \right\} \] (253)

\[ \leq \max_{t' \in [0, 1]} \left\{ s H_1^{1+t}(Q_Y) - \frac{s}{R} H^{1+t'}(P_X) \right\} \] (254)

\[ \leq \max_{t' \in [0, 1]} \left\{ s H_1^{1+t}(Q_Y) - \frac{s}{R} H^{1+t'}(P_X) \right\} \] (255)

where (250) follows from Lemma 9, and (254) follows by choosing \( t' = \frac{s}{1+st} \).

Therefore, if

\[ R < \min_{t' \in [0, 1]} \frac{H^{1+t'}(P_X)}{H^{1+t'}(Q_Y)} \] (256)

then

\[ \limsup_{n \to \infty} \frac{1}{n} \log \sum_{x^n} P^n_X(x^n) \left( \frac{P^n_X(x^n)}{Q^n_i(y^n_{G_X(i)})} \right)^s < 0. \] (257)
Hence $\sum x^n P^k_X(x^n) \left( \frac{P^k_Y(y^n)}{Q^k_Y(y^n)} \right)^s \to 0$. This completes the proof for $0 \leq s \leq 1$. For other $s$, it can be proven similarly (by other inequalities in Lemma 6).

APPENDIX F

PROOF OF THEOREM 5

The equality in (27) follows from Theorem 2. For (28), the case $\alpha = 0$ can be proven easily. The cases $\alpha \in (0, 1] \cup \{\infty\}$ follow by showing the achievability parts for $\alpha = 1$ and $\alpha = \infty$. Next we prove these.

Here we assume that both $P_X$ and $Q_Y$ are not uniform. The cases that $P_X$ is uniform or $Q_Y$ is uniform will be proven in Theorems 8 and 11, respectively.

Achievability part for $\alpha = 1$: Define

$$
\mathcal{A} := \left\{ x^k : e^{-k(H(P_X) + \delta)} \leq P^k_X(x^k) \leq e^{-k(H(P_X) - \delta)} \right\} \tag{258}
$$

$$
\mathcal{B} := \left\{ y^n : e^{-n(H(Q_Y) + \delta)} \leq Q^k_Y(y^n) \leq e^{-n(H(Q_Y) - \delta)} \right\}. \tag{259}
$$

Here $\delta > 0$ is a number such that $H(P_X) + \delta < H_0(P_X)$ and $\frac{1}{R} (H(P_X) - \delta) > H(Q_Y) + \delta$. We consider the following mapping.

1) Map the sequences in $\mathcal{A}^c$ to the sequences in $\mathcal{B}^c$ such that for each $y^n \in \mathcal{B}^c$, there exists at least one $x^n \in \mathcal{A}^c$ mapped to it. This is feasible since

$$
\liminf_{n \to \infty} \frac{1}{n} \log |\mathcal{A}^c| = \liminf_{n \to \infty} \frac{1}{n} \log \left( |\mathcal{X}|^n - |\mathcal{A}| \right) \geq \liminf_{n \to \infty} \frac{1}{n} \log \left( e^{kH_0(P_X)} - e^{k(H(P_X) + \delta)} \right) = \frac{H_0(P_X)}{R} \geq H_0(Q_Y) \geq \limsup_{n \to \infty} \frac{1}{n} \log |\mathcal{B}^c|, \tag{260}
$$

i.e., $|\mathcal{A}^c| > |\mathcal{B}^c|$ for sufficiently large $n$.

2) Use Mapping 1 given in Appendix I-E to map the sequences in $\mathcal{A}$ to the sequences in $\mathcal{B}$, where the distributions $P_X$ and $Q_Y$ are respectively replaced by $P^k_X(x^k) \mathbb{I}(x^k \in \mathcal{A})$ and $Q^k_Y(y^n) \mathbb{I}(y^n \in \mathcal{B})$. Observe that $\frac{1}{R} (H(P_X) - \delta) > H(Q_Y) + \delta$ implies that $P^k_X(x^k) \leq Q^k_Y(y^n)$ for $x^k \in \mathcal{A}, y^n \in \mathcal{B}$ and sufficiently large $n$. Hence by the property of Mapping 1, for $m \in \{1, \ldots, |\mathcal{B}|\}$, $\frac{P^k_X(x^k)}{Q^k_Y(y^n)} \leq P^k_Y(x^k_m) \leq Q^k_Y(y^n_m) \leq P^k_Y(x^k_m) + P^k(y^n_m)$. By the asymptotic equipartition property [29], we know that this step can be roughly considered as mapping a uniform distribution (with a larger alphabet) to another one (with a smaller alphabet). For this code, and for sufficiently large $n$, we have

$$
D(Q^k_Y \parallel P^k_Y(x^n)) = \sum_{y^n \in \mathcal{B}} Q^k_Y(y^n) \log \frac{Q^k_Y(y^n)}{P^k_Y(x^n)} + \sum_{y^n \in \mathcal{B}^c} Q^k_Y(y^n) \log \frac{Q^k_Y(y^n)}{P^k_Y(x^n)} \tag{265}
$$

$$
\leq \sum_{m \in \{1, \ldots, |\mathcal{B}|\}} Q^k_Y(y^n_m) \log \left( \frac{P^k_X(A)}{Q^k_Y(y^n)} - P^k_X(x^k_m) \right) + \sum_{y^n \in \mathcal{B}^c} Q^k_Y(y^n) \log \left( \frac{\max_y Q_Y(y) (y^n_m)}{\min_x P_X(x)} \right)^n \tag{266}
$$

$$
= -\sum_{m \in \{1, \ldots, |\mathcal{B}|\}} Q^k_Y(y^n_m) \log \left( \frac{P^k_X(A)}{Q^k_Y(y^n)} - P^k_X(x^k_m) \right) + nQ^k_Y(B^c) \log \left( \frac{\max_y Q_Y(y)}{\min_x P_X(x)} \right)^n \tag{267}
$$

$$
\leq -Q^k_Y(B) \log \left( \frac{P^k_X(A)}{Q^k_Y(B)} - \max_{m \in \{1, \ldots, |\mathcal{B}|\}} P^k_X(x^k_m) \right) \tag{268}
$$

$$
\leq -Q^k_Y(B) \log \left( \frac{P^k_X(A)}{Q^k_Y(B)} - e^{-n(H(P_X) - \delta) - (H(Q_Y) + \delta)} \right) + nQ^k_Y(B^c) \log \left( \frac{\max_y Q_Y(y)}{\min_x P_X(x)} \right)^n \tag{269}
$$

$\rightarrow 0$ \tag{270}
where (270) follows from $\frac{1}{R} (H(P_X) - \delta) > H(Q_Y) + \delta$ and the fact $P_X^k(\mathcal{A})^c, Q_Y^k(\mathcal{B})^c \to 0$ exponentially fast, as shown in the following inequalities.

