Abstract

A classical result obtained by Stein and Weiss in 1958 is extended to product spaces, by studying the strong fractional integral operator whose kernel has singularity appeared at every coordinate subspaces.

1 Introduction

Let \(0 < \alpha < N\). A fractional integral operator \(I_\alpha\) is defined by

\[
(I_\alpha f)(x) = \int_{\mathbb{R}^N} f(y) \left( \frac{1}{|x - y|} \right)^{N-\alpha} dy. \tag{1.1}
\]

Study of its regularity dates back to the early 1900’s. A result, first established in the one dimensional space by Hardy and Littlewood [1], has been extended to higher dimensions by Stein and Weiss [3].

**Theorem A: Stein and Weiss, 1958**

Let \(\omega(x) = |x|^{-\gamma}, \sigma(x) = |x|^\delta\) for \(\gamma, \delta \in \mathbb{R}\). We have

\[
\left\{ \int_{\mathbb{R}^N} (\omega I_\alpha f)^q(x) dx \right\}^{\frac{1}{q}} \leq \left\{ \int_{\mathbb{R}^N} (f\sigma)^p(x) dx \right\}^{\frac{1}{p}} \tag{1.2}
\]

for \(f \geq 0\) and \(1 < p \leq q < \infty\), if

\[
\gamma < \frac{N}{q}, \quad \delta > N\left(\frac{p-1}{p}\right), \quad \gamma + \delta \geq 0 \tag{1.3}
\]

and

\[
\frac{\alpha}{N} = \frac{1}{p} - \frac{1}{q} + \frac{\gamma + \delta}{N}. \tag{1.4}
\]

The implied constant depends only on \(p, q, \gamma, \delta, \alpha, N\).

In the special case of \(\gamma = \delta = 0\), the theorem above originally introduced in \(\mathbb{R}\) by Hardy and Littlewood [1], was proved to be true in \(\mathbb{R}^N\) by Sobolev [2]. This is known today as Hardy-Littlewood-Sobolev inequality.
Regularity of fractional integrals in weighted norms has been extensively studied over the past decades, for example, by Muckenhoupt and Wheeden [5], Coifman and Fefferman [14], Fefferman and Muckenhoupt [13], Pérez [15], Sawyer [10]-[11] and Sawyer and Wheeden [6]. It is well known that the norm inequality in (1.2) implies

\[
|Q|^{\frac{\alpha}{N} - \frac{1}{p}} \left\{ \frac{1}{|Q|} \int_Q \omega^\theta(x) dx \right\}^\frac{1}{\theta} \left\{ \frac{1}{|Q|} \int_Q \left( \frac{1}{\sigma} \right)^{\frac{1}{p'-1}} (x) dx \right\}^{\frac{p-1}{p}} < \infty \quad (1.5)
\]

for every cube \( Q \subset \mathbb{R}^N \).

The condition in (1.5), testing over all cubes in \( \mathbb{R}^N \), is called Muckenhoupt characteristic, as first investigated by Muckenhoupt for which \( \omega^\theta \) and \( \sigma^{-\frac{1}{p'-1}} \) in general are nonnegative and locally integrable functions. By taking into account that \( \omega(x) = |x|^{-\gamma}, \sigma(x) = |x|^\delta \) for \( \gamma, \delta \in \mathbb{R} \), we shall find (1.5) implying the constraints given in (1.3)-(1.4). Recall from Theorem A. Observe that (1.2), (1.3)-(1.4) and (1.5) are equivalent.

In this paper, we give an extension of Theorem A to every \( n \)-parameters product space \( \mathbb{R}^N = \mathbb{R}^{N_1} \times \mathbb{R}^{N_2} \times \cdots \times \mathbb{R}^{N_n} \), by studying the strong fractional integral operator.

Let

\[
0 < \alpha_i < N_i, \quad i = 1, 2, \ldots, n \quad \text{and} \quad \alpha = \alpha_1 + \alpha_2 + \cdots + \alpha_n. \quad (1.6)
\]

A strong fractional integral operator, denoted by \( I_\alpha \), is defined by

\[
(I_\alpha f)(x) = \int_{\mathbb{R}^N} f(y) \prod_{i=1}^n \left( \frac{1}{|x_i - y_i|} \right)^{N_i - \alpha_i} dy \quad (1.7)
\]

whose kernel has singularity on every coordinate subspaces.

The regularity theory of such product operators, commuting with a multi-parameters family of dilations, has seen little in progress since the 1980’s after a number of pioneering works accomplished by Robert Fefferman and Stein [16]-[18]. The area remains largely open for fractional integrals. Study on the subject arises again in recent years, not only for possible applications to certain nonelliptic differential operators, but also its own right of interest in harmonic analysis. For more general results regarding fractional integrals on product spaces, please see the work by Tanaka and Yabuta [9] and also by Sawyer and Wang [8].

Our main result obtained on the \( n \)-parameters product space is first conjectured by the author himself. It is later proved in the collaboration of Sawyer and Wang [7] for \( n = 2 \). Unfortunately, the delicate method used in [7] relies on the solvability of a linear system, and cannot be generalized when \( n > 2 \).

In order to prove the conjecture, we invent a new framework, where the product space is decomposed into an infinitely many dyadic cones. The consisting partial sum operator defined on each cone, is essentially an one-parameter fractional integral operator, satisfying the desired regularity. Moreover, when \( \omega, \sigma \) are suitable power functions, the operator norm decays exponentially as the eccentricity getting large. We believe that this new framework has potential to obtain further results in certain direction.

Since we are dealing with convolution operators with positive kernels, it is suffice to consider \( f \geq 0 \) throughout the rest of the paper.
2 Statement of Main Result

**Theorem A**: Let \( \omega(x) = |x|^{-\gamma}, \sigma(x) = |x|^\delta \) and \( \gamma, \delta \in \mathbb{R} \). For \( 1 < p \leq q < \infty \), the following conditions are equivalent:

1. Let \( Q_i \subset \mathbb{R}^N, i = 1, 2, \ldots, n \) to be cubes and \( Q = Q_1 \times Q_2 \times \cdots \times Q_n \). \( \omega, \sigma \) satisfy the \( n \)-parameters Muckenhoupt characteristic:

\[
\prod_{i=1}^n |Q_i|^{\frac{q_i}{N_i} - \frac{1}{q}} \left( \frac{1}{|Q|} \int_Q \omega^{q_i}(x) \, dx \right)^{\frac{1}{q}} \left( \frac{1}{|Q|} \int_Q \left( \frac{1}{\sigma^p}(x) \, dx \right)^{\frac{p}{p-1}} \right)^{\frac{p-1}{p}} < \infty \tag{2.1}
\]
for every rectangle \( Q \subset \mathbb{R}^N \).

2. \( \gamma, \delta \) satisfy the following constraints:

\[
\gamma < \frac{N}{q}, \quad \delta < N \left( \frac{p-1}{p} \right), \quad \gamma + \delta \geq 0 \tag{2.2}
\]

and

\[
\frac{\alpha}{N} = \frac{1}{p} - \frac{1}{q} + \frac{\gamma + \delta}{N}. \tag{2.3}
\]

For \( \gamma \geq 0, \delta \leq 0 \),

\[
\alpha_i - \frac{N_i}{p} < \delta, \quad i = 1, 2, \ldots, n. \tag{2.4}
\]

For \( \gamma \leq 0, \delta \geq 0 \),

\[
\alpha_i - \frac{N_i}{q} \left( \frac{q-1}{q} \right) < \gamma, \quad i = 1, 2, \ldots, n. \tag{2.5}
\]

For \( \gamma > 0, \delta > 0 \),

\[
\sum_{i \in U} \alpha_i - \frac{N_i}{p} < \delta, \quad U = \left\{ i \in \{1, 2, \ldots, n\} : \alpha_i - \frac{N_i}{p} \geq 0 \right\}, \tag{2.6}
\]

\[
\sum_{i \in V} \alpha_i - \frac{q-1}{q} N_i < \gamma, \quad V = \left\{ i \in \{1, 2, \ldots, n\} : \alpha_i - \frac{(q-1)}{q} N_i \geq 0 \right\}. \tag{2.6}
\]

3. Let \( I_\alpha \) to be defined in (1.6)-(1.7). We have

\[
\left\{ \int_{\mathbb{R}^N} (\omega I_\alpha f)^q(x) \, dx \right\}^{\frac{1}{q}} \leq \left\{ \int_{\mathbb{R}^N} (f \sigma^p(x))^p \, dx \right\}^{\frac{1}{p}} \tag{2.7}
\]

where the implied constant depends only on \( p, q, \gamma, \delta, \alpha, n, N \).

**Sketch of Proof**: We develop the new framework in Section 3 of which the consisting partial sum operators defined on dyadic cones satisfy the desired regularity. The norm inequality in (2.7) can be obtained if the summation of their norms is finite.

In Section 4, we prove that the Muckenhoupt characteristic in (2.1) implies the constraints given in (2.2)-(2.6).
In Section 5, by using these constraints, we prove that in the case of strict subbalanced indices: 
\( \alpha_i > N_i (1/p - 1/q) \) for every \( i = 1, 2, \ldots, n \), the \( r \)-bump Muckenhoupt characteristic

\[
\prod_{i=1}^{n} |Q_i|^{- \frac{\alpha_i}{N_i} - \left( \frac{1}{p} - \frac{1}{q} \right)} \left\{ \frac{1}{|Q|} \int_{Q} \omega^{q r} (x) \, dx \right\}^{\frac{1}{q r}} \left\{ \frac{1}{|Q|} \int_{Q} \left( \frac{1}{\sigma} \right)^{\frac{q r}{p}} (x) \, dx \right\}^{\frac{p-1}{q r}} , \quad r \geq 1 \quad (2.8)
\]
decays exponentially, as \( Q \) varying on the eccentricities. The assertion of \( r > 1 \) in \((2.8)\) is analogue to Fefferman-Phong’s condition \([12]\), initially introduced for \( 1 < p = q < \infty \).

In Section 6, we handle the case of fully balanced indices: 
\( \alpha_i = N_i (1/p - 1/q) \) for every \( i = 1, 2, \ldots, n \) which happens when \( \gamma + \delta = 0 \).

We prove the theorem in Section 7, by decomposing \( I_{\alpha} \) where the resulting estimates can be reduced to either of the two cases.

## 3 Cone Decomposition and Eccentricity Summability

Let \( \nu \in \{1, 2, \ldots, n\} \). We omit on some notations, by writing \( t = t(\nu) \) that denotes the \( n \)-tuple \((2^{-t_1}, 2^{-t_2}, \ldots, 2^{-t_n})\) for which \( t_\nu \neq i \in \{1, 2, \ldots, n\} \) are nonnegative integers and \( t_\nu = 0 \). Define

\[
(\Delta_{t(\alpha)} f)(x) = \int_{\Gamma_t(x)} f(y) \prod_{i=1}^{n} \left( \frac{1}{|x_i - y_i|} \right)^{N_i - \alpha_i} dy \quad (3.1)
\]

where

\[
\Gamma_t(x) = \bigotimes_{i \neq \nu} \left\{ y_i \in \mathbb{R}^N : 2^{-t_{i-1}} \leq \frac{|x_i - y_i|}{|x_\nu - y_\nu|} \leq 2^{-t_i} \right\} . \quad (3.2)
\]

Observe that \( \Gamma_t(x) \) is a dyadic cone centered on \( x \in \mathbb{R}^N \) with its eccentricity depending on \( t \). In particular, we write

\[
\Gamma_0(x) = \Gamma_t(x) \quad \text{for} \quad t_1 = t_2 = \cdots = t_n = 0 . \quad (3.3)
\]

Notice that by using Minkowski inequality, it is suffice to estimate \( \sum_{t} \Delta_{t(\alpha)} f \) of which the summation is taking over all \( t = t(\nu) \) for any fixed \( \nu \in \{1, 2, \ldots, n\} \).

