A monster is an automaton in which every function from states to states is represented by at least one letter. A modifier is a set of functions allowing one to transform a set of automata into one automaton. We revisit some language transformation algorithms in terms of modifier and monster. These new theoretical concepts allow one to find easily some state complexities. We illustrate this by retrieving the state complexity of the Star of Intersection and the one of the Square root operation.

1 Introduction

The studies around state complexities last for more than twenty years now. Mainly initiated by Yu et al \cite{Yu1970} and very active ever since, this research area dates back in fact to the beginning of the 1970s. In particular, in \cite{Maslov1973} Maslov gives values (without proofs) for the state complexity of some operations: square root, cyclic shift and proportional removal. From these foundations, tens and tens of papers have been produced and different sub-domains have appeared depending on whether the used automata are deterministic or not, whether the languages are finite or infinite, belongs to some classes (codes, star-free, \ldots) and so on. We focus here on the deterministic case for any language.

The state complexity of a rational language is the size of its minimal automaton and the state complexity of a rational operation is the maximal one of those languages obtained by applying this operation onto languages of fixed state complexities. So, to compute a state complexity, most of the time the approach is to calculate an upper bound from the characteristics of the considered operation and to provide a witness, that is a specific example reaching the bound which is then the desired state complexity.

This work has been done for numerous unary and binary operations. See, for example, \cite{Caron2004}, \cite{Hamel2004}, \cite{Luque2004}, \cite{Patrou2004} and \cite{Caron2005} for a survey of the subject. More recently, the state complexity of combinations of operations has also been studied. In most of the cases the result is not simply the mathematical composition of the individual complexities and studies lead to interesting situations. Examples can be found in \cite{Brzozowski2008}, \cite{Hamel2009}, \cite{Caron2010} or \cite{Caron2012}.

Beyond the search of state complexities and witnesses, some studies try to improve the given witnesses, especially the size of their alphabet \cite{Caron2004, Hammoud2009}. Others try to unify the techniques and the approaches used to solve the different encountered problems. In \cite{Brzozowski2008}, Brzozowski proposes to use some fundamental configurations to produce witnesses in many situations. In \cite{Caron2004}, the authors show how to compute the state complexities of 16 combinations by only studying three of them.

In this paper, we propose a general method to build witnesses, consisting in maximizing the transition function of automata. Among the resulting automata, called monsters, at least one of them is a witness. We just have to discuss the finality of the states to determine which ones are. We illustrate this technique by recomputing the state complexity of the operation obtained in combining star with intersection. The state complexity of the square root operation is also computed and improved (compared to the bound given by Maslov) as another illustration.

The paper is organized as follows. Section 2 gives definitions and notations about automata and combinatorics. In Section 3, we define modifiers and give some properties of these algebraic structures. In Section 4, monsters automata are defined and their use in automata computation is shown. The next section is devoted to show how these new tools can be used to compute tight bounds for state complexity. Star of intersection and square root examples are described.

2 Preliminaries

Let $\Sigma$ denote a finite alphabet. A word $w$ over $\Sigma$ is a finite sequence of symbols of $\Sigma$. The length of $w$, denoted by $|w|$, is the number of occurrences of symbols of $\Sigma$ in $w$. For $a \in \Sigma$, we denote by $|w_a|$ the number of occurrences of $a$ in $w$. The set of all finite words over $\Sigma$ is denoted by $\Sigma^*$. The empty word is denoted by $\varepsilon$. A language is a subset of $\Sigma^*$. The cardinality of a finite set $E$ is denoted by $|E|$. The set of subsets of $E$ is denoted by $2^E$. An automaton $A$ is complete and deterministic (CDF $A$) if $|Q|$, the set of subsets of $E$ is denoted by $2^E$. A CDF $A$ is minimal if there does not exist any equivalent CDF $A$ with less states for any $q \in Q$, $q \sim q'$. Such an equivalence is denoted $q \sim q'$. A CDF $A$ is minimal if there does not exist any equivalent CDF $A$ with less states and it is well known that for any DFA, there exists a unique minimal equivalent one [12]. Such a minimal CDF $A$ can be obtained from $D$ by computing the accessible part of the automaton $D/\sim = (\Sigma, Q_D/\sim, i_D, F_D/\sim, \delta_\sim)$ where for any $q \in Q_D$, $[q]$ is the $\sim$-class of the state $q$ and satisfies the property $\delta_\sim([q], a) = [\delta(q,a)]$, for any $a \in \Sigma$. The number of its states is defined by $\#_{\text{Min}}(D)$. In a minimal CDF $A$, any two distinct states are pairwise inequivalent.

