Abstract
On the basis of Sz. Nagy-Foiaş-Langer and von Neumann-Wold decompositions, two decompositions for dissipative linear relations are given and they are realized by transforming invariant subspaces for contractions, by means of the Z transform. These decompositions permit the separation of the selfadjoint and completely nonselfadjoint parts of a dissipative relation.

Mathematics Subject Classification(2010): 47A06, 47B44, 47A45, 47A15.
Keywords: Linear relations; Dissipative relations; Invariant and reducing subspaces; Canonical decompositions.
1. Introduction

This paper deals with dissipative linear relations in Hilbert spaces, in which we are interested in decompose any closed dissipative relation into the selfadjoint and completely nonselfadjoint parts. In particular, decompose symmetric relations which do not admit proper dissipative extensions.

The theory of linear relations is nowadays a widely abstract tool and of practical importance in extension theory, spectral analysis of dissipative and selfadjoint operators, canonical systems, and so forth. The concept of linear relation generalizes the notion of linear operator, when this is identified by its graph (some works refer to a linear relation as a multivalued linear operator cf. [12]). Actually, a linear relation is an operator whenever its multivalued part is the trivial space. we refer the reader to [1, 3, 12, 22, 24] for be familiar with the theory of linear relations and [5, 10, 14, 30, 31] for the theory of dissipative relations.

The importance to studying dissipative linear operators arises in applications to problems in mathematical physics, since they are connected with dissipative systems i. e. systems in which the energy is in general nonconstant and nonincreasing in time (see for example [13,16,18,27]). Phillips introduced the term of a dissipative operator in his seminal work [28], motivated to obtain a solution of the Cauchy problem for dissipative hyperbolic systems of partial differential equations. Besides, he showed that a maximal dissipative operator generates a strongly continuous semi-group of contraction operators (see also [37]). We draw the reader’s attention to [4, 19, 20, 38, 39], for more applications of dissipative operators.

The theory of dissipative operators has its roots in the theory of contractions, i. e. linear operators $T$ such that $\|T\| \leq 1$ (see [35, 36], for an exhaustive exposition of contractions). The class of contractions has been amply studied and is a well-understood class of operators (some generalizations of the concept of contraction can be found in [11,15]). We would point out that a motivation for studying contractions stems from the invariant subspace problem [21,29,30]. Besides, contractions and dissipative operators are related with notable properties by virtue of the Cayley transform [36, Chap. 4, Sec. 4]. In order to take advantage of these eminent properties, we use a small variation of the Cayley transform, named the Z transform (cf. [17]).

The present work is concerned with a particular feature of contractions, namely to the fact that they admit useful decompositions. We focus our attention on two kinds of decompositions, the Sz. Nagy-Foiaş-Langer and the von Neumann-Wold decompositions [26,36] (see [34] for a more general setting). Our goal is to give a decomposition of any closed dissipative relation, in which we isolate its selfadjoint part (see Theorem 3.3). Particularly, in Theorem 3.5 we show that any symmetric relation, which does not admit dissipative proper extensions, is separated into its selfadjoint part and its elementary maximal part, i. e. a relation whose Z transform is a unilateral shift. These decompositions are made by means of transforming invariant subspaces for contractions. It is worth mentioning that the decompositions we show in this
work, were intended as an application of boundary and quasi boundary triples, since on these theories appear by natural way the dissipative linear relations [6,7,23,32]. On the other hand, these decompositions arise naturally in functional models of dissipative operators [9,25,33].

The paper is organized as follows. In Section 2 we briefly recall some of the standard definitions on linear relations. It is one of the main objectives in this section to deal with the problem of invariant and reducing subspaces for linear relations. Here, we show that the adjoint is distributed on reducing subspaces (see Theorem 2.1). Also, we show that linear relations of the form $K \oplus K$, where $K$ is a linear set, are invariant under the $Z$ transform (see Remark 3). A consequence of this is that the $Z$ transform preserve reducing subspaces for any linear relation (See Theorem 2.2). We deal in Section 3 with the general theory of contractions, in particular, the Sz. Nagy-Foiaş-Langer and the von Neumann-Wold decompositions, in which the Sz. Nagy-Foiaş-Langer decomposition is extended to any closed contraction (see Theorem 3.1). These results, together with the theory of reducing subspaces developed in the preceding section, are combined with the theory of the $Z$ transform to obtain the required decomposition of any closed dissipative relation. Finally, as an illustrative example of the abstract techniques in this work, we present in Section 4 a maximal symmetric relation, with nontrivial multivalued part as well as its corresponding decomposition.

2. Invariant and reducing subspaces for linear relations

Let $(\mathcal{H}, \langle \cdot, \cdot \rangle)$ be a separable Hilbert space, with inner product antilinear in its left argument. We denote $\mathcal{H} \oplus \mathcal{H}$ as the orthogonal sum of two copies of the Hilbert space $\mathcal{H}$ cf. [8, Sec. 2.3]. Throughout this work, any linear set $T$ in $\mathcal{H} \oplus \mathcal{H}$, is called a linear relation (or merely relation), with

$$\text{dom } T := \left\{ f \in \mathcal{H} : \begin{pmatrix} f \\ g \end{pmatrix} \in T \right\} \quad \text{ran } T := \left\{ g \in \mathcal{H} : \begin{pmatrix} f \\ g \end{pmatrix} \in T \right\}$$

$$\ker T := \left\{ f \in \mathcal{H} : \begin{pmatrix} f \\ 0 \end{pmatrix} \in T \right\} \quad \text{mul } T := \left\{ g \in \mathcal{H} : \begin{pmatrix} 0 \\ g \end{pmatrix} \in T \right\}.$$

The concept of linear relation generalizes the notion of linear operator. Actually, a relation $T$ is an operator (when it is identified by its graph) if and only its multivalued part $\text{mul } T = \{0\}$.  