$$Q_Y^k(\mathcal{B}^c) = \sum_{y^n \in \mathcal{B}^c} Q_Y^n(y^n)$$

$$= \sum_{y^n \in \mathcal{B}^c} Q_Y^n(\mathcal{T}_{TV}) + \sum_{y^n \in \mathcal{B}^c} \mathcal{T}_{TV}$$

$$\leq \max_{TV} : \sum_{y^n \in \mathcal{B}^c} T_V(y) \log Q_Y^n(y) \geq H(Q_Y) + \delta$$

$$\leq e^{-n D(T_V \| Q_Y)} + \max_{TV} : \sum_{y^n \in \mathcal{B}^c} T_V(y) \log Q_Y^n(y) \leq H(Q_Y) - \delta$$

$$\leq e^{-n D(T_V \| Q_Y)} + e^{-n \min_{\mathcal{B}^c} \sum_{y^n \in \mathcal{B}^c} T_V(y) \log Q_Y^n(y) \leq H(Q_Y) - \delta} D(\hat{P}_V \| Q_Y)$$

$$\leq e^{-n E} = -e^{-n E}$$

$$\leq e^{-n E}$$

where $E := \min \left\{ \min_{\mathcal{B}^c} \sum_{y^n \in \mathcal{B}^c} T_V(y) \log Q_Y^n(y) \geq H(Q_Y) + \delta} D(\hat{P}_V \| Q_Y), \min_{\mathcal{B}^c} \sum_{y^n \in \mathcal{B}^c} T_V(y) \log Q_Y^n(y) \leq H(Q_Y) - \delta} D(\hat{P}_V \| Q_Y) \right\} > 0.$

Achievability part for $\alpha = \infty$: Partition $X^k$ into four parts:

$$A_1 := \left\{ x_k : P_X^k(x_k) > e^{-k(H(P_X) - \delta)} \right\},$$

$$A_2 := \left\{ x_k : e^{-k(H_x(P_X) - \delta)} < P_X^k(x_k) \leq e^{-k(H(P_X) - \delta)} \right\},$$

$$A_3 := \left\{ x_k : e^{-k(H_x(P_X) - \delta)} \leq P_X^k(x_k) \leq e^{-k(H_x(P_X) - \delta)} \right\},$$

$$A_4 := \left\{ x_k : P_X^k(x_k) < e^{-k(H_x(P_X) - \delta)} \right\}.$$

Define $E^* := E_{Q_Y}^{-1} \left( \frac{1}{P_X} \left( E_{P_X}(H^*(P_X)) \right) \right)$. Partition $Y^n$ into two parts:

$$B_1 := \left\{ y^n : Q_Y^k(y^n) \geq e^{-n E^*} \right\},$$

$$B_2 := \left\{ y^n : Q_Y^k(y^n) < e^{-n E^*} \right\}.$$

Consider the following mappings.

1) Map the sequences in $A_1 \cup A_4$ to those in $Y^n$ in any way.
2) Use Mapping 1 given in Appendix I-E to map the sequences in $A_2$ to the sequences in $B_1$.
3) Use Mapping 2 given in Appendix I-E to map the sequences in $A_3$ to the sequences in $B_2$.

Assume

$$R < \min_{\alpha \in [0, \infty]} \frac{H_{\mathcal{T}_{TV}}(P_X)}{H_{\mathcal{T}_{TV}}(Q_Y)}.$$

By Lemma 11, we have

$$\frac{1}{R} \hat{E}_{P_X}(R_j) < \hat{E}_{Q_Y}(j), \forall j \in 1 \frac{1}{R} [H(P_X), -1 \sum_{x \in X} \log P_X(x)]$$

$$R < \frac{H_0(P_X)}{H_0(Q_Y)}.$$

We first prove $\log \max_{y^n \in B_1} \frac{Q_Y^n(y^n)}{P_X^n(y^n)} \to 0$. Observe that $P_X^k(A_2), Q_Y^k(B_1) \to 1$ as $n \to \infty$. Define $\tilde{P}_X^k(x_k) := \frac{P_X^k(x_k) 1 \{ x_k \in A_2 \}}{P_X^k(A_2)}$ and $\tilde{Q}_Y^n(y^n) := \frac{Q_Y^n(y^n) 1 \{ y^n \in B_1 \}}{Q_Y^n(B_1)}$. To prove $\log \max_{j \in B_1} \frac{Q_Y^n(y^n)}{P_X^n(y^n)} \to 0$, we only need to prove $\log \max_{y^n \in B_1} \frac{Q_Y^n(y^n)}{P_X^n(y^n)} \to 0$, where $P_Y^n(y^n) := \frac{P_X^n(y^n) 1 \{ y^n \in A_2 \}}{P_X^n(A_2)}$. Define $J_1 := \frac{1}{R} [H(P_X) - \delta, H(P_X)]$ and $J_2 := \frac{1}{R} [H(P_X), H(P_X) - \delta]$. Then for $j \in J_2$, we have that

$$\lim_{k \to \infty} -\frac{1}{k} \log \left( 1 - F_{\tilde{P}_X^k}(j) \right)$$

$$= \lim_{k \to \infty} -\frac{1}{k} \log \tilde{P}_X^k \left( x_k : -\frac{1}{k} \log \tilde{P}_X^k(x_k) \geq j \right)$$

$$= \lim_{k \to \infty} -\frac{1}{k} \log \frac{1}{P_X^k(A_2)} P_X^k \left( x_k \in A_2 : -\frac{1}{k} \log \frac{P_X^k(x_k)}{P_X^k(A_2)} \geq j \right)$$

$$= \lim_{k \to \infty} -\frac{1}{k} \log P_X^k \left( x_k \in A_2 : -\frac{1}{k} \log P_X^k(x_k) \geq j + o(1) \right)$$

$$= \hat{E}_{P_X}(j).$$
where (288) follows from Lemma 12. Similarly, for \( j \in [H_\infty(Q_Y), E^*), \)

\[
\lim_{n \to \infty} \frac{1}{n} \log \left( 1 - F_{Q_Y^n}(j) \right) = \tilde{E}_{Q_Y}(j),
\]

(289)

Observe that by Lemma 9, \( \tilde{E}_{Q_Y}(j) \) is continuous. Hence (283) implies that there exists some \( \epsilon > 0 \) such that for any \( j \in J_2, \)

\[
\frac{1}{R} \tilde{E}_{P_X}(R_j) \leq \tilde{E}_{Q_Y}(j - \epsilon) - \epsilon.
\]

(290)
i.e.,

\[
\limsup_{n \to \infty} \frac{1}{n} \log \sup_{j \in J_2} \frac{1 - F_{Q_Y^n}(j - \epsilon)}{1 - F_{P_X^n}(R_j)} \leq -\epsilon.
\]

(291)
or equivalently,

\[
\liminf_{n \to \infty} \inf_{\theta \in F_{P_X^n}(R, J_2)} \left\{ \frac{1}{R} \frac{F_{P_X^{-1}}(\theta)}{F_{Q_Y^{-1}}(\theta)} - F_{Q_Y^n}(1 - (1 - \theta)e^{-n\epsilon}) \right\} \geq \epsilon.
\]

