Abstract: Elaboration of some fundamental relations in 3-dimensional quantum mechanics is considered taking into account the restricted character of areas in radial distance. In such cases the boundary behavior of the radial wave function and singularity of operators at the origin of coordinates contribute to these relations. We derive the relation between the average value of the operator’s time derivative and the time derivative of mean value of this operator, which is usually considered to be the same by definition. The deviation from the known result is deduced and manifested by extra term, which depends on the boundary behavior mentioned above. The general form for this extra term takes place in the hypervirial-like theorems. As a particular case, the virial theorem for Coulomb potential is considered and correction to the Kramers’ sum rule is derived. Moreover the corrected Ehrenfest theorem is deduced and its consistency with real physical picture is demonstrated.

Key-words: singular operators, time derivative, hypervirial theorem, Ehrenfest theorem, Coulomb potential.

1. Introduction

During decades there the papers in which the authors try to reconsider some fundamental relations of quantum mechanics on strong mathematical properties of the operators and their matrix elements appeared. For example, the Ehrenfest theorem or/and, in general, mean values of time derivatives of the operators are encountered [1-8].

In the textbooks on quantum mechanics most formulations concerned mainly one-dimensional problems, and in these cases, as a rule, wave functions decrease at infinity (Hilbert space). Mostly the problems are considered in full infinite space. However, as is well known, when the system is located in finite volume the inclusion of boundary conditions becomes necessary as well as the restrictions of the allowed classes of wave functions. It is so, because operators are defined not only by their action (i.e, what they do to the function on, which they operate), but also by their domain (that is, the set of functions on which they operate). The situations are encountered frequently, when domain is essential.

This problem often arises in many-dimensional cases, when the polar (spherical) coordinates are necessarily introduced, because the radial functions are defined in semi-space.

Therefore, the question arises: whether or not some of the well-known theorems are altered, when the boundary behavior problem comes into play.

Though this problem was well investigated in one-dimensional case, three dimensions has its specific peculiarities therefore our attention will be focused to three dimensions.

The aim of this article is to study some quantum mechanical theorems with this point of view. We see that in most cases great caution must be exercised especially in the cases, when the potential in the Schrodinger equation is singular or the operators are singular themselves. Our considerations below concern spherically symmetric operators.

This paper is organized as follows: First of all the time derivative of mean value of the operator is studied and the extra term in the usual relation is obtained, owing to restricted character of the area in radial space. The obtained surface term depends on the behavior of radial wave function and considered operators in the origin of coordinates. After that new relation between time derivatives is established. This fact has an influence on the relation between mean values and the integrals of motion in various special cases.

The remained part of this manuscript is devoted to some applications of obtained results. Namely, the generalization of hypervirial theorem is considered taking account this extra term. As a result new form of hypervirial theorem is derived. This modified theorem is verified in case
of Coulomb potential and it is shown that the well-known Kramers’ theorem should be corrected. The modified version of this theorem works with success. At last the explicit calculations of this extra term for various forms of operators are carried out. The application to the Ehrenfest theorem is considered as well and possible modifications are discussed. It is shown that the obtained extra term plays a role of the so-called “boundary quantum force” and its physical meaning is cleared up.

2. **Time derivative of the operator’s mean value**

It is well known that in quantum mechanics derivative of time-dependent operator \( \hat{A}(t) \) satisfies the Heisenberg equation

\[
\frac{d\hat{A}}{dt} = \frac{\partial \hat{A}}{\partial t} + \frac{i}{\hbar} \left[ \hat{H}, \hat{A} \right]
\] (2.1)

Averaging this expression by the state functions one derives

\[
\left\langle \frac{d\hat{A}}{dt} \right\rangle = \left\langle \frac{\partial \hat{A}}{\partial t} \right\rangle + \frac{i}{\hbar} \left\langle \left[ \hat{H}, \hat{A} \right] \right\rangle
\] (2.2)

As a rule one believes that these two operations, – time derivative and average procedures, can be interchanged. Let us cite a quotation from the book of Landau and Lifshitz [9] “The idea of the derivative with respect of time must be differently defined in quantum mechanics. It is natural **to define** the derivative \( \dot{f} \) of a quantity \( f \) as a quantity whose mean value is equal to the derivative, with respect to time, of the mean value \( \bar{f} \). Thus we have the **definition** \( \bar{f} = \dot{f} \).” *(Underlining is ours).* Therefore, according to this book it is the definition. In several textbooks (see for example [10]), relations (2.1-2) are derived from the equations of quantum mechanics, while this problem reduces to definition at long last.

In either case, the equation is said to be valid always and therefore it may be written as follows

\[
\left\langle \frac{d\hat{A}}{dt} \right\rangle = \frac{d\left\langle \hat{A} \right\rangle}{dt} = \left\langle \frac{\partial \hat{A}}{\partial t} \right\rangle + \frac{i}{\hbar} \left\langle \left[ \hat{H}, \hat{A} \right] \right\rangle
\] (2.3)

Let us see, if it is so or not in general, when the problem is considered in 3-dimensional space. With this aim we calculate

\[
\frac{d\left\langle \hat{A} \right\rangle}{dt} = \frac{d}{dt} \langle \psi | \hat{A} | \psi \rangle = \left\langle \frac{\partial \psi}{\partial t} | \hat{A} | \psi \rangle \right\rangle + \left\langle \psi | \frac{\partial \hat{A}}{\partial t} | \psi \rangle \right\rangle + \left\langle \psi | \hat{A} \left( \frac{\partial \psi}{\partial t} \right) \right\rangle
\] (2.4)

We use here the time dependent Schrodinger equation and its complex conjugate one
\[ i \hbar \frac{\partial \psi}{\partial t} = \hat{H} \psi, \quad -i \hbar \frac{\partial \psi^*}{\partial t} = (\hat{H} \psi)^* \]  

(2.5)

Then we have

\[
\frac{d}{dt} \left\langle \hat{A} \right\rangle = i \frac{\hbar}{\psi} \left\langle \hat{H} \psi | \hat{A} \psi \right\rangle - i \frac{\hbar}{\psi} \left\langle \psi | \hat{A} \hat{H} \psi \right\rangle + \left\langle \psi \right| \frac{\partial \hat{A}}{\partial t} \left| \psi \right\rangle 
\]

(2.6)

Where for any moment of time we must have [3,4]

\[ \psi \in \text{Dom}(\hat{A}) \cap \text{Dom}(\hat{H}) \cap \text{Dom} \left( \frac{\partial \hat{A}}{\partial t} \right) \]  