For any integer $n$, let us denote $[n]$ for $\{0, \ldots, n-1\}$. When there is no ambiguity, for any character $X$ and any integer $k$ given by the context, we write $X^k$ for $(X_1, \ldots, X_k)$. The state complexity of a regular language $L$ denoted by $sc(L)$ is the number of states of its minimal CDF $A$. Let $\mathcal{L}_n$ be the set of languages of state complexity $n$. The state complexity of a unary operation $\otimes$ is the function $sc_\otimes$ associating with an integer $n$, the maximum of the state complexities of $\otimes L$ for $L \in \mathcal{L}_n$. A language $L \in \mathcal{L}_n$ is a witness (for $\otimes$) if $sc(\otimes(L)) = sc_\otimes(n)$. This can be generalized, and the state complexity of a $k$-ary operation $\otimes$ is the $k$-ary function which associates with any
We also need some background from finite transformation semigroup theory \[9\]. Let \( n \) be an integer. A transformation \( t \) is an element of \( [n]^{[n]} \). We denote by \( i^t \) the image of \( i \) under \( t \). A transformation of \( [n] \) can be represented by \( t = [i_0, i_1, \ldots, i_{n-1}] \) which means that \( i_k = kt \) for each \( k \in [n] \) and \( i_k \in [n] \). A permutation is a bijective transformation on \( [n] \). The identity permutation is denoted by \( 1 \). A cycle of length \( \ell \leq n \) is a permutation \( c \), denoted by \( (i_0, i_1, \ldots, i_{\ell-1}) \), on a subset \( I = \{i_0, \ldots, i_{\ell-1}\} \) of \([n]\) where \( i_k = i_{k+1} \) for \( 0 \leq k < \ell - 1 \) and \( i_{\ell-1} = i_0 \). A transposition \( t = (i, j) \) is a permutation on \([n]\) where \( i = j \) and \( j \neq i \) and for every elements \( k \in \mathbb{Q} \setminus \{i, j\} \), \( k \neq k \). A contraction \( t = \left(\begin{smallmatrix} k \\ i \\ j \end{smallmatrix}\right) \) is a transformation where \( i = j \) and for every elements \( k \in [n] \setminus \{i\}, k = k \).

Let \( L \) and \( L' \) be two regular languages defined over an alphabet \( \Sigma \). Let \( \text{Union}(L, L') = \{w \mid w \in L \lor w \in L'\}, \text{Inter}(L, L') = \{w \mid w \in L \land w \in L'\}, \text{Xor}(L, L') = \{w \mid w \in L \lor w \notin L' \lor w \notin L \land w \notin L'\}\), \( \text{Prefin}(L) = \{w = uv \mid u \in L, v \in \Sigma^*\}, \text{Comp}(L) = \{w \mid w \notin L\}, \text{Conc}(L, L') = \{w = uv \mid u \in L, v \in L'\}, \text{Star}(L) = \{w = u_1 \cdots u_n \mid u_i \in L\}, \text{SRoot}(L) = \{w \in \Sigma^* \mid w w \in L\} \).
The automaton $\text{Prefin}(A_1)$ is given by

$$
\begin{array}{c}
0 \\
\xrightarrow{b} 1 \\
\xrightarrow{a, b} 2 \\
\end{array}
$$

**Definition 2** We consider an operation $\otimes$ acting on $k$-tuples of languages defined on the same alphabet. The operation $\otimes$ is said to be depictsible (m-depictsible) if there exists a $k$-modifier $m$ such that for any $k$-tuple of DFA $A$, we have $L(mA) = \otimes(L(A_1), \ldots, L(A_k))$.

**Example 2** The operation $\text{Prefin}$ defined by $\text{Prefin}(L) = L\Sigma^*$ for any $L \subseteq \Sigma^*$ is the $\text{Prefin}$-deictsible operation where $\text{Prefin}$ is the modifier defined in Table 1.

It is often handy to describe the states of the resulting automaton by combinatorial objects instead of numbers. For the modifiers $\cup$, $\cap$ and $\oplus$, a state is an element of the cartesian product of the automata of the input. For the $\text{Conc}$ modifier, a state is a pair composed of a state of the first input and a subset of states of the second input. For the $\text{Star}$ modifier, a state is a subset of states of the input. For the $\text{SRoot}$ modifier, each state is a function from the set of states to the set of states of the input.

**Example 3 (Mirror modifier)** Let us define the 1-modifier $\text{Mirror} = (\mathfrak{M}, \delta, \iota, f)$ as:

- $\mathfrak{M}(n_1) = 2^n$, and the states are identified with subsets of $\llbracket n_1 \rrbracket$,
- $\delta(\delta_1^n, F_1)$ is defined as $E \to E'$ with $E' = \bigcup_{q \in E} \{q' \mid \delta_1^n(q') = q\}$,
- $\iota(n_1, F_1) = F_1$,
- $f(n_1, F_1) = \{E \subseteq \llbracket n_1 \rrbracket \mid 0 \in E\}$.

Let $A_1 = (\Sigma, \llbracket n_1 \rrbracket, 0, F_1, \delta_1)$. The mirror operation is depictsible, indeed, the mirror of $L(A_1)$ is $L(\text{Mirror}(A_1))$. Applying the $\text{Mirror}$ modifier on the automaton $A$ of Figure 1 leads to the automaton of Figure 2.

$$
\begin{array}{c}
0 \\
\xrightarrow{a} 1 \\
\xrightarrow{a, b} 2 \\
\end{array}
$$

where $E^x = E \cup \{x\}$ if $E \cap F \neq \emptyset$ and $E$ otherwise, and $E \cup \{y\}$ if $x \in F$ and $(x, E)$ otherwise.

**Proposition 1** Let $\otimes$ be a k-ary depictable operation and $X, X', Y$ be three alphabets such that $X \cap X' = \emptyset$. Let $\varphi$ be a bijection between $X$ and $Y$, naturally extended as an isomorphism of monoids from $X^*$ to $Y^*$. Let $\eta : 2^{(X \cup X')} \rightarrow 2^Y$ defined by $\eta(L) = \varphi(L \cap X')$. For any $L \in (2^{(X \cup X')})^k$ we have