(292)

Since \( F_{Q_Y^n}^{-1}(\theta) \) is nonincreasing in \( \theta, \) (292) implies

\[
\liminf_{n \to \infty} \inf_{\theta \in F_{P_X^n}(R, J_1)} \left\{ \frac{1}{R} \frac{F_{P_X^{-1}}(\theta)}{F_{Q_Y^{-1}}(\theta)} - F_{Q_Y^n}(\theta) \right\} \geq \epsilon.
\]

(293)

On the other hand, by choosing \( \delta > 0 \) small enough, we have \( H(Q_Y) < \frac{1}{R}(H(P_X) - \delta). \) This implies that for some \( \epsilon > 0, \)

\[
\liminf_{n \to \infty} \inf_{\theta \in F_{P_X^n}(R, J_1)} \left\{ \frac{1}{R} \frac{F_{P_X^{-1}}(\theta)}{F_{Q_Y^{-1}}(\theta)} - F_{Q_Y^n}(\theta) \right\} \geq \epsilon.
\]

(294)

Combining (293) and (294) gives us that for some \( \epsilon > 0, \)

\[
\liminf_{n \to \infty} \inf_{\theta \in F_{P_X^n}(R, J_1 \cup J_2)} \left\{ \frac{1}{R} \frac{F_{P_X^{-1}}(\theta)}{F_{Q_Y^{-1}}(\theta)} - F_{Q_Y^n}(\theta) \right\} \geq \epsilon.
\]

(295)

Observe that \( F_{P_X^{-1}}(\theta) \) is finite, hence (293) also holds if \( R \) is replaced with \( \frac{1}{R}. \) Furthermore, similarly in Subsection I-E, we sort the elements in \( A_2 \) as \( x_1^1, x_2^1, ..., x_{|A_2|}^1 \) such that \( P_{X_k}(x_1^1) \geq P_{X_k}(x_2^1) \geq ... \geq P_{X_k}(x_{|A_2|}^1). \) Define \( \tilde{G}_{X_k}(i) := \tilde{P}_{X_k}(x_l^1 : l \leq i) \) and \( \tilde{G}_{X_k}^{-1}(\theta) := \max \left\{ i \in \mathbb{N} : \tilde{G}_{X_k}(i) \leq \theta \right\}. \) Similarly, for \( Q_Y^n, \) we define \( \tilde{G}_{Q_Y}(j) := \tilde{Q}_{Y^n}(y_l^j : l \leq j) \) and \( \tilde{G}_{Q_Y}^{-1}(\theta) := \min \left\{ j \in \mathbb{N} : \tilde{G}_{Q_Y}(j) \geq \theta \right\}. \) Hence the mapping used here is \( j = \tilde{G}_{Q_Y}^{-1}(\tilde{G}_{X_k}(i)). \) For each \( i \in [1 : |A_2|], \)

\( \tilde{G}_{X_k}(i) \in F_{P_X}(J), \) Hence we have

\[
\liminf_{n \to \infty} \inf_{i \in [1 : |A_2|]} \frac{1}{n} \log \frac{\tilde{Q}_{Y^n}(y_i^n)}{P_{X_k}(x_i^j)}
\]

\[
= \liminf_{n \to \infty} \inf_{i \in [1 : |A_2|]} \left\{ \frac{k}{n} F_{P_X}(\tilde{G}_{X_k}(i)) - F_{Q_Y^n}(\tilde{G}_{X_k}(i)) \right\}
\]

\[
\geq \liminf_{n \to \infty} \inf_{\theta \in F_{P_X}(R, J_1 \cup J_2)} \left\{ \frac{k}{n} F_{P_X}(\theta) - F_{Q_Y^n}(\theta) \right\}
\]

\[
\geq \epsilon,
\]

(296)

(297)

(298)

where \( j = \tilde{G}_{Q_Y}^{-1}(\tilde{G}_{X_k}(i)). \) Hence \( \frac{\tilde{Q}_{Y^n}(y_i^n)}{P_{X_k}(x_i^j)} \to 0 \) for any \( i \in [1 : |A_2|]. \) Therefore, we have

\[
\log \max_{j \in [1 : |B_1|]} \frac{\tilde{Q}_{Y^n}(y_j^n)}{P_{Y^n}(y_j^n)}
\]

\[
\leq \log \max_{j \in [1 : |B_1|]} \frac{\tilde{Q}_{Y^n}(y_j^n)}{P_{Y^n}(y_j^n)} - \max_{j \in [1 : |B_1|]} \frac{\tilde{Q}_{Y^n}(y_j^n)}{P_{X_k}(x_j^j)}
\]

\[
\to 0.
\]

(299)

(300)
Hence \( \log \max_{y^n \in \mathcal{B}_2} Q_Y^n(y^n) \rightarrow 0 \).

We next prove \( \log \max_{y^n \in \mathcal{B}_2} Q_Y^n(y^n) \leq 0 \). Observe that

\[
\lim_{n \to \infty} -\frac{1}{n} \log Q_Y^n(B_2) = \frac{1}{R} \left( \mathcal{E}_{P_X}(H^n(P_X)) \right) = \frac{1}{R} D(\text{Unif}(\mathcal{X}) \| P_X),
\]

\[
\lim_{n \to \infty} -\frac{1}{n} \log (|Y|^n p_0) = \frac{1}{R} H^n(P_X) - H_0(Q_Y) = \frac{1}{R} H_0(P_X) + \frac{1}{R} D(\text{Unif}(\mathcal{X}) \| P_X) - H_0(Q_Y)
\]

\[
> \frac{1}{R} D(\text{Unif}(\mathcal{X}) \| P_X),
\]

Hence for sufficiently large \( n \), it holds that

\[
Q_Y^n(B_2) + |Y|^n p_0 \leq P_X^k(\mathcal{A}_3),
\]

which implies that by Mapping 2, \( Q_Y^n(y^n) \leq P_Y^n(y^n) \) for \( y^n \in \mathcal{B}_2 \). That is, \( \log \max_{y^n \in \mathcal{B}_2} Q_Y^n(y^n) \leq 0 \).

**APPENDIX G**

**Proof of Theorem 6**

By the equality \( D_\alpha(Q \| P) = \frac{\alpha}{1 - \alpha} D_{1-\alpha}(P \| Q) \) for \( \alpha \in (0, 1) \), the case \( \alpha \in (0, 1) \) has been proven in Theorem 4. Furthermore, it is easy to verify that the mapping used to prove for case \( \alpha = 0 \) in Theorem 4 also satisfies \( D_0(Q_Y^n \| P_Y^n) \rightarrow 0 \). So this proves the case \( \alpha = 0 \). The case \( \alpha = 1 \) can be proven by a proof similar to that in Appendix F. In the following, we consider the case \( \alpha = \infty \).

