Global Well-Posedness and Exponential Stability for
Heterogeneous Anisotropic Maxwell’s Equations under a
Nonlinear Boundary Feedback with Delay

Andrii Anikushyn∗           Michael Pokojovy†

October 9, 2018

Abstract

We consider an initial-boundary value problem for the Maxwell’s system in a bounded do-
main with a linear inhomogeneous anisotropic instantaneous material law subject to a nonlinear
Silver–Müller-type boundary feedback mechanism incorporating both an instantaneous damp-
ing and a time-localized delay effect. By proving the maximal monotonicity property of the
underlying nonlinear generator, we establish the global well-posedness in an appropriate Hilbert
space. Further, under suitable assumptions and geometric conditions, we show the system is
exponentially stable.

Key words:       Maxwell’s equations, nonlinear boundary feedback, instantaneous damping,
time-localized delay, well-posedness, exponential stability

1 Introduction

Consider the macroscopic formulation of Maxwell’s equations in a bounded domain $G \subset \mathbb{R}^3$ with
$\nu: \Gamma \rightarrow \mathbb{R}^3$ standing for the outer normal vector to its smooth boundary $\Gamma := \partial G$ and the functions
$E, D, H, B: [0, \infty) \times G \rightarrow \mathbb{R}^3$ denoting the electric, displacement, magnetic and magnetizing fields,
respectively. With $\rho: [0, \infty) \times G \rightarrow \mathbb{R}$ representing the electric charge density, Gauss’ law along
with Gauss’ law for magnetism yield

$$\text{div } D = \rho \quad \text{and} \quad \text{div } B = 0 \quad \text{in } (0, \infty) \times G,$$

(1.1)

while Faraday’s law of induction and Ampère’s circuital law mandate

$$\partial_t D = \text{curl } H - J \quad \text{and} \quad \partial_t B = -\text{curl } E \quad \text{in } (0, \infty) \times G.$$

(1.2)

Typically, $J: [0, \infty) \times G \rightarrow \mathbb{R}^3$ is a (given) total current density.

Since the system (1.1)–(1.2) is underdetermined, two more equations relating the four un-
known vector fields $E, D, H, B$ need to be postulated. Letting $\varepsilon, \mu: G \rightarrow \mathbb{R}^{3 \times 3}$ be symmetric,

∗Department of Computer Sciences and Cybernetics, Taras Shevchenko National University of Kyiv

uniformly positive definite matrix-valued permittivity and permeability tensor fields, the instantaneous anisotropic material laws read as

\[ D = \varepsilon E \quad \text{and} \quad B = \mu H. \tag{1.3} \]

Combining Equations (1.1)–(1.3), we arrive at

\[ \partial_t (\varepsilon E) = \text{curl} \, H - J, \quad \text{div} \, (\varepsilon E) = \rho \quad \text{in} \; (0, \infty) \times G, \quad \tag{1.4} \]
\[ \partial_t (\mu H) = - \text{curl} \, E, \quad \text{div} \, (\mu H) = 0 \quad \text{in} \; (0, \infty) \times G. \tag{1.5} \]

Various boundary conditions for Equations (1.4)–(1.5) are known in the literature. Eller et al. [9] considered the nonlinear version

\[ \mathbf{H} \times \nu + \mathbf{g}(\mathbf{E} \times \nu) \times \nu = 0 \quad \text{on} \; (0, \infty) \times \Gamma \tag{1.6} \]

of the classical Silver–Müller boundary condition

\[ \mathbf{H} \times \nu + \kappa \cdot (\mathbf{E} \times \nu) \times \nu = 0 \quad \text{on} \; (0, \infty) \times \Gamma. \tag{1.7} \]

Here, \( \mathbf{g} : \mathbb{R}^3 \to \mathbb{R}^3 \) is a smooth function with \( \mathbf{g}(0) = 0 \) and \( \kappa > 0 \) is a constant. Equations (1.6) and (1.7) model scattering of electromagnetic waves by an obstacle \( G \) under the assumption that the waves cannot penetrate the obstacle too deeply [3, p. 20]. The Silver–Müller boundary condition (1.7) arises as a first-order approximation to the so-called transparent boundary condition but, despite of being dissipative, allows for reflections back into the domain \( G \) [3, p. 136].

In the present paper, we modify the nonlinear feedback-type boundary condition (1.6) by incorporating a nonlinear time-localized delay effect:

\[ \mathbf{H}(t, \cdot) \times \nu + \gamma_1 \mathbf{g}(\mathbf{E}(t, \cdot) \times \nu) \times \nu + \gamma_2 \mathbf{g}(\mathbf{E}(t - \tau, \cdot) \times \nu) \times \nu = 0 \quad \text{on} \; (0, \infty) \times \Gamma \tag{1.8} \]

with a delay parameter \( \tau > 0 \) and appropriate constants \( \gamma_1, \gamma_2 > 0 \). Viewing the instantaneous Silver–Müller boundary conditions (1.6) and (1.7) as a feedback boundary control, the latter being a common stabilization instrument widely used in engineering, an extra delay term in Equation (1.8) becomes indispensable to adequately account for time retardations, which inevitably arise due a time lag in the interaction between a sensor measuring \( \mathbf{E} \times \nu \) and the actuator updating \( \mathbf{H} \times \nu \) on the boundary \( \Gamma \).

Pulling Equations (1.4)–(1.5), (1.8) together, we arrive at

\[ \partial_t (\varepsilon E) = \text{curl} \, H - J, \quad \text{div} \, (\varepsilon E) = \rho \quad \text{in} \; (0, \infty) \times G, \]
\[ \partial_t (\mu H) = - \text{curl} \, E, \quad \text{div} \, (\mu H) = 0 \quad \text{in} \; (0, \infty) \times G, \]
\[ \mathbf{H}(t, \cdot) \times \nu + \gamma_1 \mathbf{g}(\mathbf{E}(t, \cdot) \times \nu) \times \nu + \gamma_2 \mathbf{g}(\mathbf{E}(t - \tau, \cdot) \times \nu) \times \nu = 0 \quad \text{on} \; (0, \infty) \times \Gamma. \]

In the following, let \( J \equiv 0 \) and \( \rho \equiv 0 \). This corresponds to the case both electrical sources and resistance effects are absent. While not affecting the well-posedness results to follow, compared to the case of electrical resistance, i.e., \( J = \sigma(\mathbf{E}, \mathbf{H}) \mathbf{E} \) as mandated by the Ohm’s law, the condition \( J \equiv 0 \) reduces the overall amount of damping in the system making the stability analysis more challenging. Adding the usual initial conditions, we arrive at the system

\[ \partial_t (\varepsilon E) = \text{curl} \, H, \quad \text{div} \, (\varepsilon E) = 0 \quad \text{in} \; (0, \infty) \times G, \quad \tag{1.9} \]
\[ \partial_t (\mu H) = - \text{curl} \, E, \quad \text{div} \, (\mu H) = 0 \quad \text{in} \; (0, \infty) \times G, \quad \tag{1.10} \]
\[ \mathbf{H}(t, \cdot) \times \nu + \gamma_1 \mathbf{g}(\mathbf{E}(t, \cdot) \times \nu) \times \nu + \gamma_2 \mathbf{g}(\mathbf{E}(t - \tau, \cdot) \times \nu) \times \nu = 0 \quad \text{on} \; (0, \infty) \times \Gamma. \quad \tag{1.11} \]
\( E(0, \cdot) = E^0, \ H(0, \cdot) = H^0 \) in \( G \), \( E(-\tau, \cdot) \times \nu = \Phi^0 \) in \( (0, 1) \times \Gamma \). (1.13)

Partial (not mentioning ordinary!) differential equations (PDEs) have widely been studied in the literature. Time-delays along with other types of time-nonlocalities such as memory effects, etc., can typically enter a PDE in one of the two ways – either through a time-nonlocal material law \[1, 13\] or a time-delayed feedback mechanism (so-called “closed-loop control”) \[3, 5, 18, 23, 26\], etc. Whereas time-delayed material laws mostly lead to ill-posedness \[13\], the effect of time-delay in feedback mechanisms can range from a “mere” reduction of the decay rate to destabilization to even ill-posedness. We refer the reader to the famous Datko’s example \[5\], which illustrates the later dichotomy. Our goal is to investigate the impact of the nonlinear boundary delay feedback from Equation (1.11) on system (1.9)–(1.13). Before proceeding with our study, we first give a short literature review. In our brief review below, we restrict ourselves to instantaneous material laws but discuss both instantaneous and nonlocal boundary conditions.

Lagnese \[16\] studied the exact boundary controllability of homogeneous isotropic Maxwell’s equations

\[
\begin{align*}
\partial_t E - \text{curl}(\varepsilon^{-1} H) &= 0, & \partial_t H + \text{curl}(\mu^{-1} E) &= 0 \text{ in } (0, \infty) \times G, \\
\text{div} E &= \text{div} H = 0 \text{ in } (0, \infty) \times G, \\
E(0) &= E^0, & H(0) &= H^0 \text{ in } G \\
\end{align*}
\]

subject to boundary condition

\[
\nu \times H = -J \text{ on } \Gamma \times (0, \infty)
\]

in star-shaped regions \( G \). Here, the current density \( J \) plays the role of a distributed open-loop control. The electric permittivity \( \varepsilon \) and magnetic permeability \( \mu \) were assumed constant, while the region \( G \) was selected to be star-shaped with respect to some point.

Nicaise \[19\] investigated the exact controllability of isotropic non-homogeneous Maxwell’s equations \[1.9\]–\[1.10\] with the boundary conditions

\[
\begin{align*}
H \times \nu &= J \text{ on } (0, T) \times \Gamma_0, \\
H \times \nu &= 0 \text{ on } (0, T) \times (\Gamma \setminus \Gamma_0), \\
E \times \nu &= 0 \text{ on } (0, T) \times \Gamma
\end{align*}
\]

via a boundary control \( J \) under appropriate conditions on the coefficients and the geometry of \( G \). Here, \( \Gamma_0 \) is a non-empty, relatively open subset of \( \Gamma \).

Eller & Masters \[10\] later used multiplier techniques to prove the exact controllability for Equations \[1.14\]–\[1.16\] via of the boundary control

\[
\nu \times (\varepsilon^{-1} H) = J \text{ on } (0, T) \times \Gamma
\]

for nonhomogeneous \( \mu, \varepsilon \) in connected domains \( G \).

Krigman \[15\] studied a similar problem for the system

\[
\begin{align*}
\varepsilon \partial_t E - \text{curl}(H) + \sigma E &= 0, & \mu \partial_t H + \text{curl}(E) &= 0 \text{ in } (0, \infty) \times G \\
\text{div}(\varepsilon E) &= 0, & \text{div}(\mu H) &= 0 \text{ in } (0, \infty) \times G
\end{align*}
\]

with the initial conditions \[1.16\] and boundary condition \[1.17\] in simply connected star-shaped domains \( G \).
Eller [7] studied Equations (1.9)–(1.10) subject to boundary conditions

\[ \nu \times E = 0, \quad \nu \cdot (\mu H) = 0 \text{ on } (0, T) \times \Gamma. \]

Assuming the star-shapedness of \( G \) and exploiting the method of multipliers, a boundary observability inequality was proved.