2
For two relations \( T, S \) and \( \zeta \in \mathbb{C} \), we denote the following linear relations:

\[
T + S := \{ (f + h) : (f, g) \in T, (g, h) \in S \}, \quad \zeta T := \{ (f \zeta g) : (f, g) \in T \}
\]

\[
ST := \{ (f k) : (f, g) \in T, (g, k) \in S \}, \quad T^{-1} := \{ (g f) : (f, g) \in T \}.
\]

The adjoint of a relation \( T \) is defined by

\[
T^* := \left\{ \begin{pmatrix} h \\ k \end{pmatrix} \in H \oplus H : \langle k, f \rangle = \langle h, g \rangle, \quad \forall (f, g) \in T \right\},
\]

which turns out to be a closed relation with the following properties:

\[
T^* = (-T^{-1})^\perp, \quad S \subset T \Rightarrow T^* \subset S^*, \quad (\alpha T)^* = \overline{\alpha} T^*, \quad \text{with } \alpha \neq 0, \quad (T^*)^{-1} = (T^{-1})^*, \quad \ker T^* = (\text{ran } T)^\perp.
\]

Here and subsequently, a relation \( T \) is bounded whenever there exists a positive constant \( C \) such that \( \|g\| \leq C \|f\| \), for all \( (f, g) \in T \). It is of our interest to point out that the boundedness definition for relations is not unique (see [12]). The boundedness condition we use in this paper implies that any bounded relation is an operator.

We denote the quasi-regular set of a linear relation \( T \) by

\[
\hat{\rho}(T) := \{ \zeta \in \mathbb{C} : (T - \zeta I)^{-1} \text{ is bounded} \},
\]

As in the case of operators, the quasi-regular set of a closed relation \( T \) is open.

Let us consider the deficiency space of \( T \), given by

\[
\mathcal{N}_\zeta(T) := \left\{ \begin{pmatrix} f \\ \zeta f \end{pmatrix} \in T \right\}, \quad \zeta \in \mathbb{C},
\]

which is a bounded relation with \( \text{dom } \mathcal{N}_\zeta(T) = \ker(T - \zeta I) \). Moreover,

\[
\dim \mathcal{N}_{\zeta(T^*)}, \quad \zeta \in \hat{\rho}(T), \quad (2.2)
\]

remains constant, on each connected component of \( \hat{\rho}(T) \) (cf. [3] Thm. 3.7.4)

The regular set of a relation \( T \), is defined by

\[
\rho(T) := \{ \zeta \in \mathbb{C} : (T - \zeta I)^{-1} \in \mathcal{B}(\mathcal{H}) \},
\]

where \( \mathcal{B}(\mathcal{H}) \) denotes the class of bounded operators defined in the whole space \( \mathcal{H} \). Also, the regular set is open and consists of all connected components of \( \hat{\rho}(T) \), in
which (2.2) is equal zero.

For a relation $T$, we consider the following sets:

\[
\begin{align*}
\sigma(T) &:= \mathbb{C} \setminus \rho(T) \quad \text{(spectrum)} \\
\hat{\sigma}(T) &:= \mathbb{C} \setminus \hat{\rho}(T) \quad \text{(spectral core)} \\
\sigma_p(T) &:= \{ \zeta \in \mathbb{C} : \dim \mathbf{N}_\zeta(T) \neq 0 \} \quad \text{(point spectrum)} \\
\sigma_c(T) &:= \{ \zeta \in \mathbb{C} : \operatorname{ran}(T - \zeta I) \neq \overline{\operatorname{ran}(T - \zeta I)} \} \quad \text{(continuous spectrum)} \\
\sigma_r(T) &= \sigma(T) \setminus \hat{\sigma}(T) \quad \text{(residual spectrum)}
\end{align*}
\]

Analogously to the case of operators, it fulfills

\[\sigma_p(T) \cup \sigma_c(T) = \hat{\sigma}(T). \quad (2.3)\]

**Remark 1.** For a closed relation $T$, one has that $\sigma(T^*)$ is the complex conjugate of $\sigma(T)$ [30, Prop. 2.5]. The same holds for the continuous spectrum, since $\operatorname{ran}(T - \zeta I)$ and $\operatorname{ran}(T^* - \overline{\zeta} I)$ are simultaneously closed (see [14, Lem. 2.3]).

**Proposition 2.1.** Let $T$ be a closed relation. If $\zeta \in \sigma_r(T)$ then $\overline{\zeta} \in \sigma_p(T^*) \setminus \sigma_c(T^*)$.

**Proof.** Since $\zeta \in \sigma_r(T)$, one has that $(T - \zeta I)^{-1}$ is closed and bounded, which is not defined on the whole space. In this fashion, $\operatorname{ran}(T - \zeta I)$ is closed as well as $\operatorname{ran}(T^* - \overline{\zeta} I)$ and

\[\ker(T^* - \overline{\zeta} I) = [\operatorname{ran}(T - \zeta I)]^\perp \neq \{0\}.
\]

These facts imply the required. \hfill \square

Before we proceed to the theory of invariant subspaces, we shall set the following. For a relation $T$ in $\mathcal{H} \oplus \mathcal{H}$ and a linear set $\mathcal{K}$ in $\mathcal{H}$, we denote

\[T_{\mathcal{K}} := T \cap (\mathcal{K} \oplus \mathcal{K}), \quad (2.4)\]

where $\mathcal{K} \oplus \mathcal{K}$ represents the orthogonal sum of two copies of $\mathcal{K}$. It is clear that $T_\mathcal{H} = T$ and $T_{\{0\}} = \{0\} \oplus \{0\}$.