We first prove the following bounds for the normalized and unnormalized Rényi conversion rates for general simulation problem (the seed and target distributions are not limited to product distributions). For general distributions \( P_X^n \) and \( Q_Y^n \), we use \( P_X^n \) to approximate \( Q_Y^n \). Define \( F_{P_X}^k(j) := P_X(x^k : -\frac{1}{k} \log P_X(x^k) < j) \) and \( F_{P_X}^{-1}(\theta) := \sup \{ j : F_{P_X}^k(j) \leq \theta \} \). For \( Q_Y^n \), we define \( F_{Q_Y^n} \) and \( F_{Q_Y^n}^{-1} \) similarly. Then we have the following bounds.

**Lemma 13.**

\[
\sup \left\{ R : \limsup_{\epsilon > 0} \limsup_{n \to \infty} \frac{1}{n} \log \sup_{j \geq 0} \frac{F_{P_X}^k(\frac{n}{k}(j - \epsilon))}{F_{Q_Y^n}(j)} \leq 0, \sup \limsup_{n \to \infty} \frac{1}{n} \log \sup_{j \geq 0} \frac{1 - F_{Q_Y^n}(j)}{1 - F_{P_X}^k(\frac{n}{k}(j - \epsilon))} \leq 0 \right\}
\]

\[
\geq \sup \left\{ R : \frac{1}{n} D_{\max}(P_Y^n, Q_Y^n) \rightarrow 0 \right\}
\]

\[
\geq \sup \left\{ R : D_{\max}(P_Y^n, Q_Y^n) \rightarrow 0 \right\}
\]

\[
\geq \sup \left\{ R : \liminf_{n \to \infty} \inf_{\theta \in [0, 1]} \left\{ \frac{k}{n} F_{P_X}^{-1}(\theta) - F_{Q_Y^n}^{-1}(\theta) \right\} > 0 \right\}.
\]

**Remark 20.** The upper bound can be rewritten as

\[
\sup \left\{ R : \inf \liminf_{n \to \infty} \inf_{\theta \in [0, e^{-n\epsilon}]} \frac{k}{n} F_{P_X}^{-1}(\theta e^{n\epsilon}) - F_{Q_Y^n}^{-1}(\theta) \geq 0, \inf \liminf_{n \to \infty} \inf_{\theta \in [0, 1]} \left\{ \frac{k}{n} F_{P_X}^{-1}(1 - (1 - \theta) e^{-n\epsilon}) - F_{Q_Y^n}^{-1}(\theta) \right\} \geq 0 \right\},
\]

and the lower bound can be further lower bounded by

\[
\sup \left\{ R : \inf \limsup_{n \to \infty} \sup_{j \geq 0} \left\{ F_{P_X}(\frac{n}{k}(j + \epsilon)) - F_{Q_Y^n}(j) \right\} < 0 \right\}.
\]

Similar expressions for bounds on the conversion rate under the TV distance measure can be found in [30].
Remark 21. By similar proofs, one can show a better upper bound and a better lower bound for the unnormalized Rényi conversion rate.

\[
\begin{align*}
&\sup \left\{ R : \sup_{\epsilon>0} \lim_{n \to \infty} \sup_{j \geq 0} \left\{ F_{P_{X^k}} \left( \frac{n}{k} (j - \epsilon) \right) - F_{Q_Y^n}(j) \right\} \leq 0 \right\} \\
&\geq \sup \left\{ R : D_{\infty}^{\text{max}}(P_{Y^n}, Q_Y^n) \to 0 \right\} \\
&\geq \sup \left\{ R : \lim_{n \to \infty} \inf_{\theta \in [0,1]} \left\{ \frac{k F_{P_{X^k}}^{-1}(\theta) - n F_{Q_Y^n}^{-1}(\theta)}{\theta} \right\} = \infty \right\}.
\end{align*}
\]

**Proof:** Achievability (Lower Bound): If \( \lim \inf_{n \to \infty} \inf_{\theta \in [0,1]} \left\{ \frac{k F_{P_{X^k}}^{-1}(\theta) - n F_{Q_Y^n}^{-1}(\theta)}{\theta} \right\} > 0 \), then there exists a sufficiently small \( \epsilon > 0 \) and a sufficiently large \( K \) such that \( \frac{k F_{P_{X^k}}^{-1}(\theta) - n F_{Q_Y^n}^{-1}(\theta)}{\theta} > 0 \) for any \( \theta \in [0,1] \) and for any \( k \geq K \). Assume \( x_1^k, x_2^k, \ldots, x_n \in \mathcal{X}^k \) is a sequence such that \( P_{X^k}(x_1^k) \geq P_{X^k}(x_2^k) \geq \ldots \geq P_{X^k}(x_n^k) \). Define \( G_{X^k}(i) = P_{X^k}(x_l^k : l \leq i) \) and \( G_{X^k}^{-1}(\theta) := \max \{ i \in \mathbb{N} : F_{X^k}(i) \leq \theta \} \). Similarly, for \( Q_Y^n \), we define \( G_{Y^n}(i) := Q_Y^n(y_l^i : l \leq i) \) and \( G_{Y^n}^{-1}(\theta) := \min \{ j \in \mathbb{N} : G_{Y^n}(j) \geq \theta \} \). Use Mapping 1 given in Appendix I-E to map the sequences in \( \mathcal{X}^k \) to the sequences in \( \mathcal{Y}^n \), where the distributions \( P_{X^k} \) and \( Q_Y^n \) are respectively replaced by \( P_{X^k} \) and \( Q_Y^n \). That is, for each \( i \in \{ 1 : |\mathcal{X}|^k \}, x_i^k \) is mapped to \( y_j^n \) where \( j = G_{Y^n}^{-1}(G_{X^k}(i)) \). Hence for each \( i \in \{ 1 : |\mathcal{Y}|^n \}, \)

\[
Q_Y^n(y_j^n) - P_{X^k}(x_i^k) \leq Q_Y^n(y_j^n) + P_{X^k}(x_i^k).
\]

where \( i = G_{X^k}^{-1}(G_{X^k}(j)) \). By the assumption, we have \( \frac{1}{n} \log \frac{P_{X^k}(x_i^k)}{Q_Y^n(y_j^n)} = F_{Q_Y^n}^{-1}(G_{X^k}(i)) - \frac{k}{n} F_{P_{X^k}}^{-1}(G_{X^k}(i)) < 0 \) for \( i = G_{X^k}^{-1}(G_{X^k}(j)) \). Hence \( \frac{P_{X^k}(x_i^k)}{Q_Y^n(y_j^n)} \to 0 \). Therefore, we have

\[
D_{\infty}(P_Y^n || Q_Y^n) = \max_{j} \log \frac{P_Y^n(y_j^n)}{Q_Y^n(y_j^n)} \leq \log \frac{Q_Y^n(y_j^n) + P_{X^k}(x_i^k)}{Q_Y^n(y_j^n)} \to 0, \quad (317)
\]

and

\[
D_{\infty}(Q_Y^n || P_Y^n) = \max_{j} \log \frac{Q_Y^n(y_j^n)}{P_Y^n(y_j^n)} \leq \log \frac{Q_Y^n(y_j^n) - P_{X^k}(x_i^k)}{Q_Y^n(y_j^n)} \to 0.
\]