Eller et al. [9] examined the problem of stabilizing Maxwell’s equations (1.9)–(1.10) subject to boundary condition

\[ H \times \nu + g(E \times \nu) \times \nu = 0 \text{ on } (0, \infty) \times \Gamma. \]

The (scalar) \( \varepsilon \) and \( \mu \) were assumed real positive fields and \( g(\cdot) \) a continuous mapping satisfying certain monotonicity and boundedness conditions. To prove the well-posedness, monotone operator theory and nonlinear semigroup theory were used, while the exponential stability – both in the linear and the nonlinear cases – was shown via exact controllability established using multiplier techniques.

Zhou [28] investigated the exact controllability under the action of a distributed control \( u \)

\[ \partial_t E - \text{curl}(H) = \chi_G(x)u \text{ in } (0, \infty) \times G, \]
\[ \partial_t H + \text{curl}(E) = 0 \text{ in } (0, \infty) \times G, \]
\[ \text{div} H = \text{div} E = 0 \text{ in } (0, \infty) \times G, \]
\[ H(0) = H_0 \text{ in } G, \]

where \( \chi_G(\cdot) \) is the indicator function of a set \( \omega \subset G \). This result was further extended by Zhang [27] to time-dependent \( \omega \)’s using multiplier techniques.

A series of important results were obtained by Nicaise & Pignotti. In [20], under monotonicity and boundedness assumptions on \( g(\cdot) \), the authors considered a stabilization problem for Maxwell’s equations

\[ \partial_t E - \text{curl}(\lambda H) = 0 \text{ in } (0, \infty) \times G, \]
\[ \partial_t H + \text{curl}(\mu E) = 0 \text{ in } (0, \infty) \times G, \]
\[ \text{div} E = \text{div} H = 0 \text{ in } (0, \infty) \times G, \]
\[ E(0) = E^0, \quad H(0) = H^0 \text{ in } G, \]

with space-time variable (scalar) coefficients \( \mu = \mu(x, t), \lambda = \lambda(x, t) \) and a nonlinear Silver–Müller boundary condition

\[ g(x, E \times \nu) + H \times \nu = 0 \text{ on } (0, \infty) \times \Gamma. \]

Another article [21] by the same authors was dedicated to the problem of stabilization of Maxwell’s equations via a distributed feedback arising from the linear Ohm’s law:

\[ \partial_t E - \text{curl}(\lambda H) + \sigma E = 0 \text{ in } (0, \infty) \times G, \]
\[ \partial_t H + \text{curl}(\mu E) = 0 \text{ in } (0, \infty) \times G, \]
\[ \text{div} H = 0 \text{ in } (0, \infty) \times G, \]
\[ E \times \nu = 0, \quad H \cdot \nu = 0 \text{ on } (0, \infty) \times \Gamma, \]
\[ E(0) = E^0, \quad H(0) = H^0 \text{ in } G. \]
The method of multipliers was used to establish an observability estimate in the paper. Same authors \[22\] also obtained an observability estimate for the standard isotropic homogeneous Maxwell’s system \((1.18)–(1.21)\) subject to boundary conditions \((1.25)\). The impact of boundary conditions that include tangential components were studied by numerous authors. Kapitonov \[12\] considered Equations \((1.18)–(1.21)\) in \((0, T) \times G\) with dissipative boundary conditions
\[
\nu \times E - \alpha(\cdot) H = 0,
\]
where \(\alpha(\cdot)\) is a continuously differentiable function on \(\Gamma\) with \(\text{Re} \, \alpha > 0\). Here and in the sequel, \(H_t := H - (H \times \nu)H\) (1.27) denotes the tangential component of \(H\). Using the semigroup approach to investigate the well-posedness, the author further utilized geometrical properties of the domain to obtain results on exact boundary controllability of the solution to \((1.18)–(1.21)\) in \((0, T) \times G\) with boundary condition
\[
\nu \times E - ia(x) H = \mathbf{p}(t, x),
\]
where \(a(x)\) is a continuously differentiable scalar function on \(\Gamma\). Cagnol and Eller \[2\] studied a well-posedness for anisotropic Maxwell’s equations with the so-called “absorbing boundary” condition
\[
\nu \times E - \alpha H = \mathbf{g} \text{ on } (0, T) \times \Gamma.
\]
Nonlocal boundary conditions are also known in the literature. Nibbi & Polidoro \[18\] proved the exponential stability of ‘Graffi’-type free energy associated with the isotropic Maxwell’s equations subject to a memory-type boundary condition
\[
E_r(t, \cdot) = \eta_0 H(t, \cdot) \times \nu + \int_0^\infty \eta(s) H(t - s, \cdot) \times \nu \, ds.
\]
In contrast, the impact of time-delayed boundary conditions from Equation \((1.11)\) on Maxwell’s equations has not been studied in the literature before. At the same time, such boundary conditions proved to be very interesting – both from theoretical in practical point of view – for other types of hyperbolic systems. For example, Nicaise & Pignotti \[23\] investigated the stability of a delay wave equation subject to a time-delayed boundary feedback
\[
\begin{align*}
\partial_t u(t, x) - \Delta u(t, x) &= 0 \text{ for } (t, x) \in (0, \infty) \times G, \\
u u(t, x) &= 0 \text{ for } (t, x) \in (0, \infty) \times \Gamma_0, \\
\partial_u u(t, x) &= -\mu_1 u(t, x) - \mu_2 u(t - \tau, x) \text{ for } (t, x) \in (0, \infty) \times (\Gamma \setminus \Gamma_0), \\
u u(0, x) &= u_0(x), \quad \partial_t u(0, x) = u_1(x) \text{ for } x \in G, \\
u u(t - \tau, x) &= f_0(t - \tau, x) \text{ for } (t, x) \in (0, \tau) \times (\Gamma \setminus \Gamma_0). 
\end{align*}
\]
Under suitable conditions on \(\Gamma_0\), the initial-boundary-value problem was shown to possess a unique strong solution, which is exponentially stable given \(\mu_2 < \mu_1\).

Nicaise & Pignotti \[24\] studied Equations \((1.13)–(1.15)\) subject to the linear feedback \(g(x) = x\) in the boundary condition \((1.11)\) and a similar system subject to an internal delay feedack
\[
\partial_t (\varepsilon E) - \text{curl } H + \sigma (\mu_1 E + \mu_2 E(\cdot - \tau, \cdot)) = 0, \quad \text{div } (\varepsilon E) = 0 \text{ in } (0, \infty) \times G \tag{1.28}
\]
in lieu of Equation (1.9) with homogeneous, isotropic $\varepsilon, \mu$. Having established a well-posedness theory for both systems for the case $\mu_2 \leq \mu_1$, exponential stability in simply connected bounded domains for $\mu_2 < \mu_1$ was proved and optimality of the latter condition was illustrated for both systems.

The rest of the paper has the following outline. In Section 2, partial difference-differential Equations (1.9)–(1.13) are transformed to an abstract nonlinear evolution equation on the extended phase space. By showing maximal monotonicity of the generator and exploiting the nonlinear semigroup theory, the well-posedness is proved. In Section 3, under a star-shapedness assumption on the domain $G$, the exponential stability of the system is shown by using standard Rellich’s multipliers and auxiliary functions inspired by [13]. In the Appendix section, for the sake of completeness, a “folklore” method (which probably goes back to early works of I. Lasiecka) that establishes a connection between dissipativity, an observability-through-damping inequality and exponential stability is formulated and proved.

2 Well-Posedness

Following [7], for a symmetric, positive definite matrix-valued $\alpha \in L^\infty(G, \mathbb{R}^{3 \times 3})$, we define the spaces
\[
H(\text{curl}, G) := \left\{ u \in (L^2(G))^3 \mid \text{curl} u \in (L^2(G))^3 \right\},
\]
\[
H(\text{div}_\alpha 0, G) := \left\{ u \in (L^2(G))^3 \mid \text{div}(\alpha u) = 0 \right\}
\]
and introduce the Hilbert space
\[
\mathcal{H} := H(\text{div}_\varepsilon 0, G) \times H(\text{div}_\mu 0, G)
\]
edowed with the inner product
\[
\langle (E, H)^T, (\tilde{E}, \tilde{H})^T \rangle_{\mathcal{H}} := \int_G \varepsilon E : \tilde{E} \, dx + \int_G \mu H : \tilde{H} \, dx.
\]
(The completeness follows from [16]).

Similar to [9], we formally define the operator
\[
\mathcal{A} : \begin{pmatrix} E \\ H \end{pmatrix} \mapsto \begin{pmatrix} -\varepsilon^{-1} \text{curl} H \\ -\mu^{-1} \text{curl} E \end{pmatrix}.
\]

Our goal is to transform Equations (1.9)–(1.13) to an abstract Cauchy problem on the extended phase space (cf. [13] [23] [24])
\[
\mathcal{H} := \mathcal{H} \times L^2(0, 1; L^2_\tau(\Gamma, \mathbb{R}^3))
\]
edowed with the scalar product
\[
\langle (E, H, Z)^T, (\tilde{E}, \tilde{H}, \tilde{Z})^T \rangle_{\mathcal{H}} := \langle (E, H)^T, (\tilde{E}, \tilde{H})^T \rangle_{\mathcal{H}} + \tau \int_0^1 \int_\Gamma (Z(s, \cdot) \times \nu) : (\tilde{Z}(s, \cdot) \times \nu) \, dx \, ds.
\]

Here, following [24] Equation (2.12)], the ‘tangential’ $L^2$-space on $\Gamma L^2_\tau$ is defined as
\[
L^2_\tau(\Gamma, \mathbb{R}^3) := \{ \Psi \in L^2(\Gamma, \mathbb{R}^3) \mid \Psi \cdot \nu = 0 \text{ on } \Gamma \}.
\]

This choice will later prove crucial for showing the density of the generator.
Letting formally
\[
V(t, \cdot) := \begin{pmatrix}
E(t, \cdot) \\
H(t, \cdot)
\end{pmatrix}_{(0, 1) \ni s \mapsto Z(t, s, \cdot)} \equiv \begin{pmatrix}
E(t, \cdot) \\
H(t, \cdot)
\end{pmatrix}_{(0, 1) \ni s \mapsto (E(t - \tau s) \times \nu)|_{\Gamma}},
\]
we define the operator
\[
\mathcal{A}: D(\mathcal{A}) \subset \mathcal{H} \to \mathcal{H}, \quad (E, H, Z)^T \mapsto \left(\frac{1}{\nu} \partial_s Z + \mathcal{A}(E, H)^T\right)
\]
with the domain
\[
D(\mathcal{A}) := \left\{ (E, H, Z)^T \in \mathcal{H} \mid (A(E, H)^T, \frac{1}{\nu} \partial_s Z)^T \in \mathcal{H}, \quad E \times \nu|_{\Gamma}, H \times \nu|_{\Gamma} \in (L^2(\Gamma))^3, \right. \\
H \times \nu + \gamma_1 g(E \times \nu) \times \nu + \gamma_2 g(Z|_{s=1}) \times \nu = 0 \text{ on } \Gamma, \\
Z|_{s=0} = E \times \nu \left\}ight..
\]
The latter explicitly reads as
\[
D(\mathcal{A}) := \left\{ (E, H, Z)^T \in \mathcal{H} \mid E, H \in H(\text{curl}, G), \quad Z \in H^1(0, 1; (L^2(\Gamma))^3), \right. \\
E \times \nu|_{\Gamma}, H \times \nu|_{\Gamma} \in (L^2(\Gamma))^3, \\
H \times \nu + \gamma_1 g(E \times \nu) \times \nu + \gamma_2 g(Z|_{s=1}) \times \nu = 0 \text{ on } \Gamma, \\
Z|_{s=0} = E \times \nu \left\}ight..
\]
Equations (1.9) – (1.13) can equivalently be written as an abstract evolution equation
\[
\partial_t V(t) + \mathcal{A}(V(t)) = 0 \text{ for } t > 0, \quad V(0) = V^0 \tag{2.1}
\]
with \(V^0 := (E^0, H^0, \Phi^0)^T\).