(2.7)

And

\[ \hat{H} \psi \in \text{Dom}(\hat{A}) \cap \text{Dom} \left( \frac{\partial \hat{A}}{\partial t} \right) \]  

(2.8)

It must be underlined especially that if the following condition

\[ \hat{A} \psi \in \text{Dom}(\hat{H}) \]  

(2.9)

is satisfied, we can introduce a commutator \([\hat{H}, \hat{A}]\) and rewrite (2.6) in the following way

\[
\frac{d}{dt} \left\langle \hat{A} \right\rangle = i \frac{\hbar}{\psi} \left\langle \hat{H} \psi | \hat{A} \psi \right\rangle - i \frac{\hbar}{\psi} \left\langle \psi | \hat{A} \hat{H} \psi \right\rangle + i \frac{\hbar}{\psi} \left\langle \psi \right| \left[ \hat{H}, \hat{A} \right] \left| \psi \right\rangle + \left\langle \psi \right| \frac{\partial \hat{A}}{\partial t} \left| \psi \right\rangle 
\]

(2.10)

Comparing this with Eq. (2.3), we conclude that the first two terms here are new. Exactly these terms are taken into account in [1-5] for one dimensional case and are calculated in the simplest models.

Below in contrast with the above mentioned papers, we consider the 3-dimensional case, when we have arbitrary central potential and \( \hat{A} \) operator depends only on radial distance \( \hat{A} = \hat{A}(r,...) \). Corresponding radial Hamiltonian is

\[
\hat{H} = \frac{1}{2m} \left( -\frac{d^2}{dr^2} - \frac{2}{r} \frac{d}{dr} \right) + \frac{l(l+1)}{2mr^2} + V(r,t)
\]

(2.11)

Remark that the potential energy depends on time, otherwise wave functions should be stationary.
In the process of calculation of additional terms in Eq. (2.10) “redistribution” of radial wave function with Hamiltonian is employed in order to construct the radial Hamiltonian again. For example, the first term in (2.4) looks like

\[
I_1 = \left( \frac{\partial \psi}{\partial t} \right) | \hat{A} \psi \rangle = -\frac{1}{i\hbar} \int_0^\infty (\hat{H} \psi)^* \hat{A} \psi dx dy dz = -\frac{1}{i\hbar} \int_0^\infty (\hat{H} \hat{R})^* \hat{A} \hat{R}^2 dr = -\frac{1}{i\hbar} \int_0^\infty \hat{H} \hat{R}^* \hat{A} \hat{R}^2 dr \tag{2.12}
\]

where \( R = R(r) \) is a radial function, \( \psi(r) = R(r) Y_l^m(\theta, \varphi) \). The function \( \hat{R}^* \) needs to be placed at the top of integrand expression. For this replacement only the kinetic part of Hamiltonian operates. Therefore, let us study only the following expression

\[
\int_0^\infty \hat{H} \hat{R}^* \hat{A} \hat{R}^2 dr \Rightarrow \int_0^\infty \left[ -\frac{\hbar^2}{2m} \left( \frac{d^2}{dr^2} + \frac{2}{r} \frac{d}{dr} \right) R^* \right] \hat{A} \hat{R}^2 dr \tag{2.13}
\]

Remaining terms of the Hamiltonian do not contribute to the procedure carried out.

Now let us integrate by parts two times in order to transfer differentiation to the right and construct the radial Hamiltonian again. Then we obtain

\[
\int_0^\infty \frac{d^2 R^*}{dr^2} \hat{A} \hat{R}^2 dr = \int_0^\infty \left( \hat{A} \hat{R} \frac{d^2 R^*}{dr^2} r^2 dr \right) = \hat{A} \hat{R}^2 \left( \frac{d^2 R^*}{dr^2} \right) \int_0^\infty \frac{d}{dr} \left( \hat{A} \hat{R}^2 \right) \frac{dR^*}{dr} dr = \hat{A} \hat{R}^2 \left| \frac{d^2 R^*}{dr^2} \right|_0^\infty - \frac{d}{dr} \left( \hat{A} \hat{R}^2 \right) \left| R^* \right|_0^\infty + \int_0^\infty \frac{d}{dr} \left( \hat{A} \hat{R}^2 \right) \frac{dR^*}{dr} dr \tag{2.14}
\]

Here we take into account that for the bound states the radial function tends to zero at partial infinity, but the contribution from the origin remains in general. Proceeding this way, we obtains at the end

\[
\int \hat{H} \hat{R}^* \hat{A} \psi dx dy dz = \psi^* \hat{H} \hat{R}^* \psi dx dy dz + \frac{\hbar^2}{2m} \lim_{r \to 0} \left\{ \hat{A} \hat{R}^2 \frac{dR^*}{dr} - r^2 R^* \frac{d}{dr} \left( \hat{A} R \right) \right\} \tag{2.15}
\]

Considering the same procedure in all the terms we derive for the required derivative

\[
\frac{d\langle \hat{A} \rangle}{dt} = \frac{i}{\hbar} \left[ \hat{H}, \hat{A} \right] + \frac{d}{dt} \left\langle \frac{\partial \hat{A}}{\partial t} \right\rangle + \Pi \tag{2.16}
\]

where we obtained the extra term

\[
\Pi = \frac{i}{2m} \lim_{r \to 0} \left\{ r^2 \left[ \hat{A} R \frac{dR^*}{dr} - R^* \frac{d}{dr} \left( \hat{A} R \right) \right] \right\} \tag{2.17}
\]
Exactly this term corresponds to the additional contribution mentioned in Eq. (2.10). This term is not zero in general, because it depends on the behavior of wave function and the operator in the origin of coordinates. Evidently, this term has a purely quantum origin. It has no classical analogue (in the limit of $\hbar \to 0$, this term also tends to zero).

3. Analysis of the additional term

As it is clear from the above value of $\Pi$ depends explicitly on the behavior of the radial function at the origin. It is known that under general requirements the radial function must behave like 

$$rR(r) = 0 \quad \text{as} \quad r \to 0$$ (3.1)

This condition corresponds to the Dirichlet boundary condition for reduced $u = rR$ wave function (for details see [11-14]). More precisely the behavior depends on potential under consideration. From this point of view the following classification is known:

- (1). Regular potentials: They behave as 

$$\lim_{r \to 0} r^2V(r) = 0,$$ (3.2)

For which solution in the origin behaves like 

$$R_{r \to 0} = C_1 r^l + C_2 r^{-(l+1)}$$ (3.3)

Clearly, the second term is very singular and contradicts to (3.1). Therefore we must retain only the first term ($C_2 = 0$) or

$$R_{r \to 0} \approx C_1 r^l$$ (3.4)

- (2). Singular potentials, for which 

$$r^2V(r) \to \pm \infty \quad \text{as} \quad r \to 0$$ (3.5)

For them the “falling to the center” happens and is not interesting for us now.