Let \( Q^t \) be a dilated variant of \( Q \) such that \( |Q^t|^{\frac{1}{p}} = 2^{-t_i} |Q|^{\frac{1}{p}} \) for every \( i = 1, 2, \ldots, n \). Denote the \( n \)-parameters dilation

\[
\tau x = \left( 2^{-t_1} x_1, 2^{-t_2} x_2, \ldots, 2^{-t_n} x_n \right) . \quad (3.4)
\]

We have

\[
\prod_{i=1}^{n} |Q_i|^\nu_i \left( \frac{1}{p} - \frac{1}{q} \right) \left\{ \frac{1}{|Q|} \int_{Q} \omega^{q r} (\tau x) \, d\tau x \right\}^{\frac{1}{q r}} \left\{ \frac{1}{|Q|} \int_{Q} \left( \frac{1}{\sigma} \right)^{\frac{q r}{p}} (\tau x) \, d\tau x \right\}^{\frac{p-1}{q r}} , \quad r \geq 1
\]

\[
= \prod_{i=1}^{n} 2^{\nu_i \frac{N_i}{p} + \nu_i \frac{N_i}{q}} \prod_{i=1}^{n} |Q_i|^\nu_i \left( \frac{1}{p} - \frac{1}{q} \right) \left\{ \frac{1}{|Q|} \int_{Q} \omega^{q r} (x) \, dx \right\}^{\frac{1}{q r}} \left\{ \frac{1}{|Q|} \int_{Q} \left( \frac{1}{\sigma} \right)^{\frac{q r}{p}} (x) \, dx \right\}^{\frac{p-1}{q r}}
\]

for every \( Q \subset \mathbb{R}^N \).
Let \( t \) to be fixed. Consider \( Q \subset \mathbb{R}^N \) such that
\[
|Q|^{\frac{1}{N}}/|Q_i|^{\frac{1}{N}} = 2^{-i}, \quad i = 1, 2, \ldots, n.
\] (3. 6)
We define
\[
A_{pqr}^\alpha (t : \omega, \sigma) = \sup \prod_{i=1}^n |Q_i|^{\frac{\alpha}{N}} \left\{ \frac{1}{|Q|} \int_Q \omega^q r (x) \, dx \right\}^{\frac{1}{p}} \left\{ \frac{1}{|Q_i|} \int_{Q_i} \left( \frac{1}{\sigma} \right)^{\frac{r}{p-1}} (x) \, dx \right\}^{\frac{p-1}{p}}
\] (3. 7)
where the supremum is taking over all \( Q \subset \mathbb{R}^N \) satisfying (3. 6).
On the other hand, suppose that \( Q \) is actually a cube in \( \mathbb{R}^N \), whereas
\[
|Q|^{\frac{1}{N}} = |Q_1|^{\frac{1}{N}} = \cdots = |Q_n|^{\frac{1}{N}}.
\] (3. 8)
From (3. 5)-(3. 8), we have
\[
|Q|^{\frac{\alpha}{N} - (\frac{1}{p} - \frac{1}{q})} \left\{ \frac{1}{|Q|} \int_Q \omega^q r (x) \, dx \right\}^{\frac{1}{p}} \left\{ \frac{1}{|Q_i|} \int_{Q_i} \left( \frac{1}{\sigma} \right)^{\frac{r}{p-1}} (x) \, dx \right\}^{\frac{p-1}{p}} = \prod_{i=1}^n |Q_i|^{\frac{\alpha}{N}} \left( \frac{1}{|Q|} \int_Q \omega^q r (tx) \, dx \right)^{\frac{1}{p}} \left( \frac{1}{|Q_i|} \int_{Q_i} \left( \frac{1}{\sigma} \right)^{\frac{r}{p-1}} (tx) \, dx \right)^{\frac{p-1}{p}} \leq \prod_{i=1}^n 2^{2 \left( \frac{\alpha}{N} - \frac{N}{p} + \frac{N}{q} \right)} A_{pqr}^\alpha (t : \omega, \sigma).
\] (3. 9)
We now recall the weighted norm inequality for one-parameter fractional integrals proved by Sawyer and Wheeden [6]. More precisely, Theorem 1 in [6] implies
\[
\left\{ \int_{\mathbb{R}^N} \left( \int_{\mathbb{R}^N} f(y) \left( \frac{1}{|x - y|} \right)^{N-\alpha} \, dy \right)^q \omega^q(x) \, dx \right\}^{\frac{1}{q}} \leq \left\{ \int_{\mathbb{R}^N} \left( f \omega^q \right)(x) \, dx \right\}^{\frac{1}{q}}
\] (3. 10)
for \( 1 < p \leq q < \infty \), if there is some \( r > 1 \) such that
\[
\sup_{|Q|^{\frac{1}{N}} = \cdots = |Q_n|^{\frac{1}{N}}} \left\{ \frac{1}{|Q|} \int_Q \omega^q r (x) \, dx \right\}^{\frac{1}{p}} \left\{ \frac{1}{|Q_i|} \int_{Q_i} \left( \frac{1}{\sigma} \right)^{\frac{r}{p-1}} (x) \, dx \right\}^{\frac{p-1}{p}} < \infty.
\] (3. 11)
Moreover, by carrying out the proof of the applied theorem above given in Section 2 of [6], we find that the implied constant in (3. 10) equals the supremum in (3. 11) multiplied by a constant depending only on \( p, q, r, \alpha, N \).

Let \( 1 < p \leq q < \infty \) and \( r > 1 \). The one-parameter Muckenhoupt characteristic in (3. 8)-(3. 9), testing over all cubes in \( \mathbb{R}^N \), therefore implies
\[
\left\{ \int_{\mathbb{R}^N} \left( \int_{\mathbb{R}^N} f(y) \left( \frac{1}{|x - y|} \right)^{N-\alpha} \, dy \right)^q \omega^q(tx) \, dx \right\}^{\frac{1}{q}} \leq \prod_{i=1}^n 2^{2 \left( \frac{\alpha}{N} - \frac{N}{p} + \frac{N}{q} \right)} A_{pqr}^\alpha (t : \omega, \sigma) \left\{ \int_{\mathbb{R}^N} \left( f \omega^q \right)(tx) \, dx \right\}^{\frac{1}{q}}.
\] (3. 12)
By changing dilations $x \mapsto tx$, $y \mapsto ty$, direct computation shows

\[
\left\{ \int_{\mathbb{R}^N} \left( \Delta t^{\alpha} f \right)^q(x) dx \right\}^{\frac{1}{q}} = \left\{ \int_{\mathbb{R}^N} \left( \int_{\Gamma_t(x)} f(y) \prod_{i=1}^n \left( \frac{1}{|x_i - y_i|} \right)^{N-\alpha_i} dy \right)^q dx \right\}^{\frac{1}{q}} \leq \prod_{i=1}^n \int_{\mathbb{R}^N} f(ty) \left( \frac{1}{|x - y|} \right)^{N-\alpha} dy \right\}^{\frac{1}{q}} \omega^q(tx) \prod_{i=1}^n 2^{-t N_i} dx \right)^{\frac{1}{q}}.
\]

(3.13)

\[
= \mathbf{A}_{ppr}^{\alpha} (t : \omega, \sigma) \prod_{i=1}^n 2^{-t \left( \alpha_i + \frac{N_i}{r} \right)} 2^{t \left( \alpha_i - \frac{N_i}{r} + \frac{N_i}{q} \right)} \left\{ \int_{\mathbb{R}^N} \left( f \sigma \right)^p(x) dx \right\}^{\frac{1}{p}}.
\]

The implied constants in (3.12)-(3.13) depend only on $p, q, r, \alpha, N$.

Observe that $\Delta t^{\alpha} f$ is essentially an one-parameter fractional integral operator, satisfying the desired regularity in weighted norms. By applying Minkowski inequality, we have $\left\| (\sum_t \Delta t^{\alpha} f) \right\|_{L^q(\mathbb{R}^N)} \leq \left\| f \sigma \right\|_{L^p(\mathbb{R}^N)}$ for $1 < p \leq q < \infty$ provided that

\[
\sum_t \mathbf{A}_{ppr}^{\alpha} (t : \omega, \sigma) < \infty.
\]

(3.14)

**Remark 3.1** Our estimates developed in this section are valid for $\omega, \sigma$ in general, which are not necessarily to be power functions.

### 4 Characteristic Estimates for Power Functions

For the sake of self-contained, we first show that the Muckenhoupt characteristic in (2.1) is an necessity for the norm inequality to hold in (2.7). The regarding estimates shall be familiar in the area of fractional integrals in weighted norms.

Let $\chi_Q$ to be the characteristic function of any $Q \subset \mathbb{R}^N$. Consider $f(x) \equiv \chi_Q(x) \left( \frac{1}{\sigma(x)} \right)^{\frac{2}{p-1}}$. 
Observe that

\[
\int_{\mathbb{R}^N} f(y) \prod_{i=1}^n \left( \frac{1}{|x_i - y_i|} \right)^{\alpha_i y_i} \ dy \geq \prod_{i=1}^n |Q_i|^{\alpha_i - \alpha_i y_i} \left\{ \int_Q \left( \frac{1}{|x|} \right)^{\frac{n}{p-1}} (y) dy \right\} \chi_Q(x). \tag{4.1}
\]

The norm inequality in (2.7) together with (4.1) imply

\[
\prod_{i=1}^n |Q_i|^{\alpha_i - \alpha_i y_i} \left\{ \int_Q \left( \frac{1}{|x|} \right)^{\frac{n}{p-1}} (x) dx \right\} \frac{p-1}{p} < \infty \tag{4.2}
\]

for every \( Q \subset \mathbb{R}^N \).

Let \( Q_i \) shrink to a Lebesgue point in \( \mathbb{R}^N \) and \( |Q_i|^{\frac{1}{N_i}} = 1 \) for all \( i \neq j \in \{1, 2, \ldots, n\} \) in (4.2). By applying Lebesgue Differentiation Theorem, the product of two brackets is bounded from below, except that \( \omega \) and \( \sigma \) have disjoint supports.

By taking into account that \( \omega(x) = |x|^{-\gamma}, \sigma(x) = |x|^{-\delta} \) for \( \gamma, \delta \in \mathbb{R} \), the inequality holds for every \( Q \subset \mathbb{R}^N \) in (4.2) implies

\[
\frac{\alpha_i}{N_i} \geq \frac{1}{p} - \frac{1}{q}, \quad i = 1, 2, \ldots, n. \tag{4.3}
\]

Our main objective is to show that

\[
\prod_{i=1}^n |Q_i|^{\frac{\alpha_i}{N_i} - \frac{1}{p} + \frac{1}{q}} \left\{ \frac{1}{|Q_i|} \int_Q \left( \frac{1}{|x|} \right)^{\gamma q} dx \right\} \frac{1}{p} \left\{ \frac{1}{|Q_i|} \int_Q \left( \frac{1}{|x|} \right)^{\delta(p/q)} dx \right\} \frac{p-1}{p} < \infty \tag{4.4}
\]

for every \( Q \subset \mathbb{R}^N \), implies the constraints given in (2.2)-(2.6). For this purpose, it is sufficient to assume \( Q \) centered on the origin.

Let \( Q^\lambda \) to be a dilated variant of \( Q \) such that \( |Q^\lambda_i|^{\frac{1}{N_i}} = \lambda |Q_i|^{\frac{1}{N_i}}, \ i = 1, 2, \ldots, n \) for \( \lambda > 0 \). We have

\[
\prod_{i=1}^n |Q^\lambda_i|^{\frac{\alpha_i}{N_i} - \frac{1}{p} + \frac{1}{q}} \left\{ \frac{1}{|Q^\lambda_i|} \int_Q \left( \frac{1}{|x|} \right)^{\gamma q} dx \right\} \frac{1}{p} \left\{ \frac{1}{|Q^\lambda_i|} \int_Q \left( \frac{1}{|x|} \right)^{\delta(p/q)} dx \right\} \frac{p-1}{p} < \infty \tag{4.5}
\]

Consider \( |Q_i|^{\frac{1}{N_i}} = |Q_2|^{\frac{1}{N_2}} = \cdots = |Q_n|^{\frac{1}{N_n}} = 1 \). The first line of (4.5) is bounded from below. Suppose \( \gamma + \delta - \alpha + N \left( \frac{1}{p} - \frac{1}{q} \right) \neq 0 \). By either letting \( \lambda \to 0 \) or \( \lambda \to \infty \), the last line of (4.5) is vanished because of (4.4). This shows that (2.3) is necessary. On the other hand, it is essential to have \( \gamma q < N \) and \( \delta(p/q) < N \) since \( \omega^q \) and \( \sigma^\frac{p}{p-1} \) must be locally integrable in \( \mathbb{R}^N \). By putting together (4.3) with (2.3), it follows that \( \gamma + \delta \geq 0 \). Therefore (2.2) is required.
Let $S$ to be a proper subset of $\{1, 2, \ldots, n\}$. Define

\[ Q_i(t_i) = \begin{cases} \mathcal{Q}_i \cap [2^{-t_i-1} \leq |x_i| < 2^{-t_i}] & \text{if } t_i > 0, \\ \mathcal{Q}_i \cap [|x_i| \geq 1] & \text{if } t_i = 0 \end{cases} \]  

(4.6)

for every $i \in S$. We write $\mathcal{Q}(t) = \bigotimes_{i \in S} \mathcal{Q}_i(t_i) \times \bigotimes_{i \in S^c} \mathcal{Q}_i$. For $\lambda > 0$, we set $|\mathcal{Q}_i|^{\frac{1}{\lambda}} = 1$ for $i \in S$ and $|\mathcal{Q}_i|^{\frac{1}{\lambda}} = \lambda$ for $i \in S^c$. Moreover, $\mathcal{Q}_S = \bigotimes_{i \in S} \mathcal{Q}_i \subset \bigotimes_{i \in S} \mathbb{R}^{N_i} \cong \mathbb{R}^{N_S}$ and $x_S$ denotes the variable in the subspace $\mathbb{R}^{N_S}$.