Converse (Upper Bound): By Lemma 1, \( \frac{1}{n} D_{\infty}(P_Y^n || Q_Y^n) \leq \epsilon \) implies

\[
\frac{1}{n} \log \sup_{j \geq 0} P_Y^n \left( y^n : -\frac{1}{n} \log Q_Y^n(y^n) < j \right) \leq \log \sup_{y^n} Q_Y^n(y^n) \leq \epsilon.
\]

Therefore,

\[
P_Y^n \left( y^n : -\frac{1}{n} \log Q_Y^n(y^n) < j \right) \geq P_Y^n \left( y^n : -\frac{1}{n} \log P_Y^n(y^n) < j - \epsilon \right) = F_{P_Y^n}(j - \epsilon).
\]

Observe that \( Y^n \) is a function of \( X^n \). By [30, Lemma 3.5] we have

\[
F_{P_{X^k}} \left( \frac{n}{k} (j - \epsilon) \right) \leq F_{P_Y^n}(j - \epsilon).
\]

Therefore, combining this with (323) gives

\[
\limsup_{n \to \infty} \frac{1}{n} \log \sup_{j \geq 0} \frac{F_{P_{X^k}} \left( \frac{n}{k} (j - \epsilon) \right)}{F_{Q_Y^n}(j)} \leq \epsilon.
\]

On the other hand, (323) also implies

\[
P_Y^n \left( y^n : -\frac{1}{n} \log Q_Y^n(y^n) \geq j \right) \leq P_Y^n \left( y^n : -\frac{1}{n} \log P_Y^n(y^n) \geq j - \epsilon \right) = 1 - F_{P_Y^n}(j - \epsilon),
\]

and \( \frac{1}{n} D_{\infty}(Q_Y^n || P_Y^n) \leq \epsilon \) implies

\[
\frac{1}{n} \log \sup_{j \geq 0} \frac{1 - F_{Q_Y^n}(j)}{F_{Q_Y^n}(j)} \leq \frac{1}{n} \log \sup_{y^n} \frac{Q_Y^n(y^n)}{P_Y^n(y^n)} \leq \epsilon.
\]
Combining (327) and (328) gives

\[
\limsup_{k \to \infty} \frac{1}{n} \log \sup_{j \geq 0} \frac{1 - F_{Q^X_n}(j)}{1 - F_{P^X_k}(\frac{\epsilon}{n} (j - \epsilon))} \leq \epsilon.
\] (329)

Since \( \epsilon > 0 \) can be arbitrarily small,

\[
\sup_{\epsilon > 0} \limsup_{k \to \infty} \frac{1}{n} \log \sup_{j \geq 0} \frac{F_{P^X_k}(\frac{\epsilon}{n} (j - \epsilon))}{F_{Q^X_n}(j)} - \epsilon \leq 0,
\] (330)

\[
\sup_{\epsilon > 0} \limsup_{k \to \infty} \frac{1}{n} \log \sup_{j \geq 0} \frac{1 - F_{Q^X_n}(j)}{1 - F_{P^X_k}(\frac{\epsilon}{n} (j - \epsilon))} - \epsilon \leq 0.
\] (331)

These two inequalities are equivalent to

\[
\sup_{\epsilon > 0} \limsup_{k \to \infty} \frac{1}{n} \log \sup_{j \geq 0} \frac{F_{P^X_k}(\frac{\epsilon}{n} (j - \epsilon))}{F_{Q^X_n}(j)} \leq 0,
\] (332)

\[
\sup_{\epsilon > 0} \limsup_{k \to \infty} \frac{1}{n} \log \sup_{j \geq 0} \frac{1 - F_{Q^X_n}(j)}{1 - F_{P^X_k}(\frac{\epsilon}{n} (j - \epsilon))} \leq 0.
\] (333)

Now we turn back to proving Theorem 6. We first focus on the converse part. Consider product distributions \( P^X_k \) and \( Q^Y_\infty \). Then \( \sup_{\epsilon > 0} \limsup_{n \to \infty} \frac{1}{n} \log \sup_{j \geq 0} \frac{F_{P^X_k}(\frac{\epsilon}{n} (j - \epsilon))}{F_{Q^Y_\infty}(j)} \leq 0 \) and \( \sup_{\epsilon > 0} \limsup_{n \to \infty} \frac{1}{n} \log \sup_{j \geq 0} \frac{1 - F_{Q^Y_\infty}(j)}{1 - F_{P^X_k}(\frac{\epsilon}{n} (j - \epsilon))} \leq 0 \) respectively imply

\[
\frac{1}{R} E_{P^X}(R_j) \geq E_{Q^Y}(j), \forall j \in \frac{1}{R}[H_{\infty}(P^X), H(P^X)]
\] (334)

\[
\frac{1}{R} \tilde{E}_{P^X}(R_j) \leq \tilde{E}_{Q^Y}(j), \forall j \in \frac{1}{R}[H(P^X), H_{\infty}(P^X)].
\] (335)

By Lemma 11, \( R \leq \min_{\beta \in [0,1]} \frac{H_\beta(P^X)}{H_\beta(Q^Y)} \).

Now we prove the achievability part (lower bound). Assume \( R < \min_{\beta \in [0,1]} \frac{H_\beta(P^X)}{H_\beta(Q^Y)} \). Then by Lemma 11,

\[
\frac{1}{R} E_{P^X}(R_j) > E_{Q^Y}(j), \forall j \in \frac{1}{R}[H_{\infty}(P^X), H(P^X)]
\] (336)

\[
\frac{1}{R} \tilde{E}_{P^X}(R_j) < \tilde{E}_{Q^Y}(j), \forall j \in \frac{1}{R}[H(P^X), H_{\infty}(P^X)].
\] (337)

Since \( E_{Q^Y}(j) \) and \( \tilde{E}_{Q^Y}(j) \) are continuous, there exists a value \( \epsilon > 0 \) such that

\[
\frac{1}{R} E_{P^X}(R_j) > E_{Q^Y}(j - \epsilon) - \epsilon, \forall j \in \frac{1}{R}[H_{\infty}(P^X), H(P^X)]
\] (338)

\[
\frac{1}{R} \tilde{E}_{P^X}(R_j) < \tilde{E}_{Q^Y}(j - \epsilon) - \epsilon, \forall j \in \frac{1}{R}[H(P^X), H_{\infty}(P^X)].
\] (339)