- (3) “Soft” singular potentials, for which 

$$r^2V(r) \to \pm V_0, \quad (V_0 = \text{const} > 0)$$ (3.6)

Here the (+) sign corresponds to repulsion, while the (-) sign – to attraction. For such potential the wave function has the following behavior [11-14]:

$$\lim_{r \to 0} R = a_{sr} r^{-1/2+p} + a_{add} r^{-1/2-p} \equiv R_{sr} + R_{add},$$ (3.7)

where
\[ P = \sqrt{(l+1/2)^2 - \frac{2mV_0}{\hbar^2}} \quad (3.8) \]

In the region \( 0 < P < 1/2 \) the second solution satisfies also the boundary condition (3.1), therefore it must be retained in general and thus perform the self adjoint extension [13]. As for the region \( P \geq 1/2 \) only the first (standard or regular) solution remains.

Now, let us return to consideration of additional contribution in Eq. (2.16). First, consider regular potentials. It is obvious from Eq. (2.17) that upon calculation of the limit the singularity of the operator \( \hat{A} \) in the origin will be also important. We take it as

\[ \hat{A}(r) \sim \frac{1}{r^\beta} ; \quad \beta > 0 \quad (3.9) \]

Here, it is implied not only explicit dependence on \( r \), but also its scale dimension (derivative et al.). Taking all these into account, we obtain

\[ \hat{A} r^l \sim r^{l-\beta} \quad (3.10) \]

Then, we have

\[ \Pi_{reg} = \frac{i\hbar C_i^2}{2m} \lim_{r \to 0} r^2 \left[ r^{l-\beta} r^{-1} - r^l \frac{d}{dr} r^{l-\beta} \right] = \frac{i\hbar C_i^2}{2m} \lim_{r \to 0} r^{2l+1-\beta} \quad (3.11) \]

In order that this expression will not be diverging we must require

\[ 2l+1 > \beta \quad (3.12) \]

In this case the additional term vanishes. If the inequality be reflected, then the divergent result follows and we are unable to write the equation (2.2).

On the other hand, if the operator is such that

\[ 2l+1 = \beta \quad (3.13) \]

then the extra term remains on the right-hand side

\[ \frac{d\hat{A}}{dt} = \left\langle \frac{\delta \hat{A}}{\delta t} \right\rangle + i\hbar \left\langle [\hat{H}, \hat{A}] \right\rangle + \frac{i\hbar C_i}{m} \left( l + \frac{1}{2} \right) \quad (3.14) \]

We see that the averaging relation is not so trivial, as it looks at the first glance, but depends on singularity of operator under consideration.

Let us now return to the case of soft singular potential (3.6). First of all, for the sake of definiteness, ignore the additional contribution \( (a_{add} = 0) \) and use only the regular solution

\[ R = R_{st} = a_{st} r^{-1/2 + P} ; \]

\[ \Pi_{st} = \frac{i\hbar a_{st}^2}{2m} \lim_{r \to 0} r^2 \left\{ r^{-1/2+P-\beta} (\frac{1}{2} + P) r^{P-3/2} - r^{-1/2+P} \frac{d}{dr} r^{P-1/2+P-\beta} \right\} = \frac{i\hbar a_{st}^2 \beta}{2m} \lim_{r \to 0} r^{2P-\beta} \quad (3.15) \]

Here, the index under \( \Pi \) indicates that only the regular solutions of (3.6) are considered, here also we get \( \Pi_{st} = 0 \) zero, when \( 2P > \beta \).

But for

\[ 2P = \beta \quad (3.16) \]

the finite contribution follows
\[
\frac{d\langle \hat{A} \rangle}{dt} = \left\langle \frac{\partial \hat{A}}{\partial t} \right\rangle + \frac{i}{\hbar} \left\langle \left[ \hat{H}, \hat{A} \right] \right\rangle + \frac{i\hbar a^2}{m} P
\]

(3.17)

According to the obtained results we can conclude that even in ordinary quantum mechanics the well-known averaging relation is validate only in the cases, when the condition (3.12) between orbital momentum and operator singularity at the origin is satisfied. At the same time for “soft” singular potentials the standard solutions must obey the restriction \(2P > \beta\). It is evident that this strange result is provided by singular character of the considered operator. But it is strange, that the time derivative of the average value does not coincide to the average of derivative of the operator, if the derivative of the operator is defined by Eq.(2.1). Indeed, from (2.2) and (2.16) it follows

\[
\left\langle \frac{d\hat{A}}{dt} \right\rangle = \frac{d\langle \hat{A} \rangle}{dt} - \Pi
\]

(3.18)

Even, when the operator does not depend on time explicitly, the above consideration shows that

\[
\frac{d\langle \hat{A} \rangle}{dt} = \frac{i}{\hbar} \left\langle \left[ \hat{H}, \hat{A} \right] \right\rangle + \Pi
\]

(3.19)

Therefore, if the operator has “bad” singularity ((3.13) or (3.16)), its average value is not an integral of the motion, even if it commutes with the Hamiltonian.

In conclusion, we have demonstrated that when one considers the time evolution in spherical coordinates, a definite caution is necessary, particularly, the singular character of the considered operator should be taken into account, as well as the singularity of the wave function itself.