**Assumption 2.1 (Tensor fields \(\varepsilon\) and \(\mu\)).** Let \(\varepsilon, \mu \in C^0(\bar{G}, \mathbb{R}^{3 \times 3})\) satisfy
\[
(\varepsilon(x))^T = \varepsilon(x) \text{ and } (\mu(x))^T = \mu(x) \text{ for } x \in \bar{G} \tag{2.2}
\]
as well as
\[
\lambda_{\text{min}}(\varepsilon) > 0 \text{ and } \lambda_{\text{min}}(\mu) > 0,
\]
where
\[
\lambda_{\text{min}}(\varphi) := \min_{x \in \bar{G}} \min_{|\xi|=1} \xi \cdot (\varphi(x)\xi) \text{ for } \varphi \in C^0(\bar{G}, \mathbb{R}^{3 \times 3}).
\]
Denote
\[
\alpha = \min\{\lambda_{\text{min}}(\varepsilon), \lambda_{\text{min}}(\mu)\}. \tag{2.3}
\]

**Assumption 2.2 (Nonlinearity \(g(\cdot)\)).** Suppose the nonlinear function \(g: \mathbb{R}^3 \to \mathbb{R}^3\) satisfies:
1. \(g(0) = 0\),
2. There exists \(c_1 > 0\) such that \((g(E) - g(\bar{E})) \cdot (E - \bar{E}) \geq c_1 |E - \bar{E}|^2\) for any \(E, \bar{E} \in \mathbb{R}^3\),
3. There exists \(c_2 > 0\) such that \(|g(E) - g(\bar{E})| \leq c_2 |E - \bar{E}|\) for any \(E, \bar{E} \in \mathbb{R}^3\).
Remark 2.3. In contrast to the wave equation, which is known [7] to admit feedback functions with a superlinear growth rate (in y, not y'), this is no longer true for Maxwell's equations since superlinear terms can cause the solution to leave the basic $L^2$-space thus destroying the well-posedness. In this sense, the results of our paper appear to be optimal – at least at the basic energy level.

The following two lemmas are quoted from [9].

Lemma 2.4. For all $\mathbf{E}, \mathbf{H} \in H(\text{curl}, G)$ with $\mathbf{E} \times \mathbf{\nu} \big|_\Gamma, \mathbf{H} \times \mathbf{\nu} \big|_\Gamma \in (L^2(\Gamma))^3$, we have
$$\int_G (\text{curl} \mathbf{E} \cdot \mathbf{H} - \text{curl} \mathbf{H} \cdot \mathbf{E}) \, dx = \int_\Gamma (\mathbf{H} \times \mathbf{\nu}) \cdot \mathbf{E} \, dx.$$  

Remark 2.5. By virtue of [4] Chapter 2], the statement of Lemma remains true for general fields $\mathbf{E}, \mathbf{H} \in H(\text{curl}, G)$ if the latter integral is replaced by the dual paring between the spaces $H^{-1/2}(\text{div}, \Gamma)$ and $H^{1/2}(\text{curl}, \Gamma)$.

Let $P_\chi$ denote the orthogonal projection on $H(\text{div}_\varepsilon 0, G)$ in $(L^2(\Gamma))^3$. Combining Lemma 2.3 with the ‘tangentiality’ of $Z \in L^2_\varepsilon (\Gamma, \mathbb{R}^3)$, we get:

Lemma 2.6. The image $P_\chi ((D(G))^3)$ is dense in $H(\text{div}_\varepsilon 0, G)$. The domain of the operator $\mathcal{A}$ is dense in $\mathcal{H}$.

Remark 2.7. For all $\chi \in C^\infty(G)$, we have $\text{curl}(P_\chi \chi) = \text{curl} \chi$ in $G$ and $(P_\chi \chi) \times \mathbf{\nu} = \chi \times \mathbf{\nu}$ on $\Gamma$.

Now, we can prove the following lemma.

Lemma 2.8. There exists a positive number $C$ such that $C \text{id} + \mathcal{A}$ is a maximal monotone operator.

Proof. Monotonicity: Consider a new inner product on $\mathcal{H}$ defined via
$$\langle (\mathbf{E}, \mathbf{H}, Z)^T, (\mathbf{E}', \mathbf{H}', Z')^T \rangle_{\mathcal{H}} := \langle (\mathbf{E}, \mathbf{H})^T, (\mathbf{E}', \mathbf{H}')^T \rangle_{\mathcal{H}}$$

$$+ \xi \tau \int_0^1 \int_\Gamma e^{cs} (\mathbf{E}(t - \tau s) \times \mathbf{\nu}) \cdot (\mathbf{E}(t - \tau s) \times \mathbf{\nu}) \, ds \, dx.$$

Here $c, \xi$ are positive numbers and will be chosen later. Obviously, $\langle \cdot, \cdot \rangle_{\mathcal{H}}$ is equivalent with the original inner product $\langle \cdot, \cdot \rangle_{\mathcal{H}}$.

First, we show that $C \text{id} + \mathcal{A}$ is a monotone operator for some $C > 0$. For all $(\mathbf{E}, \mathbf{H}, Z)^T$, $(\mathbf{E}', \mathbf{H}', Z')^T \in D(\mathcal{A})$, letting $(\tilde{\mathbf{E}}, \tilde{\mathbf{H}}, \tilde{Z})^T = (\mathbf{E}, \mathbf{H}, Z)^T - (\mathbf{E}', \mathbf{H}', Z')^T$, we obtain

$$\langle (C \text{id} + \mathcal{A}) (\mathbf{E}, \mathbf{H})^T - (C \text{id} + \mathcal{A}) (\mathbf{E}', \mathbf{H}')^T, (\mathbf{E}, \mathbf{H})^T - (\mathbf{E}', \mathbf{H}')^T \rangle_{\mathcal{H}}$$

$$= C \left\| \begin{pmatrix} \tilde{\mathbf{E}} \\ \tilde{\mathbf{H}} \\ \tilde{Z} \end{pmatrix} \right\|_{\mathcal{H}}^2 + \langle \mathcal{A} (\tilde{\mathbf{E}}, \tilde{\mathbf{H}}, \tilde{Z})^T, (\mathbf{E}, \mathbf{H}, Z)^T - (\mathbf{E}', \mathbf{H}', Z')^T \rangle_{\mathcal{H}}$$

$$= C \left\| \begin{pmatrix} \tilde{\mathbf{E}} \\ \tilde{\mathbf{H}} \\ \tilde{Z} \end{pmatrix} \right\|_{\mathcal{H}}^2 + \int_G (\text{curl} \tilde{\mathbf{E}} \cdot \tilde{\mathbf{H}} - \text{curl} \tilde{\mathbf{H}} \cdot \tilde{\mathbf{E}}) \, dx + \xi \int_0^1 \int_\Gamma e^{cs} \partial_s \tilde{Z} \cdot \tilde{Z} \, ds \, dx.$$  

(2.4)
Using Lemma 2.4 and the boundary condition from Equation (1.11), we get

\[ \int_G (\text{curl} \tilde{E} \cdot \tilde{H} - \text{curl} \tilde{H} \cdot \tilde{E}) \, dx = \int_\Gamma \tilde{H} \times \nu \cdot \tilde{E} \, dx \]

\[ = \int_\Gamma (\gamma_1 g(E' \times \nu) \times \nu + \gamma_2 g(Z'|_{s=1}) \times \nu - \gamma_1 g(E \times \nu) \times \nu - \gamma_2 g(Z|_{s=1}) \times \nu) \cdot (E - E') \, dx \]

\[ = \int_\Gamma (\gamma_1 g(E' \times \nu) + \gamma_2 g(Z|_{s=1}) - \gamma_1 g(E \times \nu) - \gamma_2 g(Z|_{s=1}) \times \nu) \cdot (E - E') \, dx \]

\[ = \int_\Gamma \gamma_1 (g(E \times \nu) - g(E' \times \nu)) \cdot (E \times \nu - E' \times \nu) + \gamma_2 (g(Z|_{s=1}) - g(Z'|_{s=1})) \cdot (\tilde{Z}|_{s=0}) \, dx. \]

Recalling Assumption 2.2 and using Cauchy & Schwarz’ inequality, the latter integral can be estimated both on the low

\[ \int_\Gamma \gamma_1 (g(E \times \nu) - g(E' \times \nu)) \cdot (E \times \nu - E' \times \nu) \, dx \geq \int_\Gamma \gamma_1 c_1 |E \times \nu - E' \times \nu|^2 \, dx \]

\[ = \gamma_1 c_1 \int_\Gamma \tilde{Z}^2|_{s=0} \, dx = \gamma_1 c_1 \| \tilde{Z}|_{s=0} \|^2_{(L^2(\Gamma))^3} \] (2.6)

and the high side

\[ \int_\Gamma \gamma_2 (g(Z|_{s=1}) - g(Z'|_{s=1})) \cdot (\tilde{Z}|_{s=0}) \, dx \]

\[ \geq -\gamma_2 \left( \int_\Gamma (g(Z|_{s=1}) - g(Z'|_{s=1}))^2 \, dx \int_\Gamma \tilde{Z}^2|_{s=0} \, dx \right)^{\frac{1}{2}} \]

\[ \geq -\gamma_2 \left( \int_\Gamma (c_2 (Z|_{s=1} - Z'|_{s=1}))^2 \, dx \int_\Gamma \tilde{Z}^2|_{s=0} \, dx \right)^{\frac{1}{2}} \]

\[ = -\gamma_2 c_2 \| \tilde{Z}|_{s=1} \|^2_{(L^2(\Gamma))^3} \cdot \| \tilde{Z}|_{s=0} \|^2_{(L^2(\Gamma))^3}. \] (2.7)