Suppose that there exists at least one $i \in S^c$ such that $\alpha_i - N_i\left(\frac{1}{p} - \frac{1}{q}\right) > 0$. We have

\[
\lim_{\lambda \to 0} \prod_{i=1}^n |\mathcal{Q}_i|^{\frac{\gamma}{\lambda} - \left(\frac{1}{p} - \frac{1}{q}\right)} \left\{ \frac{1}{|\mathcal{Q}|} \int_{\mathcal{Q}} \left(\frac{1}{|x|}\right)^\gamma dx \right\} \left\{ \frac{1}{|\mathcal{Q}|} \int_{\mathcal{Q}} \left(\frac{1}{|x|}\right)^\delta \left(\frac{p}{\lambda - 1}\right) dx \right\} \frac{p-1}{p} 
\]

\[
= \lim_{\lambda \to 0} \left(\lambda\right)^{\sum_{i \in S} \alpha_i - N_i\left(\frac{1}{p} - \frac{1}{q}\right)} \left\{ \sum_{i} \frac{1}{|\mathcal{Q}|} \int_{\mathcal{Q}_i} \left(\frac{1}{|x|}\right)^\gamma dx \right\} \left\{ \sum_{i} \frac{1}{|\mathcal{Q}|} \int_{\mathcal{Q}_i} \left(\frac{1}{|x|}\right)^\delta \left(\frac{p}{\lambda - 1}\right) dx \right\} \frac{p-1}{p} 
\]

\[
= \left\{ \sum_{i} \left(\lambda\right)^{\frac{1}{2} \sum_{i \in S} \alpha_i - N_i\left(\frac{1}{p} - \frac{1}{q}\right)} \frac{1}{|\mathcal{Q}|} \int_{\mathcal{Q}_i} \left(\frac{1}{|x|}\right)^\gamma dx \right\} \left\{ \sum_{i} \left(\lambda\right)^{\frac{1}{2} \sum_{i \in S} \alpha_i - N_i\left(\frac{1}{p} - \frac{1}{q}\right)} \frac{1}{|\mathcal{Q}|} \int_{\mathcal{Q}_i} \left(\frac{1}{|x|}\right)^\delta \left(\frac{p}{\lambda - 1}\right) dx \right\} \frac{p-1}{p} 
\]

\[
\times \left\{ \sum_{i} \left(\lambda\right)^{\frac{1}{2} \sum_{i \in S} \alpha_i - N_i\left(\frac{1}{p} - \frac{1}{q}\right)} \frac{1}{|\mathcal{Q}|} \int_{\mathcal{Q}_i} \left(\frac{1}{|x|}\right)^\gamma dx \right\} \left\{ \sum_{i} \left(\lambda\right)^{\frac{1}{2} \sum_{i \in S} \alpha_i - N_i\left(\frac{1}{p} - \frac{1}{q}\right)} \frac{1}{|\mathcal{Q}|} \int_{\mathcal{Q}_i} \left(\frac{1}{|x|}\right)^\delta \left(\frac{p}{\lambda - 1}\right) dx \right\} \frac{p-1}{p} 
\]

\[
= \left\{ \sum_{i} \frac{0 \times \int_{\bigotimes_{i \in S} \mathcal{Q}_i(t_i)} \left(\frac{1}{|x_S|}\right)^\gamma dx_S \right\} \left\{ \sum_{i} \frac{0 \times \int_{\bigotimes_{i \in S} \mathcal{Q}_i(t_i)} \left(\frac{1}{|x_S|}\right)^\delta \left(\frac{p}{\lambda - 1}\right) dx_S \right\} \frac{p-1}{p} 
\]

by Lebesgue Differentiation Theorem

\[
= \left\{ \sum_{i} \frac{0 \times \int_{\bigotimes_{i \in S} Q_i(t_i)} \left(\frac{1}{|x_S|}\right)^\gamma dx_S \right\} \left\{ \sum_{i} \frac{0 \times \int_{\bigotimes_{i \in S} Q_i(t_i)} \left(\frac{1}{|x_S|}\right)^\delta \left(\frac{p}{\lambda - 1}\right) dx_S \right\} \frac{p-1}{p} 
\]

On the other hand, suppose $\alpha_i - N_i\left(\frac{1}{p} - \frac{1}{q}\right) = 0$ for every $i \in S^c$. By carrying out the same estimate in (4.7), we have

\[
\lim_{\lambda \to 0} \prod_{i=1}^n |\mathcal{Q}_i|^{\frac{\gamma}{\lambda} - \left(\frac{1}{p} - \frac{1}{q}\right)} \left\{ \frac{1}{|\mathcal{Q}|} \int_{\mathcal{Q}} \left(\frac{1}{|x|}\right)^\gamma dx \right\} \left\{ \frac{1}{|\mathcal{Q}|} \int_{\mathcal{Q}} \left(\frac{1}{|x|}\right)^\delta \left(\frac{p}{\lambda - 1}\right) dx \right\} \frac{p-1}{p} 
\]

(4.8)

\[
= \left\{ \sum_{i} \int_{\bigotimes_{i \in S} \mathcal{Q}_i(t_i)} \left(\frac{1}{|x_S|}\right)^\gamma dx_S \right\} \left\{ \sum_{i} \int_{\bigotimes_{i \in S} \mathcal{Q}_i(t_i)} \left(\frac{1}{|x_S|}\right)^\delta \left(\frac{p}{\lambda - 1}\right) dx_S \right\} 
\]

which is bounded from above, because of (4.4). The local integrability of $|x_S|^\gamma, |x_S|^\delta \left(\frac{p}{\lambda - 1}\right)$ required on $\mathbb{R}^{N_S}$ implies that

\[
\gamma < \frac{N_S}{q}, \quad \delta < N_S\left(\frac{p}{p-1}\right). 
\]

(4.9)
In order to prove (2. 4)-(2. 6), we develop a 3-fold estimate with respect to the three cases: 
\( \gamma \geq 0, \delta \leq 0; \gamma \leq 0, \delta \geq 0 \) and \( \gamma > 0, \delta > 0 \).

**Case One:** Consider \( \gamma \geq 0, \delta \leq 0 \). Let \( |Q_i|^{\frac{j}{p-1}} = 1 \) for \( i \in \{1, 2, \ldots, n\} \) and \( |Q_j|^{\frac{k}{q}} = \lambda \) for all \( j \neq i \). Suppose \( \alpha_j - N_j \left(\frac{1}{p} - \frac{1}{q}\right) = 0 \) for every \( j \neq i \). We have

\[
\prod_{i=1}^{n} |Q_i|^{\frac{j}{p-1}} \left(\frac{1}{Q_i} \int_Q \frac{\gamma^q}{|x|} \, dx \right)^{\frac{1}{p}} \left(\frac{1}{Q_i} \int_Q \frac{\gamma^{\left(\frac{q}{p}\right)}}{|x|} \, dx \right)^{\frac{p-1}{p}} \\
\geq \left\{ \int_{Q_i} \left(\frac{1}{\lambda + |x|} \right)^{\gamma^q} \, dx \right\}^{\frac{1}{p}} \left\{ \int_{Q_i} \left(\frac{1}{|x|} \right)^{\left(\frac{q}{p}\right)} \, dx \right\}^{\frac{p-1}{p}} \tag{4. 10} \quad (\delta \leq 0)
\]

where the implied constants depend on \( p, q, \gamma, \delta, n \) and \( N_i \). Direct computation shows

\[
\int_{\lambda < |x| \leq 1} \left(\frac{1}{\lambda + |x|} \right)^{\gamma^q} \, dx_i \approx \ln \left(\frac{1 + \lambda}{2\lambda} \right) \quad \text{if} \quad \gamma = \frac{N_i}{q},
\]

\[
\int_{\lambda < |x| \leq 1} \left(\frac{1}{\lambda + |x|} \right)^{\gamma^q} \, dx_i \approx \frac{1}{\gamma^q - N_i} \left[ \left(\frac{1}{2\lambda} \right)^{\gamma^q - N_i} - \left(\frac{1}{\lambda + 1} \right)^{\gamma^q - N_i} \right] \quad \text{if} \quad \gamma > \frac{N_i}{q}. \tag{4. 11}
\]

From (4. 10)-(4. 11), we need

\[
\gamma < \frac{N_i}{q} \tag{4. 12}
\]

in order to satisfy the inequality in (4. 4) as \( \lambda \to 0 \).

On the other hand, suppose that there exists \( j \neq i \) such that \( \alpha_j - N_j \left(\frac{1}{p} - \frac{1}{q}\right) > 0 \). We have

\[
\prod_{i=1}^{n} |Q_i|^{\frac{j}{p-1}} \left(\frac{1}{Q_i} \int_Q \frac{\gamma^q}{|x|} \, dx \right)^{\frac{1}{p}} \left(\frac{1}{Q_i} \int_Q \frac{\gamma^{\left(\frac{q}{p}\right)}}{|x|} \, dx \right)^{\frac{p-1}{p}} \\
\geq (\lambda)^{\Sigma_{j \neq i} \alpha_j - N_j \left(\frac{1}{p} - \frac{1}{q}\right)} \left\{ \int_{Q_i} \left(\frac{1}{\lambda + |x|} \right)^{\gamma^q} \, dx \right\}^{\frac{1}{p}} \left\{ \int_{Q_i} \left(\frac{1}{|x|} \right)^{\left(\frac{q}{p}\right)} \, dx \right\}^{\frac{p-1}{p}} \tag{4. 13} \quad (\delta \leq 0)
\]

where the implied constants depend on \( p, q, \gamma, \delta, n \) and \( N_i \).

Recall the estimate in (4. 7) and take \( S = |l| \). We have (4. 13) converging to zero as \( \lambda \to 0 \).

The last line of (4. 13) together with (4. 12) imply

\[
\gamma < \frac{N_i}{q} + \sum_{j \neq i} \alpha_j - N_j \left(\frac{1}{p} - \frac{1}{q}\right), \quad i = 1, 2, \ldots, n. \tag{4. 14}
\]
**Case Two:** Consider $\gamma \leq 0, \delta \geq 0$. Let $|Q_i|^{\frac{1}{p'}} = 1$ for $i \in \{1, 2, \ldots, n\}$ and $|Q_j|^{\frac{1}{p'}} = \lambda$ for all $j \neq i$. Suppose $\alpha_j - N_j \left(\frac{1}{p} - \frac{1}{q} \right) = 0$ for every $j \neq i$. We have

\[
\prod_{i=1}^{n} |Q_i|^{\frac{\alpha_i}{n}} \left(\frac{1}{p'} - \frac{1}{q} \right) \left\{ \int_{Q} \left( \frac{1}{|x|} \right)^q \, dx \right\}^\frac{1}{q} \left\{ \int_{Q} \left( \frac{1}{|x|} \right)^{\delta(p,p')} \, dx \right\}^{\frac{p-1}{p'}} \\
\geq \left\{ \int_{Q} \left( \frac{1}{|x|} \right)^q \, dx \right\}^\frac{1}{q} \left\{ \int_{Q} \left( \frac{1}{\lambda + |x|} \right)^{\delta(p,p')} \, dx \right\}^{\frac{p-1}{p'}} \quad (\gamma \leq 0) \tag{4.15}
\]

where the implied constants depend on $p, q, \gamma, \delta, n$ and $N_i$. Direct computation shows

\[
\int_{\lambda < |x| \leq 1} \left( \frac{1}{\lambda + |x|} \right)^{\delta(p,p')} \, dx_i \approx \ln \left( \frac{1 + \lambda}{2\lambda} \right) \quad \text{if} \quad \delta = N_i \left(\frac{p-1}{p} \right),
\]

\[
\int_{\lambda < |x| \leq 1} \left( \frac{1}{\lambda + |x|} \right)^{\delta(p,p')} \, dx_i \approx \frac{1}{\delta \left(\frac{p-1}{p} \right) - N_i} \left[ \left( \frac{1}{2\lambda} \right)^{\delta(p,p')-N_i} - \left( \frac{1}{\lambda + 1} \right)^{\delta(p,p')-N_i} \right] \quad \text{if} \quad \delta > N_i \left(\frac{p-1}{p} \right). \tag{4.16}
\]

From (4.15)-(4.16), we need

\[
\delta < N_i \left(\frac{p-1}{p} \right) \tag{4.17}
\]

in order to satisfy the inequality in (4.4) as $\lambda \to 0$.

On the other hand, suppose that there exists $j \neq i$ such that $\alpha_j - N_j \left(\frac{1}{p} - \frac{1}{q} \right) > 0$. We have

\[
\prod_{i=1}^{n} |Q_i|^{\frac{\alpha_i}{n}} \left(\frac{1}{p'} - \frac{1}{q} \right) \left\{ \int_{Q} \left( \frac{1}{|x|} \right)^q \, dx \right\}^\frac{1}{q} \left\{ \int_{Q} \left( \frac{1}{|x|} \right)^{\delta(p,p')} \, dx \right\}^{\frac{p-1}{p'}} \\
\geq \prod_{j \neq i} \left( \lambda \right)^{\alpha_j - N_j \left(\frac{1}{p} - \frac{1}{q} \right)} \left\{ \int_{Q} \left( \frac{1}{|x|} \right)^q \, dx \right\}^\frac{1}{q} \left\{ \int_{Q} \left( \frac{1}{\lambda + |x|} \right)^{\delta(p,p')} \, dx \right\}^{\frac{p-1}{p'}} \quad (\gamma \leq 0) \tag{4.18}
\]

\[
\geq \prod_{j \neq i} \left( \lambda \right)^{\alpha_j - N_j \left(\frac{1}{p} - \frac{1}{q} \right)} \left\{ \int_{|x| \leq \lambda} \left( \frac{1}{\lambda} \right)^{\delta(p,p')} \, dx \right\}^{\frac{p-1}{p'}} \\
\approx \left( \lambda \right)^{\frac{p-1}{p} \sum_{j \neq i} \alpha_j - N_j \left(\frac{1}{p} - \frac{1}{q} \right)}
\]

where the implied constants depend on $p, q, \gamma, \delta, n$ and $N_i$. 

10
Recall the estimate in (4. 7) and take $S = \{i\}$. We have (4. 18) converging to zero as $\lambda \to 0$. The last line of (4. 18) together with (4. 17) imply

$$\delta < N_i \left( \frac{p - 1}{p} \right) + \sum_{j \neq i} \alpha_j - N_j \left( \frac{1}{p} - \frac{1}{q} \right), \quad i = 1, 2, \ldots, n. \quad (4. 19)$$

**Case Three:** Consider $\gamma > 0$, $\delta > 0$. The estimate in (4. 5) together with the formula in (2. 3) imply that the characteristic in (4. 4) is invariant under one-parameter changing dilations.

