Abstract

This work deals with extremal properties of spectral measures corresponding to selfadjoint extensions of a regular symmetric operator with deficiency indices (1,1). We propose a generalization of the moment problem which in particular allows us to study point mass perturbations of extremal spectral measures. The results permit to obtain characterizations of spectral measures of differential operators similar to what is done for solutions of the classical moment problem.

1. Introduction

This work treats the spectral measures associated with selfadjoint extensions (including selfadjoint extensions in a larger space) of a given symmetric nonselfadjoint operator. These measures are defined via the spectral family of projectors given by the spectral theorem. There are other ways of defining measures related to selfadjoint operators; for instance, in the context of Sturm-Liouville theory, one can define spectral measures from the Weyl $m$-function. For dealing in a unified way with all these spectral measures, we use Krein’s theory on symmetric operators with deficiency indices $(1,1)$ in a general framework and obtain results on the structural properties of the set of spectral measures associated with a regular symmetric operator (see Section 3). In [15–17], results related to the classical moment problem or, in the language of operators, to Jacobi operators were extended to entire operators. In Section 4, with the help of the theory of generalized extensions due to Naimark [25] and Krein’s representation theory of symmetric operators [11], we obtain a characterization of spectral measures for operators in a class substantially wider than the class of entire operators (Theorem 4.4). This characterization allows us to single out the extremal measures and establish their properties (Theorem 4.6). The theory in [25] has been used before in constructing solutions of the moment problem with the measure having certain predefined properties [5,35].

The connection with the moment problem exhibited in Section 4 leads to the necessity of generalizing this classical problem in analysis. There are various ways of generalizing the moment problem, but we use an idea that goes back to Livshitz [22]. According to this idea, the moment problem consists in finding a measure $\rho$ such that the inner product in a Hilbert space of functions is expressed through the inner product in $L_2(\mathbb{R},\rho)$. Our setting is similar to the one of [22], but with some elements of a related proposal for generalizing the moment problem found in the introduction of [34]. The crux of the matter in our approach is the use of a particular class of spaces of analytic functions, namely de Branges spaces [7] (see Definition 5.7). Although, this choice may look restrictive, we show that the setting is not only general but de Branges spaces fit in the theory smoothly.

For dealing with our generalized moment problem, we use techniques from the theory of de Branges spaces and the results of Section 4. We connect de Branges spaces with regular symmetric operators by means of the functional model used in [29,30]. These developments are the subject of Section 5. The results of this section (Theorems 5.8, 5.10, 5.12, and 5.14) permit the use of techniques specific to the classical moment problem for studying symmetric operators and its selfadjoint extensions relevant in various applications.

Our findings on the extremality of spectral measures and solutions of the generalized moment problem allow us to treat point mass perturbations of spec-
tral measures. The motivation stems from the following phenomenon that arises
in the framework of the classical moment problem: If \( \mu \) is an indeterminate \( N \)-
exremal measure, then adding a point mass to \( \mu \), \( \text{i.e.} \)
\[
\tilde{\mu} = \mu + a\delta_x, \quad x \notin \text{supp}(\mu),
\]
yields an indeterminate non-\( N \)-extremal measure (see (5.5) for the definition
of \( \delta_x \) and [8, Prop. 4.1] for the phenomenon itself). According to the moment
problem theory, the polynomials were dense in \( L_2(\mathbb{R}, \mu) \), but are not dense in
\( L_2(\mathbb{R}, \tilde{\mu}) \). In the context of spectral measures of Jacobi operators, one has that \( \mu \)
is the spectral measure of a canonical selfadjoint extension of a Jacobi operator
while there is no canonical selfadjoint extension of any Jacobi operator having
\( \tilde{\mu} \) as its spectral measure.

For one-dimensional regular Schrödinger operators a similar phenomenon
occurs. If one perturbs the spectral measure adding one point mass, then the
resulting measure is no longer the spectral function of any selfadjoint ex-
tension associated with a regular Schrödinger differential expression. For regular
Schrödinger operators, this can be proven from the formula that describes the
distribution of eigenvalues (see [26]). A different proof is obtained by realizing
that de Branges spaces associated with the Schrödinger operators are all set-wise
equal independently of the potential function [28, Thm. 4.1] (see Remark 6.5).

On the basis of our results on extremal measures and extremal solutions
of the generalized moment problem, we prove a general perturbation result for
spectral measures when adding a mass at a single point (Theorem 6.3). We also
show that if \( \rho \) is a extremal solution of the generalized moment problem, then
certain sets of functions which are dense in \( L_2(\mathbb{R}, \rho) \) are no longer dense under
point mass perturbations of \( \rho \) (Corollary 6.7). These results may have several
applications to the inverse spectral analysis of operators as is shown in [8] for
Jacobi operators. The relation to [10] is touched upon in Remark 6.6.

Section 7 illustrates some of the obtained results in two examples: Jacobi
and regular Schrödinger operators. While the first example is used to put our
results in the context of the classical moment problem, the second one reflects
how moment problem techniques provide new implications to the spectral theory
of differential operators.

2. Generalized resolvents

In this section, Naimark’s theory of selfadjoint extensions to a larger space
[24,25] (see a general exposition of the theory in [2, Appendix 1] and [34]) is
used together with [17] and [11, Chap. 1 Sec. 2].

Let \( \mathcal{H} \) be a separable Hilbert space. The inner product in it is denoted by
\langle \cdot, \cdot \rangle$ where we agree that the left-hand-side argument is anti-linear. We denote by $\oplus$, $\ominus$, and $\odot$ the orthogonal sum, the orthogonal complement, and the direct sum, respectively (see [4, Chap. 2 Secs. 3.2, 3.3 and Chap. 3 Sec. 1.3]).