Now, consider the latter term in Equation (2.3). Integrating by parts, we get

\[ \xi \int_0^1 \int_\Gamma e^{cs} \partial_s \tilde{Z} \cdot \tilde{Z} \, dx \, ds = \xi \frac{1}{2} \int_\Gamma \int_0^1 e^{cs} \partial_s (\tilde{Z}^2) \, dx \, ds \]

\[ = \xi \frac{1}{2} \int_\Gamma \left( e^{cs} \tilde{Z}^2|_{s=0} - \int_0^1 e^{cs} \tilde{Z}^2 \, ds \right) \, dx \]

\[ = \xi \frac{1}{2} \int_\Gamma \left( e^{cs} \tilde{Z}^2|_{s=1} - \tilde{Z}^2|_{s=0} - \int_0^1 e^{cs} \tilde{Z}^2 \, ds \right) \, dx \]

\[ = e^{c \xi} \frac{1}{2} \| \tilde{Z}|_{s=1} \|^2_{(L^2(\Gamma))^3} - \frac{\xi}{2} \| \tilde{Z}|_{s=0} \|^2_{(L^2(\Gamma))^3} - \frac{\xi c}{2} \int_\Gamma \int_0^1 e^{cs} \tilde{Z}^2 \, dx \, ds. \] (2.8)

Recalling Equations (2.5) – (2.8), we obtain

\[ C \left\| \left( \begin{array}{c} \tilde{E} \\ \tilde{H} \\ \tilde{Z} \end{array} \right) \right\|^2_{\tilde{\mathcal{F}}} + \int_G (\text{curl} \tilde{E} \cdot \tilde{H} - \text{curl} \tilde{H} \cdot \tilde{E}) \, dx + \xi \int_0^1 \int_\Gamma e^{cs} \partial_s \tilde{Z} \cdot \tilde{Z} \, dx \, ds \]

9
In particular, from the regularity of $E$, further using Equation (2.10), we obtain

$$E + \lambda b \leq C \int_0^1 \int_{\Gamma} e^{cs} \tilde{Z}^2 dx ds + (\gamma_1 c_1 - \frac{\xi}{2}) \|\tilde{Z}\|_{L^2(\Gamma)}^2 + \frac{\xi e^c}{2} \|\tilde{Z}\|_{s=1}^2 \|L^2(\Gamma)\|^3$$

$$- \frac{\xi}{2} \int_0^1 \int_{\Gamma} e^{cs} \tilde{Z}^2 dx ds - \gamma_2 c_2 \|\tilde{Z}\|_{s=1} \|L^2(\Gamma)\|^3 \cdot \|\tilde{Z}\|_{s=0} \|L^2(\Gamma)\|^3.$$

Taking now $\xi < 2\gamma_1 c_1$ and applying Cauchy & Schwarz’ inequality, we arrive at

$$C \left\| \left( \begin{array}{c} \tilde{E} \\ \tilde{H} \end{array} \right) \right\|_{L^2(\Gamma)}^2 + C \xi \int_0^1 \int_{\Gamma} e^{cs} \tilde{Z}^2 dx ds + \frac{\xi e^c}{2} \|\tilde{Z}\|_{s=1}^2 \|L^2(\Gamma)\|^3$$

$$- \frac{\xi}{2} \int_0^1 \int_{\Gamma} e^{cs} \tilde{Z}^2 dx ds - \gamma_2 c_2 \|\tilde{Z}\|_{s=1} \|L^2(\Gamma)\|^3 \cdot \|\tilde{Z}\|_{s=0} \|L^2(\Gamma)\|^3$$

$$\geq C \left\| \left( \begin{array}{c} \tilde{E} \\ \tilde{H} \end{array} \right) \right\|_{L^2(\Gamma)}^2 + 2 \left( \gamma_1 c_1 - \frac{\xi}{2} \right) \frac{\xi e^c}{2} \|\tilde{Z}\|_{s=1} \|L^2(\Gamma)\|^3 \cdot \|\tilde{Z}\|_{s=0} \|L^2(\Gamma)\|^3$$

$$+ \xi \left( C \xi - \frac{\xi}{2} \right) \int_0^1 \int_{\Gamma} e^{cs} \tilde{Z}^2 dx ds - \gamma_2 c_2 \|\tilde{Z}\|_{s=1} \|L^2(\Gamma)\|^3 \cdot \|\tilde{Z}\|_{s=0} \|L^2(\Gamma)\|^3. \tag{2.9}$$

Finally, selecting $c$ such that $2 \left( \gamma_1 c_1 - \frac{\xi}{2} \right) \frac{\xi e^c}{2} \|L^2(\Gamma)\|^3 \cdot \|\tilde{Z}\|_{s=0} \|L^2(\Gamma)\|^3 \geq \gamma_2 c_2$ and then choosing $C > \frac{\xi}{2}$, the right hand side of Equation (2.9) is rendered positive implying the monotonicity of $\mathcal{A}$.

**Maximality:** By virtue of Browder & Minty’s Theorem [1, Theorem 2.2], it suffices to prove $(C + \lambda) \text{id} + \mathcal{A}$ is surjective for at least one $\lambda > 0$, i.e., for any $(F_1, F_2, F_3)^T \in \mathcal{H}$, we need to find $(E, H, Z) \in D(\mathcal{A})$ such that

$$((C + \lambda) \text{id} + \mathcal{A}) \left( \begin{array}{c} E \\ H \\ Z \end{array} \right) = \left( \begin{array}{c} F_1 \\ F_2 \\ F_3 \end{array} \right). \tag{2.10}$$

Let $b = C + 1$. From Equation (2.10), we have $bZ + \tau^{-1} \partial_t Z = F_3$, whence we easily get

$$Z(t, s, x) = e^{-\tau b} \left( \int_0^s F_3(t, s, x) e^{\tau b} dr + E(t, x) \times \nu \right). \tag{2.11}$$

In particular,

$$Z(t, s, x)_{s=1} = e^{-\tau b} \left( \int_0^1 F_3(t, r, x) e^{\tau b} dr + E(t, x) \times \nu \right), \tag{2.12}$$

$$Z(t, s, x)_{s=0} = E(t, x) \times \nu. \tag{2.13}$$

Further, using Equation (2.10), we obtain

$$H = b^{-1} (F_2 - \mu^{-1} \text{curl } E) \tag{2.14}$$

to arrive at

$$b^2 \varepsilon E - \text{curl}(F_2 - \mu^{-1} \text{curl } E) = b \varepsilon F_1. \tag{2.15}$$

At the first glance, $H \in (L^2(G))^3$, but curl $H \in (L^2(G))^3$ and $\nu \times H \in (L^2(G))^3$ will later follow from the regularity of $E$ (cf. [24], p. 38)].
Equation (2.15) is formally equivalent with
\[ b^2 \varepsilon E + \text{curl}(\mu^{-1} \text{curl} E) = b \varepsilon F_1 + \text{curl} F_2, \tag{2.16} \]
while the boundary condition in Equation (1.11) can formally be transformed to
\[ -b^{-1} \mu^{-1} \text{curl} E \times \nu + \gamma_1 g(Z|_{s=0}) \times \nu + \gamma_2 g(Z|_{s=1}) \times \nu = -b^{-1} F_2 \times \nu, \tag{2.17} \]
where \( Z|_{s=1} \) and \( Z|_{s=0} \) are given by Equations (2.12) and (2.13), respectively.

Define the Hilbert space
\[ W_\varepsilon = \left\{ E \in (L^2(G))^3 \mid \text{curl} E \in (L^2(G))^3, \text{div}(\varepsilon E) \in L^2(G), E \times \nu \in (L^2(\Gamma))^3 \right\} \tag{2.18} \]
endowed with the norm
\[ \|E\|_{W_\varepsilon}^2 = \int_G |E|^2 + |\text{curl} E|^2 + |\text{div}(\varepsilon E)|^2 \, dx + \int_\Gamma |E \times \nu|^2 \, dx. \tag{2.19} \]

Consider the variational problem: Find \( E \in W_\varepsilon \) such that
\[ a(E, E') = \int_G b \varepsilon F_1 \cdot E' + F_2 \cdot \text{curl} E' \, dx \text{ for any } E' \in W_\varepsilon. \tag{2.20} \]

Here, the nonlinear form \( a(\cdot, \cdot) \) is defined by
\[ a(E, E') := \int_G b^2 \varepsilon E \cdot E' + \mu^{-1} \text{curl} E \cdot \text{curl} E' + s \text{div}(\varepsilon E) \text{div}(\varepsilon E') \, dx \]
\[ + b \int_\Gamma (E' \times \nu) \cdot (\gamma_1 g(Z|_{s=0}) + \gamma_2 g(Z|_{s=1})) \, dx, \]
where \( Z|_{s=1} \) and \( Z|_{s=0} \) are given by Equations (2.12) and (2.13), respectively, and \( s \) is a positive number to be chosen later.

Similar to [9], consider the operator
\[ B : W_\varepsilon \to W'_\varepsilon, \quad Bu(\nu) = a(u, \nu). \tag{2.21} \]

Observing that right-hand side of Equation (2.20) belongs to the space \( W'_\varepsilon \), the solvability of Equation (2.20) needs to follow from surjectivity of the operator \( B \). Using [25] Corollary 2.2 and the fact that strong monotonicity implies coercivity, it is sufficient to prove \( B \) is strongly monotone, hemiconcave, and bounded.

**Strong monotonicity:** For any \( E, E' \in W_\varepsilon \), letting \( \tilde{E} = E - E' \), we have
\[ \langle (BE - BE'), E - E' \rangle_{W'_\varepsilon \times W_\varepsilon} = \langle BE, E - E' \rangle_{W'_\varepsilon \times W_\varepsilon} - \langle BE', E - E' \rangle_{W'_\varepsilon \times W_\varepsilon} = a(E, E - E') - a(E', E - E') \]
\[ = \int_G b^2 \varepsilon E \cdot \tilde{E} + \mu^{-1} \text{curl} E \cdot \text{curl} \tilde{E} + s \text{div}(\varepsilon E) \text{div}(\varepsilon \tilde{E}) \, dx + \]
\[ + b \int_\Gamma (\tilde{E} \times \nu) \cdot (\gamma_1 g(E \times \nu) + \gamma_2 g(e^{-\tau b}(\int_0^1 \mathcal{F}_3(r)e^{\tau br}dr + E \times \nu))) \, dx - \]
\[ \int_G b^2 \varepsilon E' \cdot \tilde{E} + \mu^{-1} \text{curl} E' \cdot \text{curl} \tilde{E} + s \text{div}(\varepsilon E') \text{div}(\varepsilon \tilde{E}) \, dx + \]
\[ - b \int_\Gamma (\tilde{E} \times \nu) \cdot (\gamma_1 g(E' \times \nu) + \gamma_2 g(e^{-\tau b}(\int_0^1 \mathcal{F}_3(r)e^{\tau br}dr + E' \times \nu))) \, dx. \]
On the strength of Assumption 2.2, we get the continuity of $g$ for some positive $Hence,

\[ b \gamma_1 \int_{\Gamma} (\tilde{E} \times \nu) \cdot (g(\tilde{E} \times \nu) - g(E' \times \nu)) \, dx \]

\[ + b \gamma_2 \int_{\Gamma} (\tilde{E} \times \nu) \cdot (g(e^{-\tau b}(\int_{0}^{1} F_3(r)e^{\tau br} \, dr + E' \times \nu))) \, dx \]

Utilizing Assumption 2.2, we obtain

\[ b \gamma_1 \int_{\Gamma} (\tilde{E} \times \nu) \cdot (g(\tilde{E} \times \nu) - g(E' \times \nu)) \, dx \geq b \gamma_1 \int_{\Gamma} c_1 |\tilde{E} \times \nu|^2 \, dx \]  

and

\[ b \gamma_2 \int_{\Gamma} (\tilde{E} \times \nu) \cdot (g(e^{-\tau b}(\int_{0}^{1} F_3(r)e^{\tau br} \, dr + E' \times \nu))) \, dx \]

\geq b \gamma_2 e^{-\tau b} \int_{\Gamma} c_1 |e^{-\tau b}(\tilde{E} \times \nu)|^2 \, dx = b \gamma_2 c_1 e^{-\tau b} \int_{\Gamma} |(\tilde{E} \times \nu)|^2 \, dx. 