Suppose $U$ and $V$ are the subsets defined respectively in (2. 6).

Let $|Q_i|^\frac{N_i}{p} = \lambda^{-1}$ for every $i \in U$ and $|Q_i|^\frac{N_i}{p} = 1$ for all other $i \notin U$. We have

$$\prod_{i=1}^n |Q_i|^\frac{N_i}{N_i - \left( \frac{1}{p} - \frac{1}{q} \right)} \left\{ \frac{1}{|Q_i|} \int_{Q_i} \left( \frac{1}{|x|} \right)^q dx \right\}^\frac{1}{q} \left\{ \frac{1}{|Q_i|} \int_{Q_i} \left( \frac{1}{|x|} \right)^p dx \right\}^\frac{1}{p} \geq \left( \frac{1}{\lambda} \right)^{\sum_{i \in U} \alpha_i - \frac{N_i}{p}} \left( \prod_{i \in U} (\lambda)^{N_i} \int \cdots \int_{\mathbb{R}^n} (\lambda)^{\frac{p}{p-1}} \prod_{i \in U} dx_i \right)^{\frac{p-1}{p}} (0 < \lambda < 1)$$

$$\geq \left( \frac{1}{\lambda} \right)^{\sum_{i \in U} \alpha_i - \frac{N_i}{p} - \delta} \quad (4. 20)$$

where the implied constants depend on $p, q, \gamma, \delta, n$ and $N_U = \sum_{i \in U} N_i$.

In order to satisfy the inequality in (4. 4) as $\lambda \to 0$, we essentially need $\sum_{i \in U} \alpha_i - \frac{N_i}{p} \leq \delta$.

In the case of $U = \{1, 2, \ldots, n\}$, since $\gamma$ satisfies the first strict inequality in (2. 2), by using the formula in (2. 3), we find

$$\delta = \frac{N_i}{q} - \gamma + \sum_{i=1}^n \alpha_i - \frac{N_i}{p} > \sum_{i=1}^n \alpha_i - \frac{N_i}{p} = \sum_{i \in U} \alpha_i - \frac{N_i}{p}. \quad (4. 21)$$

Suppose that $U$ is a proper subset of $\{1, 2, \ldots, n\}$ and there exists at least one $i \in U^c$ such that $\alpha_i - N_i \left( \frac{1}{p} - \frac{1}{q} \right) > 0$. By applying the estimate in (4. 7) with $S = U$, we have (4. 20) converging to zero as $\lambda \to 0$. The last line of (4. 20) implies

$$\sum_{i \in U} \alpha_i - \frac{N_i}{p} < \delta. \quad (4. 22)$$
Let $U$ be a proper subset of $\{1, 2, \ldots, n\}$ where $\alpha_i - N_i \left( \frac{1}{p} - \frac{1}{q} \right) = 0$ for every $i \in U$. The estimates in (4.8)-(4.9) with $S = U$ implies
\[
\gamma < \frac{N_u}{q}, \quad \delta < \frac{1}{p} - \frac{1}{q}.
\]
(4.23)

On the other hand, directly from (2.3), we have
\[
\frac{\alpha_U}{N_u} = \frac{1}{p} - \frac{1}{q} + \frac{\gamma + \delta}{N_u}, \quad \alpha_U = \sum_{i \in U} \alpha_i.
\]
(4.24)

By putting together (4.23) and (4.24), we have
\[
\delta = \frac{N_u}{q} - \gamma + \sum_{i \in U} \alpha_i - \frac{N_i}{p} > \sum_{i \in U} \alpha_i - \frac{N_i}{p}.
\]
(4.25)

Let $|Q|^N = \lambda$ for every $i \in V$ and $|Q|^N = 1$ for all other $i \notin V$. We have
\[
\prod_{i=1}^n |Q_i|^{\frac{\alpha_i - (\frac{q-1}{q})N_i}{\lambda}} \left\{ \int_{|x|} \left( \frac{1}{|x|} \right)^{\gamma q} dx \right\}^{\frac{1}{\gamma}} \left\{ \int_{|x|} \left( \frac{1}{|x|} \right)^{\delta(\frac{p}{p-1})} dx \right\}^{\frac{p-1}{p}}
\]
\[
\approx \left( \frac{1}{\lambda} \right)^{\sum_{i \in V} \alpha_i - (\frac{q-1}{q})N_i} \left\{ \prod_{i \in V} (\lambda)^N_i \int \cdots \int \prod_{i \in V} (\lambda)^q dx_i \right\}^{\frac{1}{\gamma}} \left\{ \int \cdots \int \prod_{i \in V} (\lambda)^{\delta(1+\sum_{i \in V} |x_i|)} dx_i \right\}^{\frac{p-1}{p}}
\]
\[
\approx \left( \frac{1}{\lambda} \right)^{\sum_{i \in V} \alpha_i - (\frac{q-1}{q})N_i - \gamma} \left\{ \int \cdots \int \prod_{i \in V} (\lambda)^q dx_i \right\}^{\frac{1}{\gamma}} \left\{ \int \cdots \int \prod_{i \in V} (\lambda)^{\delta(1+\sum_{i \in V} |x_i|)} dx_i \right\}^{\frac{p-1}{p}}
\]
\[
\approx \left( \frac{1}{\lambda} \right)^{\sum_{i \in V} \alpha_i - (\frac{q-1}{q})N_i - \gamma}
\]
(4.26)

where the implied constants depend on $p, q, \gamma, \delta, n$ and $N_v = \sum_{i \in V} N_i$.

In order to satisfy the inequality in (4.4) as $\lambda \to 0$, we essentially need $\sum_{i \in V} \alpha_i - (\frac{q-1}{q})N_i \leq \gamma$.

In the case of $V = \{1, 2, \ldots, n\}$, since $\delta$ satisfies the second strict inequality in (2.2), by using the formula in (2.3), we find
\[
\gamma = \left( \frac{p-1}{p} \right) - \delta + \sum_{i=1}^n \alpha_i - N_i \left( \frac{q-1}{q} \right)
\]
\[
> \sum_{i=1}^n \alpha_i - N_i \left( \frac{q-1}{q} \right) = \sum_{i \in V} \alpha_i - N_i \left( \frac{q-1}{q} \right).
\]
(4.27)
Suppose that $V$ is a proper subset of $\{1, 2, \ldots, n\}$ and there exists at least one $i \in V^c$ such that $\alpha_i - N_i \left( \frac{1}{p} - \frac{1}{q} \right) > 0$. By applying the estimate in (4.7) with $S = V$, we have (4.26) converging to zero as $\lambda \to 0$. The last line of (4.26) implies

$$\sum_{i \in V} \alpha_i - \left( \frac{q-1}{q} \right) N_i < \gamma.$$  \hspace{1cm} (4.28)

Suppose that $V$ is a proper subset of $\{1, 2, \ldots, n\}$ where $\alpha_i - N_i \left( \frac{1}{p} - \frac{1}{q} \right) = 0$ for every $i \in V^c$. The estimates in (4.8)-(4.9) with $S = V$ imply

$$\gamma < \frac{N_{V}}{q}, \quad \delta < \frac{N_{V}}{p} \left( \frac{p-1}{p} \right).$$  \hspace{1cm} (4.29)

On the other hand, directly from (2.3), we have

$$\frac{\alpha_V}{N_{V}} = \frac{1}{p} - \frac{1}{q} + \gamma + \delta, \quad \alpha_V = \sum_{i \in V} \alpha_i.$$  \hspace{1cm} (4.30)

By putting together (4.29) and (4.30), we have

$$\gamma = \left( \frac{p-1}{p} \right) N_{V} - \delta + \sum_{i \in V} \alpha_i - N_i \left( \frac{q-1}{q} \right) > \sum_{i \in V} \alpha_i - N_i \left( \frac{q-1}{q} \right).$$  \hspace{1cm} (4.31)

**Remark 4.1** We recall the two constraints obtained in (4.14) and (4.19) which are in fact equivalent to those given in (2.4) and (2.5) respectively. Namely,

for $\gamma \geq 0, \delta \leq 0$,

$$\gamma < \frac{N_i}{q} + \sum_{j \neq i} \alpha_j - N_j \left( \frac{1}{p} - \frac{1}{q} \right) \iff \alpha_i - \frac{N_i}{p} < \delta,$$  \hspace{1cm} (4.32)

$i = 1, 2, \ldots, n$ and

for $\gamma \leq 0, \delta \geq 0$,

$$\delta < N_i \left( \frac{p-1}{p} \right) + \sum_{j \neq i} \alpha_j - N_j \left( \frac{1}{p} - \frac{1}{q} \right) \iff \alpha_i - N_i \left( \frac{q-1}{q} \right) < \gamma,$$  \hspace{1cm} (4.33)

$i = 1, 2, \ldots, n$.

Notice that (4.32) and (4.33) can be easily verified by using the formula in (2.3).

### 5 Decaying Estimate on Variant of Eccentricities

Suppose

$$\frac{\alpha_i}{N_i} > \frac{1}{p} - \frac{1}{q}, \quad i = 1, 2, \ldots, n.$$  \hspace{1cm} (5.1)

We aim to show that the $r$-bump Muckenhoupt characteristic defined in (2.8) for some $r > 1$, decays exponentially as $Q$ varying on eccentricities, whenever $\omega(x) = |x|^\gamma, \sigma(x) = |x|^\delta$ for $\gamma, \delta$ satisfying the constraints given in (2.2)-(2.6), except on some permissible endpoints.
Lemma 5.1 Let $\gamma, \delta$ satisfying (2.2)-(2.6). Moreover, they belong to the ranges

$$
\frac{1}{q} \sum_{i=1}^{m-1} N_i < \gamma < \frac{1}{q} \sum_{i=1}^{m} N_i, \quad \delta \leq 0, \quad 1 \leq m \leq n
$$

(5.2)

or

$$
\left(\frac{p-1}{p}\right) \sum_{i=1}^{m-1} N_i < \gamma < \left(\frac{p-1}{p}\right) \sum_{i=1}^{m} N_i, \quad \gamma \leq 0, \quad 1 \leq m \leq n
$$

(5.3)

or

$$
\frac{1}{q} \sum_{i=1}^{m-1} N_i < \gamma < \frac{1}{q} \sum_{i=1}^{m} N_i, \quad \left(\frac{p-1}{p}\right) \sum_{i=1}^{l-1} N_i < \delta < \left(\frac{p-1}{p}\right) \sum_{i=1}^{l} N_i, \quad 1 \leq m, l \leq n.
$$

(5.4)

We have

$$
\prod_{i=1}^{n} |Q_i|^{\frac{1}{n^r} \left(\frac{1}{q} \frac{1}{\beta} \frac{1}{\gamma} \delta\right)} \left\{ \frac{1}{|Q_i|} \int_{Q_i} \left(\frac{1}{|x|}\right)^{\gamma q r} dx \right\}^{\frac{1}{p}} \left\{ \frac{1}{|Q_i|} \int_{Q_i} \left(\frac{1}{|x|}\right)^{\lambda p r} dx \right\}^{\frac{1}{p}} < \infty
$$

(5.5)

for some $r > 1$ and every $Q \subset \mathbb{R}^n$.

Let $\nu \in \{1, 2, \ldots, n\}$ and $0 < \lambda_i \leq 1$ such that $\lambda_\nu = 1$ and

$$
\lambda_i = \frac{|Q_i|^1}{|Q_\nu|^1}, \quad \nu \neq i \in \{1, 2, \ldots, n\}.
$$

(5.6)

Suppose that (5.1) is satisfied. There exists an $\varepsilon > 0$ such that

$$
\prod_{i=1}^{n} |Q_i|^{\frac{1}{n^r} \left(\frac{1}{q} \frac{1}{\beta} \frac{1}{\gamma} \delta\right)} \left\{ \frac{1}{|Q_i|} \int_{Q_i} \left(\frac{1}{|x|}\right)^{\gamma q r} dx \right\}^{\frac{1}{p}} \left\{ \frac{1}{|Q_i|} \int_{Q_i} \left(\frac{1}{|x|}\right)^{\lambda p r} dx \right\}^{\frac{1}{p}} \leq \prod_{i=1}^{n} (\lambda_i)^\varepsilon
$$

(5.7)

for some $r > 1$ and every $Q \subset \mathbb{R}^n$ satisfying (5.6).

The values of $\varepsilon, r$ and the implied constant in (5.7) depend only on $p, q, \gamma, \delta, \alpha, n, N$.

Proof: By carrying out the same estimate in (4.5) and using the formula in (2.3), we find that the $r$-bump characteristic in (5.7) is invariant under one-parameter changing dilations. It is then sufficient to consider $|Q_\nu|^1 = 1$. Let $Q_i^* \subset \mathbb{R}^n$ to be centered on the origin and

$$
|Q_i^*|^1 = \frac{|Q_i|^1}{^1|Q_\nu|^1} = 3|Q_i|^1, \quad i = 1, 2, \ldots, n.
$$

(5.8)

Recall that $Q_i$ is a cube in $\mathbb{R}^n$. From (5.8) and a geometric interpretation, the following fact can be easily verified.

Remark 5.1 Suppose $Q_i \notin Q_i^*$ defined in (5.8). There is another cube $Q_i^o \subset Q_i^*$ centered on the origin with $|Q_i^o|^1 = |Q_i|^1$ such that $|x_i| \geq |x_i^o|$ for every $x_i \in Q_i$ and every $x_i^o \in Q_i^o$.