$$\otimes (\eta(L_1), \cdots, \eta(L_k)) = \eta(\otimes L).$$

**Proof:** Let $A_1$ be a $k$-tuple of CDFA $A = (X \cup X', \{n_i\}, 0, F_1, \delta_1)$ such that $L(A_i) = L_i$. Since $\otimes$
is depictable, there exists a modifier \( m = (\emptyset, b, i, f) \) such that \( L(mA) = \emptyset L \). We have \( mA_2 = (X \cup X', \emptyset(n), i(n, F), f(n, F), \delta) \) with \( \delta^d = b(\delta^i, F) \). Then the language \( \emptyset(\emptyset A) \) is recognized by the CDFA \( A_2 = (Y, \emptyset(n), i(n, F), f(n, F), \delta, \epsilon) \) with \( \delta^d_2 = \delta^{\emptyset^{-1}}(a) = b(\delta^{\emptyset^{-1}}(a), F) \). Now, let \( A_2 \) be the \( k \)-tuple of CDFA \( A_3 = (Y, \emptyset(n), i(n, F), f(n, F), \delta, \emptyset) \) with \( \delta^a = \delta^{\emptyset^{-1}}(a) \). Clearly, \( A_3 \) recognizes \( \emptyset(L) \). Since \( \emptyset \) is depictable, \( mA_3 = (Y, \emptyset(n), i(n, F), f(n, F), \delta, \emptyset) \) with \( \delta^d_3 = b(\delta^i_3, F) = b(\delta^{\emptyset^{-1}}(a), F) = \delta^d_2 \) which ends the proof. □

Immediately as special cases of the previous proposition, we obtain:

**Corollary 1** Let \( \otimes \) be a \( k \)-ary depictable operation and \( Y \) be an alphabet. Let \( L \) be a \( k \)-tuple of regular languages over \( Y \). Then

- If \( X \subset Y \) then \( \otimes(L_1 \cap X', \cdots, L_k \cap X') = \otimes L \cap X' \).
- For any bijection \( \sigma : Y \to Y \) extended as an automorphism of monoids, we have \( \otimes(\sigma(L_1), \cdots, \sigma(L_k)) = \sigma(\emptyset L) \).

**Example 4** This result allows us to build examples of non-depictable operations.

- We consider the binary operation defined by \( \otimes(L_1, L_2) = L_1 \cup L_2 \). This operation is not depictable because it violates the first condition of Corollary 1. For instance, let \( X = \{a, b, c\}, L_1 = \{abc\}, \) and \( L_2 = \{c\} \). We have \( \otimes(L_1 \cap \{a\}^*, L_2 \cap \{a\}^*) = \emptyset \emptyset^{-1} = \emptyset \) while \( \otimes(L_1, L_2) \cap \{a\}^* = \{ab\} \).

- We consider the unary operation defined by \( \otimes(L) = L \setminus \{a\} \) if the words \( a \) and \( a^2 \) belongs to \( L \) and \( \otimes(L) = L \) otherwise. This operation satisfies the first condition of Corollary 1 but it violates the second one. Indeed, if \( X = \{a, b\} \) then \( \otimes(\{a, a^2\}) = \{a^2\} \) while \( \otimes(\{b, b^2\}) = \{b, b^2\} \). So it is not depictable.

**Remark 1** There exist \( k \)-modifiers that can not be associated to operations. For instance, consider the modifier \( \emptyset \emptyset 1 = (\emptyset, b, i, f) \) such that

- \( \emptyset = Id_N \),
- \( \emptyset(b(\delta^i_1, F)(q)) = \delta^q_1(q) \) if \( q \notin F \) and \( \emptyset(b(\delta^i_1, F)(q)) = \min\{1, n - 1\} \) otherwise,
- \( i(n, F) = F \),
- \( f(n, F) = 0 \).

If \( A_1 \) and \( A_1' \) are two deterministic automata recognizing the same language then we have in general \( L(\emptyset \emptyset 1(A_1)) \neq L(\emptyset \emptyset 1(A_1')) \) because the recognized language depends on the labels of the states of \( A_1 \) and \( A_1' \). For instance, the two following automata recognize the same language \( a^2 a^* \).

\[ \begin{array}{c}
0 & \xrightarrow{a} & 1 & \xrightarrow{a} & 2 \\
\end{array} \quad \begin{array}{c}
0 & \xrightarrow{a} & 2 & \xrightarrow{a} & 1 \\
\end{array} \]

But applying \( \emptyset \emptyset 1 \) on the first one gives
which recognizes \((aa)^+\) while \(\mathcal{Gto1}\) lets the second automaton unchanged.

**Definition 3** Let \(m_1 = (\mathcal{R}^{(1)}, \mathcal{B}^{(1)}, \mathcal{I}^{(1)}, \mathcal{F}^{(1)})\) be a \(k_1\)-ary modifier and \(m_2 = (\mathcal{R}^{(2)}, \mathcal{B}^{(2)}, \mathcal{I}^{(2)}, \mathcal{F}^{(2)})\) be a \(k_2\)-ary modifier. We define the \((k_1 + k_2 - 1)\)-ary modifier \(m_1 \circ m_2 = (\mathcal{R}, \mathcal{B}, \mathcal{I}, \mathcal{F})\) by

1. \(\mathcal{R} = \mathcal{R}^{(1)} \circ \mathcal{R}^{(2)}\) where \(\mathcal{R} = (n_1, \ldots, n_{i-1}, \mathcal{R}^{(2)}(n_i, \ldots, n_{i+k_2-1}), n_{i+k_2}, \ldots, n_{k_1+k_2-1})\)
2. \(\mathcal{B}(\mathcal{S}_1, \mathcal{F}) = \mathcal{B}^{(1)}(\mathcal{S}_1, \mathcal{F}^{(2)}(\mathcal{S}_1, \mathcal{F}(\mathcal{S}_1, \mathcal{F}(\mathcal{S}_1, \ldots, \mathcal{F}(\mathcal{S}_1, n_{i+k_2}, \ldots, n_{k_1+k_2-1}))))\)

where \(\mathcal{F} = (F_1, \ldots, F_{i-1}, F_i, \ldots, F_{i+k_2-1}, F_{i+k_2}, \ldots, F_{k_1+k_2-1})\)
3. \(\mathcal{I}(\mathcal{U}, \mathcal{F}) = \mathcal{I}^{(1)}(\mathcal{U}, \mathcal{F}^{(2)}\mathcal{U})\)
4. \(\mathcal{F}(\mathcal{U}, \mathcal{F}) = \mathcal{F}^{(1)}(\mathcal{U}, \mathcal{F}^{(2)}\mathcal{U})\).