**Definition 1.** Let $T$ be a relation in $\mathcal{H} \oplus \mathcal{H}$. A subspace $\mathcal{K} \subset \mathcal{H}$ is called **invariant** for $T$ (briefly $T$-invariant), when the following conditions are true:

(i) $\operatorname{dom} T = (\operatorname{dom} T \cap \mathcal{K}) \oplus (\operatorname{dom} T \cap \mathcal{K}^\perp)$.

(ii) $\operatorname{mul} T = (\operatorname{mul} T \cap \mathcal{K}) \oplus (\operatorname{mul} T \cap \mathcal{K}^\perp)$.

(iii) $\operatorname{dom} T_{\mathcal{K}} = \operatorname{dom} T \cap \mathcal{K}$.

We see at once that $\mathcal{H}$ and $\{0\}$ are invariant, for any linear relation.
Definition 2. For a relation $T$ in $\mathcal{H} \oplus \mathcal{H}$, a subspace $\mathcal{K} \subset \mathcal{H}$ is said to reduce $T$ if

$$T = T_\mathcal{K} \oplus T_{\mathcal{K}^\perp}$$

The subspaces $\mathcal{K}$ and $\mathcal{K}^\perp$ reduce $T$ simultaneously and in this case

$$\begin{align*}
dom T &= \dom T_\mathcal{K} \oplus \dom T_{\mathcal{K}^\perp}, & \ker T &= \ker T_\mathcal{K} \oplus \ker T_{\mathcal{K}^\perp}, \\
\ran T &= \ran T_\mathcal{K} \oplus \ran T_{\mathcal{K}^\perp}, & \mul T &= \mul T_\mathcal{K} \oplus \mul T_{\mathcal{K}^\perp}. 
\end{align*}$$

(2.5)

Remark 2. The existence of relations $T_1 \subset \mathcal{K} \oplus \mathcal{K}$ and $T_2 \subset \mathcal{K}^\perp \oplus \mathcal{K}^\perp$, in which

$$T = T_1 \oplus T_2,$$

implies that $\mathcal{K}$ reduces $T$, with $T_1 = T_\mathcal{K}$ and $T_2 = T_{\mathcal{K}^\perp}$.

Proposition 2.2. A subspace $\mathcal{K}$ reduces $T$ if and only if $\mathcal{K}$ and $\mathcal{K}^\perp$ are $T$-invariant.

Proof. If $\mathcal{K}$ reduces $T$, then by verifying the inclusions in both directions, one arrives at

$$\begin{align*}
\dom T_\mathcal{K} &= \dom T \cap \mathcal{K}, & \ran T_\mathcal{K} &= \ran T \cap \mathcal{K}, \\
\ker T_\mathcal{K} &= \ker T \cap \mathcal{K}, & \mul T_\mathcal{K} &= \mul T \cap \mathcal{K}.
\end{align*}$$

Therefore, one has by (2.5) that $\mathcal{K}$ is $T$-invariant. This also holds for $\mathcal{K}^\perp$, since it reduces $T$.

The converse follows once we show that $T \subset T_\mathcal{K} \oplus T_{\mathcal{K}^\perp}$. By inclusion, let $\begin{pmatrix} f \\ g \end{pmatrix} \in T$ and the first condition of $T$-invariant implies that there exist

$$\begin{pmatrix} a \\ s \end{pmatrix} \in T_\mathcal{K}; \quad \begin{pmatrix} b \\ t \end{pmatrix} \in T_{\mathcal{K}^\perp},$$

(2.6)

such that $f = a + b$. Thus $\begin{pmatrix} f \\ s + t \end{pmatrix} \in T$, which yields $\begin{pmatrix} 0 \\ g - (s + t) \end{pmatrix} \in T$. The second condition of $T$-invariant indicates the existence of

$$\begin{pmatrix} 0 \\ h \end{pmatrix} \in T_\mathcal{K}; \quad \begin{pmatrix} 0 \\ k \end{pmatrix} \in T_{\mathcal{K}^\perp},$$

(2.7)

such that $g - (s + t) = h + k$. Hence, (2.6) and (2.7) produce

$$\begin{pmatrix} f \\ g \end{pmatrix} = \begin{pmatrix} a \\ s + h \end{pmatrix} + \begin{pmatrix} b \\ t + k \end{pmatrix} \in T_\mathcal{K} \oplus T_{\mathcal{K}^\perp},$$

(2.8)

as required. \qed

Let us note the following property, which is required in the next assertion. If $\mathcal{K}$
reduces $T$, then by a simple computation, one obtains
\[ T = T_K \oplus T_{K^\perp}. \] (2.9)
This implies that $T$ is closed if and only if $T_K$ and $T_{K^\perp}$ are closed.