Hence,

\[ \langle \mathcal{B}E - \mathcal{B}E', E - E' \rangle_{W_2^1 \times W_2} \geq \int_{G} b^2 \varepsilon \tilde{E} \cdot \tilde{E} + \mu^{-1} |\text{curl} \tilde{E}|^2 + s |\text{div} \tilde{E}|^2 \, dx \]

\[ + bc_1(\gamma_1 + e^{-\tau b}\gamma_2) \int_{\Gamma} c_1 |\tilde{E} \times \nu|^2 \, dx \]

\[ \geq c^* ||E - E'||_{W_2^1}^2 \]

for some positive $c^*$.

**Hemicontinuity:** For any $E, E' \in W_\varepsilon$, we can write

\[ \langle \mathcal{B}(E + t'E), E' \rangle_{W_2^1 \times W_2} = a(E + t'E, E') \]

\[ = \int_{G} b^2 \varepsilon(E + t'E) \cdot (E' + \mu^{-1} \text{curl}(E + t'E)) \cdot \text{curl}(E + t'E) + s \text{div}(E + t'E) \text{div}(E'E') \, dx \]

\[ + b \gamma_1 \int_{\Gamma} (E' \times \nu) \cdot g((E + t'E) \times \nu) \, dx \]

\[ + b \gamma_2 \int_{\Gamma} (E' \times \nu) \cdot g(e^{-\tau b}(\int_{0}^{1} F_3(r)e^{\tau br} \, dr + (E + t'E) \times \nu)) \, dx. \]

On the strength of Assumption 2.2, we get the continuity of $g(\cdot)$. Now, by virtue of Equation (2.25), the continuity of $t \mapsto \langle \mathcal{B}(E + t'E), E' \rangle_{W_2^1 \times W_2}$ follows.

**Boundedness:** Suppose $||E||_{W_2} \leq c$. Then,

\[ ||\langle \mathcal{B}E, E' \rangle_{W_2^1 \times W_2}|| = |a(E, E')| \]
\[ \begin{align*}
\leq & \int_G b^2 |\varepsilon E \cdot E'| + |\mu^{-1} \text{curl } E \cdot \text{curl } E'| + s |\text{div}(\varepsilon E) \text{div}(\varepsilon E')| \, dx \\
+ & b\gamma_1 \int_G |(E' \times \nu) \cdot g(E \times \nu)| \, dx \\
+ & b\gamma_2 \int_G |(E' \times \nu) \cdot g(e^{-\tau_b}(\int_0^1 F_3(r)e^{\tau br} \, dr + E \times \nu))| \, dx.
\end{align*} \]

Using Cauchy & Schwarz' inequality and Assumption 2.2, we estimate

\[ b\gamma_1 \int_G |(E' \times \nu) \cdot g(E \times \nu)| \, dx \leq b\gamma_1 \left( \int_G |E' \times \nu|^2 \, dx \int_G |g(E \times \nu)|^2 \, dx \right)^{1/2} \]

\[ \leq b\gamma_1 c_2 \left( \int_G |E' \times \nu|^2 \, dx \int_G |E \times \nu|^2 \, dx \right)^{1/2} \]

\[ = b\gamma_1 c_2 \|E' \times \nu\|_{(L^2(\Gamma))^3} \|E \times \nu\|_{(L^2(\Gamma))^3} \]

\[ \leq b\gamma_1 c_2 \|E'\|_{W_\varepsilon} \|E\|_{W_\varepsilon} \]

\[ \leq b\gamma_1 c_2 \|E'\|_{W_\varepsilon} \]

and

\[ b\gamma_2 \int_G |(E' \times \nu) \cdot g(e^{-\tau_b}(\int_0^1 F_3(r)e^{\tau br} \, dr + E \times \nu))| \, dx \]

\[ \leq b\gamma_2 c_2 \left( \int_G |E' \times \nu|^2 \, dx \int_G e^{-\tau_b}(\int_0^1 F_3(r)e^{\tau br} \, dr + E \times \nu)|^2 \, dx \right)^{1/2} \]

\[ \leq b\gamma_2 c_2 e^{-\tau_b} \|E' \times \nu\|_{(L^2(\Gamma))^3} \left( \int_G 2(\int_0^1 F_3(r)e^{\tau br} \, dr)^2 + 2 |E \times \nu|^2 \, dx \right)^{1/2} \]

\[ \leq 2b\gamma_2 c_2 e^{-\tau_b} \|E'\|_{W_\varepsilon} \left( \|\mathcal{I} F_3\|_{(L^2(\Gamma))^3} + \|E \times \nu\|_{(L^2(\Gamma))^3} \right) \]

\[ \leq 2b\gamma_2 c_2 e^{-\tau_b} \|E'\|_{W_\varepsilon} \left( \|\mathcal{I} F_3\|_{(L^2(\Gamma))^3} + c \right), \]

where \( \mathcal{I} F_3 = \int_0^1 F_3(r)e^{\tau br} \, dr \). Therefore, \( \|\mathcal{B} E, E'\|_{W_\varepsilon \times W_\varepsilon} \leq c^* \) for a suitable \( c^* \). Thus, \( \|\mathcal{B} E\|_{W_\varepsilon} \leq c^* \) and the conclusion follows.

In summary, \( \mathcal{B} \) is surjective and the problem (2.20) possesses a (weak) solution. Since \( \mathcal{B} \) is strongly monotone, the solution is unique.

**Strongness of solution:** We now prove the (weak) solution \( E \in W_\varepsilon \) to Equation (2.20) along with corresponding \( H, Z \) satisfy Equation (2.10).

First, we show that \( \text{div}(\varepsilon E) = 0 \). Following [9], consider the set

\[ D = \{ \varphi \in H_0^1(G) \mid \text{div}(\varepsilon \nabla \varphi) \in L^2(G) \}. \]

(2.26)

Letting \( E' = \nabla \varphi \) for arbitrary, but fixed \( \varphi \in D \), we can rewrite Equation (2.20) as

\[ \int_G b^2 \varepsilon E \cdot \nabla \varphi + s \text{div}(\varepsilon E) \text{div}(\varepsilon \nabla \varphi) \, dx = \int_G b E F_1 \cdot \nabla \varphi \, dx \text{ for any } \varphi \in D. \]

Using Green's formula, we get

\[ \int_G -b^2 \text{div}(\varepsilon E) \varphi + s \text{div}(\varepsilon E) \text{div}(\varepsilon \nabla \varphi) \, dx = -\int_G b \text{div}(\varepsilon F_1) \varphi \, dx \text{ for any } \varphi \in D. \]

(2.27)
Since \( (\mathbf{F}_1, \mathbf{F}_2, \mathbf{F}_3)^T \in \mathcal{H} \), it follows that \( \mathbf{F}_1 \in H(\text{div} \, 0, G) \). Thus, the latter integral in Equation (2.27) vanishes. Hence,

\[
\int_G \text{div}(\varepsilon \mathbf{E})(-b^2 \varphi + s \text{div}(\varepsilon \nabla \varphi)) \, d\mathbf{x} = 0 \text{ for any } \varphi \in D.
\]

(2.28)

Since the spectrum of \( \text{div}(\varepsilon \nabla \cdot) \) with homogeneous Dirichlet boundary conditions is discrete, there exists a positive number \( s \) such that \( b^2/s \) belongs to the resolvent set. Then, from Equation (2.28), we conclude that \( \text{div}(\varepsilon \mathbf{E}) = 0 \) holds strongly in \( G \).

Therefore, Equation (2.20) becomes

\[
\int_G b^2 \varepsilon \mathbf{E} \cdot \mathbf{E}' + \mu^{-1} \text{curl} \mathbf{E} \cdot \text{curl} \mathbf{E}' + b \int_{\Gamma}(\mathbf{E}' \times \nu) \cdot \left( (\gamma_1 \mathbf{g}(\mathbf{Z}|_{s=0}) + \gamma_2 \mathbf{g}(\mathbf{Z}|_{s=1})) \right) \, d\mathbf{x}
\]

\[
= \int_G b \varepsilon \mathbf{F}_1 \cdot \mathbf{E}' + \mathbf{F}_2 \cdot \text{curl} \mathbf{E}' \, d\mathbf{x} \text{ for any } \mathbf{E}' \in W_\varepsilon.
\]

(2.29)

Recalling the definition of \( \mathbf{H} \) from Equation (2.14) and applying Green’s formula to Equation (2.29), we arrive at

\[
\int_G \varepsilon b \mathbf{E} \cdot \mathbf{E}' + \mathbf{H} \cdot \text{curl} \mathbf{E}' \, d\mathbf{x} + \int_{\Gamma}(\mathbf{E}' \times \nu) \cdot \left( (\gamma_1 \mathbf{g}(\mathbf{Z}|_{s=0}) + \gamma_2 \mathbf{g}(\mathbf{Z}|_{s=1})) \right) \, d\mathbf{x}
\]

\[
= \int_G \varepsilon \mathbf{F}_1 \cdot \mathbf{E}' \, d\mathbf{x} \text{ for any } \mathbf{E}' \in W_\varepsilon.
\]

Choosing \( \mathbf{E}' = P_\varepsilon \chi \) with \( \chi \in (\mathcal{D}(G))^3 \), we get

\[
\int_G \varepsilon b \mathbf{E} \cdot P_\varepsilon \chi + \mathbf{H} \cdot \text{curl}(P_\varepsilon \chi) \, d\mathbf{x} = \int_G \varepsilon \mathbf{F}_1 \cdot P_\varepsilon \chi \, d\mathbf{x} \text{ for any } \chi \in (\mathcal{D}(G))^3
\]

or, after using Green’s formula,

\[
\int_G (\varepsilon b \mathbf{E} - \text{curl} \mathbf{H}) \cdot P_\varepsilon \chi \, d\mathbf{x} = \int_G \varepsilon \mathbf{F}_1 \cdot P_\varepsilon \chi \, d\mathbf{x} \text{ for any } \chi \in (\mathcal{D}(G))^3.
\]

Since \( P_\varepsilon(\mathcal{D}(G))^3 \) is dense in \( H(\text{div} \, 0, G) \), there identity

\[
\varepsilon b \mathbf{E} - \text{curl} \mathbf{H} = \varepsilon \mathbf{F}_1
\]

(2.30)

follows in the strong sense.