**Claim 1** For any \(A_1, \ldots, A_{k_1+k_2-1}\) we have

\[
m_1 \circ m_2(A_1, \ldots, A_{k_1+k_2-1}) = m_1(A_1, \ldots, A_{i-1}, m_2(A_i, \ldots, A_{i+k_2-1}), A_{i+k_2}, \ldots, A_{k_1+k_2-1}).
\]

**Proposition 2** Let \(\otimes\) be a \(k_1\)-ary \(m_1\)-depictable operation and \(\oplus\) be a \(k_2\)-ary \(m_2\)-depictable operation. Then the operation defined by

\[
\otimes \circ \oplus(L_1, \ldots, L_{k_1+k_2-1}) = \otimes(\oplus(L_1, \ldots, L_{i-1}, \oplus(L_i, \ldots, L_{i+k_2-1}), L_{i+k_2}, \ldots, L_{k_1+k_2-1}))
\]

is a \((k_1 + k_2 - 1)\)-ary \((m_1 \circ m_2)\)-depictable operation for any \(i \in \{1, \ldots, k_1\}\).

**Proof:** As

\[
\begin{align*}
\otimes(\oplus(L_1, \ldots, L_{i-1}, \oplus(L_i, \ldots, L_{i+k_2-1}), L_{i+k_2}, \ldots, L_{k_1+k_2-1})) &= L(m_1(A_1, \ldots, A_{i-1}, m_2(A_i, \ldots, A_{i+k_2-1}), A_{i+k_2}, \ldots, A_{k_1+k_2-1})).
\end{align*}
\]

From the previous claim we have

\[
L(m_1 \circ m_2(A_1, \ldots, A_{k_1+k_2-1})) = \otimes \circ \oplus(L(A_1, \ldots, L(A_{k_1+k_2-1})).
\]

\[ \square \]

### 4 Monsters

One-monster automata of size \(n\) are minimal DFAs having \(n^n\) letters representing every function from \(\mathbb{N}^{(n)}\) to \(\mathbb{N}\). There are \(2^n\) different 1-monster automata depending on the set of their final states. The idea of a \(k\)-monster is to have a common alphabet for \(k\) automata.

The idea of using combinatorial objects to denote letters has already been used by Sakoda and Sipser ([9]) (letters were assimilated to graphs and words spell out paths in these graphs) to obtain results for two-way automata, or by Birget ([10]) to obtain deterministic state complexity.
4.1 Definitions

**Definition 4** A $k$-monster is a $k$-tuple of automata $M_{k, \mathcal{E}} = (M_1, \ldots, M_k)$ where each $M_j = (\Sigma, \{n_j\}, 0, F_j, \delta_j)$ is defined by

- the common alphabet $\Sigma = \{n_1\}^{n_1} \times \{n_2\}^{n_2} \times \cdots \times \{n_k\}^{n_k}$,
- the set of states $\{n_j\}$,
- the initial state $0$,
- the set of final states $F_j$,
- the transition function $\delta_j$ defined by $\delta_j(q, g) = g_j(q)$ for $g = (g_1, \ldots, g_k) \in \Sigma$, i.e., $\delta g = g$.

**Example 5** ($k$-monster for $k = 1$ and $k = 2$)

- The 1-monster $M_{2,\{1\}}$ is given by the following automaton

  ![Automaton Diagram]

  Each symbol codes a function $\{0, 1\} \rightarrow \{0, 1\}$.

- The 2-monster $M_{(2,2),\{(1,1),\{(0,0)\}}$ is given by the following pair of automata on an alphabet with $2^2 \times 2^2 = 16$ symbols:

  ![Automaton Diagram]

  Each symbol codes a pair of functions, denoted by the word of their image.

  $a_{1,1} = [01, 01]$ $a_{1,2} = [01, 11]$ $a_{1,3} = [01, 00]$ $a_{1,4} = [01, 10]$

  $a_{2,1} = [11, 01]$ $a_{2,2} = [11, 11]$ $a_{2,3} = [11, 00]$ $a_{2,4} = [11, 10]$

  $a_{3,1} = [00, 01]$ $a_{3,2} = [00, 11]$ $a_{3,3} = [00, 00]$ $a_{3,4} = [00, 10]$

  $a_{4,1} = [10, 01]$ $a_{4,2} = [10, 11]$ $a_{4,3} = [10, 00]$ $a_{4,4} = [10, 10]$. 

New tools for state complexity

For instance, \(a_{1,2} = [01, 11]\) means that the symbol \(a_{1,2}\) labels a transition from 0 to 0 and a transition from 1 to 1 in the first automaton and a transition from 0 to 1 and a transition from 1 to 1 in the second automaton.

4.2 Using monsters to compute state complexity

If an operation is depictable, it is sufficient to study the behavior of its modifiers over monsters to compute its state complexity.