**Theorem 2.1.** If $\mathcal{K}$ reduces $T$, then $\mathcal{K}$ reduces $T^*$ and the following holds
\[ (T_K \oplus T_{K^\perp})^* = (T_K)^* \oplus (T_{K^\perp})^*. \] (2.10)

**Proof.** By hypothesis $T = T_K \oplus T_{K^\perp}$. Besides, the first property of (2.1) yields
\[ -(T_K)^{-1} \oplus (T_K)^* = \mathcal{K} \oplus \mathcal{K}; \quad -(T_{K^\perp})^{-1} \oplus (T_{K^\perp})^* = \mathcal{K}^\perp \oplus \mathcal{K}^\perp. \] (2.11)
Thus, in view of (2.9) and (2.11),
\[ -(T)^{-1} \oplus [(T_K)^* \oplus (T_{K^\perp})^*] = -[T_K \oplus T_{K^\perp}]^{-1} \oplus [(T_K)^* \oplus (T_{K^\perp})^*] = -(T_K)^{-1} \oplus (T_K)^* \oplus -(T_{K^\perp})^{-1} \oplus (T_{K^\perp})^* \]
\[ = (\mathcal{K} \oplus \mathcal{K}) \oplus (\mathcal{K}^\perp \oplus \mathcal{K}^\perp) \]
\[ = \mathcal{H} \oplus \mathcal{H} = -(T)^{-1} \oplus T^*. \]
whence one arrives at (2.10). Moreover, (2.11) also implies that $(T_K)^* \subset \mathcal{K} \oplus \mathcal{K}$ and $(T_{K^\perp})^* \subset \mathcal{K}^\perp \oplus \mathcal{K}^\perp$. Hence from Remark (2), $\mathcal{K}$ reduces $T^*$. \qed

Following the last result, if $\mathcal{K}$ reduces $T$ then
\[ (T_K)^* = (T^*)_\mathcal{K}; \quad (T_{K^\perp})^* = (T^*)_\mathcal{K}^\perp. \] (2.12)

We shall introduce a version of the Cayley transform for linear relations (cf. [17]).

**Definition 3.** For a relation $T$ and $\zeta \in \mathbb{C}$, we define the $Z$ transform of $T$ by
\[ Z_\zeta(T) := \left\{ \left( \frac{g - \bar{\zeta}f}{\zeta g - |\zeta|^2 f} \right) : \left( \begin{array}{c} f \\ g \end{array} \right) \in T \right\}. \]
The $Z$ transform is a linear relation with
\[ \text{dom} Z_\zeta(T) = \text{ran}(T - \zeta I), \quad \text{ran} Z_\zeta(T) = \text{ran}(T - \zeta I), \]
\[ \text{mul} Z_\zeta(T) = \ker(T - \zeta I), \quad \ker Z_\zeta(T) = \ker(T - \zeta I). \] (2.13)
Moreover, the following properties hold (see [14] Lems. 2.6, 2.7 and [17] Props. 3.6, 3.7). For any $\zeta \in \mathbb{C}$:

(i) $Z_\zeta(Z_\zeta(T)) = T$.

(ii) $Z_\zeta(T) \subset Z_\zeta(S) \Leftrightarrow T \subset S$.  

(iii) $Z_{-\zeta}(T) = -Z_{\zeta}(-T)$.

(iv) $Z_{\zeta}(T^{-1}) = Z_{\zeta}^{-1}(T) = (Z_{\zeta}(T))^{-1}$, if $|\zeta| = 1$.

For any $\zeta \in \mathbb{C} \setminus \mathbb{R}$:

(v) $Z_{\zeta}(T + S) = Z_{\zeta}(T) + Z_{\zeta}(S)$.

(vi) $Z_{\pm i}(T \oplus S) = Z_{\pm i}(T) \oplus Z_{\pm i}(S)$.

(vii) $Z_{\zeta}(T^*) = (Z_{\zeta}(T))^*$.

(viii) $\overline{Z_{\zeta}(T)} = Z_{\overline{\zeta}}(T)$.

**Remark 3.** For any linear set $K \subset \mathcal{H}$, the following holds:

$$Z_{\zeta}(K \oplus K) = K \oplus K \quad (\zeta \in \mathbb{C}) . \tag{2.14}$$

Indeed, it is straightforward to see that $Z_{\zeta}(K \oplus K) \subset K \oplus K$ and the other inclusion follows applying the property (ii) of the $Z$ transform.

**Theorem 2.2.** A subspace $K$ reduces $T$ if and only if it reduces $Z_{\pm i}(T)$ (the assertion is meant to hold separately for $+i$ and $-i$).

**Proof.** If $K$ reduces $T$, then $T = T_K \oplus T_{K^\perp}$ and thus

$$Z_{\pm i}(T) = Z_{\pm i}(T_K) \oplus Z_{\pm i}(T_{K^\perp}) .$$

Since $T_K \subset K \oplus K$ and $T_{K^\perp} \subset K^\perp \oplus K^\perp$, one has by (2.14) that

$$Z_{\pm i}(T_K) \subset K \oplus K; \quad Z_{\pm i}(T_{K^\perp}) \subset K^\perp \oplus K^\perp .$$

Therefore $K$ reduces $Z_{\pm i}(T)$. The converse follows replacing $T$ by $Z_{\pm i}(T)$, in the reasoning above. \qed

3. The canonical decomposition of dissipative relations

We begin this section with a brief exposition on general concepts of contractions. We recall that a linear operator $V$ in $\mathcal{H} \oplus \mathcal{H}$ (seen as a linear relation) is a contraction if it is bounded with $\|V\| \leq 1$. Particularly, $V$ is an isometry if $V^{-1} \subset V^*$ or unitary whenever $V^{-1} = V^*$. In both cases its norm is equal one.

We say that $V$ is a maximal contraction if it does not admit proper contractive extensions. This property is equivalent to say that $V$ belongs to the class $\mathcal{B}(\mathcal{H})$.

**Definition 4.** A contraction $V$ is said to be completely nonunitary (c.n.u. for short), when there is no nonzero reducing subspace $K$ for $V$, in which $V_K$ is unitary.
The following result is an extension of the so-called Sz. Nagy-Foiaş-Langer decomposition (see [36, Chap. I, Sec. 3, Thm. 3.2]), which is proven for contractions in $\mathcal{B}(\mathcal{H})$.