By permuting the indices $i = 1, 2, \ldots, n$, we can assume $\nu = 1$ and

$$
1 = \lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_n.
$$

(5.9)
Let $\gamma, \delta$ belonging to the ranges given in (5.2). Consider $Q$ centered on $z \in \mathbb{R}^N$ where $|z| \leq 3$. For $r$ sufficiently close to 1, we have

$$\prod_{i=1}^{n} \left[ Q \cap \left( \frac{1}{|x|} \right)^{\gamma qr} dx \right]^{\frac{1}{\gamma}} \left[ Q \cap \left( \frac{1}{|x|} \right)^{\delta qr} dx \right]^{\frac{1}{\delta}} \leq \prod_{i=1}^{n} (\lambda_i)^{\alpha - N(\frac{1}{p} - \frac{1}{q})} \left( \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i} \int \int_{Q_i} \left( \frac{1}{|x_1| + \cdots + |x_n|} \right)^{\gamma qr} dx_1 \cdots dx_n \right)^{\frac{1}{\gamma}} \quad (\delta \leq 0)$$

$$\times \left\{ \int \int_{\mathbb{R}^N} \left( \frac{1}{x_1 + \cdots + x_n} \right)^{\gamma qr - \sum_{i=1}^{m-1} N_i} dx_m \cdots dx_n \right\}^{\frac{1}{\gamma}} \quad (\gamma > \sum_{i=1}^{m-1} N_i)$$

$$\leq \prod_{i=1}^{n} (\lambda_i)^{\alpha - N(\frac{1}{p} - \frac{1}{q})} \left( \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i} \int \int_{Q_i} \left( \frac{1}{|x_1| + \cdots + |x_n|} \right)^{\gamma qr - \sum_{i=1}^{m-1} N_i} dx_m \cdots dx_n \right)^{\frac{1}{\gamma}}$$

$$\leq \prod_{i=1}^{n} (\lambda_i)^{\alpha - N(\frac{1}{p} - \frac{1}{q})} \left( \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i} \int \int_{Q_i} \left( \frac{1}{|x_1| + \cdots + |x_n|} \right)^{\gamma qr - \sum_{i=1}^{m-1} N_i} dx_m \cdots dx_n \right)^{\frac{1}{\gamma}}$$

$$\leq (\lambda_m)^{\frac{1}{p} \sum_{i=1}^{m} N_i - \gamma} \prod_{i=1}^{m} \left( \frac{1}{\lambda_i} \right)^{N_i} \prod_{i=m+1}^{n} (\lambda_i)^{\alpha - N(\frac{1}{p} - \frac{1}{q})} \quad (\text{by Remark 5.1})$$

The implied constants in (5.10) depend only on $p, q, \gamma, \delta, \alpha, n, N$. From direct computations, the last line of (5.10) can be rewritten as

$$= (\lambda_m)^{\frac{1}{p} \sum_{i=2}^{m} N_i - \gamma} \prod_{i=2}^{m} (\lambda_i)^{\alpha - N(\frac{1}{p} - \frac{1}{q})} \prod_{i=m+1}^{n} (\lambda_i)^{\alpha - N(\frac{1}{p} - \frac{1}{q})} \quad (\lambda_1 = 1) \quad (5.11)$$

$$= (\lambda_m)^{\frac{N_n}{p} + \sum_{i=2}^{m} N_i (\frac{1}{p} - \frac{1}{q}) - \gamma} \prod_{i=2}^{m} \left( \frac{\lambda_i}{\lambda_m} \right)^{\alpha_i - N(\frac{1}{p} - \frac{1}{q})} \prod_{i=m+1}^{n} \left( \frac{\lambda_i}{\lambda_m} \right)^{\alpha - N(\frac{1}{p} - \frac{1}{q})}$$
Recall from Remark 4.1. \( \gamma \geq 0, \delta \leq 0 \) satisfy the two equivalent strict inequalities in (4. 32). For \( r \) sufficiently close to 1, we have

\[
\alpha_i - \frac{N_i}{p} + \left( 1 - \frac{1}{r} \right) \frac{N_i}{q} < 0, \quad i = 1, 2, \ldots, n. \quad (5. 12)
\]

Moreover, define \( 0 \leq \delta \leq 1 \) implicitly by \( \lambda_m = \lambda_n^\delta \). Together with (5. 1), we have

\[
\delta \left[ \frac{N_i}{q} + \sum_{i=2}^{n} \alpha_i - N_i \left( \frac{1}{p} - \frac{1}{q} \right) \right] + \left( 1 - \delta \right) \left[ \alpha_n - N_n \left( \frac{1}{p} - \frac{1}{q} \right) \right] > 0. \quad (5. 13)
\]

By using the estimates in (5. 12)-(5. 13), we observe that (5. 11) is bounded by a constant multiple of \( \lambda_n^\varepsilon \) for some \( \varepsilon > 0 \).

Let \( \gamma, \delta \) belonging to the ranges given in (5. 3). Consider \( Q \) centered on \( z \in \mathbb{R}^n \) where \( |z| \leq 3 \). For \( r \) sufficiently close to 1, we have

\[
\prod_{i=1}^{n} |Q|^\frac{\alpha_i}{N_i} \left( \frac{1}{|x|} \right)^{\gamma} \left( \frac{1}{|x|} \right)^{\delta} \left( \frac{1}{|x|} \right)^{\sum_{i=1}^{n-1} N_i} \left( \frac{1}{|x| + \ldots + |x_n|} \right)^{\delta} dx_1 \cdots dx_n \]

\[
\leq \prod_{i=1}^{n} (\lambda_i)^{\alpha_i - N_i} \frac{1}{\lambda_i} \left( \frac{1}{|x|} \right)^{\gamma} \left( \frac{1}{|x|} \right)^{\delta} \left( \frac{1}{|x| + \ldots + |x_n|} \right)^{\delta} dx_1 \cdots dx_n \]

\[
\leq \prod_{i=1}^{n} (\lambda_i)^{\alpha_i - N_i} \frac{1}{\lambda_i} \left( \frac{1}{|x|} \right)^{\gamma} \left( \frac{1}{|x|} \right)^{\delta} \left( \frac{1}{|x| + \ldots + |x_n|} \right)^{\delta} dx_1 \cdots dx_n \]

\[
\leq \prod_{i=1}^{n} (\lambda_i)^{\alpha_i - N_i} \frac{1}{\lambda_i} \left( \frac{1}{|x|} \right)^{\gamma} \left( \frac{1}{|x|} \right)^{\delta} \left( \frac{1}{|x| + \ldots + |x_n|} \right)^{\delta} dx_1 \cdots dx_n \]

\[
\leq (\lambda_m)^{\delta} \prod_{i=1}^{m} \left( \frac{1}{\lambda_i} \right)^{N_i} \prod_{i=1}^{n} (\lambda_i)^{\alpha_i - N_i} \left( \frac{1}{|x|} \right)^{\gamma} \left( \frac{1}{|x|} \right)^{\delta} \left( \frac{1}{|x| + \ldots + |x_n|} \right)^{\delta} dx_1 \cdots dx_n \]

\[
(5. 14)
\]
Moreover, define \( 0 \leq r \) for some \( \gamma > 0 \), because of (5.1).

From direct computations, the last line of (5.14) can be rewritten as

\[
(\lambda_m)^{\frac{p-1}{pr} \sum_{i=1}^m N_i - \delta} \prod_{i=1}^m (\lambda_i)^{\alpha_i - N_i \left( \frac{1}{p} - \frac{1}{q} \right) - \left( \frac{p-1}{pr} \right) N_i} \prod_{i=m+1}^n (\lambda_i)^{\alpha_i - N_i \left( \frac{1}{p} - \frac{1}{q} \right)} = (\lambda_m)^{\frac{p-1}{pr} \sum_{i=1}^m N_i - \delta} \prod_{i=1}^m (\lambda_i)^{\alpha_i - N_i \left( \frac{1}{p} - \frac{1}{q} \right) - \left( \frac{p-1}{pr} \right) N_i} \prod_{i=m+1}^n (\lambda_i)^{\alpha_i - N_i \left( \frac{1}{p} - \frac{1}{q} \right)} (\lambda_1 = 1) \quad (5.15)
\]

Recall from Remark 4.1. \( \gamma \leq 0, \delta \geq 0 \) satisfy the two equivalent strict inequalities in (4.33). For \( r \) sufficiently close to 1, we have

\[
\alpha_i - N_i \left( \frac{q-1}{q} \right) + \left( 1 - \frac{1}{r} \right) \left( \frac{p-1}{p} \right) N_i < 0, \quad i = 1, 2, \ldots n. \quad (5.16)
\]

Moreover, define \( 0 \leq \delta \leq 1 \) implicitly by \( \lambda_m = \lambda_m^\delta \). Together with (5.1), we have

\[
\delta \left[ N_1 \left( \frac{p-1}{pr} \right) + \sum_{i=2}^n \alpha_i - N_i \left( 1 - \frac{1}{p} \right) - \left( \frac{p-1}{pr} \right) N_i \right] + (1 - \delta) \left[ \alpha_n - N_n \left( 1 - \frac{1}{p} \right) \right] > 0. \quad (5.17)
\]

By using the estimates in (5.16)-(5.17), we observe that (5.15) is bounded by a constant multiple of \( \lambda_n^\varepsilon \) for some \( \varepsilon > 0 \).

Consider \( Q \) centered on \( z \in \mathbb{R}^N \) for \( |z| > 3 \). Since \( Q \) has a diameter equal to 1, we have

\[
|x| \approx |z|, \quad x \in Q. \quad (5.18)
\]

It follows that

\[
\prod_{i=1}^n |Q_i|^{\frac{q-1}{q} - \left( \frac{1}{p} - \frac{1}{q} \right)} \left( \frac{1}{|Q|} \int_Q \left( \frac{1}{|x|} \right)^{\gamma q r} dx \right)^{-\frac{1}{r}} \left( \frac{1}{|Q|} \int_Q \left( \frac{1}{|x|} \right)^{\gamma p r} dx \right)^{-\frac{p-1}{pr}} \lesssim \left( \frac{1}{|z|} \right)^{\gamma + \delta} \prod_{i=1}^n (\lambda_i)^{\alpha_i - N_i \left( \frac{1}{p} - \frac{1}{q} \right)} \quad \text{by (5.18)}
\]

\[
\lesssim \prod_{i=1}^n (\lambda_i)^{\alpha_i - N_i \left( \frac{1}{p} - \frac{1}{q} \right)} (\gamma + \delta \geq 0) \quad (5.19)
\]

\[
\lesssim \prod_{i=1}^n (\lambda_i)^{\varepsilon}
\]

for some \( \varepsilon > 0 \), because of (5.1).
Let $\gamma, \delta$ belonging to the ranges given in (5. 4). For $r$ sufficiently close to 1, we have

$$
\prod_{i=1}^{n} |Q_i|^\gamma \left( \frac{1}{|Q_i|} \int_{Q_i} \left( \frac{1}{|x|} \right)^{\gamma q r} \, dx \right)^{\frac{1}{\gamma q}} \left\{ \frac{1}{|Q_i|} \int_{Q_i} \left( \frac{1}{|x|} \right)^{\delta \left( \frac{p}{p-1} \right)} \, dx \right\}^{\frac{p-1}{p}} 
\leq \prod_{i=1}^{n} (\lambda_i)^{\alpha_i - N_i \left( \frac{1}{p} - \frac{1}{r} \right)} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{\frac{N_i}{p}} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} 
\times \left\{ \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} \right\}^{\frac{1}{p q r}} \left( \gamma q > \sum_{i=1}^{n-1} N_i \right) 
\times \left\{ \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} \right\}^{\frac{p-1}{p}} \left( \delta \left( \frac{p}{p-1} \right) > \sum_{i=1}^{n-1} N_i \right) 
\leq \prod_{i=1}^{n} \left( \lambda_i \right)^{\alpha_i - N_i \left( \frac{1}{p} - \frac{1}{r} \right)} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{\frac{N_i}{p}} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} 
\times \left\{ \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} \right\}^{\frac{1}{\gamma q}} \left\{ \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} \right\}^{\frac{p-1}{p}} \left( \gamma q > \sum_{i=1}^{n-1} N_i \right) 
\times \left\{ \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} \right\}^{\frac{p-1}{p}} \left( \delta \left( \frac{p}{p-1} \right) > \sum_{i=1}^{n-1} N_i \right) 
\leq \prod_{i=1}^{n} \left( \lambda_i \right)^{\alpha_i - N_i \left( \frac{1}{p} - \frac{1}{r} \right)} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{\frac{N_i}{p}} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} 
\times \left\{ \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} \right\}^{\frac{1}{\gamma q}} \left\{ \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} \right\}^{\frac{p-1}{p}} \left( \gamma q > \sum_{i=1}^{n-1} N_i \right) 
\times \left\{ \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} \right\}^{\frac{p-1}{p}} \left( \delta \left( \frac{p}{p-1} \right) > \sum_{i=1}^{n-1} N_i \right) 
\leq \prod_{i=1}^{n} \left( \lambda_i \right)^{\alpha_i - N_i \left( \frac{1}{p} - \frac{1}{r} \right)} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{\frac{N_i}{p}} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} 
\times \left\{ \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} \right\}^{\frac{1}{\gamma q}} \left\{ \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} \right\}^{\frac{p-1}{p}} \left( \gamma q > \sum_{i=1}^{n-1} N_i \right) 
\times \left\{ \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} \right\}^{\frac{p-1}{p}} \left( \delta \left( \frac{p}{p-1} \right) > \sum_{i=1}^{n-1} N_i \right) 
\leq \left( \lambda_m \right)^{\frac{1}{p} \sum_{i=1}^{n} N_i - \gamma} \lambda_i \left( \frac{p-1}{p} \right) \sum_{i=1}^{n} N_i - \delta \prod_{i=1}^{n} \left( \lambda_i \right)^{\alpha_i - N_i \left( \frac{1}{p} - \frac{1}{r} \right)} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{\frac{N_i}{p}} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{N_i \left( \frac{p-1}{p} \right)} \right). 
(5. 20)
The implied constants in (5.20) depend only on \(p, q, \gamma, \delta, \alpha, n, N\).