**Theorem 1** Let \(m\) be a modifier and \(\otimes\) be an \(m\)-depictable operation. We have

\[
\text{sc}_{\otimes} = \max \{ \#_{\text{Min}}(mM_{\otimes} L) \mid F \subset \llbracket n_1 \rrbracket \times \ldots \times \llbracket n_k \rrbracket \}.
\]

**Proof:** Let \(A\) be a \(k\)-tuple of automata having \(n\) states and having \(F\) as set of final states recognizing a \(k\)-tuple of languages \(L\) over an alphabet \(\Sigma\). Let \(\delta_A\) be the transition function of \(mA\) and \(\delta_M\) the transition function of \(mM_{\otimes} L\). By definition of a modifier, the states of \(mA\) and of \(mM_{\otimes} L\) are the same. For any letter \(a\), and any state \(q\) of \(mA\), we have:

\[
\delta_A(a)(q) = \delta_M(a, \delta^a)(q) = \delta_M(q, \delta^a).
\]

And so, for any word \(w\) over alphabet \(\Sigma\):

\[
\delta_A(q, w) = \delta_M(q, \delta^w).
\]

Therefore, all states accessible in \(mA\) are also accessible in \(mM_{\otimes} L\) and, for any word \(w\) over the alphabet \(\Sigma\), \(\delta_A(q, w) \in f(n, L)\) if and only if \(\delta_M(q, \delta^w) \in f(n, F)\), which implies that all pairs of states separable in \(mA\) are also separable in \(mM_{\otimes} L\). Therefore,

\[
\#_{\text{Min}} mA \leq \#_{\text{Min}} mM_{\otimes} L.
\]

\[\square\]

**Example 6 (Mirror modifier of a 1-monster)** Let us now compute the automaton \(\text{Mirror}(M_{n_1, [n_1-1]})\) as in Example 3.

We show that the automaton \(\text{Mirror}(M_{n_1, [n_1-1]})\) is minimal when \(n_1 > 1\). Indeed,

- Each state is accessible. Let \(g_E\) be the symbol that sends each element of a set \(E \subset \llbracket n_1 \rrbracket\) on \(n_1 - 1\) and the others \((\llbracket n_1 \rrbracket \setminus E)\) on 0. Then, we have \(\delta^E(n_1 - 1) = g_E^{-1}(n_1 - 1) = E\) (Notice that it also works with \(E = 0\)).

- States are pairwise non-equivalent. Indeed, let \(i \in E \setminus E'\) and let \(g\) be the symbol which sends 0 on \(i\) and any other state on \(n_1 - 1\). Then \(0 \in \delta^E\) because \(0 = g^{-1}(i) \subset \delta^E(E)\). So \(\delta^E(E)\) is final while \(\delta^E(E') \subset \{n_1 - 1\}\) is not.

We can describe in an algorithm the way to compute the state complexity of an operation using monsters and modifiers.
1. Describing the transformation with the help of a modifier whose states are represented by combinatorial objects;

2. Applying the modifier to well-chosen $k$-monsters. We will have to discuss the final states;

3. Minimizing the resulting automaton and estimating its size.

5 Applications

5.1 The Star of intersection example

In this section, we illustrate our method on an operation, the star of intersection, the state complexity of which is already known \[20\]. After having checked the upper bound, we show that this bound is tight and that the modifier of the monster $(\text{Star} \circ \text{Inter})\mathcal{M}$ is a witness for this operation.

Consider the 2-modifier $\text{Star} \circ \text{Inter} = (\varpi, b, \iota, f)$. This modifier satisfies

- $\varpi(n_1, n_2) = 2^{n_1n_2}$ and the states are identified with elements of $2^{[n_1] \times [n_2]}$
- For $\vartheta(\delta', F)$ we have

\[
\vartheta(\delta', F)(E) = \begin{cases} 
(\delta'_1(0), \delta'_2(0)), & \text{if } E = \emptyset \\
(\delta'_1, \delta'_2)(E), & \text{otherwise}
\end{cases}
\]

with $F = (F_1 \times F_2)$.

- $\iota(n_1, n_2, F_1, F_2) = \{E \in 2^{[n_1] \times [n_2]} \mid E \cap F \neq \emptyset \} \cup \{\emptyset\}$,
- $\iota(n_1, n_2, F_1, F_2) = \emptyset$.
We can see elements of $2^{[n_1] \times [n_2]}$ as boolean matrices of size $n_1 \times n_2$. Such a matrix will be called a tableau. We denote by $T_{x,y}$ the value of the tableau $T$ at row $x$ and column $y$. The number of 1s in a tableau $T$ will be denoted by $\# T$.

As a consequence of Proposition 2, for any pair of rational languages $(L_1, L_2)$ over the same alphabet and any pair of complete deterministic automata $\overline{A} = (A_1, A_2)$ such that $L_1 = L(A_1)$ and $L_2 = L(A_2)$ we have $(L_1 \cap L_2)^* = L((\ast \cap \text{int}) \overline{A})$.

Now, let $n_1$ and $n_2$ be two positive integers and let $(F_1, F_2)$ be a subset of $[n_1] \times [n_2]$. An upper bound of the state complexity of the composition of star and inter operations is obtained by maximizing the number of states of $\widehat{M}_{(F_1,F_2)}$ where $M_{(F_1,F_2)}$ is the automaton deduced from $(\ast \cap \text{int}) \overline{M}_{(F_1,F_2)}$ by removing tableaux having a 1 in $(x, y) \in F_1 \times F_2$ but no 1 in $(0,0)$. Indeed, such states are not accessible in $(\ast \cap \text{int}) \overline{M}_{(F_1,F_2)}$.

We first remark that the initial state of $\text{int} M_{(0,0)}$ is the only final state. This implies that $L((\ast \cap \text{int}) \overline{M}_{(0,0)}) = L(\text{int} M_{(0,0)})^* = L(\text{int} M_{(0,0)})$, which in turn implies that $\# \text{Min}(\overline{M}_{(0,0)}) \leq \# \text{Min}(\text{int} M_{(0,0)}) \leq n_1 n_2$.