**Theorem 3.1.** For every closed contraction $V$, there exists a unique reducing subspace $\mathcal{K}$ for $V$, such that $V_\mathcal{K}$ is unitary and $V_{\mathcal{K}^\perp}$ is completely nonunitary.

**Proof.** We begin by denoting

$$\hat{V} := V \oplus W, \quad \text{where} \quad W = \left\{ \begin{pmatrix} h \\ 0 \end{pmatrix} : h \in \mathcal{H} \ominus \text{dom } V \right\}. \quad (3.1)$$

Inasmuch as dom $V$ is closed, $\hat{V}$ is a maximal contraction. Then, the Sz. Nagy-Foiaş-Langer decomposition asserts that there exists a unique reducing subspace $\mathcal{K}$ for $\hat{V}$, such that $\hat{V}_\mathcal{K}$ is unitary and $\hat{V}_{\mathcal{K}^\perp}$ is c.n.u. Thus, for every $\begin{pmatrix} f \\ g \end{pmatrix} \in \hat{V}_\mathcal{K} \subset \hat{V}$, in view of $(3.1)$, there is $\begin{pmatrix} f_1 \\ g \end{pmatrix} \in V$ and $f_2 \in (\text{dom } V)^\perp$, such that $f = f_1 + f_2$. Thereby,

$$\|f_1\|^2 \geq \|g\|^2 = \|f\|^2 = \|f_1 + f_2\|^2 = \|f_1\|^2 + \|f_2\|^2,$$

wherefrom $f_2 = 0$. Hence, $\hat{V}_\mathcal{K} \subset V_\mathcal{K}$ and they are the same, since $V \subset \hat{V}$. The previous reasoning implies that $\mathcal{K}$ reduces $V$ as well as $W \subset \hat{V}_\mathcal{K}^\perp$. Furthermore, $V_{\mathcal{K}^\perp} = \hat{V}_{\mathcal{K}^\perp} \ominus W$, which is a c.n.u. contraction. The uniqueness follows directly, bearing in mind that a reducing subspace for $V$, also reduces $\hat{V}$. \hfill $\blacksquare$

In what follows, we will turn our attention to a particular class of isometries, known as unilateral shifts.

For an isometry $V$ in $\mathcal{B}(\mathcal{H})$, we say that a subspace $\mathcal{L} \subset \mathcal{H}$ is a wandering space for $V$, if for all $n, m \in \mathbb{N} \cup \{0\}$, with $n \neq m$,

$$V^n \mathcal{L} \perp V^m \mathcal{L}.$$

**Definition 5.** An isometric operator $V$ in $\mathcal{B}(\mathcal{H})$ is called unilateral shift, if there exists a wandering space $\mathcal{L}$ for $V$, such that

$$\mathcal{L} \oplus V \mathcal{L} \oplus V^2 \mathcal{L} \oplus \cdots = \mathcal{H}. \quad (3.2)$$

The wandering space for a unilateral shift $V$ is uniquely determined by

$$\mathcal{L} = \mathcal{H} \oplus \text{ran } V.$$

Besides, it is straightforward to computes that

$$V^* = V^{-1} \oplus \left\{ \begin{pmatrix} l \\ 0 \end{pmatrix} : l \in \mathcal{L} \right\}.$$
Let us introduce the following assertion which is well-known as the von Neumann-Wold decomposition [36, Chap. I, Sec. 1, Thm. 1.1].

**Theorem 3.2.** For every isometric operator $V$ in $\mathcal{B}(\mathcal{H})$, there exists a unique reducing subspace $\mathcal{K}$ for $V$, such that $V|_{\mathcal{K}}$ is unitary and $V|_{\mathcal{K}^\perp}$ is a unilateral shift. Namely,

$$\mathcal{K} := \bigcap_{n=0}^{\infty} \text{ran} V^n \quad \text{then} \quad \mathcal{K}^\perp = \bigoplus_{n=0}^{\infty} V^n \mathcal{L}, \quad \text{where} \quad \mathcal{L} = \mathcal{H} \ominus \text{ran} V. \quad (3.3)$$

In the last result, the space $\mathcal{K}$ may be trivial or the whole space.

**Corollary 3.1.** An isometric operator in $\mathcal{B}(\mathcal{H})$ is a unilateral shift if and only if it is completely nonunitary.

**Proof.** Assume $V$ is a unilateral shift and suppose that $\mathcal{K}$ is a reducing subspace for $V$, in which $V|_{\mathcal{K}}$ is unitary. Then $\mathcal{K} = V^n \mathcal{K} \subset V^n \mathcal{H}$, for $n = 0, 1, 2, \ldots$ On the other hand, in view of (3.2), the wandering space $\mathcal{L}$ for $V$, satisfies

$$V^n \mathcal{L} = V^n \mathcal{H} \ominus V^{n+1} \mathcal{H}.$$ 

Consequently, $\mathcal{K} \perp V^n \mathcal{L}$, for all $n \in \mathbb{N} \cup \{0\}$. Thus (3.2) implies $\mathcal{K} = \{0\}$ and hence $V$ is c.n.u. The converse follows from Theorem 3.2. \qed

Theorems 3.1 and 3.2 present two kind of decompositions for closed contraction, uniquely determined by their unitary and completely nonunitary parts. Hereinafter, we will address the dissipative relations to give the counterpart to these theorems.

**Definition 6.** A relation $L$ is called **dissipative** if for all $\begin{pmatrix} f \\ g \end{pmatrix} \in L$,

$$\text{Im} \langle f, g \rangle \geq 0.$$ 

In particular, $L$ is **symmetric** if $L \subset L^*$ and **selfadjoint** when $L = L^*$. Furthermore, $L$ is say to be **maximal dissipative** if it does not have proper dissipative extensions.