That is,

\[
\limsup_{n \to \infty} \frac{1}{n} \log \sup_{j \geq 0} \frac{F_{P^X_k}(R_j)}{F_{Q^Y_\infty}(j - \epsilon)} \leq -\epsilon,
\] (340)

\[
\limsup_{n \to \infty} \frac{1}{n} \log \sup_{j \geq 0} \frac{1 - F_{Q^Y_\infty}(j - \epsilon)}{1 - F_{P^X_k}(R_j)} \leq -\epsilon,
\] (341)

which in turn respectively imply

\[
\liminf_{n \to \infty} \inf_{\theta \in [0,1]} \left\{ \frac{1}{R} F_{P^X_k}^{-1}(\theta e^{-n\epsilon}) - F_{Q^Y_\infty}^{-1}(\theta) \right\} \geq \epsilon,
\] (342)

\[
\liminf_{n \to \infty} \inf_{\theta \in [0,1]} \left\{ \frac{1}{R} F_{P^X_k}^{-1}(1 - (1 - \theta)e^{n\epsilon}) - F_{Q^Y_\infty}^{-1}(\theta) \right\} \geq \epsilon.
\] (343)

Since \( F_{P^X_k}^{-1}(\theta) \) is nondecreasing in \( \theta \), we have both (342) and (343) imply

\[
\liminf_{k \to \infty} \inf_{\theta \in [0,1]} \left\{ \frac{1}{R} F_{P^X_k}^{-1}(\theta) - F_{Q^Y_\infty}^{-1}(\theta) \right\} \geq \epsilon.
\] (344)

Therefore, (344) always holds. Observe that \( F_{P^X_k}^{-1}(\theta) \) is bounded for any \( \theta \in [0,1) \), hence (344) also holds if \( R \) is replaced with \( \frac{1}{2} \). Combining this with Lemma 13 completes the proof for the lower bound.
APPENDIX H
PROOF OF THEOREM 7

Define $A := \{ y^n : Q_Y^n(y^n) \geq e^{-n(H(Q_Y)+\delta)} \}$ for $\delta > 0$. Define $P_Y^\infty(y^n) := \frac{1}{M} \left[ \sum_{y \in A} Q_Y^n(y^n) \right]$ or $\frac{1}{M} \left[ \frac{pQ_Y^n(y^n)}{\mu Q_Y^n(A)} \right]$ for $y^n \in A$; 0 otherwise. Obviously, $P_Y^\infty$ is an M-type distribution. Note that this mapping corresponds to Mapping 1 given in Appendix I-E. For this mapping, we have

$$D_\infty(P_Y^\infty, Q_Y^n) = \log \max_{y^n} \frac{P_Y^\infty(y^n)}{Q_Y^n(y^n)}$$

$$\leq \log \max_{y^n \in A} \left( \frac{Q_Y^n(y^n)}{pQ_Y^n(y^n)} \right)$$

$$\leq \log \left( \frac{Q_Y^n(A)}{Q_Y^n(A)} + \frac{1}{M} \max_{y^n \in A} Q_Y^n(y^n) \right)$$

By the fact that $Q_Y^n(A) \to 1$ at least exponentially fast as $n \to \infty$, we have that for $\bar{R} > H(Q_Y) + \delta$, $D_\infty(P_Y^\infty, Q_Y^n) \to 0$ at least exponentially fast. Since $\delta > 0$ is arbitrary, we have for $\bar{R} > H(Q_Y)$, $D_\infty(P_Y^\infty, Q_Y^n) \to 0$ at least exponentially fast as $n \to \infty$.

APPENDIX I
PROOF OF THEOREM 8

Define $A := \{ y^n : Q_Y^n(y^n) \geq e^{-n(H(Q_Y)+\delta)} \}$. Set $P_Y^\infty(y^n) := \frac{1}{M} \left[ \sum_{y \in A} Q_Y^n(y^n) \right]$ for $y^n \notin A$ (this mapping corresponds to Mapping 2 given in Appendix I-E); $P_Y^\infty(y^n) := \frac{1}{M} \left[ \frac{pQ_Y^n(y^n)}{\mu Q_Y^n(A)} \right]$ for $y^n \in A$, where $p = 1 - \sum_{y^n \notin A} \frac{1}{M} \left[ \frac{Q_Y^n(y^n)}{\mu} \right]$.

$$D_\infty(Q_Y^n, P_Y^\infty) = \log \max_{y^n} \frac{Q_Y^n(y^n)}{P_Y^\infty(y^n)}$$

$$\leq \log \max_{y^n \in A} \frac{Q_Y^n(y^n)}{pQ_Y^n(y^n)}$$

$$\leq \log \max_{y^n \in A} \frac{Q_Y^n(\supp(Q_Y^n)) y^n}{Q_Y^n(A)}$$

$$\leq -\log \left( \frac{Q_Y^n(A)}{Q_Y^n(A)} - \frac{\supp(Q_Y^n) y^n}{Q_Y^n(A)} \right)$$

By the fact that $Q_Y^n(A) \to 1$ at least exponentially fast as $n \to \infty$, we have that for $\bar{R} > \max \{ H(0(Q_Y), H(Q_Y) + \delta) \}$, $D_\infty(Q_Y^n, P_Y^\infty) \to 0$ at least exponentially fast as $n \to \infty$. Since $\delta > 0$ is arbitrary, we have for $\bar{R} > H(0(Q_Y))$, $D_\infty(Q_Y^n, P_Y^\infty) \to 0$ at least exponentially fast as $n \to \infty$.

APPENDIX J
PROOF OF THEOREM 9

Define $A := \{ y^n : Q_Y^n(y^n) \geq e^{-n(\bar{R}-\delta)} \}$. Use the same mapping as the one in Appendix I. That is, set $P_Y^\infty(y^n) := \frac{1}{M} \left[ \frac{Q_Y^n(y^n)}{\mu} \right]$ for $y^n \notin A$; $P_Y^\infty(y^n) := \frac{1}{M} \left[ \frac{pQ_Y^n(y^n)}{\mu Q_Y^n(A)} \right]$ for $y^n \in A$. Here $p := 1 - \sum_{y^n \notin A} \frac{1}{M} \left[ \frac{Q_Y^n(y^n)}{\mu} \right]$. Hence
$Q^n_Y(A) - \frac{|\text{supp}(Q_Y)|^n}{M} \leq p \leq Q^n_Y(A)$. For $\alpha = 1 + s \in (1, \infty)$,

$$D_{1+s}(P_Y^n \| Q^n_Y) = \frac{1}{s} \log \sum_{y^n} P_Y^n(y^n)^{1+s} Q^n_Y(y^n)^{-s}$$

$$\leq \frac{1}{s} \log \left( \sum_{y^n \in A} P_Y^n(y^n) \left( \frac{\left[ pQ^n_Y(y^n) \right]}{Q^n_Y(y^n)} \right)^{-s} + \sum_{y^n \in A} \left( \frac{1}{M} \left[ Q^n_Y(y^n) \right] \right)^{1+s} \right)$$

$$\leq \frac{1}{s} \log \left( P_Y^n(A) \left( 1 + \max_{y^n \in A} \frac{1}{Q^n_Y(y^n)M} \right) + \sum_{y^n \in A} Q^n_Y(y^n) + \frac{1}{M} \right)^{1+s}$$

$$\leq \frac{1}{s} \log \left( P_Y^n(A) \left( 1 + e^{-n\delta} \right) + \sum_{y^n : Q^n_Y(y^n) \leq e^{-n(R - \delta)}} \left( 2e^{-n(R - \delta)} \right)^{1+s} Q^n_Y(y^n)^{-s} \right)$$

$$\leq \frac{1}{s} \log \left( (1 + e^{-n\delta})^s + 2^{1+s}e^{-n(1+s)(R - \delta)} \sum_{y^n} Q^n_Y(y^n)^{-s} \right)$$

$$= \frac{1}{s} \log \left( (1 + e^{-n\delta})^s + 2^{1+s}e^{-n(1+s)(R - \delta) + n(1+s)H_{-s}(Q_Y)} \right).$$

Hence if

$$\tilde{R} - \delta > H_{-s}(Q_Y)$$

then (360) converges to zero.