Notice also that if $\#(F_1 \times F_2) = 0$, then $\widehat{M}_{(F_1,F_2)}$ recognizes the empty language, which trivially implies that $\# \text{Min}(\overline{M}) \leq 1$.

**Lemma 1** The maximal number of states of $\widehat{M}_{(F_1,F_2)}$ with $F_1 \times F_2 \not\subseteq \{(0,0), \emptyset\}$ is when $\#(F_1 \times F_2) = 1$.

**Proof:**

$$\# \widehat{M}_{(F_1,F_2)} = \# 2^{[n_1] \times [n_2]} - \# \{T \in 2^{[n_1] \times [n_2]} \mid \exists (x,y) \in F_1 \times F_2 \text{ s.t. } T_{x,y} = 1 \wedge T_{0,0} = 0\}$$

$$= 2^{n_1 n_2} - (\# \{T \in 2^{[n_1] \times [n_2]} \mid T_{0,0} = 0\} - \# \{T \in 2^{[n_1] \times [n_2]} \mid \forall (x,y) \in F_1 \times F_2, T_{x,y} = 0 \wedge T_{0,0} = 0\})$$

$$= \begin{cases} 2^{n_1 n_2} - (2^{n_1 n_2 - 1} - 2^{n_1 n_2 - \#(F_1) \#(F_2) - 1}) & \text{if } (0,0) \not\in F_1 \times F_2 \\ 2^{n_1 n_2} - (2^{n_1 n_2 - 1} - 2^{n_1 n_2 - \#(F_1) \#(F_2)}) & \text{otherwise} \end{cases}$$

In conclusion, the maximal number of states of $\widehat{M}_{(F_1,F_2)}$ with $F_1 \times F_2 \not\subseteq \{(0,0), \emptyset\}$ is reached when $\# F_1 \times \# F_2 = 1$ and is $\frac{1}{4} 2^{n_1 n_2}$.

**Corollary 2** $\# \text{Min}(\overline{M}_{(F_1,F_2)}) \leq \frac{1}{4} 2^{n_1 n_2}$

**Proof:** From Lemma 2, we maximize the number of tableaux when $\# F_1 \times \# F_2 = 1$. So the upper bound is $2^{n_1 n_2} - (2^{n_1 n_2 - 1} - 2^{n_1 n_2 - 1 - 1}) = \frac{1}{4} 2^{n_1 n_2}$.

Now we show that this upper bound is the state complexity of the combination of the star and the intersection operations.

Let $F_1, F_2$ be $\{n_1 - 1\}, \{n_2 - 1\}$ and let $\widehat{M} = \widehat{M}_{(F_1,F_2)}$.

**Lemma 2** All states of $\widehat{M}$ are accessible.
Proof: Let $T$ be a state of $\widehat{M}$. Let us define an order $<$ on tableaux as $T < T'$ if and only if

1. $(\#(T) < \#(T'))$ or
2. $(\#(T) = \#(T')$ and $T_{n_1-1,n_2-1} = 1$ and $T'_{n_1-1,n_2-1} = 0$) or
3. $(\#(T) = \#(T')$ and $T_{n_1-1,n_2-1} = T'_{n_1-1,n_2-1}$ and $T_{0,0} = 1$ and $T'_{0,0} = 0$).

Let us prove the assertion by induction on non-empty tableaux of $\widehat{M}$ for the partial order $<$

Now let us take a tableau $\hat{W}$. We distinguish the cases below, according to some properties of $\hat{W}$:

1. $T_{0,0} = 1$ (which implies that $T$ is a state of $\widehat{M}$),
2. $\delta(f,g)(T) = (f,g)(T) = T'$ (where $(f,g)(T) = \{(f(i),g(j)) \mid (i,j) \in T\}$), and
3. $T < T'$.

- $T_{n_1-1,n_2-1} = 0$.
  - $T_{0,0} = 0$. Let $(i,j)$ be the index of a 1 in $T'$. Define $(f,g)$ as $((0,i),(0,j))$ where $(0,i)$ and $(0,j)$ denote transpositions, and $T = (f,g)(T')$.
  - $T'_{0,0} = 1$.
    * There exists $(i,j) \in \{1,2,...,n_1-1\} \times \{1,2,...,n_2-1\}$ such that $T'_{i,j} = 1$. Define $(f,g)$ as $((n_1-1,i),(n_2-1,j))$, then $T = (f,g)(T')$.
    * For all $(i,j) \in \{1,2,...,n_1-1\} \times \{1,2,...,n_2-1\}$, $T'_{i,j} = 0$ if and only if $T'_{0,n_2-1} = 1$ and $T_{n_1-1,0} = 1$.
      - In that case, define $(f,g)$ as $(Id,(n_2-1,0))$, and $T$ as $(f,g)(T')$.
    * For all $(i,j) \in \{1,2,...,n_1-1\} \times \{1,2,...,n_2-1\}$, $T'_{i,j} = 0$ if and only if $T'_{0,n_2-1} = 1$ and $T_{n_1-1,0} = 0$.
      - Define $(f,g)$ as $\{\binom{n-1}{n_2-1},Id\}$.

Then $T$ is defined as

$$\begin{cases}
T_{0,n_2-1} = 0 \\
T_{n_1-1,n_2-1} = 1 \\
T_{i,j} = T'_{i,j} \text{ if } (i,j) \notin (0,n_2-1), (n_1-1,n_2-1)
\end{cases}$$

- For all $(i,j) \in \{1,2,...,n_1-1\} \times \{1,2,...,n_2-1\}$, $T'_{i,j} = 0$ if and only if $T'_{0,n_2-1} = 0$ and $T_{n_1-1,0} = 1$.
  - This case is symmetrical to the case above.