Choosing \( \mathbf{E}' = P_\varepsilon \chi \) with \( \chi \in (C^\infty(G))^3 \), we get

\[
\int_G \varepsilon b \mathbf{E} \cdot P_\varepsilon \chi + \mathbf{H} \cdot \text{curl}(P_\varepsilon \chi) \, d\mathbf{x} + \int_{\Gamma}(P_\varepsilon \chi \times \nu) \cdot \left( (\gamma_1 \mathbf{g}(\mathbf{Z}|_{s=0}) + \gamma_2 \mathbf{g}(\mathbf{Z}|_{s=1})) \right) \, d\mathbf{x}
\]

\[
= \int_G \varepsilon \mathbf{F}_1 \cdot P_\varepsilon \chi \, d\mathbf{x} \text{ for all } \chi \in (\mathcal{D}(G))^3.
\]

Using Equation (2.30), Lemma 2.7 and Green’s formula, we finally conclude

\[
\int_{\Gamma} -\mathbf{H} \cdot \nu \cdot \chi \, d\mathbf{x} + \int_{\Gamma} \left( \nu \times (\gamma_1 \mathbf{g}(\mathbf{Z}|_{s=0}) + \gamma_2 \mathbf{g}(\mathbf{Z}|_{s=1})) \right) \cdot \chi \, d\mathbf{x} = 0
\]

for all \( \chi \in (\mathcal{D}(G))^3 \). Thus, we have \( -\mathbf{H} \times \nu - (\gamma_1 \mathbf{g}(\mathbf{Z}|_{s=0}) + \gamma_2 \mathbf{g}(\mathbf{Z}|_{s=1})) \times \nu = 0 \) in the strong sense. Therefore, \( (\mathbf{E}, \mathbf{H}, \mathbf{Z})^T \in D(\mathcal{A}) \) and Equation (2.10) is satisfied.
Theorem 2.9. Under Assumptions 2.1 and 2.2, suppose \( V^0 \in \mathcal{H} \). Then, Equation (2.1) possesses a unique global mild solution \( V \in C^0 \left([0, \infty), \mathcal{H}\right) \).

If, moreover, \( V^0 \in D(\mathcal{A}) \), the mild solution \( V \) is a strong solution satisfying
\[
V \in W^{1,\infty}_{\text{loc}}(0, \infty; \mathcal{H}) \cap L^\infty_{\text{loc}}(0, \infty; D(\mathcal{A})).
\]

Proof. Since the operator \( C\text{id} + A \) is maximally monotone for a sufficiently large \( C > 0 \), using [1, Corollary 4.1], any initial value \( V^0 \in D(\mathcal{A}) \) admits a unique mild solution. By virtue of Lemma 2.6, this remains true for \( V^0 \in \mathcal{H} \). As for the strong solution, [1, Theorem 4.5] applies.

Remark 2.10. In contrast to Datko’s ‘counterexamples’ of destabilizing boundary delays, our nonlinear system (1.9)–(1.13) as well as its linearization studied by Nicaise & Pignotti [24] are well-posed for two basic reasons: 1) the boundary conditions involve instantaneous terms of matching order and has a correct sign; 2) the orders of the delayed and the instantaneous terms are not too high. Indeed, adopting the step method commonly used for difference-differential equations, a delayed system can only be well-posed if the delay operator constitutes an ‘admissible control operator’ as widely applied in infinite-dimensional control theory. In this sense, systems with maximal \( L^p \)-regularity (which Equations (1.9)–(1.13) are lacking) subject to ‘strong’ delay can behave completely differently from those without this important property.

3 Exponential Stability

Our thrust is to prove the exponential stability for Equations (1.9)–(1.13). To this end, we consider the “natural energy” functional
\[
E(t) := \frac{1}{2} \| V \|^2 \mathcal{H} \equiv \frac{1}{2} \int_G |E(t, \cdot)|^2 \, dx + \frac{1}{2} \int_G |H(t, \cdot)|^2 \, dx + \tau \int_0^1 \int_\Gamma |E(t-\tau s, x) \times \nu|^2 \, dx \, ds.
\]

In the following, we apply a combination of Rellich’s multiplier techniques developed for boundary control problems along with Lyapunov’s techniques for delay differential equations in the spirit of [13].

For \( x_0 \in \mathbb{R}^3 \), consider the vector field \( m(x) := x - x_0 \).

Assumption 3.1 (Regularity and geometric conditions). Suppose the following conditions are satisfied:

1. \( G \) is a bounded \( C^2 \)-domain.
2. \( G \) is strictly star-shaped with respect to \( x_0 \in G \), i.e.,
   \[
   m(x) \cdot \nu(x) > 0 \text{ for } x \in \Gamma.
   \]
3. \( \varepsilon, \mu \in C^1(\bar{G}, \mathbb{R}^{3 \times 3}) \).
4. There exists a constant \( d_1 > 0 \) such that
   \[
   \varepsilon + (m \cdot \nabla) \varepsilon \geq d_1 \varepsilon \quad \text{and} \quad \mu + (m \cdot \nabla) \mu \geq d_1 \mu \text{ in } \bar{G},
   \]
Lemma 3.3. Suppose \( (ξ t, τs, x) \) is a positive number such that
\[
\gamma_1 c_1 - \frac{\gamma_2 c_2}{2} > ξ > \frac{\gamma_2 c_2}{2}.
\] (3.3)
Obviously, \( ξ \) exists if \( \gamma_1 c_1 > \gamma_2 c_2 \).

**Lemma 3.3.** Suppose \( \gamma_1 c_1 > \gamma_2 c_2 \). Then, there exist positive numbers \( c_1^E, c_2^E \) such that for all \( t_2 > t_1 \geq 0 \) the following inequality holds
\[
-c_1^E \int_{t_1}^{t_2} \int_\Gamma Z_{s=0}^2 + Z_{s=1}^2 \, dx \, dt \geq E_ξ(t_2) - E_ξ(t_1) \geq -c_2^E \int_{t_1}^{t_2} \int_\Gamma Z_{s=0}^2 + Z_{s=1}^2 \, dx \, dt
\]
(3.4)
where \( (E, H, Z)^T \) is a strong solution of Equation (2.1).

**Proof.** Similar to [9] Lemma 2.7, multiplying Equations (1.9) and (1.10) in \( L^2(0, T; (L^2(G))^3) \) with \( E \) and \( H \), respectively, integrating by parts and using the boundary condition from Equation (1.11), we get
\[
E_ξ(t_2) - E_ξ(t_1) = -\int_{t_1}^{t_2} \int_\Gamma (\gamma_1 g(Z)_{s=0} + \gamma_2 g(Z)_{s=1}) \cdot (E(t, \cdot) \times ν) \, dx \, dt
\] (3.5)
\[+ ξ \int_{t_1}^{t_2} \int_0^1 \int_\Gamma 2(E(t-τs, \cdot) \times ν) \cdot \partial_t(E(t-τs, \cdot) \times ν) dν dS dt.
\]
Recalling
\[Z(t, s, \cdot) = E(t-τs, \cdot) \times ν \text{ for } s \in [0, 1]\]
and following [13], we obtain
\[τ \partial_t Z(t, s, \cdot) + \partial_s Z(t, s, \cdot) = 0 \text{ for } (t, s) \in (0, \infty) \times (0, 1).
\]
Therefore,
\[
ξ \int_0^1 \int_\Gamma 2(E(t-τs, \cdot) \times ν) \cdot \partial_t(E(t-τs, \cdot) \times ν) dν dS = -ξ \int_0^1 \int_\Gamma 2(E(t-τs, \cdot) \times ν) \cdot \partial_s(E(t-τs, \cdot) \times ν) dν dS
\]
\[= -ξ \int_0^1 \int_\Gamma |E(t-τs, \cdot) \times ν|^2 dν dS = -ξ \int_0^1 \int_\Gamma |E(t-τs, \cdot) \times ν|^2 s=0 dν dx
\]
Thus, Equation (3.6) can further be estimated as follows:

\[
\xi \int \Gamma Z_{|s=0}^2 - Z_{|s=1}^2 \, dx.
\]

After plugging the latter identity into Equation (3.5), we arrive at

\[
E_\xi(t_2) - E_\xi(t_1) = - \int_{t_1}^{t_2} \int \gamma_1 g(Z_{|s=0}) + \gamma_2 g(Z_{|s=1}) \cdot Z_{|s=0} \, dx \, dt
\]

\[
+ \xi \int_{t_1}^{t_2} \int \Gamma Z_{|s=0}^2 - Z_{|s=1}^2 \, dx \, dt.
\]

Using Assumption 2.2 and Young’s inequality, we get

\[
\int \Gamma g(Z_{|s=0}) \cdot Z_{|s=0} \, dx \geq c_1 \int \Gamma Z_{|s=0}^2 \, dx \quad \text{and}
\]

\[
\int \Gamma g(Z_{|s=1}) \cdot Z_{|s=0} \, dx \geq -c_2 \int \Gamma Z_{|s=1} \cdot Z_{|s=0} \, dx \geq -\frac{c_2}{2} \int \Gamma Z_{|s=0}^2 \, dx.
\]

Then, Equation (3.6) can further be estimated as follows:

\[
E_\xi(t_2) - E_\xi(t_1) \leq \int_{t_1}^{t_2} \left( -\gamma_1 c_1 \int \Gamma Z_{|s=0}^2 \, dx + \frac{\gamma_2 c_2}{2} \int \Gamma Z_{|s=1}^2 \, dx + \frac{\gamma_2 c_2}{2} \int \Gamma Z_{|s=0}^2 \, dx \right) \, dt
\]

\[
+ \xi \int_{t_1}^{t_2} \int \Gamma Z_{|s=0}^2 - Z_{|s=1}^2 \, dx \, dt
\]

\[
= - (\gamma_1 c_1 - \frac{\gamma_2 c_2}{2} - \xi) \int_{t_1}^{t_2} \int \Gamma Z_{|s=0}^2 \, dx dt - (\xi - \frac{\gamma_2 c_2}{2}) \int_{t_1}^{t_2} \int \Gamma Z_{|s=1}^2 \, dx dt. \quad (3.9)
\]