Let \(0 \leq k \leq n - 1\). From direct computations, we have

\[
\frac{1}{r} \left( \frac{1}{q} + \frac{p - 1}{p} \right) \sum_{i=1}^{k} N_i - (\gamma + \delta) + \sum_{i=k+1}^{n} \alpha_i - N_i \left( \frac{1}{p} - \frac{1}{q} \right) = \frac{N}{r} \left( \frac{1}{q} + \frac{p - 1}{p} \right) \sum_{i=1}^{n} N_i - (\gamma + \delta) + \sum_{i=k+1}^{n} \alpha_i - N_i \left( \frac{1}{p} - \frac{1}{q} \right) \] by (2.3)

\[
= \frac{(N - \alpha)}{r} + N \left( \frac{1}{r} \right) \left( \frac{1}{p} - \frac{1}{q} \right) + \sum_{i=k+1}^{n} \alpha_i - N_i \left( \frac{1}{r} \right) \left( \frac{1}{p} - \frac{1}{q} \right) = \sum_{i=1}^{k} \frac{N_i}{r} - \alpha_i + N_i \left( \frac{1}{r} \right) \left( \frac{1}{p} - \frac{1}{q} \right).
\] (5.21)

Suppose \(l \leq m\). The last line of (5.20) can be rewritten as

\[
(\lambda_m)^{\frac{1}{r} \left( \frac{1}{q} + \frac{p - 1}{p} \right) \sum_{i=1}^{n} N_i - (\gamma + \delta) \left( \frac{\lambda_i}{\lambda_m} \right)^{\frac{m}{q}} \sum_{i=1}^{m} N_i - \alpha_i N_i \left( \frac{1}{q} + \frac{p - 1}{p} \right) \left( \frac{\lambda_i}{\lambda_m} \right)^{\frac{m - 1}{q}} \sum_{i=1}^{m} \left( \frac{1}{\lambda_i} \right)^{\frac{1}{r} \left( \frac{1}{q} + \frac{p - 1}{p} \right) N_i} = (\lambda_m)^{\frac{1}{r} \left( \frac{1}{q} + \frac{p - 1}{p} \right) \sum_{i=1}^{n} N_i - (\gamma + \delta) \left( \frac{\lambda_i}{\lambda_m} \right)^{\frac{m}{q}} \sum_{i=1}^{m} \left( \frac{1}{\lambda_i} \right)^{\frac{1}{r} \left( \frac{1}{q} + \frac{p - 1}{p} \right) N_i} \left( \frac{\lambda_i}{\lambda_m} \right)^{\alpha_i - N_i} \left( \frac{1}{q} + \frac{p - 1}{p} \right) N_i \left( \frac{\lambda_i}{\lambda_m} \right)^{\frac{m - 1}{q} - \alpha_i \left( \frac{1}{q} + \frac{p - 1}{p} \right) N_i} \] by (5.21)

\[
= \left( \frac{\lambda_i}{\lambda_m} \right)^{\frac{1}{r} \left( \frac{1}{q} + \frac{p - 1}{p} \right) \sum_{i=1}^{m} N_i - \alpha_i N_i \left( \frac{1}{q} + \frac{p - 1}{p} \right) \left( \frac{\lambda_i}{\lambda_m} \right)^{\frac{m - 1}{q} \sum_{i=1}^{m} \left( \frac{1}{\lambda_i} \right)^{\frac{1}{r} \left( \frac{1}{q} + \frac{p - 1}{p} \right) N_i} - \alpha_i \left( \frac{1}{q} + \frac{p - 1}{p} \right) N_i \] \]

Recall the subset \( U \) defined in (2.6) whereas \( \alpha_i - N_i / p < 0 \) for every \( i \notin U \).
Notice that \( \lambda_m \leq \lambda_l \) when \( l \leq m \). For \( r \) sufficiently close to 1, we have

\[
\left( \frac{\lambda_m}{\lambda_l} \right)^{\sum_{i=1}^{l-1} \frac{N_i}{p} - \alpha_i - \left(1 - \frac{1}{r} \right) \frac{N_i}{q} + \delta} \prod_{i=l}^{m} \left( \frac{\lambda_m}{\lambda_i} \right)^{\frac{N_i}{p} - \alpha_i - \left(1 - \frac{1}{r} \right) \frac{N_i}{q}} \leq \left( \frac{\lambda_m}{\lambda_l} \right)^{\sum_{i=U \cap \{1, \ldots, m\}} \frac{N_i}{p} - \alpha_l - \left(1 - \frac{1}{r} \right) \frac{N_i}{q} + \delta} \times \prod_{i=U \cap \{1, \ldots, m\}} \left( \frac{\lambda_m}{\lambda_i} \right)^{\frac{N_i}{p} - \alpha_i - \left(1 - \frac{1}{r} \right) \frac{N_i}{q}}.
\]

(5.23)

By bringing the estimates in (5.22)-(5.23) back to (5.20), we find

\[
\left( \frac{\lambda_m}{\lambda_l} \right)^{\frac{1}{p} \sum_{i=1}^{n} N_i - \gamma} \left( \frac{\lambda_l}{\lambda_m} \right)^{\frac{1}{p} \sum_{i=1}^{l-1} N_i - \delta} \prod_{i=1}^{n} \left( \frac{\lambda_l}{\lambda_i} \right)^{\frac{1}{p} - \alpha_i - \left(1 - \frac{1}{r} \right) \frac{1}{q}} \prod_{i=1}^{l-1} \left( \frac{\lambda_l}{\lambda_i} \right)^{\frac{1}{p} - \alpha_i + \left(1 - \frac{1}{r} \right) \frac{1}{q}} N_i \leq \left( \frac{\lambda_m}{\lambda_l} \right)^{\sum_{i=U \cap \{1, \ldots, m\}} \frac{N_i}{p} - \alpha_l - \left(1 - \frac{1}{r} \right) \frac{1}{q} + \delta} \prod_{i=U \cap \{1, \ldots, m\}} \left( \frac{\lambda_m}{\lambda_i} \right)^{\frac{N_i}{p} - \alpha_i + \left(1 - \frac{1}{r} \right) \frac{1}{q}} \prod_{i=m+1}^{n} \left( \frac{\lambda_m}{\lambda_i} \right)^{\alpha_i - \frac{1}{q}} \frac{1}{q} N_i.
\]

(5.24)

Recall that \( \delta > 0 \) satisfies the first strict inequality in (2.6). From (5.1) and (1.6), we also have \( \left( \frac{1}{p} - \frac{1}{q} \right) N_i < \alpha_i < N_i \) for every \( i = 1, 2, \ldots, n \). Define \( 0 \leq \delta_1 \leq \delta_2 \leq 1 \) implicitly by letting \( \lambda_l = \lambda_n^{\delta_1} \) and \( \lambda_m = \lambda_n^{\delta_2} \).

For \( r \) sufficiently close to 1, we have

\[
\delta_1 \left[ \frac{N_1}{r} - \alpha_1 + \left( 1 - \frac{1}{r} \right) \left( \frac{1}{p} - \frac{1}{q} \right) N_1 \right] + (1 - \delta_2) \left[ \alpha_1 - N_1 \left( \frac{1}{p} - \frac{1}{q} \right) \right]
\]

\[
+ (\delta_2 - \delta_1) \left[ \sum_{i \in U \cap \{1, \ldots, m\}} \frac{N_i}{p} - \alpha_i - \left(1 - \frac{1}{r} \right) \frac{N_i}{q} + \delta \right] > 0.
\]

(5.25)

The estimate in (5.25) implies (5.24) bounded by a constant multiple of \( \lambda_n^{\varepsilon} \) for some \( \varepsilon > 0 \).
On the other hand, suppose \( m \leq l \). The last line of (5.20) can be rewritten as

\[
(\lambda_m)^{\frac{1}{q}} \sum_{i=1}^{m-1} N_i \gamma (\lambda_i)^{\left(\frac{p+1}{p}\right)} \prod_{i=1}^{l} \left(\frac{1}{\lambda_i}\right)^{\frac{m-1}{p}} \prod_{i=1}^{l} \left(\frac{1}{\lambda_i}\right) \prod_{i=m}^{l} \left(\frac{1}{\lambda_i}\right)^{\frac{m-1}{p}} N_i
\]

\[
= (\lambda_l)^{\frac{1}{q}} \sum_{i=1}^{m-1} N_i \gamma \prod_{i=m}^{l} \left(\frac{1}{\lambda_i}\right)^{\frac{m-1}{p}} N_i
\]

\[
\times \prod_{i=m}^{l} \left(\frac{1}{\lambda_i}\right)^{\frac{m-1}{p}} N_i \gamma \prod_{i=m}^{l} \left(\frac{1}{\lambda_i}\right)^{\frac{m-1}{p}} N_i
\]

\[
= (\lambda_m)^{\frac{1}{q}} \sum_{i=1}^{m-1} N_i \gamma \prod_{i=m}^{l} \left(\frac{1}{\lambda_i}\right)^{\frac{m-1}{p}} N_i \gamma \prod_{i=m}^{l} \left(\frac{1}{\lambda_i}\right)^{\frac{m-1}{p}} N_i
\]

by (5.21)

\[
= (\lambda_l)^{\frac{1}{q}} \sum_{i=1}^{m-1} N_i \gamma \prod_{i=m}^{l} \left(\frac{1}{\lambda_i}\right)^{\frac{m-1}{p}} N_i \gamma \prod_{i=m}^{l} \left(\frac{1}{\lambda_i}\right)^{\frac{m-1}{p}} N_i
\]

\[
= \prod_{i=m+1}^{l} \left(\frac{1}{\lambda_i}\right) \left(\frac{1}{\lambda_i}\right)^{\frac{m-1}{p}} N_i \gamma \prod_{i=m}^{l} \left(\frac{1}{\lambda_i}\right)^{\frac{m-1}{p}} N_i
\]

Recall the subset \( V \) defined in (2.6) where \( \alpha_i - N_i \left(\frac{\alpha-1}{\alpha}\right) < 0 \) for every \( i \notin V \).

Notice that \( \lambda_l \leq \lambda_m \) when \( m \leq l \). For \( r \) sufficiently close to 1, we have

\[
(\lambda_l)^{\frac{1}{q}} \sum_{i=1}^{m-1} N_i \gamma (\lambda_i)^{\left(\frac{p+1}{p}\right)} \prod_{i=m}^{l} \left(\frac{1}{\lambda_i}\right)^{\frac{m-1}{p}} N_i \gamma
\]

\[
\leq (\lambda_l)^{\frac{1}{q}} \sum_{i \in V \cap \{1, \ldots, m-1\}} \left(\frac{\alpha-1}{\alpha}\right) N_i \gamma \left(\frac{\alpha-1}{\alpha}\right) N_i \gamma \prod_{i=m}^{l} \left(\frac{1}{\lambda_i}\right)^{\frac{m-1}{p}} N_i \gamma
\]

\[
\times \prod_{i \in V \cap \{m+1, \ldots, l\}} \left(\frac{\alpha-1}{\alpha}\right) N_i \gamma \prod_{i=m}^{l} \left(\frac{1}{\lambda_i}\right)^{\frac{m-1}{p}} N_i \gamma
\]

(5.27)
By bringing the estimates in (5. 26)-(5. 27) back to (5. 20), we find

\[
(\lambda_m)^{\frac{1}{q}} \sum_{i=1}^{n} N_i \gamma_I (\lambda_i) \left( \frac{1}{p} \right) \sum_{i=1}^{n} N_{i-\delta} \prod_{i=1}^{n} \left( \frac{\lambda_i}{\lambda} \right)^{\alpha_i} \prod_{i=1}^{n} \left( \frac{\lambda_m}{\lambda} \right)^{\alpha_{i-\delta}} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{\sum_{i=1}^{n} (\frac{1}{q} - \frac{1}{r}) N_i}
\]

\[
= \prod_{i=1}^{n} \left( \frac{\lambda_i}{\lambda} \right)^{\alpha_i} \prod_{i=1}^{n} \left( \frac{\lambda_m}{\lambda} \right)^{\alpha_{i-\delta}} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{\sum_{i=1}^{n} (\frac{1}{q} - \frac{1}{r}) N_i}
\]

\[
\leq \left( \frac{\lambda_i}{\lambda} \right)^{\sum_{i=1}^{n} (\frac{1}{q} - \frac{1}{r}) N_i - \alpha_i - \delta} \prod_{i=1}^{n} \left( \frac{\lambda_m}{\lambda} \right)^{\alpha_{i-\delta}} \prod_{i=1}^{n} \left( \frac{1}{\lambda_i} \right)^{\sum_{i=1}^{n} (\frac{1}{q} - \frac{1}{r}) N_i - \alpha_i}.
\]

(5. 28)

Recall that \( \gamma > 0 \) satisfies the second strict inequality in (2. 6). From (5. 1) and (1. 6), we also have \( (\frac{1}{p} - \frac{1}{q}) N_i < \alpha_i < N_i \) for every \( i = 1, 2, \ldots, n \). Define \( 0 \leq \delta_1 \leq \delta_2 \leq 1 \) implicitly by letting \( \lambda_m = \lambda_n^{\delta_1} \) and \( \lambda_i = \lambda_i^{\delta_2} \).