For the reader’s convenience, the following result from [30] is brought up.

**Proposition 3.1.** If $\zeta$ is in the upper half plane $\mathbb{C}_+$, such that $|\zeta| = 1$, then a linear relation $L$ is (closed, maximal) dissipative (symmetric, selfadjoint) if and only if $Z_\zeta(L)$ is a (closed, maximal) contraction (isometry, unitary).

The above assertion clarifies that the $Z$ transform gives a one-to-one correspondence between contractions and dissipative relations.

**Definition 7.** We call a dissipative relation $L$ **completely nonselfadjoint** (briefly c.n.s.), if there is no nonzero reducing subspace $\mathcal{K}$ for $L$, in which $L|_{\mathcal{K}}$ is selfadjoint.
Remark 4. If a closed dissipative relation $L$ is c.n.s., then it is an operator. Indeed, since $\text{dom} \ L \subset (\text{mul} \ L)_{\perp}$ (cf. [5, Sec. 2]), one has that $\text{mul} \ L$ is a reducing subspace for $L$, in which $L$ is selfadjoint. Hence, $\text{mul} \ L = \{0\}$.

**Proposition 3.2.** A relation $L$ is a completely nonselfadjoint, dissipative relation if and only if $V = Z_i(L)$ is a completely nonunitary, contraction.

**Proof.** We first suppose that $L$ is a c.n.s. dissipative relation. By Proposition 3.1, one has that $V = Z_i(L)$ is a contraction. Besides, if there exists a nonzero reducing subspace $\mathcal{K}$ for $V$, such that $V_\mathcal{K}$ is unitary, then Theorem 2.2 implies that $\mathcal{K}$ also reduces $L$ and Proposition 3.1 states that $Z_i(V_\mathcal{K}) \subset L$ is selfadjoint. This contradicts our assumption that $L$ is c.n.s. Therefore, $V$ is c.n.u. The proof of the converse is handled in the same lines.

We shall continue with the analogue of the Sz. Nagy-Foiaș-Langer decomposition for dissipative relations.

**Theorem 3.3.** If $L$ is a closed dissipative relation, then there exists a unique reducing subspace $\mathcal{K}$ for $L$, such that $L_\mathcal{K}$ is selfadjoint and $L_{\mathcal{K}^\perp}$ is completely nonselfadjoint.

**Proof.** Inasmuch as $L$ is a closed dissipative relation, then by Proposition 3.1 one has that $V = Z_i(L)$ is a closed contraction. Thus, in accordance to Theorem 3.1, there exists a unique reducing subspace $\mathcal{K}$ for $Z_i(L)$, in which $Z_i(L_\mathcal{K})$ is unitary and $Z_i(L_{\mathcal{K}^\perp})$ is c.n.u. In this fashion, Theorem 2.2 implies that $\mathcal{K}$ reduces $L$ and besides,

$$L = Z_i(Z_i(L))$$

$$= Z_i(Z_i(L_\mathcal{K}) \oplus Z_i(L_{\mathcal{K}^\perp}))$$

$$= Z_i(Z_i(L_\mathcal{K})) \oplus Z_i(Z_i(L_{\mathcal{K}^\perp})).$$ (3.4)

Concluding, from Remark 2 and Proposition 3.1 one has that $L_\mathcal{K} = Z_i(Z_i(L_\mathcal{K}))$ is selfadjoint and $L_{\mathcal{K}^\perp} = Z_i(Z_i(L_{\mathcal{K}^\perp}))$ is c.n.s., by virtue of Proposition 3.2.

To prove the uniqueness. If $\mathcal{K}'$ holds the same properties of $\mathcal{K}$, for $L$. Then, Theorem 2.2 asserts that $\mathcal{K}'$ also reduces

$$Z_i(L) = Z_i(L_{\mathcal{K}'}) \oplus Z_i(L_{\mathcal{K}'^\perp})$$

Moreover, again by Remark 2 and Propositions 3.1 3.2 one obtains that $\mathcal{K}'$ satisfies the same properties of $\mathcal{K}$, for $Z_i(L)$. Hence $\mathcal{K}' = \mathcal{K}$, since $\mathcal{K}$ is unique for $Z_i(L)$.

As consequence of the last result and Remark 41 the multivalued part of a closed dissipative relation only can inside in its selfadjoint part.

To present the other decomposition, we shall work in the class of symmetric relations. We follow [30] in assuming that the core spectrum of a symmetric relation $A$, satisfies $\delta(A) \subset \mathbb{R}$. Furthermore, if $A$ is maximal then $\sigma(A) \subset \mathbb{C}_+ \cup \mathbb{R}$.
Remark 5. Taking into account (2.3), if $A$ is a completely nonselfadjoint, symmetric relation, then $\sigma_c(A) = \hat{\sigma}(A)$. Indeed, the linear envelope of every eigenvector of $A$ is a reducing subspace for $A$, in which $A$ is selfadjoint.

Definition 8. A symmetric relation $A$ is called elementary maximal, if its transform $Z_\zeta(A)$ is a unilateral shift (cf. [2, Sec. 82]).

Remark 6. An elementary maximal relation $A$ is actually maximal, since the unilateral shifts are maximal. This involves that $\dim N_\zeta(A^\ast) = 0$, for all $\zeta \in \mathbb{C}_-$(cf. [30]). Thus, the first von Neumann formula for relations (see for instance [14, Thm. 6.1]) implies that

$$A^\ast = A \oplus N_\zeta(A^\ast), \quad \zeta \in \mathbb{C}_-, \quad (3.5)$$

where for $\zeta = -i$, the direct sum turns to be orthogonal.