Since \( \xi \) is selected to satisfy Equation (3.3), we arrive at

\[
E_\xi(t_2) - E_\xi(t_1) \leq -c_1^E \int_{t_1}^{t_2} \int \Gamma Z_{|s=0}^2 + Z_{|s=1}^2 \, dx dt.
\]

On the other hand,

\[
\left| \int \Gamma g(Z_{|s=0}) \cdot Z_{|s=0} \, dx \right| \leq c_2 \int \Gamma Z_{|s=0}^2 \, dx \quad \text{and}
\]

\[
\left| \int \Gamma g(Z_{|s=1}) \cdot Z_{|s=0} \, dx \right| \leq c_2 \int \Gamma Z_{|s=1} \cdot Z_{|s=0} \, dx \leq \frac{c_2}{2} \int \Gamma Z_{|s=1}^2 \, dx + \frac{c_2}{2} \int \Gamma Z_{|s=0}^2 \, dx. \quad (3.10)
\]

Thus,

\[
E_\xi(t_2) - E_\xi(t_1) \geq - \left| \int_{t_1}^{t_2} \int \Gamma (\gamma_1 g(Z_{|s=0}) + \gamma_2 g(Z_{|s=1})) \cdot Z_{|s=0} \, dx \, dt \right|
\]

\[
- \xi \left| \int_{t_1}^{t_2} \int \Gamma Z_{|s=0}^2 - Z_{|s=1}^2 \, dx \, dt \right|
\]

\[
\geq \int_{t_1}^{t_2} \left( -\gamma_1 c_2 \int \Gamma Z_{|s=0}^2 \, dx - \frac{\gamma_2 c_2}{2} \int \Gamma Z_{|s=1}^2 \, dx - \frac{\gamma_2 c_2}{2} \int \Gamma Z_{|s=0}^2 \, dx \right) \, dt.
\]
The left-hand side can be estimated using inequalities in Equation (3.2) as

$$\xi \int_{t_1}^{t_2} \int_{\Gamma} |Z|_{s=0}^2 \, dx \, dt - \xi \int_{t_1}^{t_2} \int_{\Gamma} |Z|_{s=1}^2 \, dx \, dt$$

$$\geq -c_2^E \int_{t_1}^{t_2} \int_{\Gamma} |Z|_{s=0}^2 + |Z|_{s=1}^2 \, dx \, dt,$$

which finishes the proof. □

**Lemma 3.4.** There exist positive numbers $c, c_T$ such that the estimate

$$\int_0^T E_\xi(t) \, dt \leq c(E_\xi(0) + E_\xi(T)) + c_T \int_0^T \int_{\Gamma} |Z|_{s=0}^2 + |Z|_{s=1}^2 \, dx \, dt$$

(3.12)

holds true for every $T > 0$ along any strong solution $(E, H, Z)^T$ of Equation (2.1).

**Proof.** Similar to [7, Section 3.1, pp. 193–195], using Rellich’s multipliers $m \times (\varepsilon E)$ and $m \times (\mu H)$, we obtain

$$\frac{1}{2} \int_0^T \int_G (\varepsilon + (m \cdot \nabla)\varepsilon)E \cdot E + (\mu + (m \cdot \nabla)\mu)H \cdot H \, dx \, dt$$

$$= -\frac{1}{2} \int_0^T \int_{\Gamma} \nu \cdot m(\mu H \cdot H + \varepsilon E \cdot E) \, dx \, dt$$

$$+ \int_0^T \int_{\Gamma} (\nu \times E) \cdot (m \times \varepsilon E) \, dx \, dt + \int_0^T \int_{\Gamma} (\nu \times H) \cdot (m \times \mu H) \, dx \, dt$$

$$+ \int_G (m \times \varepsilon E(T)) \cdot (\mu H(T)) \, dx - \int_G (m \times \varepsilon E(0)) \cdot (\mu H(0)) \, dx.$$

The left-hand side can be estimated using inequalities in Equation (3.2) as

$$\frac{1}{2} \int_0^T \int_G (\varepsilon + (m \cdot \nabla)\varepsilon)E \cdot E + (\mu + (m \cdot \nabla)\mu)H \cdot H \, dx \, dt \geq \frac{d_1}{2} \int_0^T \int_G \varepsilon E \cdot E + \mu H \cdot H \, dx \, dt.$$

From Assumption (2.1) and Equation (2.3), we get $\varepsilon E \cdot E \geq \alpha |E|^2$, $\mu E \cdot E \geq \alpha |E|^2$ for all $E \in \mathbb{R}^3$. Therefore,

$$\frac{1}{2} \int_0^T \int_G (\varepsilon + (m \cdot \nabla)\varepsilon)E \cdot E + (\mu + (m \cdot \nabla)\mu)H \cdot H \, dx \, dt$$

$$\geq \frac{d_1 \alpha}{2} \int_0^T \int_G |E|^2 + |H|^2 \, dx \, dt.$$

From the compactness of $\Gamma$ and the continuity of $m$, we get $m \cdot \nu \geq \beta > 0$ uniformly on $\Gamma$. Thus, the first term on the right-hand side of Equation (3.13) can be estimated via

$$-\frac{1}{2} \int_0^T \int_{\Gamma} \nu \cdot m(\mu H \cdot H + \varepsilon E \cdot E) \, dx \, dt \leq -\frac{1}{2} \int_0^T \int_{\Gamma} \nu \cdot m(\mu H \cdot H + \varepsilon E \cdot E) \, dx \, dt$$

$$\leq -\frac{\beta}{2} \int_0^T \int_{\Gamma} \mu H \cdot H + \varepsilon E \cdot E \, dx \, dt.$$
Utilizing Young’s inequality, we further get
\[
\left| \int_G (\mathbf{m} \times \varepsilon \mathbf{E}(T)) \cdot (\mu \mathbf{H}(T)) \, dx \right| \leq \int_G |\mathbf{m}| \cdot |\varepsilon \mathbf{E}(T)| \cdot |\mu \mathbf{H}(T)| \, dx
\]
\[
\leq \sup_{x \in G} |\mathbf{m}(x)| |\lambda_{\max}(\varepsilon)\lambda_{\max}(\mu)| \int_G |\mathbf{E}(T)| \cdot |\mathbf{H}(T)| \, dx
\]
\[
\leq \frac{1}{2} \sup_{x \in G} |\mathbf{m}(x)| |\lambda_{\max}(\varepsilon)\lambda_{\max}(\mu)| \int_G |\mathbf{E}(T)|^2 + |\mathbf{H}(T)|^2 \, dx
\]
\[
\leq \sup_{x \in G} |\mathbf{m}(x)| |\lambda_{\max}(\varepsilon)\lambda_{\max}(\mu)| E_\xi(T).
\] (3.16)

Similarly, we obtain
\[
\left| \int_G (\mathbf{m} \times \varepsilon \mathbf{E}(0)) \cdot (\mu \mathbf{H}(0)) \, dx \right| \leq \sup_{x \in G} |\mathbf{m}(x)| |\lambda_{\max}(\varepsilon)\lambda_{\max}(\mu)| E_\xi(0).
\] (3.17)

Next, we estimate \( \int_0^T \int_\Gamma (\mathbf{v} \times \mathbf{E}) \cdot (\mathbf{m} \times \varepsilon \mathbf{E}) \, dx \, dt \). By virtue of Young’s inequality, we get
\[
| (\mathbf{v} \times \mathbf{E}) \cdot (\mathbf{m} \times \varepsilon \mathbf{E}) | \leq |\mathbf{v} \times \mathbf{E}| \cdot |\mathbf{m} \times \varepsilon \mathbf{E}| \leq \frac{1}{2\delta} |\mathbf{v} \times \mathbf{E}|^2 + \frac{\delta}{2} \mathbf{m} \times \varepsilon \mathbf{E}^2
\] (3.18)

Using the uniform positive definiteness of \( \varepsilon \), we further find
\[
|\mathbf{m} \times \varepsilon \mathbf{E}|^2 \leq \sup_{x \in G} |\mathbf{m}(x)|^2 \cdot |\varepsilon \mathbf{E}|^2 \leq \sup_{x \in G} |\mathbf{m}(x)|^2 (\lambda_{\max}(\varepsilon)|\mathbf{E}|)^2
\]
\[
\leq \sup_{x \in G} |\mathbf{m}(x)|^2 (\lambda_{\max}(\varepsilon))^2 \frac{1}{\alpha} \varepsilon \cdot \mathbf{E}.
\]

Integrating the latter inequality, we get
\[
\int_0^T \int_\Gamma |\mathbf{m} \times \varepsilon \mathbf{E}|^2 \, dx \, dt \leq \frac{1}{\alpha} \sup_{x \in G} |\mathbf{m}(x)|^2 (\lambda_{\max}(\varepsilon))^2 \int_0^T \int_\Gamma \varepsilon \cdot \mathbf{E} \, d\mathbf{d} \, dt.
\] (3.19)

Using Equations (3.18) and (3.19), we obtain
\[
\int_0^T \int_\Gamma (\mathbf{v} \times \mathbf{E}) \cdot (\mathbf{m} \times \varepsilon \mathbf{E}) \, dx \, dt \leq \int_0^T \int_\Gamma \frac{1}{2\delta} |\mathbf{v} \times \mathbf{E}|^2 + \frac{\delta}{2} |\mathbf{m} \times \varepsilon \mathbf{E}|^2 \, dx \, dt
\]
\[
\leq \frac{1}{2\delta} \int_0^T \int_\Gamma |\mathbf{v} \times \mathbf{E}|^2 \, dx \, dt
\]
\[
+ \frac{\delta}{2\alpha} \sup_{x \in G} |\mathbf{m}(x)|^2 (\lambda_{\max}(\varepsilon))^2 \int_0^T \int_\Gamma \varepsilon \cdot \mathbf{E} \, d\mathbf{d} \, dt.
\] (3.20)

In the same fashion, we get
\[
\int_0^T \int_\Gamma (\mathbf{v} \times \mathbf{H}) \cdot (\mathbf{m} \times \mu \mathbf{H}) \, dx \, dt \leq \int_0^T \int_\Gamma \frac{1}{2\delta} |\mathbf{v} \times \mathbf{H}|^2 + \frac{\delta}{2} |\mathbf{m} \times \mu \mathbf{H}|^2 \, dx \, dt
\]
\[
\leq \frac{1}{2\delta} \int_0^T \int_\Gamma |\mathbf{v} \times \mathbf{H}|^2 \, dx \, dt
\]
\[
+ \frac{\delta}{2\alpha} \sup_{x \in G} |\mathbf{m}(x)|^2 (\lambda_{\max}(\mu))^2 \int_0^T \int_\Gamma \mu \mathbf{H} \cdot \mathbf{H} \, d\mathbf{d} \, dt.
\] (3.21)
Recalling the boundary condition in Equation (1.11), we estimate
\[
\frac{1}{2\delta} \int_0^T \int_{\Gamma} |\nu \times \mathbf{H}|^2 \, dx \, dt = \frac{1}{2\delta} \int_0^T \int_{\Gamma} (|\gamma_1 \mathbf{g}(\mathbf{Z}|_{s=0}) + \gamma_2 \mathbf{g}(\mathbf{Z}|_{s=1})|) \times \nu|^2 \, dx \, dt \\
\leq \frac{1}{2\delta} \int_0^T \int_{\Gamma} (|\gamma_1 \mathbf{g}(\mathbf{Z}|_{s=0}) + \gamma_2 \mathbf{g}(\mathbf{Z}|_{s=1})|)^2 \, dx \, dt \\
\leq \frac{\max\{\gamma_1^2, \gamma_2^2\}}{\delta} \int_0^T \int_{\Gamma} \mathbf{g}^2(\mathbf{Z}|_{s=0}) + \mathbf{g}^2(\mathbf{Z}|_{s=1}) \, dx \, dt \\
\leq \frac{c_2^2 \max\{\gamma_1^2, \gamma_2^2\}}{\delta} \int_0^T \int_{\Gamma} \mathbf{Z}_{s=0}^2 + \mathbf{Z}_{s=1}^2 \, dx \, dt.
\] (3.22)