4. Stationary states and integrals of motion

Let us apply now the derived results and consider the case when the Hamiltonian doesn’t explicitly depend on time. For stationary states wave function has the following dependence

\[
\psi \left( r, t \right) = e^{\frac{-iE_t}{\hbar}} \phi \left( r \right)
\]

(4.1)

When the operator \( \hat{A} \) doesn’t explicitly dependent on time, we should have an operatorial equality

\[
\frac{d\hat{A}}{dt} = \frac{i}{\hbar} \left[ \hat{H}, \hat{A} \right]
\]

(4.2)

Averaging this equality by means of (4.1), we get

\[
\left\langle \frac{d\hat{A}}{dt} \right\rangle = \left\langle \frac{i}{\hbar} \left[ \hat{H}, \hat{A} \right] \right\rangle,
\]

(4.3)
Or explicitly
\[
\int \psi^* \frac{d\hat{A}}{dt} \psi d^3r = i \int_0^\infty \phi^* \left[ \hat{H}, \hat{A} \right] \phi d^3r = i \int_0^\infty R^* \left( \hat{H} \hat{A} - \hat{A} \hat{H} \right) R r^2 dr = \]
\[
= \frac{i}{\hbar} \int_0^\infty R^* \hat{H} \hat{A} r^2 dr - \frac{i}{\hbar} E \int_0^\infty R^* \hat{A} r^2 dr
\]

Here, we used that \( \phi \) to be eigenfunction of \( \hat{H} \) with eigenvalue \( E \). Therefore,
\[
\left\langle \frac{d\hat{A}}{dt} \right\rangle = \frac{i}{\hbar} \left\{ \int_0^\infty R^* \hat{H} \hat{A} r^2 dr - E \int_0^\infty R^* \hat{A} r^2 dr \right\}
\]

Let us consider two cases:

(a). \( \hat{A} \) commutes with \( \hat{H} \). Then it follows
\[
\left\langle \frac{d\hat{A}}{dt} \right\rangle = \frac{d\left\langle \hat{A} \right\rangle}{dt} = 0
\]

Hence, for stationary state, if the operator \( \hat{A} \) is explicitly time-independent and commutes with the Hamiltonian, then in spite of its singular character, the relation (4.6) is valid, that is the mean value of this operator is conserved and is an integral of motion.

(b) Let us consider the case when Hamiltonian does not commute with the operator \( \hat{A} \). Let us study the following integral entering (4.5)
\[
I = \frac{i}{\hbar} \int_0^\infty R^* \hat{H} \hat{A} r^2 dr
\]

If we repeat all above consideration again, we derive
\[
I = \frac{i}{\hbar} \int_0^\infty \hat{H} R^* \hat{A} r^2 dr - \Pi = \frac{i}{\hbar} E \int_0^\infty R^* \hat{A} r^2 dr - \Pi
\]

where \( \Pi \) is given by Eq. (2.17). Taking this into account, we obtain
\[
\left\langle \frac{d\hat{A}}{dt} \right\rangle = -\Pi
\]

On the other hand, when \( \hat{A} \) is independent on time, we have
\[
\left\langle \hat{A} \right\rangle = \int e^{\frac{i}{\hbar} E t} \phi^* \left( r \right) \hat{A} e^{\frac{i}{\hbar} E t} \phi \left( r \right) d^3r = \int \phi^* \left( r \right) \hat{A} \phi \left( r \right) d^3r
\]

It is evident that
So we obtain”strange” result: for stationary states, in case of non-commutativity $\hat{A}\hat{H} \neq \hat{H}\hat{A}$, Eq. (4.11) is valid or $\langle \hat{A} \rangle$ is conserved, but at the same time according to Eq. (4.9) $\langle \frac{d\hat{A}}{dt} \rangle \neq 0$. In this particular case this ‘strange” result is provided by singularity of operator $\hat{A}$. Therefore, we conclude from this result that the definition, given initially by Eq. (2.3), depends on the singularity of the considered operator. Remark, that this point(operator’s singularity) was not discussed in the literature up to now.

5. Modified hypervirial theorems

Comparing Eqs. (4.3) and (4.9), one derives

$$\frac{i}{\hbar} \langle [\hat{H}, \hat{A}] \rangle = -\Pi$$

(5.1)

It follows that the well-known hypervirial theorems should be corrected. The traditional hypervirial theorem looks- like is formulated as [15-17]:

If $\phi$ is a bound state eigenfunction of the Hamiltonian $\hat{H}$ and if $\hat{A}$ is an arbitrary Hermitian time-independent operator involving the coordinates and momenta, then hypervirial theorem for $\hat{A}$ states that

$$\langle \phi, [\hat{H}, \hat{A}] \phi \rangle = 0$$

(5.2)

It is clear that this theorem must be modified and according to Eq. (5.1) it should have the following form:

$$\langle \phi, [\hat{H}, \hat{A}] \phi \rangle = i\hbar \Pi$$

(5.3)

Here the choice of the operator $\hat{A}$ is very important and the definite relations between the average values can be derived.

First of all, let us remember the known relation for the Coulomb potential $V = -\frac{e^2}{r}$ and oscillator, $V = \frac{m}{2} \omega^2 r^2$ as regular potentials [18-20]:

$$2E(s+1)\langle \rho^s \rangle + e^2(s+1)\langle \rho^{s+1} \rangle + \frac{s\hbar^2}{4m} \left[ s^2 - (2l+1)^2 \right] \langle \rho^{s-2} \rangle = 0$$

(5.4)
\[2E(s+1)r^s - \frac{m\omega^2(s+2)r^{s+2}}{4m} + \frac{sh^2}{4m}\left[r^2 - (2l+1)^2\right]r^{s-2} = 0\] (5.5)

It is remarked in textbooks and various articles, that these relations are valid only if \(s > -(2l+1)\). But there are papers [21-23], in which these relations are modified for arbitrary \(N\)-dimensional Schrodinger equation and have a form

\[(2L+1)^2C^2_\delta s_{L-2L} = \frac{2m}{\hbar^2}\left\{r^s \frac{d}{dr}\left[r^2 V - 2S\left[r^{s-1}V\right]ight] + \frac{1}{2}(S-1)(2L+1)^2 - (S-1)^2\right\}r^{s-3}\] (5.6)

Where \(L = l + \frac{N-3}{2}\) and \(\lim_{r \to 0} r^{-l} = C_l\)

In our paper [24] significantly more general relations were derived. Namely, we considered a general second order differential equation

\[R^s(r) + \frac{2}{r} R'(r) + L(r)R(r) = 0\] (5.7)

This equation reduces to the known equations (radial Schrodinger, one- and two-body Klein-Gordon etc.). Then after multiplication of Eq. (5.7) on an arbitrary three-times differentiable function \(f(r)\) and partial integration we derived very general hypervirial theorem (see, [24])

\[\left\{f\left[R^2 - r^2 RR'' + r^2 R'^2\right] - f' R[rR' + R] + \frac{1}{2} f'' r^2 R^2\right\} = -2 < f'L > - < fL' > - \frac{1}{2} < f'' >\] (5.8)

from which by choosing of \(f(r)\), one can obtain several interesting relations. Some of them are exhibited in mentioned paper.