- For all $(i,j) \in \{1,2,...,n_1-1\} \times \{1,2,...,n_2-1\}$, $T'_{i,j} = 0$ if and only if $T'_{0,n_2-1} = 0$ and $T_{n_1-1,0} = 0$.
  - Let $(i,j) \neq (0,0)$ be a 1 in $T'$. Define $(f,g) = \{\binom{n_1-1}{1},\binom{n_2-1}{1}\}$, and define $T$ as follows

$$\begin{cases}
T_{i,j} = 0 \\
T_{n_1-1,n_2-1} = 1 \\
T_{i,j'} = T'_{i,j'} \text{ if } (i,j') \notin (i,j), (n_1-1,n_2-1)
\end{cases}$$
then the two functions \( h \) of generality, suppose that

\[ \text{Lemma 4} \]

For each pair \( a \) and \( b \) such that \( a \neq b \) in \( \mathbb{N} \) and \( g_{a,b}(x) = a \) if \( x \in F \) and \( g_{a,b}(x) = b \) otherwise.

\[ \text{Lemma 4} \]

For each pair \( a, b \) in \( \mathbb{N} \) such that \( a \neq b \), the two states \( g_{a,b} \) and \( g_{b,a} \) are not separable in \( \mathcal{E}\text{Root}(M_{a,b}) \).

\[ \text{Proof:} \]

Let us prove that for any \( h \), the functions \( h \circ g_{a,b} \) and \( h \circ g_{b,a} \) are both final or both non-final. In fact we have only two values of \( h \) to investigate: \( h(a) \) and \( h(b) \). If \( h(a), h(b) \in F \) or \( h(a), h(b) \notin F \) then the two functions \( h \circ g_{a,b} \) and \( h \circ g_{b,a} \) are obviously both final or both non-final. Without loss of generality, suppose that \( h(a) \in F \) (and so \( h(b) \notin F \)). We have to examine two possibilities:
Three cases have to be considered:

- **Either** $0 \in F$, in this case $h(g_{a,b}(0)) = h(a) \in F$. Then $g_{a,b}(h(g_{a,b}(0))) = a$ and $h(g_{a,b}(h(g_{a,b}(0)))) = h(a) \in F$. But $h(g_{a,b}(0)) = h(b) \notin F$. Hence, $g_{b,a}(h(g_{b,a}(0))) = a$, so $h(g_{b,a}(h(g_{b,a}(0)))) \notin F$. This implies that the two states are final.

- **Or** $0 \notin F$, in this case $h(g_{a,b}(0)) = h(b) \notin F$. Then $g_{a,b}(h(g_{a,b}(0))) = b$ and $h(g_{a,b}(h(g_{a,b}(0)))) = h(b) \notin F$. But we also have $h(g_{b,a}(0)) = h(a) \in F$. Hence, $g_{b,a}(h(g_{b,a}(0))) = b$, so $h(g_{b,a}(h(g_{b,a}(0)))) \notin F$. This implies that the two states are not final.

We deduce that the two states are not separable.

\[ \square \]

**Corollary 3**

\[ \text{sc} \chi(n) \leq n^n - \binom{n}{2} \]

Notice that the state complexity is lower than the bound given by Maslov [18].

**Lemma 5** Let $F = \{n - 1\}$, and $P = \{(g, g') \mid g \neq g'\}$ and $\forall a, b \in \mathbb{Z}_n$, $(g, g') \neq (g_{a,b}, g_{b,a})$. For any pair of distinct states $(g, g') \in P$, $g$ and $g'$ are separable in $\mathbb{Z} \text{Root}(M_{n,F})$.

**Proof:** Three cases have to be considered:

- **Suppose that** $g(0) = g'(0)$. Then there exists $x \in \mathbb{Z}_n \setminus \{0\}$ such that $g(x) \neq g'(x)$. We set $h(g(0)) = x$. Hence, $h(g(h(g(0))) = h(g(x))$ and $h(g'(h(g'(0))) = h(g'(x))$. But, as $g(x) \neq g'(x)$, it is always possible to choose $h$ such that $h(g(x)) = n - 1$ while $h(g'(x)) \neq n - 1$. Thus $h \circ g$ is a final state while $h \circ g'$ is not.

- **Suppose that** $g(0) \neq g'(0)$ and that $\text{Card}(\text{Im}(g) \cup \text{Im}(g')) > 2$. Without loss of generality, one assumes that there exists $x \in \text{Im}(g)$ such that $x \notin \{g(0), g'(0)\}$. So the values $h(g(0)), h(g'(0))$ and $h(x)$ can be chosen independently each from the others. We set $h(g(0)) = y$ with $g(y) = x$, $h(g'(0)) = 0$, and $h(x) = n - 1$. We check that $h \circ g$ is a final state while $h \circ g'$ is not final.

- **Suppose that** $g(0) \neq g'(0)$ and that $\text{Card}(\text{Im}(g) \cup \text{Im}(g')) = 2$. The fact that $(g, g') \neq (g_{a,b}, g_{b,a})$ implies that there exists $x \neq n - 1$ such that $g(x) = g(n - 1)$ or $g'(x) = g'(n - 1)$. Let us denote by $m$ the minimal element of $\mathbb{Z}_n$ having this property and without loss of generality assume than $g(m) = g(n - 1)$. We have two cases to consider. If $m = 0$ then we set $h(g(0)) = n - 1$ and $h(g'(0)) = 0$. Obviously, $h(g'(h(g'(0)))) = 0$. On the other hand, $h(g(h(g(0)))) = h(g(n - 1)) = h(g(0)) = n - 1$. Hence, $h \circ g$ is final while $h \circ g'$ is not final. If $m > 0$ then we have $g(m) = g'(0)$ (because there are exactly two values in the image of $g$ and $g'$). Furthermore, $g'(n - 1) \neq g'(0)$ and so $g'(n - 1) = g(0)$. We set $h(g(0)) = m$ and $h(g'(0)) = n - 1$. We have $h(g(h(g(0)))) = h(g(m)) = h(g'(0)) = n - 1$. In the other hand, $h(g'(h(g'(0)))) = h(g'(n - 1)) = h(g(0)) = m \neq n - 1$. It follows that $h \circ g$ is final while $h \circ g'$ is not final.

\[ \square \]
Theorem 3 \( \text{sc} \sqrt{n} = n^{a} - \binom{n}{2} \).