Lemma 3.1. A maximal symmetric relation is elementary maximal if and only if it is completely nonselfadjoint.

Proof. It follows straightforward from Corollary 3.1 and Propositions 3.1, 3.2.

The following assertion uses the fact that a maximal dissipative relation $L$ satisfies $\overline{\text{dom } L} = (\text{mul } L)\perp$ (cf. [5, Lem. 2.1]).

Theorem 3.4. If $A$ is an elementary maximal relation, then $A$ is an unbounded densely defined operator, with the following spectral properties:

$$\sigma_p(A) = \emptyset, \quad \sigma_c(A) = \mathbb{R}, \quad \sigma_r(A) = \mathbb{C}_+, \quad \sigma_p(A^\ast) = \mathbb{C}_-, \quad \sigma_c(A^\ast) = \mathbb{R}, \quad \sigma_r(A^\ast) = \emptyset. \quad (3.6)$$

Proof. Since $A$ is maximal, then it is closed. Besides, $A$ is an operator, in according to Lemma 3.1 and Remark 4. This fact also implies that $\text{dom } A$ is dense but not the whole space, otherwise $A$ has to be selfadjoint, but this contradicts Lemma 3.1. Also, in this way, one obtains that $A$ is unbounded.

We now proceed to show (3.6). Since $A$ is c.n.s, it is straightforward to see from Remark 5 that $\sigma_p(A) = \emptyset$. Additionally, Proposition 2.4 implies $\sigma_r(A^\ast) \subset \sigma_p(A) = \emptyset$. On the other hand, (3.5) yields $\dim N_\zeta(A^\ast) \neq 0$, for all $\zeta \in \mathbb{C}_-$, which means $\mathbb{C}_- \subset \sigma_p(A^\ast)$. To show the other inclusion, if $\zeta \in \sigma_p(A^\ast)$, then there exists $\left( \begin{array}{c} f \\ \zeta f \end{array} \right) \in A^\ast$, with $\| f \| = 1$. Again by (3.5), there is $\left( \begin{array}{c} h \\ k \end{array} \right) \in A$ and $\left( \begin{array}{c} t \\ -it \end{array} \right) \in A^\ast$, such that

$$\left( \begin{array}{c} f \\ \zeta f \end{array} \right) = \left( \begin{array}{c} h \\ k \end{array} \right) + \left( \begin{array}{c} t \\ -it \end{array} \right), \quad (3.7)$$

11
Observe that $t \neq 0$, since $\sigma_p(A) = \emptyset$. Moreover, by virtue of $A$ is symmetric, one produces $\langle h, k \rangle \in \mathbb{R}$ and $\langle k, t \rangle = -i\langle h, t \rangle$. Thus, taking into account (3.7),

$$\text{Im } \zeta = \text{Im } \langle f, \zeta f \rangle$$

$$= \text{Im } (\langle h, k \rangle + 2 \text{Re} \langle t, k \rangle - i\|t\|^2) < 0.$$  

This proves $\sigma_p(A^*) \subset C_-$ and hence they are equals.

The maximality of $A$ implies that $\sigma(A) \subset \mathbb{C}_+ \cup \mathbb{R}$. Consequently, by Remark 1 and since $\sigma_r(A^*) = \emptyset$, one has $\hat{\sigma}(A^*) = \mathbb{C}_- \cup \mathbb{R}$. Then, $\hat{\sigma}(A^*) = C_- \cup \mathbb{R}$, since $\hat{\sigma}(A^*)$ is closed and contains the lower half plane. Hence, by virtue of (2.3), one obtains $\sigma_c(A^*) = \mathbb{R}$. To conclude, again Remark 1 yields $\sigma_c(A) = \mathbb{R}$ and $\sigma(A) = C_+ \cup \mathbb{R}$, which asserts $\sigma_r(A) = C_+$. 

The method used in the last proof can be carried over to unilateral shift operators, holding similar properties to (3.6) in the following sense: If $V$ is a unilateral shift, then:

$$\sigma_p(V) = \emptyset, \quad \sigma_c(V) = \partial \mathbb{D}, \quad \sigma_r(V) = \mathbb{D},$$

$$\sigma_p(V^*) = \mathbb{D}, \quad \sigma_c(V^*) = \partial \mathbb{D}, \quad \sigma_r(V^*) = \emptyset,$$

where $\mathbb{D}$ is the open unit disc and $\partial \mathbb{D}$ its boundary.

We conclude this section by showing the analogue of the von Neumann-Wold decomposition for symmetric relations.

**Theorem 3.5.** If $A$ is a maximal symmetric relation, then

$$\mathcal{K} = \bigoplus_{n=0}^{\infty} Z_i(A)^n \mathcal{L}, \quad \text{with} \quad \mathcal{L} = \text{dom } N_{-i}(A^*),$$

(3.8)

is the unique reducing subspace for $A$, such that $A_{\mathcal{K}}$ is elementary maximal and $A_{\mathcal{K}^\perp}$ is selfadjoint.