Consider now some applications of a new modified hypervirial theorem (5.3). First of all, let analyze cases which were discussed earlier in literature. Consider the following operator [18]

\[A = \hat{p}_r r^{s+1}\] (5.9)

Where \(\hat{p}_r\) is a radial momentum operator [9-10]

\[\hat{p}_r = \frac{\hbar}{i}\left(\frac{\partial}{\partial r} + \frac{1}{r}\right)\] (5.10)

It follows from Eqs. (2.17) and (3.7) that for standard solutions

\[\Pi_{\mu} = -\frac{h^2 a_s^2 s\left(P + s + \frac{3}{2}\right)}{2m^2} \lim_{r \to 0} r^{2P+s}\] (5.11)

It is clear that if \(2P > -s\), then \(\Pi_{\mu} = 0\), but when \(2P = -s\), then
\[ \Pi_s = -\frac{\hbar^2 a_s}{4m} s(s+3) \]  

(5.12)

\( \Pi_s \) diverges when \( 2P < -s \), or for singular potentials in this case the hypervirial theorem does not work. Remark, that there is no restriction on \( s \) in above mentioned works.

For regular potentials when \( P = l + \frac{1}{2} \), above relation takes the form

\[ \Pi_{reg, s} = \frac{\hbar^2 C^2}{2m} (2l+1)(1-l) \lim_{r \to 0} r^{2l+s+1} \]  

(5.13)

Which survives, if \( s = -(2l+1) \). In this case

\[ \Pi_{reg, s} = \frac{\hbar^2 C^2}{2m} (2l+1)(1-l) \]  

(5.14)

Let us now consider more general operator

\[ \hat{A} = \hat{p}_r f(\hat{r}) \]  

(5.15)

Where \( f(r) \) is a three-times differentiable. Calculate the commutator

\[ [\hat{H}, \hat{A}] = -\frac{i\hbar}{2m} \left( p_r^2 + \frac{df}{dr} p_r^2 + i\hbar f(r) \frac{dV}{dr} \right) - \frac{\hbar^2 d^2 f}{2m r^2} p_r + i\hbar f(r) \frac{dV}{dr} - i\hbar^3 \frac{l(l+1)}{mr^2} f \]  

(5.16)

Entering here \( \hat{p}^2_r \) and \( \hat{p}_r \) rewrite as

\[ -\frac{p_r^2}{2m} = -H + \frac{\hbar^2 l(l+1)}{2mr^2} + V \]  

(5.17)

\[ -\frac{\hbar}{m} \frac{d^2 f}{dr^2} p_r = \left[ H, \frac{df}{dr} \right] + \frac{\hbar^2}{2m} f'' \]  

(5.18)

Finally

\[ [\hat{H}, \hat{A}] = -i\hbar f' (H - V) + i\hbar^3 \frac{l(l+1)}{m} \left[ \frac{f'}{r^2} - \frac{f'}{r^3} \right] - i\hbar^3 \frac{f'' + i\hbar f'}{4m} f'' + \frac{3}{2} i\hbar [\hat{H}, f'] \]  

(5.19)

This place is principally important. In [24] an analogous relation was derived and was remarked that “the hypervirial theorem demands the expectation values of both \([H, A]\) and \([H, f']\) to be zero”. But it is not correct. In particular, the expectation value of \([H, f']\) is not zero. Indeed, if we use the relation (2.17) for \( \frac{d(f')}{dt} \) or repeat a direct calculation for this average, we obtain
\[
\frac{d\langle f' \rangle}{dt} = \frac{i}{\hbar} \langle [\hat{H}, f'] \rangle + \Pi'
\] (5.20)

Where

\[
\Pi' = \frac{\hbar}{2m} \lim_{r \to 0} \left\{ r^2 \left[ f'R \frac{dR}{dr} - R \frac{df}{dr} (fR) \right] \right\} = -\frac{\hbar}{2m} \lim_{r \to 0} \left\{ r^2 R^2 f'' \right\}
\] (5.21)

It follows from these relations ones again that the singularity of \( \hat{A} \) operator (\( f \) in this case) participates into calculations. For stationary states \( \frac{d\langle f \rangle}{dt} = 0 \), therefore (5.20) reads

\[
\frac{i}{\hbar} \langle [\hat{H}, f] \rangle = -\Pi'
\] (5.22)

Or finally

\[
\langle [\hat{H}, \dot{A}] \rangle = \left\langle -i \hbar f'' (H - V) + \hbar^2 \frac{l(l+1)}{m} \left[ \frac{f'}{r^2} - \frac{f}{r^3} \right] - \frac{i\hbar^3}{4m} f''' + i\hbar f (r) V' \right\rangle = -\left( \Pi_{reg,l} + \Pi_1 \right),
\] (5.23)

where

\[
\Pi_1 = -\frac{3}{2} \frac{i\hbar}{m} \Pi' = -\frac{3\hbar^2}{4m} \lim_{r \to 0} \left\{ r^2 R^2 f'' \right\}
\] (5.24)

Eq. (5.23) is a correct form of hypervirial theorem. For its application let us take

\[ f = r^{s+1} \] (5.25)

Which means that we return to operator (5.9). Taking into account (5.22), the hypervirial theorem takes the following form

\[
(2l+1)^2 C_i^2 \delta_{s+1,-2l} = \frac{2m}{\hbar^2} \left\{ \langle r^{s+1} \frac{dV}{dr} \rangle + 2(s+1) \langle \dot{r}^s V \rangle - E \langle r^s \rangle \right\} + \frac{1}{2} S \left[ (2l+1)^2 - S^2 \right] \langle r^{s-2} \rangle
\] (5.26)

This form coincides with eq. (5.6) if in Eq. (5.26) we replace \( s+1 \to s \), which means that calculation by commutator gives the same result as a calculation by means of integration by part. In conclusion we can say that the modified hypervirial theorems for the Coulomb and oscillator potentials have the forms

\[
2E(s+1)\langle r^s \rangle + e^2 (2s+1) \langle r^{s+1} \rangle + \frac{sh^2}{4m} \left[ s^2 - (2l+1)^2 \right] \langle r^{s-2} \rangle = -\frac{\hbar^2}{2m} (2l+1)^2 C_i^2 \delta_{s+1,-2l}
\] (5.27)

\[
2E(s+1)\langle r^s \rangle - m\omega^2 (s+2) \langle r^{s+2} \rangle + \frac{sh^2}{4m} \left[ s^2 - (2l+1)^2 \right] \langle r^{s-2} \rangle = -\frac{\hbar^2}{2m} (2l+1)^2 C_i^2 \delta_{s+1,-2l}
\] (5.28)
Let us make two comments:

1. For \( s = 0 \) from (5.27-28) follows the usual virial theorem. So in this case the usual virial theorem is correct.
2. For \( s = -1 \) or \( f = \text{const} \) it follows from (5.21) that \( \Pi' = 0 \). This case will be considered below in connection of Ehrenfest theorem.