Furthermore we have

Proposition 3 For any rational language \( L \) over an alphabet with at most two letters, if \( \text{sc}(L) = n > 2 \) then \( \text{sc}(\sqrt{L}) < \text{sc} \sqrt{n} \).

Lemma 6 Any submonoid of \( \mathbb{N}^{n} \) generated by two distinct elements is a proper submonoid of \( \mathbb{N}^{n} \).

Proof: Suppose that \( \mathbb{N}^{n} \) is generated by two elements \( f \) and \( g \). Recall first that we need at least two permutations for generating the symmetric group \( \mathfrak{S}_{n} \). We notice also that \( \mathbb{N}^{n} \) is an ideal of \( \mathbb{N}^{n} \), that is if \( t \in \mathbb{N}^{n} \setminus \mathfrak{S}_{n} \) and \( t' \in \mathbb{N}^{n} \) then \( t \circ t', t' \circ t \in \mathbb{N}^{n} \setminus \mathfrak{S}_{n} \). This shows that \( f, g \in \mathfrak{S}_{n} \). But since \( \mathfrak{S}_{n} \) is a submonoid, it is stable by composition. It follows that \( \mathfrak{S}_{n} = \mathbb{N}^{n} \). Since this is absurd we deduce the result. \( \square \)

Lemma 7 The monoid \( \mathbb{N}^{n} \) is generated by the two permutations \((0, 1)\) and \((0, 1, \ldots, n - 1)\) together with any of the contractions \((i)\).

Proof: It is known that \( \mathbb{N}^{n} \) is generated by \((0, 1), (0, 1, \ldots, n - 1)\) and \((i)\). The result is just a consequence of the equality \((i) \circ (1, j) \circ (0, i) = (i)\). \( \square \)

Proof of Proposition 3 Let \( L \) be a language with \( \text{sc}(L) = n > 2 \) and \( A = ([a, b], \mathbb{N}, \{0\}, E, \cdot) \) be a minimal CDFA recognizing \( L \). Since \( \text{sc}(L) = n > 2 \), the set of final states \( F \) is a proper subset of \( \mathbb{N} \). Suppose that \( \#_{\text{Min}}(\mathfrak{E}\text{Root}(A)) = \text{sc} \sqrt{n} \). Since \( \#_{a,F} \) is a morphism the set of the states of \( \mathfrak{E}\text{Root}(A) \) is a submonoid \( M \) of \( \mathbb{N}^{n} \) generated by two elements. Let us suppose that \( f \) and \( g \) are these two elements associated to the letters \( a \) and \( b \). As \( \#_{\text{Min}}(\mathfrak{E}\text{Root}(A)) = \text{sc} \sqrt{n} \) we have \( t \notin \{g_{p,q} | p, q \in \mathbb{N}, p \neq q\} \) implies \( t \in M \). Obviously, we have \( (0, 1), (0, 1, \ldots, n - 1) \notin \{g_{p,q} | p, q \in \mathbb{N}, p \neq q\} \) and so \((0, 1), (0, 1, \ldots, n - 1) \notin M \). Furthermore, we have:

Lemma 8 There exists \( i, j \in \mathbb{N} \) such that \( i \neq j \) and \((i) \notin \{g_{p,q} | p, q \in \mathbb{N}, p \neq q\} \).

Proof: Since \( n > 2 \), either \#\( F \) > 1 or \( n - \#\( F \) > 1 \). We denote \( E = F \) if \#\( F \) > 1 and \( E = \mathbb{N} \setminus F \) otherwise. Also we set \( E' = \mathbb{N} \setminus E \). Let \( i \in E \) and \( j \in E' \), we check that \((i) \notin \{g_{p,q} | p, q \in \mathbb{N}, p \neq q\} \). \( \square \)

From the previous lemma there exists \( i, j \in \mathbb{N} \) such that \( i \neq j \) and \((i) \in M \). So by lemma 3, \( M = \mathbb{N}^{n} \). But, by Lemma 6, \( M \) is a proper submonoid of \( \mathbb{N}^{n} \) which contradicts the hypothesis. So there exists a transformation \( t \notin \{g_{p,q} | p, q \in \mathbb{N}, p \neq q\} \) such that \( t \notin M \) and thus \( \#_{\text{Min}}(\mathfrak{E}\text{Root}(A)) < \text{sc} \sqrt{n} \). \( \square \)

Let us notice that Krawetz et al. \([17]\) found a very similar result not quite for square root, but for the closely related operation \( \text{Root}(L) = \{w | \exists n \text{ such that } w^{n} \in L\} \).
6  Conclusion

New tools for computing state complexity are provided. As there is a witness among monster automata, one can focus on them to obtain a tight bound for state complexity. One of our future works is to use these tools on operations where the bound is not tight or not known as cyclic shift or star of xor. As these tools produce very large size alphabet, it remains to study how it is possible to improve this size by obtaining in some cases a constant size alphabet.

The authors learned that Sylvie Davies has independently and in the same time obtained some of the results presented in this paper. Her work can be found in [7].