Combining Equations (3.13)–(3.17) and (3.20)–(3.22), we deduce
\[
\frac{d_1 \alpha}{2} \int_0^T \int_G |\mathbf{E}|^2 + |\mathbf{H}|^2 \, dx \, dt \leq -\frac{\beta}{2} \int_0^T \int_{\Gamma} \mu \mathbf{H} \cdot \mathbf{H} + \varepsilon \mathbf{E} \cdot \mathbf{E} \, dx \, dt \\
+ \frac{1}{2\delta} \int_0^T \int_{\Gamma} |\nu \times \mathbf{E}|^2 \, dx \, dt \\
+ \frac{\delta}{2} \cdot \frac{1}{\alpha} \sup_{x \in G} |\mathbf{m}(x)|^2 (\lambda_{\max}(\varepsilon))^2 \int_0^T \int_{\Gamma} \varepsilon \mathbf{E} \cdot \mathbf{E} \, dx \, dt \\
+ \frac{c_2^2 \max\{\gamma_1^2, \gamma_2^2\}}{\delta} \int_0^T \int_{\Gamma} \mathbf{Z}_{s=0}^2 + \mathbf{Z}_{s=1}^2 \, dx \, dt \\
+ \frac{\delta}{2} \sup_{x \in G} |\mathbf{m}(x)|^2 (\lambda_{\max}(\mu))^2 \int_0^T \int_{\Gamma} \mu \mathbf{H} \cdot \mathbf{H} \, dx \, dt \\
+ \sup_{x \in G} |\mathbf{m}(x)| \lambda_{\max}(\varepsilon) \lambda_{\max}(\mu) \left( E_\xi(T) + E_\xi(0) \right).
\]

Choosing \( \delta > 0 \) such that
\[
\frac{\delta}{2} \sup_{x \in G} |\mathbf{m}(x)|^2 \max\{ (\lambda_{\max}(\varepsilon))^2, (\lambda_{\max}(\mu))^2 \} \leq \frac{\beta}{2},
\] (3.23)
we arrive at
\[
\frac{d_1 \alpha}{2} \int_0^T \int_G |\mathbf{E}|^2 + |\mathbf{H}|^2 \, dx \, dt \leq \frac{1}{2\delta} \int_0^T \int_{\Gamma} \mathbf{Z}_{s=0}^2 \, dx \, dt \\
+ \frac{c_2^2 \max\{\gamma_1^2, \gamma_2^2\}}{\delta} \int_0^T \int_{\Gamma} \mathbf{Z}_{s=0}^2 + \mathbf{Z}_{s=1}^2 \, dx \, dt \\
+ \sup_{x \in G} |\mathbf{m}(x)| \lambda_{\max}(\varepsilon) \lambda_{\max}(\mu) \left( E_\xi(T) + E_\xi(0) \right).
\] (3.24)

There remains to estimate
\[
I = \int_0^T \int_0^1 \int_{\Gamma} |\mathbf{E}(t - \tau s, x) \times \nu|^2 \, dx \, ds \, dt.
\]

Making substitution \( u = t - \tau s \) and \( v = t \), we get
\[
I = \frac{1}{\tau} \int_0^T \int_{v - \tau}^{v} \int_{\Gamma} |\mathbf{E}(u, x) \times \nu|^2 \, dx \, dv.
\]
\[
= \frac{1}{\tau} \int_{-\tau}^{0} (u + \tau) \int_{\Gamma} |E(u, x) \times \nu|^{2} \, dx \, du + \frac{1}{\tau} \int_{0}^{T-\tau} \int_{\Gamma} |E(u, x) \times \nu|^{2} \, dx \, du \\
+ \frac{1}{\tau} \int_{T-\tau}^{T} (T - u) \int_{\Gamma} |E(u, x) \times \nu|^{2} \, dx \, du \\
\leq \int_{-\tau}^{0} \int_{\Gamma} |E(u, x) \times \nu|^{2} \, dx \, du + \int_{0}^{T-\tau} \int_{\Gamma} |E(u, x) \times \nu|^{2} \, dx \, du \\
+ \int_{T-\tau}^{T} \int_{\Gamma} |E(u, x) \times \nu|^{2} \, dx \, du \\
\leq \int_{0}^{T} \int_{\Gamma} |E(u, x) \times \nu|^{2} \, dx \, du + \int_{0}^{T} \int_{\Gamma} |E(u, x) \times \nu|^{2} \, dx \, du \\
= \int_{0}^{T} \int_{\Gamma} Z_{s=0}^{2} + Z_{s=1}^{2} \, dx \, dt \\
(3.25)
\]

Now, multiplying Equation (3.25) by $\xi \tau$ and adding the result to Equation (3.24) divided by $d_{1}\alpha$, the claim follows with appropriate constants $c, c_{T}$.

**Theorem 3.5.** Let $V$ be the unique strong solution given in Theorem 2.9 Under Assumption 3.1, if $c_{1} \gamma_{1} > c_{2} \gamma_{2}$ (i.e., the delay term is not too strong), there exist $C, \lambda > 0$ such that the associated energy satisfies

\[ E(t) \leq Ce^{-\lambda t}E(0) \text{ for } t \geq 0. \]

**Proof.** From Lemmas 3.3, 3.4 and Theorem A.1 in the appendix with

\[ D(t) = \int_{\Gamma} Z_{s=0}^{2} + Z_{s=1}^{2} \, dx, \]

we get the desired inequality for $E_{\xi}(\cdot)$ in place of $E(\cdot)$. Taking into account the equivalence of $E(\cdot)$ and $E_{\xi}(\cdot)$, the original claim follows.

Due to the density of $D(\mathcal{A})$ in $\mathcal{H}$, we have:

**Corollary 3.6.** The conclusions of Theorem 3.5 remain true for mild solutions, i.e., if $V^{0} \in \mathcal{H}$.

**A Proof of Exponential Stability**

**Theorem A.1.** Suppose there exist a non-negative function $D(t)$ and positive numbers $c_1^E, c_2^E, c$ and $c_T$ such that

$$-c_1^E \int_{t_1}^{t_2} D(t) \, dt \geq E(t_2) - E(t_1) \geq -c_2^E \int_{t_1}^{t_2} D(t) \, dt \text{ for all } t_2 > t_1 \geq 0$$

(A.1)

and

$$\int_0^T E(t) \, dt \leq c(E(0) + E(T)) + c_T \int_0^T D(t) \, dt \text{ for arbitrarily large } T.$$  \hspace{1cm} (A.2)

Then, there exist $C, \lambda > 0$ such that the function $E(t)$ satisfies

$$E(t) \leq Ce^{-\lambda t}E(0) \text{ for } t \geq 0.$$  \hspace{1cm} (A.3)

**Proof.** Taking $t_1 = 0$ and $t_2 = T$ in Equation (A.1), we get

$$E(0) \leq E(T) + c_2^E \int_0^T D(t) \, dt.$$  \hspace{1cm} (A.3)

Thus, from Equation (A.2), we obtain

$$\int_0^T E(t) \, dt \leq 2cE(T) + (c_T + cc_2^E) \int_0^T D(t) \, dt.$$  \hspace{1cm} (A.4)
Now, using Equation (A.1) with \( t_2 = T \) and \( t_1 = t \), we get

\[
E(t) \geq E(T) + c^E_1 \int_t^T D(s) \, ds. \tag{A.5}
\]

Integrating the latter inequality from 0 to \( T \) with respect to \( t \) and taking into account Equation (A.4), we arrive at

\[
T E(T) + c^E_1 \int_0^T E(t) \, dt \leq \int_0^T E(t) \, dt \leq 2c E(T) + (c_T + cc^E_2) \int_0^T D(t) \, dt. \tag{A.6}
\]

Choosing \( T > 4c \), we have

\[
T^2 E(T) + c^E_1 \int_0^T \int_t^T D(s) \, ds \, dt \leq (c_T + cc^E_2) \int_0^T D(t) \, dt. \tag{A.7}
\]

Since \( D(s) \) is non-negative, we estimate

\[
\frac{T}{2} E(T) \leq (c_T + cc^E_2) \int_0^T D(t) \, dt. \tag{A.8}
\]

Applying Equation (A.1) with \( t_1 = 0 \) and \( t_2 = T \) to the inequality in Equation (A.8), we get

\[
\frac{T}{2} E(T) \leq \frac{c_T + cc^E_2}{c^E_1} (E(0) - E(T)), \tag{A.9}
\]

which finally leads us to

\[
\left( \frac{T}{2} + \tilde{c} \right) E(T) \leq \tilde{c} E(0) \tag{A.10}
\]

with \( \tilde{c} = \frac{c_T + cc^E_2}{c^E_1} \). Thus,

\[
E(T) \leq \gamma E(0) \text{ for } \gamma = \frac{\tilde{c}}{\tilde{c} + T/2} < 1. \tag{A.11}
\]

Using a similar argument on each of the time segments \([ (m-1)T, mT] \) for \( m = 1, 2, \ldots \), we obtain

\[
E(mT) \leq \gamma E((m-1)T) \leq \ldots \leq \gamma^m E(0), \ m = 1, 2, \ldots \tag{A.12}
\]

Denoting \( \lambda = -T^{-1} \ln(\gamma) > 0 \), Equation (A.12) rewrites as

\[
E(mT) \leq e^{-\lambda mT} E(0), \ m = 1, 2, \ldots \tag{A.13}
\]

It easily follows from (A.1) that \( E(t) \) is monotone non-increasing. This leads to

\[
E(t) \leq E(mT) \leq e^{-\lambda mT} E(0) = \frac{1}{\gamma} e^{-\lambda (m+1)T} E(0) \leq \frac{1}{\gamma} e^{-\lambda T} E(0) \tag{A.14}
\]

for arbitrary \( t \in [mT, (m+1)T] \) for any \( m = 1, 2, \ldots \), which completes the proof. \( \square \)