6. The case of Coulomb potential

Consider for more details the Coulomb potential \( V = -\frac{e^2}{r} \). Its wave function is [9]

\[
R_{nl}(r) = \tilde{C}_{nl} \left( \frac{B}{n} \right) \left( \frac{B}{2} \right)^{\frac{1}{2}} \left( \frac{n+l+1, 2l+2}{(n-l-1)!} \right) \left( \frac{Br}{n} \right)
\]

(6.1)

Where

\[
\tilde{C}_{nl} = \frac{B}{n^2(2l+1)} \left( \frac{B}{2} \right)^{\frac{1}{2}} \left( \frac{n+l+1, 2l+2}{(n-l-1)!} \right)
\]

(6.2)

is a normalization constant, which is related to \( C_i \) as follows

\[
C_i = \tilde{C}_{nl} \left( \frac{B}{n} \right)
\]

(6.3)

And

\[
\frac{B}{n} = \frac{2}{na_0}, \quad a_0 = \frac{\hbar^2}{me^2}
\]

(6.4)

where \( a_0 \) is a Bohr’s first orbit radius. Substituting all this into Eq. (5.26), we derive a modified Kramers’ relation

\[
2E(s+1)\langle r^s \rangle + e^2(2s+1)\langle r^{s-1} \rangle + \frac{sh^2}{4m} \left[ s^2 - (2l+1)^2 \right] \langle r^{s-2} \rangle = -\frac{\hbar^2}{2m} (2l+1)^2 \tilde{C}_{nl}^2 \left( \frac{2}{na_0} \right)^{2l} \delta_{s+1,2l+2}
\]

(6.5)

Let us study this relation. It is clear that when \( s = -(2l+1) \), then it follows

\[
4E l \langle r^{-2l-1} \rangle + e^2 (4l+1) \langle r^{-2l-2} \rangle = \frac{\hbar^2}{2m} (2l+1)^2 \tilde{C}_{nl}^2 \left( \frac{2}{na_0} \right)^{2l}
\]

(6.6)

Consider some of first values of \( l \).

(i) \( l = 0 \).
This case corresponds to $s = -1$, i.e. $\hat{A} = \hat{p}_r$. Then Eq. (6.5) gives

$$e^2 \left\langle \frac{1}{r^2} \right\rangle = \frac{\hbar^2}{2m} C_{n_0}^2$$  \hspace{1cm} (6.7)

It means that if we take zero on the right-hand side (or use the Kramers’ relation (5.3)) we’ll get the obvious contradiction $- \left\langle r^{-2} \right\rangle = 0$. It must be pointed out that the above considered case lies outside the validity of Kramers’ relation. So our theorem generalizes the Kramers’ relation.

Now let us check if the formula (6.6) is fulfilled. The matrix elements of some degrees of radius for the Coulomb functions are known. For instance

$$\left\langle 1 \left| \frac{1}{r^2} \right| n \right\rangle = \frac{2}{a_0^2 n^3 (2l+1)}$$  \hspace{1cm} (6.8)

In case under consideration we have $C_0 = \tilde{C}_{n_0}$,

$$\tilde{C}_{n_0} = B \left( \frac{B}{2} \right)^{\frac{1}{2}} \sqrt{\frac{n!}{(n-1)!}} = B \left( \frac{B}{2} \right)^{\frac{1}{2}} \sqrt{n} \quad \text{or} \quad \tilde{C}_{n_0}^2 = \frac{B^2}{n^3} \frac{B}{2}.$$  \hspace{1cm} (6.9)

But $\frac{B}{2} = \frac{1}{a_0}$, and therefore

$$C_0^2 = \tilde{C}_{n_0}^2 = \frac{4}{n^3 a_0^3}$$  \hspace{1cm} (6.10)

After substitution all of these into (6.7), we obtain the identity

$$\frac{\hbar^2}{2m} \frac{4}{n^3 a_0^3} = \frac{2e^2}{n^3 a_0^2},$$  \hspace{1cm} (6.11)

From which it follows a correct relation for the Bohr’s radius. Hence, the modified Kramers’ relation is successful.

(ii) $l = 1$

In this case $s = -3$ and corresponding operator is

$$\hat{A} = \hat{p}_r \cdot \frac{1}{r^3}$$  \hspace{1cm} (6.12)

Then Eq. (6.6) gives

$$4E \left\langle r^{-3} \right\rangle + 5e^2 \left\langle r^{-4} \right\rangle = \frac{\hbar^2}{2m} 9 \tilde{C}_{n_l}^2 \left( \frac{2}{na_0} \right)^2$$  \hspace{1cm} (6.13)

Using here known relations [9]

$$\left\langle 1 \right\rangle = \frac{2}{a_0^2 n^3 l(l+1)(2l+1)^2} \quad \left\langle 1 \right\rangle = \frac{3n^2 - l(l+1)}{2 a_0^2 n^3 (l + 3/2)(l+1)(l+1/2)(l-1/2)}.$$  \hspace{1cm} (6.14)

It is easy to convince that the relation (6.6) is also satisfied precisely. So is for $l = 2$ and etc.
The other operators were considered also in literature. Particularly, in [25-26] the following operator is studied

\[ \hat{A}_1 = f(r) \hat{\rho}_r \]  

(6.15)

It differs from the above operator (5.15) by permutation

\[ \hat{A}_1 = \hat{A} + i\hbar \frac{df'}{dr} \]  

(6.16)

Hence

\[ [\hat{H}, \hat{A}_1] = [\hat{H}, \hat{A}] + i\hbar \left[ \frac{df}{dr} \right] \]  

(6.17)

We have

\[ [\hat{H}, \hat{A}_1] = -i\hbar f''(H - V) + i\hbar \frac{l(l+1)}{m} \left( \left[ \frac{f'}{r^2} - \frac{f}{r^3} \right] - \frac{i}{4m} f''' + i\hbar \frac{df}{dr} \right) \]  