**Proof.** The fact that $A$ is a maximal symmetric relation, asserts by Proposition 3.1 that $Z_i(A)$ is an isometry in $\mathcal{B}(\mathcal{H})$. Then, by Theorem 3.2, there exists a unique reducing subspace $\mathcal{K}$ for $Z_i(A)$, such that $Z_i(A)_{\mathcal{K}^\perp}$ is unitary and $Z_i(A)_{\mathcal{K}}$ is a unilateral shift. Furthermore, Theorem 2.2 shows that $\mathcal{K}$ reduces $A$. We follow the same reasoning of (3.4) to obtain

$$A = Z_i(Z_i(A)_{\mathcal{K}}) \oplus Z_i(Z_i(A)_{\mathcal{K}^\perp}).$$

Therefore, Remark 2 and Proposition 3.1 imply that $A_{\mathcal{K}^\perp} = Z_i(Z_i(A)_{\mathcal{K}^\perp})$ is selfadjoint and $A_{\mathcal{K}} = Z_i(Z_i(A)_{\mathcal{K}})$ is symmetric, which certainly is elementary maximal. To finish, we apply the properties of $Z$ transform and (2.13) in (3.3) to obtain (3.8). Uniqueness is proven following the same lines of the proof of Theorem 3.3. 

12
4. Example

Let us consider the Hilbert space of square-summable sequences \( l^2(\mathbb{N}) \), with canonical basis \( \{\delta_k\}_{k \in \mathbb{N}} \). We establish by \( l^2(\text{fin}) \subset l^2(\mathbb{N}) \), as the set of all sequences with only a finite number of nonzero entries. We define the linear operator \( \tilde{A} \), whose domain is given by

\[
\text{dom } \tilde{A} := \left\{ \sum_{k \in \mathbb{N}} (f_k - if_{k-1})\delta_k : \sum_{k \in \mathbb{N}} f_k\delta_k \in l^2(\text{fin}) \right\},
\]

such that

\[
\tilde{A} \left( \sum_{k \in \mathbb{N}} (f_k - if_{k-1})\delta_k \right) = \sum_{k \in \mathbb{N}} (if_k - f_{k-1})\delta_k.
\]

Let \( A \) denote the closure of \( \tilde{A} \). By a simple computation, one verifies that \( S := Z_i(A) \) is the shift operator \( S\delta_k = \delta_{k+1} \). Then, \( A \) is elementary maximal and in according to Theorem \([3.4]\) it is unbounded and densely defined in \( l^2(\mathbb{N}) \), with spectral properties \([3.6]\). Inasmuch as \( \text{ran } S = l^2(\mathbb{N}) \ominus \text{span}\{\delta_1\} \), one has by \([2.13]\) and \([2.1]\) that

\[
\text{span}\{\delta_1\} = l^2(\mathbb{N}) \ominus \text{ran } Z_i(A) = l^2(\mathbb{N}) \ominus \text{ran } (A - iI) = \ker(A^* + iI).
\]

Subsequently, \([3.5]\) yields

\[
A^* = A \oplus \text{span}\left\{ \begin{pmatrix} \delta_1 \\ -i\delta_1 \end{pmatrix} \right\}.
\]

For simplicity of notation, we set \( K = l^2(\mathbb{N}) \ominus \text{span}\{\delta_1\} \) and \( Y = \text{span}\left\{ \begin{pmatrix} 0 \\ \delta_1 \end{pmatrix} \right\} \).

We now consider

\[
B := A_{|K},
\]

which is a closed symmetric operator with \( Z_i(B) = S_{|K} \). Besides, it is straightforward
to compute that \( B = A \cap Y^* \) and since \( Y \) is unidimensional,
\[
B^* = (A \cap Y^*)^* \\
= - \left( (A \cap Y^*)^\perp \right)^{-1} \\
= - \left( A^\perp + (Y^*)^\perp \right)^{-1} \\
= - \left( -A^{-1}\perp + (-Y^*)^{-1}\perp \right) \\
= A^* + Y = A^* + Y.
\]

(4.3)

We observe that \( \text{ran} \ B \subset \mathcal{K} \). In this fashion, we may define the linear relation
\[
A_\infty := B \oplus Y,
\]
which is a closed symmetric extension of \( B \), with multivalued part \( Y \). In view that the maximality of \( A \) is equivalent to say \( \dim \mathcal{N}_\zeta(A^*) = 0, \ \zeta \in \mathbb{C}_- \) (cf. \[30\]). Then, in view of (4.3),
\[
\mathcal{N}_\zeta(A^*_\infty) \subset \mathcal{N}_\zeta(B^*) = \mathcal{N}_\zeta(A^*)
\]
wherefrom \( A_\infty \) is maximal. Following the same reasoning of (4.1) and (4.2), for \( B \) in \( \mathcal{K} \), one produces
\[
B^* = B \oplus \text{span} \left\{ \begin{pmatrix} \delta_2 \\ -i\delta_2 \end{pmatrix} \right\}. \quad (4.4)
\]

One notes at once that \( \mathcal{K} \) reduces \( A_\infty \). Consequently, Theorem 2.1 (2.12) and (4.4) yield
\[
(A_\infty)^* = B \oplus \text{span} \left\{ \begin{pmatrix} \delta_2 \\ -i\delta_2 \end{pmatrix} \right\} \oplus Y. \quad (4.5)
\]

Thus, \( \text{dom} \mathcal{N}_{-i}(A_\infty)^* = \text{span}\{\delta_2\} \) and
\[
\bigoplus_{n=0}^{\infty} \mathcal{Z}_i(A_\infty)^n(\text{span}\{\delta_2\}) = \bigoplus_{n=0}^{\infty} \mathcal{Z}_i(B)^n(\text{span}\{\delta_2\})
\]
\[
= \bigoplus_{n=0}^{\infty} S^n(\text{span}\{\delta_2\}) = \mathcal{K}.
\]

Therefore, by virtue of Theorem 3.5 one concludes that \( \mathcal{K} \) is the unique reducing subspace for \( A_\infty \) in which \( B \) is elementary maximal and \( Y \) is selfadjoint in \( \text{span}\{\delta_1\} \).