For \( r \) sufficiently close to 1, we have

\[
\delta_1 \left[ \frac{N_i}{r} - \alpha_i + \left( 1 - \frac{1}{r} \right) \left( \frac{1}{p} - \frac{1}{q} \right) N_i \right] + \left( 1 - \delta_2 \right) \left( \alpha_n - N_n \left( \frac{1}{p} - \frac{1}{q} \right) \right)
\]

\[
+ (\delta_2 - \delta_1) \left[ \sum_{i=1}^{n} \left( \frac{q-1}{r} \right) N_i - \alpha_i - \left( 1 - \frac{1}{r} \right) \left( \frac{p-1}{r} \right) N_i + \gamma \right] > 0.
\]

(5. 29)

The estimate in (5. 29) implies (5. 28) bounded by a constant multiple of \( \lambda^{\epsilon} \) for some \( \epsilon > 0 \).

Recall from (5. 9). It is clear that \( \lambda_n^{\epsilon} \leq \prod_{i=1}^{n} (\lambda_i)^{\frac{\epsilon}{2}} \). From the above, we observe that \( \epsilon \) depends only on \( p, q, r, \gamma, \delta, \alpha, N \) where \( r > 1 \) depends on the rest of these indices.

Lastly, without assuming (5. 1), it may happened that \( \alpha_n - N_n \left( \frac{1}{p} - \frac{1}{q} \right) = 0 \). In this situation, the left hand side of (5. 13) and (5. 17) vanish at \( \delta = 0 \) and the left hand side of (5. 25) and (5. 29) vanish at \( \delta_1 = \delta_2 = 0 \). Moreover, the right hand side of (5. 19) is possible to equal 1. Consequently, we can only conclude (5. 5) instead.

\[\square\]

6 One-Weight Inequality on Product Spaces

Consider \( \omega(x) = |x|^{-\gamma}, \sigma(x) = |x|^\sigma \) for \( \gamma + \delta = 0 \). The formula in (2. 3) together with (4. 3) imply

\[
\frac{\alpha_i}{N_i} = \frac{1}{p} - \frac{1}{q}, \quad i = 1, 2, \ldots, n.
\]

(6. 1)

In particular, we have \( \omega = \sigma \).
By taking into account that \( \omega = \sigma \) and (6. 1), the Muckenhoupt characteristic in (2. 1) becomes
\[
\left\{ \frac{1}{|Q|} \int_Q \omega^q(x) \, dx \right\} \frac{1}{2} \left\{ \frac{1}{|Q|} \int_Q \left( \frac{1}{\omega} \right)^{\frac{p}{p'}} (x) \, dx \right\}^{\frac{p}{p'}} < \infty \tag{6. 2}
\]
for every \( Q \subset \mathbb{R}^N \).

Let \( (x_i, x_i^+) \in \mathbb{R}^N \times \mathbb{R}^{N-N_i} \) and \( Q_i^+ = \bigotimes_{i \neq j} Q_i \) for every \( i = 1, 2, \ldots, n \). By shrinking \( Q_i^+ \) to \( x_i^+ \) in (6. 2) and applying Lebesgue Differentiation Theorem, we have
\[
\left\{ \frac{1}{|Q_i|} \int_{Q_i} \omega^q(x_i, x_i^+) \, dx_i \right\} \frac{1}{2} \left\{ \frac{1}{|Q_i|} \int_{Q_i} \left( \frac{1}{\omega} \right)^{\frac{p}{p'}} (x_i, x_i^+) \, dx_i \right\}^{\frac{p}{p'}} < \infty \tag{6. 3}
\]
for every \( Q_i \subset \mathbb{R}^N \) and \( a \cdot e \ x_i^+ \in \mathbb{R}^{N-N_i} \).

Notice that (6. 1) and (6. 3) are sufficient conditions of Muckenhoupt-Wheeden Theorem [5], on the subspace \( \mathbb{R}^{N_i} \) for \( i = 1, 2, \ldots, n \), which imply
\[
\left\| \left( f \ast |x_i|^{N-N_i} \right) \omega \right\|_{L^p(\mathbb{R}^{N_i})} \lesssim \left\| f \omega \right\|_{L^p(\mathbb{R}^{N_i})}, \quad 1 < p < q < \infty. \tag{6. 4}
\]
The implied constant in (6. 4) depends only on \( p, q, N_i \) and \( \omega \). We therefore have
\[
\left\{ \int_{\mathbb{R}^N} \left( \omega I_\sigma f \right)^q (x) \, dx \right\}^\frac{1}{q} = \left\{ \int_{\mathbb{R}^N} \left( \int_{\mathbb{R}^N} f(y) \prod_{i=1}^n \left( \frac{1}{|x_i - y_i|} \right)^{N_i-\alpha_i} \, dy \right)^q \omega^q(x) \, dx \right\}^\frac{1}{q}
\]
\[
= \left\{ \int_{\mathbb{R}^N} \left( \int_{\mathbb{R}^{N-N_i}} f(y_i, y_i^+) \prod_{j \neq i} \left( \frac{1}{|x_j - y_j|} \right)^{N_j-\alpha_j} \, dy_i^+ \right)^q \left( \frac{1}{|x_i - y_i|} \right)^{N_i-\alpha_i} \, dy_i \right\}^\frac{1}{q} \omega^q(x) \, dx_i
\]
\[
\leq \left\{ \int_{\mathbb{R}^{N-N_i}} \left( \int_{\mathbb{R}^{N-N_i}} f(x_i, x_i^+) \prod_{j \neq i} \left( \frac{1}{|x_j - y_j|} \right)^{N_j-\alpha_j} \, dy_i^+ \right)^p \omega^p(x_i, x_i^+) \, dx_i \right\}^\frac{1}{2} \left\{ \int_{\mathbb{R}^{N-N_i}} f(x_i, x_i^+) \prod_{j \neq i} \left( \frac{1}{|x_j - y_j|} \right)^{N_j-\alpha_j} \, dy_i^+ \right\}^\frac{1}{2} \omega^q(x_i, x_i^+) \, dx_i
\]
\[
\leq \left\{ \int_{\mathbb{R}^{N-N_i}} \left( \int_{\mathbb{R}^{N-N_i}} f(x_i, x_i^+) \prod_{j \neq i} \left( \frac{1}{|x_j - y_j|} \right)^{N_j-\alpha_j} \, dy_i^+ \right)^q \omega^q(x_i, x_i^+) \, dx_i \right\}^\frac{p}{q} \left\{ \int_{\mathbb{R}^{N-N_i}} f(x_i, x_i^+) \prod_{j \neq i} \left( \frac{1}{|x_j - y_j|} \right)^{N_j-\alpha_j} \, dy_i^+ \right\}^{\frac{p}{q}} \, dx_i
\]
\[
\leq \left\{ \int_{\mathbb{R}^N} \left( f \omega \right)^p (x) \, dx \right\}^\frac{1}{q} \tag{6. 5}
\]
for \( 1 < p < q < \infty \). The implied constants depend on \( p, q, n, N \) and \( \omega \).
7 Proof of Theorem

Recall from (4. 3). We first partition the set \{1, 2, \ldots , n\} = I \cup J by letting

\[ I = \left\{ i \in \{1, 2, \ldots , n\} : \frac{\alpha_i}{N_i} = \frac{1}{p} - \frac{1}{q} \right\}, \quad J = \left\{ i \in \{1, 2, \ldots , n\} : \frac{\alpha_i}{N_i} > \frac{1}{p} - \frac{1}{q} \right\}. \tag{7. 1} \]

Let \( \omega(x) = |x|^{-\gamma}, \sigma(x) = |x|^\delta \) for \( \gamma, \delta \in \mathbb{R} \) satisfying the Muckenhoupt characteristic in (2. 1). From Section 4, we have \( \gamma, \delta \) satisfying the constraints in (2. 2)-(2. 6). The formula in (2. 3) together with (7. 1) give us

\[ \gamma + \delta = \sum_{i=1}^{n} \alpha_i - N_i \left( \frac{1}{p} - \frac{1}{q} \right) = \sum_{i \in I} \alpha_i - N_i \left( \frac{1}{p} - \frac{1}{q} \right) \geq 0. \tag{7. 2} \]

In particular, \( \gamma + \delta = 0 \) when \( J \) is empty. In this case, our theorem is proved in Section 6 as a one-weight inequality. We shall assume that \( J \) is nonempty.

Since \( J \subset \{1, 2, \ldots , n\} \), the constraints in (2. 4)-(2. 6) imply

\[ \alpha_i - \frac{N_i}{p} < \delta, \quad i \in J \quad \text{for} \quad \gamma \geq 0, \delta \leq 0; \tag{7. 3} \]

\[ \alpha_i - N_i \left( \frac{q-1}{q} \right) < \gamma, \quad i \in J \quad \text{for} \quad \gamma \leq 0, \delta \geq 0 \tag{7. 4} \]

and for \( \gamma > 0, \delta > 0, \)

\[ \sum_{i \in U \cap J} \alpha_i - \frac{N_i}{p} < \delta, \quad U \cap J = \left\{ i \in J : \frac{\alpha_i}{N_i} - \frac{1}{p} \geq 0 \right\}, \tag{7. 5} \]

\[ \sum_{i \in V \cap J} \alpha_i - \left( \frac{q-1}{q} \right) N_i < \gamma, \quad V \cap J = \left\{ i \in J : \frac{\alpha_i}{N_i} - \left( \frac{q-1}{q} \right) \geq 0 \right\}. \]

Moreover, (7. 3)-(7. 5) further imply

\[ \sum_{i \in J} \alpha_i - \frac{N_i}{p} < \delta, \quad \sum_{i \in J} \alpha_i - \left( \frac{q-1}{q} \right) N_i < \gamma. \tag{7. 6} \]

By putting together (7. 2) and (7. 6), we find

\[ \gamma < \frac{1}{q} \sum_{i \in J} N_i, \quad \delta < \left( \frac{p-1}{p} \right) \sum_{i \in J} N_i. \tag{7. 7} \]

Let \( \mathbb{R}^{N_i} = \bigotimes_{i \in I} \mathbb{R}^{N_i} \) and \( \mathbb{R}^{N_j} = \bigotimes_{i \in J} \mathbb{R}^{N_i} \). Observe that \( \gamma, \delta \) satisfy all the necessary constraints on the subspace \( \mathbb{R}^{N_j} \).

We write \( x = (x_I, x_J) \in \mathbb{R}^{N_i} \times \mathbb{R}^{N_j} \) and denote the cardinality of \( I \) and \( J \) by \( |I| \) and \( |J| \) respectively. Define the rectangles \( Q_I = \bigotimes_{i \in I} Q_i \subset \bigotimes_{i \in J} \mathbb{R}^{N_i} = \mathbb{R}^{N_i} \) and \( Q_J = \bigotimes_{i \in J} Q_i \subset \bigotimes_{i \in J} \mathbb{R}^{N_i} = \mathbb{R}^{N_j} \). Moreover, \( a_I = \sum_{i \in I} a_i \) and \( a_J = \sum_{i \in J} a_i \).

Note: The provided content appears to be a mathematical proof, focusing on partitioning sets and proving inequalities under specific conditions, with a notation style typical of mathematical literature. The mention of rectangles and their use in the proof suggests a geometric approach to understanding the separation of variables or regions defined by the partition. However, the context and full implications of these mathematical expressions require a deep understanding of the underlying theory, which is beyond the scope of this AI's capabilities to fully elucidate without additional context or the ability to access the full document.
Proposition 7.1 Let $\omega(x_1) = |x_1|^{-\gamma}, \sigma(x_1) = |x_1|^{\delta}$ and $\gamma, \delta$ belong to the ranges given in (5.2)-(5.4) respectively. We have

$$\left\| \left( f * \prod_{i\in J} |x_i|^{{\alpha_i}-N_i} \right) \omega \right\|_{L^q(\mathbb{R}^N)} \leq \left\| f \sigma \right\|_{L^p(\mathbb{R}^N)} \quad (7.8)$$

for $1 < p \leq q < \infty$. The implied constant depends only on $p, q, \gamma, \delta, \alpha, |J|, N_j$.

**Proof:** In the case of $|J| = 1$, Theorem A by Stein and Weiss [3] shows that (7.2) and (7.7) are sufficient conditions to imply the norm inequality in (7.8).

Suppose $|J| \geq 2$. Recall that $\gamma, \delta$ satisfy the constraints in (7.2)-(7.7). From Lemma 5.1, $\omega(x_1) = |x_1|^{-\gamma}, \sigma(x_1) = |x_1|^{\delta}$ satisfy the decaying estimate in (5.6)-(5.7) with $Q$ replaced by $Q_j \subset \mathbb{R}^{N_j}$, whereas (5.1) is satisfied. This implies the summability in (3.14).