(6.18)

Therefore, now the hypervirial theorem for soft singular attractive potential (3.6) in correct form is written as

\[ \left\langle [\hat{H}, \hat{A}_1] \right\rangle = \left\langle -i\hbar f''(H - V) + i\hbar \frac{l(l+1)}{m} \left[ \frac{f'}{r^2} - \frac{f}{r^3} \right] - \frac{i}{4m} f''' + i\hbar \frac{df}{dr} \right\rangle = -(\Pi_{st} + \Pi_1) \]  

(6.19)

where \( \Pi_1 \) is given by

\[ \Pi_1 = -\frac{1}{2} i\hbar \Pi' - \frac{\hbar^2}{4m} \lim_{r \to 0} \left\{ r^2 f'' \right\} \]  

(6.20)

And

\[ \Pi_{st} = \frac{\hbar^2 a_{sp}^2}{2m} \left( \frac{1}{2} + P \right) \lim_{r \to 0} \left( \frac{f}{r} - f' \right) r^{2p} \]  

(6.21)

Now, because

\[ \lim_{r \to 0} R = a_{sp} r^{-1/2 + P} \]  

(6.22)

the right-hand side of (6.19) becomes

\[ \Pi_{tot, singular} = \Pi_{st} + \Pi_1 = \frac{\hbar^2 a_{sp}^2}{2m} \left( \frac{1}{2} + P \right) \lim_{r \to 0} \left( \frac{f}{r} - f' \right) r^{2p} + \frac{\hbar^2 a_{sp}^2}{4m} \lim_{r \to 0} \left\{ r^{2p+1} f'' \right\} = \]  

(6.23)
It is evident from here that $\Pi_{_{lo}} = 0$ if

$$\lim_{r \to 0} f r^{2p-1} = 0 \quad (6.24)$$

Moreover, if

$$\lim_{r \to 0} f r^{2p-1} = \text{const} \quad (6.25)$$

Then

$$\Pi_{_{lo,singular}} = \frac{2\hbar^2 a_n^2}{m} r^2 \quad (6.26)$$

and it follows a hypervirial theorem in the correct form

$$\left\langle -i\hbar f''(H - V) + i\hbar^3 \frac{(l + 1)}{m} \left[ \frac{f'}{r^2} - \frac{f}{r^3} \right] - \frac{\hbar^3}{4m} f'' + i\hbar f'(r) V' \right\rangle = -\frac{2\hbar^2 a_n^2}{m} r^2 \quad (6.27)$$

But if operator is more singular than (6.25), one cannot write the theorem at all. *Note that in the above mentioned papers no restrictions are imposed on $f$.*

For regular potentials, when $P = l + 1/2$, the relation (6.27) takes the form

$$\left\langle -i\hbar f''(H - V) + i\hbar^3 \frac{(l + 1)}{m} \left[ \frac{f'}{r^2} - \frac{f}{r^3} \right] - \frac{\hbar^3}{4m} f'' + i\hbar f'(r) V' \right\rangle = -\frac{\hbar^2 C_l}{2m} (2l + 1)^2 \quad (6.28)$$

It follows from restrictions (6.24)-(6.25) that, for example, for regular potentials, there appear some “critical” singular (6.15) like operators, for which $\Pi$ is done by above mentioned relations. For example,

$l = 0, \quad \hat{A} = \hat{\rho}_r,$

For $l = 1, \quad \hat{A} = r^{-2} \hat{\rho}_r,$ etc. \quad (6.29)

$l = 2, \quad \hat{A} = r^{-4} \hat{\rho}_r$

### 7. Modification of the Ehrenfest theorem

Let us now study what happens with the Ehrenfest theorem in ordinary quantum mechanics in spherical coordinates. Consider the operator of radial momentum

$$\hat{A} = \hat{\rho}_r = \hbar \left( \frac{\partial}{\partial r} + \frac{1}{r} \right) \quad (7.1)$$
Substitute it into Eq. (3.19), we have
\[
\frac{d\langle \hat{p}_r \rangle}{dt} = \frac{i}{\hbar} \langle [\hat{H}, \hat{p}_r] \rangle + \Pi_s
\]
(7.2)

where
\[
\Pi_s = \frac{a^2 h^2}{2m} \lim_{r \to 0} r^2 \left\{ \left( \frac{\partial}{\partial r} + \frac{1}{r} \right) \left[ \frac{1}{r^{3/2+p}} \right] - \frac{1}{2} + P \right\} \left( r^{-3/2+p} \right) - \left( r^{-1/2+p} \right) \frac{d}{dr} A \left( \frac{\partial}{\partial r} + \frac{1}{r} \right) \left[ \frac{1}{r^{1/2+p}} \right] =
\]
(7.3)

It is clear from this relation that \( \Pi_s = 0 \) for \( 2P > 1 \), while for \( 2P < 1 \), it diverges. But for \( 2P = 1 \) it survives
\[
\Pi_s = \frac{a^2 h^2}{2m}
\]
(7.4)

Therefore, for singular potential the usual Ehrenfest theorem
\[
\frac{d\langle \hat{p}_r \rangle}{dt} = \frac{i}{\hbar} \langle [\hat{H}, \hat{p}_r] \rangle
\]
(7.5)
is applicable only in the first case, \( 2P > 1 \). While in other cases the additional term \( 7.4 \) appears or has not place at all. Remember that in traditional textbooks this fact is not mentioned.

Let us now calculate the commutator in (7.5). We find
\[
\left[ \hat{H}, \hat{p}_r \right] = \frac{\hbar^2 l(l+1)}{2m} \left[ \frac{1}{r^2}, p_r \right] + [V(r), p_r]
\]
(7.6)

But
\[
\left[ \frac{1}{r^2}, p_r \right] = -i \frac{2\hbar}{r^3}; \quad [V, p_r] = i\hbar \frac{\partial V}{\partial r} = -i\hbar F_r
\]
(7.7)

Where \( F_r \) is a “radial force”. Therefore we get
\[
\left[ \hat{H}, \hat{p}_r \right] = -i \frac{\hbar^2 l(l+1)}{mr^3} - i\hbar F_r
\]
(7.8)

And after taking into account an additional contribution (7.2) we obtain the modified Ehrenfest theorem for time evolution of radial momentum (Newton’s “second law):
\[
\frac{d\langle \hat{p}_r \rangle}{dt} = \frac{\hbar^2 l(l+1)}{m} \left( \frac{1}{r^2} \right) + \langle F_r \rangle + \Pi_s
\]
(7.9)
This relation is a new one also.