On the other hand,

$$D_{1+s}(Q^n_Y \| P_Y^n) = \frac{1}{s} \log \sum_{y^n} Q^n_Y(y^n)^{1+s} P_Y^n(y^n)^{-s}$$

$$\leq \frac{1}{s} \log \left( \sum_{y^n \in A} \left( \frac{1}{M} \left[ \frac{Q^n_Y(y^n)}{pQ^n_Y(y^n)} \right] \right)^{-s} Q^n_Y(y^n)^{1+s} + Q^n_Y(A) \right)$$

$$\leq \frac{1}{s} \log \left( \sum_{y^n \in A} \left( \frac{Q^n_Y(y^n)}{pQ^n_Y(y^n)} - \frac{1}{M} \right)^{-s} Q^n_Y(y^n)^{1+s} + Q^n_Y(A) \right)$$

$$= \frac{1}{s} \log \left( \sum_{y^n \in A} Q^n_Y(y^n) \left( \frac{p}{Q^n_Y(A)} - \frac{1}{M} \right)^{-s} + Q^n_Y(A) \right)$$

$$\leq \frac{1}{s} \log \left( Q^n_Y(A) \left( \frac{Q^n_Y(A) - |\text{supp}(Q_Y)|^n}{M} - \frac{1}{Me^{-n(R - \delta)}} \right)^{-s} + Q^n_Y(A) \right)$$

$$\to 0,$$

where the last line follows since $Q^n_Y(A^C) \to 0$ as $n \to \infty$.

APPENDIX K
PROOF OF THEOREM 10

Sort the sequences in $|X|^n$ as $x^n_1, x^n_2, ..., x^n_{|X|^n}$ such that $P^n_X(x^n_1) \geq P^n_X(x^n_2) \geq ... \geq P^n_X(x^n_{|X|^n})$. Use Mapping 2 given in Appendix I-E to map the sequences in $X^n$ to the numbers in $\mathcal{M}$, where the distributions $P^n_X$ and $Q_Y$ are respectively replaced by $P^n_M$ and $Q_{M^n}$. That is, denote $k_m, m \in [1 : L]$ with $k_L := |X|^n$ as a sequence of integers such that for
For $m \in [1 : L - 1]$, $\sum_{i=k_{m-1}+1}^{k_m} P^n_X(x^n_i) < \frac{1}{M}$, $\sum_{i=k_m}^{k_{m+1}+1} P^n_X(x^n_i)$, and $P^n_X(x^n_{i+1}) \leq \frac{1}{M}$ or $\sum_{i=k_{m-1}+1}^{k_{m+1}} P^n_X(x^n_i) < \frac{1}{M}$. Map $x_{k_m-1}, \ldots, x_{k_m}$ to $m \in [1 : L]$. Define $T_{X,m}$ as the type of $x^n_{k_m}$. Then for $s > 0$, we have

\[
D_{1+s}(P_M || Q_M) = \frac{1}{s} \log \left( \sum_{m=1}^L M^s P^n_X(x^n_{k_m})^{1+s} \left\{ P^n_X(x^n_{k_m}) \geq \frac{1}{M} \right\} \right)
\]

\[
\leq \frac{1}{s} \log \left( 1 + \sum_{m=1}^L M^s e^{(1+s)\sum_x T_{X,m}(x) \log P_X(x)} 1 \left\{ e^{\sum_x T_{X,m}(x) \log P_X(x) < \frac{1}{M}} \right\} \right)
\]

where (369) follows since $P_M(m) = P^n_X(x^n_{k_m})$ if $P^n_X(x^n_{k_m}) \geq \frac{1}{M}$, and $P_M(m) \leq \frac{1}{M} + P^n_X(x^n_{k_m})$ if $P^n_X(x^n_{k_m}) < \frac{1}{M}$.

By Lemma 6, we have for $0 \leq s \leq 1$,

\[
D_{1+s}(P_M || Q_M) \leq \frac{1}{s} \log \left( \sum_{m=1}^L M^s P^n_X(x^n_{k_m})^{1+s} \left\{ P^n_X(x^n_{k_m}) \geq \frac{1}{M} \right\} \right)
\]

\[
\leq \frac{1}{s} \log \left( 1 + \sum_{m=1}^L M^s e^{(1+s)\sum_x T_{X,m}(x) \log P_X(x)} 1 \left\{ e^{\sum_x T_{X,m}(x) \log P_X(x) < \frac{1}{M}} \right\} \right)
\]

\[
\leq \frac{1}{s} \log \left( 1 + \sum_{T_X} e^{nH(T_X) + \max_{P_X \in \mathcal{P}(X)} (n+1)\sum_x T_X(x) \log P_X(x)} 1 \left\{ e^{\sum_x T_X(x) \log P_X(x) < \frac{1}{M}} \right\} \right)
\]

Similarly, for $1 \leq s \leq 2$,

\[
D_{1+s}(P_M || Q_M) \leq \frac{1}{s} \log \left( 1 + 2e^{ns(R-H_{1+s}(P_X)+o(1))} \right)
\]

and for $s \geq 2$,

\[
D_{1+s}(P_M || Q_M) \leq \frac{1}{s} \log \left( 1 + 2e^{ns(R-H_{1+s}(P_X)+o(1))} + 2se^{ns(R-H_{2}(P_X)+o(1))} \right)
\]

Therefore, no matter for $0 \leq s \leq 1$, $1 \leq s \leq 2$, or $s \geq 2$, $D_{1+s}(P_M || Q_M) \rightarrow 0$ if $\hat{R} < H_{1+s}(P_X)$. 