Consider $\gamma > 0, \delta > 0$. Assume that $\gamma, \delta$ belong to the ranges given in (5.4). Observe that

$$\omega(x) = |x|^{-\gamma} \leq |x_1|^{-\gamma} = \omega(x_1), \quad \sigma(x_1) = |x_1|^{\delta} \leq |x|^{\delta} = \sigma(x). \quad (7.9)$$

We have

$$\left\{ \int_{\mathbb{R}^N} \left\{ \int_{\mathbb{R}^N} f(y) \prod_{i=1}^n \left( \frac{1}{|x_i - y_i|} \right)^{N_i-\alpha_i} dy \right\}^q dx \right\} \omega^q(x)dx$$

$$\leq \left\{ \int_{\mathbb{R}^N} \left\{ \int_{\mathbb{R}^N} f(y) \prod_{i=1}^n \left( \frac{1}{|x_i - y_i|} \right)^{N_i-\alpha_i} dy \right\}^q dx \right\}^{\frac{1}{q}} \omega^q(x)dx \quad (\gamma > 0)$$

$$= \left\{ \int_{\mathbb{R}^N \times \mathbb{R}^N} \left\{ \int_{\mathbb{R}^N \times \mathbb{R}^N} f(y_L, y_J) \prod_{i\in I \cup J} \left( \frac{1}{|x_i - y_i|} \right)^{N_i-\alpha_i} dy_L dy_J \right\}^q dx_L dx_J \right\}^{\frac{1}{q}} \omega^q(x)dx \quad (7.10)$$

by Proposition 7.1

$$\leq \left\{ \int_{\mathbb{R}^N} \left\{ \int_{\mathbb{R}^N} \int_{\mathbb{R}^N} f(y_L, x_1) \prod_{i\in I} \left( \frac{1}{|x_i - y_i|} \right)^{N_i-\alpha_i} dy_L \right\}^p dx_1 \sigma^p(x_1)dx_1 \right\}^{\frac{1}{p}} \quad \frac{1}{p}$$

by Minkowski integral inequality

$$\leq \left\{ \int_{\mathbb{R}^N \times \mathbb{R}^N} \left( f(x_L, x_1) \right)^p \sigma^p(x_1)dx_L dx_1 \right\}^{\frac{1}{p}} \quad (\delta > 0)$$

for $1 < p \leq q < \infty$.

The implied constants in (7.10) depend only on $p, q, \gamma, \delta, \alpha, n, N$. 

25
On the other hand, since $I_\alpha$ is a self-dual operator, we have
\[
\|\omega I_\alpha f\|_{L^p(\mathbb{R}^N)} \lesssim \|f\|_{L^p(\mathbb{R}^N)} \quad \text{if and only if} \quad \|\sigma^{-1} I_\alpha \sigma\|_{L^{\frac{p}{p-\gamma}}(\mathbb{R}^N)} \lesssim \|g\omega^{-1}\|_{L^{\frac{p}{p-\gamma}}(\mathbb{R}^N)}
\]  
(7.11) 
for $f\sigma \in L^p(\mathbb{R}^N)$ and $g\omega^{-1} \in L^{\frac{p}{p-\gamma}}(\mathbb{R}^N)$. By taking into account that $\omega(x) = |x|^{-\gamma}, \sigma(x) = |x|^\delta$ where $\gamma, \delta$ satisfy the constraints in (2.4) and (2.5) with respect to $\gamma \geq 0, \delta \leq 0$ and $\gamma \leq 0, \delta \geq 0$, it is suffice to estimate one of two cases.

Consider $\gamma \geq 0, \delta \leq 0$. We write $I_\alpha = I_{\alpha, \chi_{|x| \leq |y|}} + I_{\alpha, \chi_{|x| > |y|}}$ where $\chi$ is the characteristic function. The operator $I_{\alpha, \chi_{|x| \leq |y|}}$ can be treated as in (7.10), by first replacing $\omega(x)$ with $\omega(x)$ since $\omega(x) \leq \omega(x)$ for $\gamma \geq 0$. Assume that $\gamma, \delta$ belong to the ranges given in (5.2). We have
\[
\left\{ \int_{\mathbb{R}^N} \left( \int_{\mathbb{R}^N} (f\chi_{|y| \leq |y|})(y) \prod_{j=1}^n \left( \frac{1}{|x_j - y_j|} \right)^{N_i - \alpha_i} dy \right)^q \right\}^{\frac{1}{q}} \lesssim \left\{ \int_{\mathbb{R}^N} (f\sigma \chi_{|x| > |y|}) \sigma^p(x) dx \right\}^{\frac{1}{p}}
\]  
(7.10)
by following the estimates in (7.10)
\[
\lesssim \left\{ \int_{\mathbb{R}^N} (f\sigma \chi_{|x| > |y|}) \sigma^p(x) dx \right\}^{\frac{1}{p}} \quad (\sigma(x) \approx \sigma(x) \text{ in the region of } |x| \leq |y|)
\]  
(7.12)
for $1 < p \leq q < \infty$. The implied constants depend only on $p, q, \gamma, \delta, \alpha, n, N$.

In order to estimate $I_{\alpha, \chi_{|x| > |y|}}$, we define a pair of new functions
\[
\rho(x) = |x|^{-(\gamma + \delta)}, \quad \eta(x) \equiv 1.
\]  
(7.13)

**Proposition 7.2** Let $\gamma + \delta$ belonging to the ranges given in (5.2). We have
\[
\left\| (f * \prod_{i \in J} |x_i|^{-\alpha_i - N_i}) \rho \right\|_{L^p(\mathbb{R}^N)} \lesssim \|f\|_{L^p(\mathbb{R}^N)}
\]  
(7.14)
for $1 < p \leq q < \infty$. The implied constant depends only on $p, q, \gamma, \delta, \alpha_J, |J|, N_J$.

**Proof:** From (7.2)-(7.3), we have
\[
\gamma + \delta = \sum_{i \in J} \alpha_i - N_i \left( \frac{1}{p} - \frac{1}{q} \right) < \frac{N_J}{q} \quad \text{and} \quad \frac{N_i}{p} < \delta \leq 0, \quad i \in J.
\]  
(7.15)
Observe that the constraints in (7.2)-(7.3) and (7.7) are still satisfied with $\gamma, \delta$ replaced by $\gamma + \delta, 0$ respectively.

In the case of $|J| = 1$, we directly apply Theorem A by Stein and Weiss [3], as in the proof of Proposition 7.1.

Suppose $|J| \geq 2$. Lemma 5.1 shows that $\rho(x_j) = |x_j|^{-(\gamma + \delta)}$, $\eta(x_j) \equiv 1$ satisfy the decaying estimate in (5.6)-(5.7) with $Q$ replaced by $Q_j \subset \mathbb{R}^N$ whereas (5.1) is satisfied. This implies the summability in (3.14).  
\[\square\]
Proposition 7.3 Let \( \omega(x_1) = \sigma(x_1) = |x_1|^\delta \) for \( -\delta \) belonging to the ranges given in (5. 2). We have
\[
\left\| \left( f * \prod_{i \in I} |x_i|^{\omega_i-N_i} \right) \right\|_{L^p(\mathbb{R}^N)} \lesssim \| f \omega \|_{L^p(\mathbb{R}^N)}
\] (7. 16)
for \( 1 < p < q < \infty \). The implied constant depends only on \( p, q, \delta, |I|, N_i \).

**Proof:** Recall from (2. 4). Together with (7. 1), we have
\[
-\delta + \delta = \sum_{i \in I} \alpha_i - N_i \left( \frac{1}{p} - \frac{1}{q} \right) \quad \text{and} \quad -\delta < \frac{N_i}{p} - \alpha = \frac{N_i}{q} \leq \frac{N_i}{q}, \quad i \in I. \quad (7. 17)
\]
Observe that the constraints in (2. 2)-(2. 4) are satisfied with \( \gamma = -\delta \) and \( \alpha, n, N \) replaced by \( \alpha_i, |I|, N_i \) respectively. From Lemma 5.1, \( \omega(x_1) = \sigma(x_1) = |x_1|^\delta \) satisfy the \( r \)-bump Muckenhoupt characteristic in (5. 5) with \( Q \) replaced by \( Q_1 \subset \mathbb{R}^N \) whereas \( \alpha_i - N_i \left( \frac{1}{p} - \frac{1}{q} \right) = 0 \) for every \( i \in I \).

We obtain the norm inequality in (7. 16) by following the argument in Section 6. \( \square \)

Recall that \( \rho(x_1) = |x_1|^{-(\gamma + \delta)} \) and \( \sigma(x_1) = |x_1|^\delta \) where \( \gamma + \delta \geq 0 \) and \( \delta \leq 0 \). It is clear that
\[
\omega(x) = |x|^{-\gamma} \leq \rho(x_1) \sigma(x_1). \quad (7. 18)
\]
Assume that \( \gamma + \delta \) and \( -\delta \) belong to the ranges given in (5. 2). We have
\[
\left\{ \int_{\mathbb{R}^N} \left( \int_{\mathbb{R}^N} \left( f \chi_{|y|>|y_j|} \right)^n \prod_{i=1}^n \left( \frac{1}{|x_i - y_i|} \right)^{N_i-\alpha_i} \right)^{q} \omega^q(x) dx \right\}^{\frac{1}{q}} \leq \left\{ \int_{\mathbb{R}^N} \left( \int_{\mathbb{R}^N} \left( f \chi_{|y|>|y_j|} \right)^n \prod_{i=1}^n \left( \frac{1}{|x_i - y_i|} \right)^{N_i-\alpha_i} \right)^{q} \rho^q(x_1) \sigma^q(x_1) dx_1 \right\}^{\frac{1}{q}} \quad \text{by (7. 18)}
\]
\[
= \left\{ \int_{\mathbb{R}^N} \left\{ \int_{\mathbb{R}^N} \left( f \chi_{|y|>|y_j|} \right)^n \prod_{i=1}^n \left( \frac{1}{|x_i - y_i|} \right)^{N_i-\alpha_i} \right)^{q} \int_{\mathbb{R}^N} \left( \frac{1}{|x_i - y_i|} \right)^{N_i-\alpha_i} \right)^{q} \rho^q(x_1) \sigma^q(x_1) dx_1 \right\}^{\frac{1}{q}} \quad \text{by Proposition 7.2}
\]
\[
\leq \left\{ \int_{\mathbb{R}^N} \left\{ \int_{\mathbb{R}^N} \left( f \chi_{|y|>|y_j|} \right)^n \prod_{i=1}^n \left( \frac{1}{|x_i - y_i|} \right)^{N_i-\alpha_i} \right)^{q} \int_{\mathbb{R}^N} \left( \frac{1}{|x_i - y_i|} \right)^{N_i-\alpha_i} \right)^{q} \sigma^q(x_1) dx_1 \right\}^{\frac{1}{q}} \quad \text{by Minkowski integral inequality}
\]
\[
\leq \left\{ \int_{\mathbb{R}^N} \left\{ \int_{\mathbb{R}^N} \left( f \chi_{|y|>|y_j|} \right)^n \prod_{i=1}^n \left( \frac{1}{|x_i - y_i|} \right)^{N_i-\alpha_i} \right)^{q} \sigma^q(x_1) dx_1 \right\}^{\frac{1}{q}} \quad \text{by Proposition 7.3}
\]
\[
\leq \left\{ \int_{\mathbb{R}^N} \left( f \sigma \right)^p(x) dx \right\}^{\frac{1}{p}} \quad \text{(\( \sigma(x_1) = \sigma(x) \) for \( \|x_1| > |x_j| \))} \quad \text{for} \quad 1 < p \leq q < \infty. \quad (7. 19)
\]
The implied constants in (7. 19) depend only on $p, q, \gamma, \delta, \alpha, n, N$.

We finish the proof by considering those endpoints of the ranges given in (5. 2) and (5. 4). Suppose that at least one of $\gamma + \delta, -\delta$ satisfies

$$
\gamma + \delta = \frac{1}{q} \sum_{i=1}^{u} N_i, \quad -\delta = \frac{1}{q} \sum_{i=1}^{v} N_i, \quad 1 \leq u, v \leq n - 1 \quad (7. 20)
$$
or at least one of $\gamma, \delta$ satisfies

$$
\gamma = \frac{1}{q} \sum_{i=1}^{m} N_i, \quad \delta = \left(\frac{p - 1}{p}\right) \sum_{i=1}^{l} N_i, \quad 1 \leq m, l \leq n - 1. \quad (7. 21)
$$

Notice that $m > 0, l > 0$ in (7. 21) since $\gamma > 0, \delta > 0$. The cases $u = 0$ when $\gamma + \delta = 0$ and $v = 0$ when $-\delta = 0$ excluded from (7. 20) both refer to the one-weight inequality of which $\omega = \sigma \equiv 1$.

Let $\varepsilon > 0$ such that $1/p_i = 1/p \pm \varepsilon$ and $1/q_i = 1/q \pm \varepsilon$ for $i = 1, 2$. By choosing $\varepsilon$ sufficiently small, all constraints in (2. 2)-(2. 6) remain to be satisfied by replacing $p, q$ with $p_i, q_i, i = 1, 2$. On the other hand, the powers $\gamma + \delta, -\delta$ and $\gamma, \delta$ belong to the ranges given in (5. 2) and (5. 4) respectively, with $p, q$ replaced by $p_i, q_i, i = 1, 2$. We therefore have the norm inequality hold in (2. 7) simultaneously for $1 < p_i \leq q_i < \infty, i = 1, 2$. By applying Stein interpolation theorem of changing measures, stated as Theorem 2 in [4], we obtain our desired result.