It is remarkable to note that in [1,2] the Ehrenfest theorem in one-dimensional Schrödinger equation is considered in finite interval \((0,a)\) and in semi-axis \((-\infty,0)\). They derived a formula

\[
\frac{d}{dt}\langle \hat{p} \rangle = \langle f_B \rangle \tag{7.10}
\]

The authors pointed out that \(f_B\) can be considered as a boundary quantum force. Note that for a particle in an infinite square well potential the boundary term (7.10) is zero. In fact, in the open interval \(\Omega = (-\infty, \infty)\) the solution and its derivative through \(x\) tends to zero when \(x \to \pm \infty\).

By comparing (7.10) with (7.9), because in spherical coordinates radial variable changes in semi-axis \((0,\infty)\) one can identify \(\Pi_m\) with the boundary quantum force \(f_B\). It is evident that if we turn to the one-dimensional case: \(r \to x \in (-\infty, \infty)\) and take \(l = 0\), then according of above discussion we derive \(\Pi = 0\) and it follows from (7.9) the true one-dimensional Ehrenfest theorem

\[
\frac{d\langle p_x \rangle}{dt} = \langle F_r \rangle
\]

For regular potentials, when \(P = l + 1/2\), only in case \(l > 0\) it follows \(\Pi_{\text{reg}} = 0\). As for \(l = 0\) it follows

\[
\Pi_{\text{reg}} = \frac{C_1^2\hbar^2}{2m}, \quad \text{evidently} \quad C_1 = C_0 \tag{7.11}
\]

We conclude here that for regular potentials the usual Ehrenfest theorem is valid only in case \(l > 0\), but in case \(l = 0\) there appears an extra term (7.11).

Now let us show that Eq. (7.9) gives correct results for Coulomb potential.

First consider the case \(l > 0\). In this case \(\Pi_{\text{reg}} = 0\). In [27-28] right-hand side of theorem consists only real forces \(\frac{\hbar^2}{m} \langle \frac{1}{r^3} \rangle + \langle F_r \rangle\): the sum of radial and centrifugal forces. In the hydrogen atom problem these two forces compensate each other. Indeed, \(F_r = -\frac{e^2}{r^2}\) and using known matrix elements for Coulomb functions

\[
\langle \frac{1}{r^2} \rangle = \frac{1}{n^3a_0^2} \frac{1}{(l+1/2)}, \quad \langle \frac{1}{r^3} \rangle = \frac{1}{n^3a_0^2l(l+1)(l+1/2)} \tag{7.12}
\]

It is easily exercise to convince that these two forces compensate each other exactly. So the Newton’s second law is satisfied.

On the other hand, the case \(l = 0\) is more interesting and crucial. In this case we have no centrifugal term, and the additional term is given by (7.11),
\[
\frac{d\langle p_r \rangle}{dt} = \langle F_r \rangle + \frac{C_i \hbar^2}{2m} \tag{7.13}
\]

At the same time (see, Eq. (7.12))

\[
\langle F_r \rangle = -\frac{2e^2}{n^3 a_0^2} \tag{7.14}
\]

As it was mentioned above, in stationary case the left-hand side of (7.13) must be zero. So we should have

\[
\frac{C_i \hbar^2}{2m} = \frac{2e^2}{n^3 a_0^2} \tag{7.15}
\]

and according to eq. (6.10), it follows a correct expression for Bohr’s first orbit radius, \( a_0 = \frac{\hbar^2}{me^2} \)

It is evident that without the extra term it should be

\[
\frac{d\langle p_r \rangle}{dt} = \langle F_r \rangle \tag{7.16}
\]

which is clear contradiction (!)

We conclude that in Eq. (7.9) the term \( \Pi_{st} \) must present necessarily for deriving correct results, which is absent in [27-28]. As it is obvious from the definitions (7.4) and (7.11) both \( \Pi_{st} > 0 \) and \( \Pi_{reg} > 0 \), so in both cases the quantum boundary force is repulsive, “so it causes the “center of mass” of quantum packet to move far from the boundary” [29].

At last consider the Ehrenfest theorem for the coordinate operator \( \hat{A} = \hat{r} \). Inserting this operator into the definition (2.17), we find

\[
\Pi = i\frac{a_0^2 \hbar^2}{2m} \lim_{r \to 0} r^2 \left\{ r \left[ r^{-1/2+P} \right] \left( -\frac{1}{2} + P \right) \left( r^{-3/2+P} \right) \right\} = -i\frac{a_0^2 \hbar^2}{2m} \lim_{r \to 0} r^{2P+1} = 0 \tag{7.17}
\]

The last equality follows because \( P > 0 \) and so, the extra term vanishes. It vanishes also for regular potentials, because for them \( P = l + 1/2 > 0 \). Therefore the theorem has a form

\[
\frac{d\langle \hat{r} \rangle}{dt} = i\frac{\hbar}{\hbar} \langle [\hat{H}, \hat{r}] \rangle \tag{7.18}
\]

both for regular as well as singular potentials. As
\[
\left[ \hat{H}, \hat{r} \right] = 2(-i\hbar) \hat{p}_r \tag{7.19}
\]

the final form is

\[
\frac{d\langle \hat{r} \rangle}{dt} = \frac{p_r}{m} \tag{7.20}
\]

The obtained results are understandable, because the momentum operator is singular at the origin in spite of the coordinate operator. It should be particularly emphasized that a mathematically rigorous derivation of Ehrenfest’s equations for the time evolution of position and momentum expectation values, under general and natural assumptions, was given in papers [30-31].

8. Conclusions

In this manuscript we consider influence of the restricted region in 3-dimensional space in the ordinary quantum mechanics, where the radial wave function is defined on a semi-space. Therefore the boundary behavior of radial function contributes to several fundamental relations. The additional contributions appear also from singular behavior of operators under consideration. The last fact was not discussed earlier.

We saw that the 3-dimensional consideration involves many significant peculiarities to such problems.

We derived the explicit algorithm of calculation of this extra term and investigated conditions, when it contributes to various fundamental relations.

Application to several known problems shows that the inclusion of the extra term is necessary in order to avoid some misunderstandings.

We believe that the above developed formalism should have many other applications also, especially, in the derivation of uncertainty relations.

Acknowledgments

First of all, we are grateful to Dr. Ljudmila Gverdciteli, who read our manuscript and gave many useful comments.