We consider the following mapping. Sort the sequences in $|X|^n$ as $x^n_1, x^n_2, \ldots, x^n_{|X|^n}$ such that $P^0_X(x^n_1) \geq P^0_X(x^n_2) \geq \ldots \geq P^0_X(x^n_{|X|^n})$. Assume $\delta > 0$ is a number such that $\hat{R} + \delta < H(P_X)$. Define $A := \{x^n : P^0_X(x^n) \geq e^{-\delta n^2} \}$. Denote $k_m, m \in [1 : M]$ as a sequence of integers such that for $m \in [1 : L]$, $\sum_{i=k_{m-1}+1}^{k_m} P^0_X(x^n_i) < \frac{1}{M} \leq \sum_{i=k_{m-1}+1}^{k_m} P^0_X(x^n_i)$, where $L$ is the maximum integer such that $P^0_X(x^n_{k_L}) \geq e^{-\delta n^2}$; and for $m \in [L + 1 : M]$, $\sum_{i=k_{m-1}+1}^{k_m} P^0_X(x^n_i) \leq \frac{p_0}{M} < \sum_{i=k_{m-1}+1}^{k_m+1} P^0_X(x^n_i)$. Here

\[
p_0 := 1 - \sum_{i=1}^{k_L} P^0_X(x^n_i) \geq P^n_X(A^c) \geq P^n_X(\mathcal{T}^n) \to 1
\]

for some $\epsilon > 0$ such that $\hat{R} + \delta < (1 - \epsilon) H(P_X)$, and

\[
M_0 := M - L \geq M - \frac{\sum_{i=1}^{k_L} P^0_X(x^n_i)}{M} = M\rho_0.
\]

Obviously, $\sum_{i=1}^{k_L} P^0_X(x^n_i) \leq 1$, hence $k_M \leq |X|^n$. We consider the following mapping.

Step 1: For each $m \in [1 : M]$, map $x^n_{k_{m-1}+1}, \ldots, x^n_{k_m}$ to $m$.

Step 2: Map $x^n_{k_{m+1}}, \ldots, x^n_{|X|^n}$ to $m \in [L+1 : M]$ such that the resulting $P_{M_0}(m), m \in [L+1 : M]$ satisfy $\sum_{i=k_{m-1}+1}^{k_m} P^0_X(x^n_i) \leq P_{M_0}(m) \leq \sum_{i=k_{m-1}+1}^{k_m+1} P^0_X(x^n_i)$.

Note that this mapping for $m \in [1 : L]$ corresponds to Mapping 2 given in Appendix I-E, and for $m \in [L+1 : M]$ corresponds to Mapping 1 given in Appendix I-E. Hence for $m \in [1 : L]$, $\hat{R} \leq P_{M_0}(m) < \frac{1}{M} + P^0_X(x^n_{k_m})$, and for $m \in [L + 1 : M]$, $\frac{p_0}{M_0} - P^0_X(x^n_{k_m}) \leq P_{M_0}(m) \leq \frac{p_0}{M_0} + P^0_X(x^n_{k_m})$.

\[
D_\infty(Q_{M_0} || P_{M_0}) = \log \max_m \frac{1}{M_0} \frac{1}{M} \leq \log \max_m \frac{1}{M_0} \frac{1}{M} - P^0_X(x^n_{k_{m-1}+1})
\]

\[
= - \log \left( \frac{M}{M_0} \rho_0 - \max_{m \in [L+1 : M]} M P^0_X(x^n_{k_{m-1}+1}) \right)
\]

\[
\leq - \log \left( \frac{M}{M_0} \rho_0 - e^{-n\delta} \right)
\]

\[
\to 0.
\]

By the fact that $P^0_X(\mathcal{T}^n) \to 1$ at least exponentially fast as $n \to \infty$, we have that for $\hat{R} + \delta < H(P_X)$, $D_\infty(Q_{M_0} || P_{M_0}) \to 0$ at least exponentially fast as $n \to \infty$. Since $\delta > 0$ is arbitrary, we have for $\hat{R} < H(P_X)$, $D_\infty(Q_{M_0} || P_{M_0}) \to 0$ at least exponentially fast as $n \to \infty$.

APPENDIX M

PROOF OF THEOREM 12

Consider the mapping given in Appendix L.

\footnote{Although there may exist simpler mappings than the one considered here, the mapping here will be reused in Appendix M.}
For $\alpha \in [1, \infty)$, we have
\[
D_{1+s}(P_{M_n} \| Q_{M_n}) = \frac{1}{s} \log \sum_m P_{M_n}(m) \left( \frac{1}{M} \right)^{1+s} \left( \frac{1}{M} \right)^{-s} \tag{388}
\]
\[
\leq \frac{1}{s} \log \left( \sum_m M^s P^n_X(x_{k_m}^n)^{1+s} 1 \left\{ P^n_X(x_{k_m}^n) \geq \frac{1}{M} \right\} \right) + \sum_m P_{M_n}(m) \left( 1 + M P^n_X(x_{k_m}^n) \right)^{s} 1 \left\{ \frac{e^{-n\delta}}{M} \leq P^n_X(x_{k_m}^n) < \frac{1}{M} \right\} \tag{389}
\]
\[
+ \sum_m P_{M_n}(m) \left( \frac{M}{M_0} p_0 + M P^n_X(x_{k_m}^n) \right)^{s} 1 \left\{ P^n_X(x_{k_m}^n) < \frac{e^{-n\delta}}{M} \right\}
\]
\[
\leq \frac{1}{s} \log \left( \sum_m M^s P^n_X(x_{k_m}^n)^{1+s} 1 \left\{ P^n_X(x_{k_m}^n) \geq \frac{1}{M} \right\} \right) + \sum_m P_{M_n}(m) \left( 1 + M P^n_X(x_{k_m}^n) \right)^{s} 1 \left\{ P^n_X(x_{k_m}^n) < \frac{1}{M} \right\}, \tag{390}
\]
where (389) follows since $P_{M_n}(m) = P^n_X(x_{k_m}^n)$ if $P^n_X(x_{k_m}^n) \geq \frac{1}{M}$; $P_{M_n}(m) \leq \frac{1}{M} + P^n_X(x_{k_m}^n)$ if $\frac{e^{-n\delta}}{M} \leq P^n_X(x_{k_m}^n) < \frac{1}{M}$; and $P_{M_n}(m) \leq \frac{P^n_X(x_{k_m}^n)}{M_0} + P^n_0(x_{k_m}^n)$ if $P^n_X(x_{k_m}^n) < \frac{e^{-n\delta}}{M}$, and (390) follows from (381).

Then following steps similar to (370)-(379), we have $D_\alpha(P_{M_n} \| Q_{M_n}) \to 0$ if $\hat{R} < H_{1+s}(P_X)$.

On the other hand,
\[
D_\infty(Q_{M_n} \| P_{M_n}) = \log \max_m \frac{1}{P_{M_n}(m)} \tag{391}
\]
\[
\leq \log \max_{m \in \{L+1:M\}} \frac{1}{\frac{M}{M_0} p_0 - M P^n_X(x_{k_m}^n)} \tag{392}
\]
\[
= - \log \left( \frac{M}{M_0} p_0 - \max_{m \in \{L+1:M\}} M P^n_X(x_{k_m}^n) \right) \tag{393}
\]
\[
= - \log \left( \frac{M}{M_0} p_0 - e^{-n\delta} \right) \tag{394}
\]
\[
\to 0. \tag{395}
\]
This implies $D_\alpha(Q_{M_n} \| P_{M_n}) \to 0$.