Let $A$ be a not necessarily densely defined linear closed symmetric operator. If $A$ is not densely defined, then $A^*$ is a multivalued linear operator (linear relation). In this case, the symmetry condition, $A \subset A^*$, remains valid (as subspaces of $\mathcal{H} \oplus \mathcal{H}$). The deficiency indices $n_+(A)$ and $n_-(A)$ of $A$ are defined as the the codimension of $\text{ran}(A - zI)$, i.e. the dimension of $\mathcal{H} \ominus \text{ran}(A - zI)$, when $z \in \mathbb{C}_+ := \{ z \in \mathbb{C} : \text{Im} z > 0 \}$ and $z \in \mathbb{C}_- := \{ z \in \mathbb{C} : \text{Im} z < 0 \}$, respectively. If $A$ has equal deficiency indices, then it has canonical selfadjoint extensions, with some of these extensions being proper linear relations if $\text{dom}(A)$ is not dense in $\mathcal{H}$ [12, Prop. 5.4]. By canonical we mean the selfadjoint extensions that are restrictions of $A^*$.

**Definition 2.1.** Consider a closed symmetric operator $A$. Let $A^+$ be a selfadjoint extension of $A$ in a Hilbert space $\mathcal{H}^+ \supset \mathcal{H}$ ($\mathcal{H}^+ = \mathcal{H}$ is allowed). For $w \in \mathbb{C}$ and $z \in \mathbb{C} \setminus \text{spec}(A^+)$, define

$$V_{A^+}(w, z) := (A^+ - wI)(A^+ - zI)^{-1} = I + (z - w)R^+(z),$$

(2.1)

where $R^+$ is the resolvent of $A^+$ (cf. [11, Ch. 1, Sec. 2.1]).

Note that this operator is the generalized Cayley transform of $A^+$. Unlike the (regular) Cayley transform of a selfadjoint operator, $V_{A^+}(w, z)$ is not always unitary. This operator, however, has various relevant properties. Indeed, directly from the first resolvent identity [4, Eq. 12, Sec. 7, Ch. 3] (which also holds when $A^+$ is a relation), one verifies that for any $v, w, z \in \mathbb{C} \setminus \text{spec}(A^+)$

$$V_{A^+}(w, z) = V_{A^+}(z, w)^{-1}, \quad V_{A^+}(w, z)V_{A^+}(z, v) = V_{A^+}(w, v).$$

(2.2)

Also, it is straightforward to establish that

$$V_{A^+}(w, z)^* = V_{A^+}(\overline{w}, \overline{z}).$$

(2.3)

By means of the first identity in (2.2), and (2.3), the following simple assertion is proven in [11, Ch. 1, Sec. 2.1].

**Proposition 2.2.** Let $z \in \mathbb{C}$ and $w \in \mathbb{C}_+$. For any selfadjoint extension $A^+$ of $A$ such that $z \not\in \text{spec}(A^+)$, the operator $V_{A^+}(w, z)$ maps $\mathcal{H}^+ \ominus \text{ran}(A - \overline{w}I)$ injectively onto $\mathcal{H}^+ \ominus \text{ran}(A - \overline{z}I)$.

**Definition 2.3.** A function with domain of analyticity containing $\mathbb{C}_+$ is a Herglotz function when

$$\text{Im} z > 0 \Rightarrow \text{Im} f(z) \geq 0 .$$
Note that we have defined the class of Herglotz functions in such a way that it includes the real constants. Denote by $\mathfrak{R}$ the union of class of Herglotz functions and the constant $\infty$.

**Definition 2.4.** Consider the notation introduced in Definition 2.1. Denote by $P^+$ the orthogonal projector of $\mathcal{H}^+$ onto $\mathcal{H}$ and by $R^+(z)$ the resolvent of $A^+$. The operator

$$R(z) := P^+ R^+(z) \mid_{\mathcal{H}}$$

for any $z \in \mathbb{C} \setminus \mathbb{R}$ is a generalized resolvent of $A$ [25] (see also [2, Appendix 1] and [34, § 3]).

In the case $n_+(A) = n_-(A)$, the resolvent of a canonical selfadjoint extension of $A$ is a particular case of a generalized resolvent.

Fix a canonical selfadjoint extension of the closed symmetric operator $A$ with deficiency indices $n_+(A) = n_-(A) = 1$ and denote it by $A_\infty$. For $w \in \mathbb{C}_+$ and $z \in \mathbb{C} \setminus \text{spec}(A_\infty)$, define

$$\psi(z) := V_{A_\infty}(w, z) \psi,$$

where $\psi \in \ker(A^* - wI)$ (cf. [2, Appendix 1, Sec. 4, Eq. 2']).

Let $R_\infty$ be resolvent of $A_\infty$. Define the operator-valued function

$$R_\tau(z) := R_\infty(z) - \frac{\langle \psi(z), \cdot \rangle}{\tau(z) + Q(z)} \psi(z),$$

where

$$Q(z) = i \text{Im} w + (z - w) \langle \psi(z), \psi(w) \rangle$$

and $\tau$ is a Herglotz function (cf. [2, Appendix 1, Eq. 8]). It is known that if $\tau(z) \equiv c$ with $c \in \mathbb{R} \cup \{\infty\}$, then $R_\tau$ is the resolvent of a canonical selfadjoint extension of $A$. If $\tau$ is a nonconstant Herglotz function, then $R_\tau$ is a generalized resolvent of $A$ which does not correspond to a canonical selfadjoint extension. Moreover, once the selfadjoint extension $A_\infty$ is fixed, there is a bijection between $\mathfrak{R}$ and the set of all generalized resolvents of $A$ given by (2.5) [14, 25, 33] [9, Thm. 6.2] [18, 19]. Equation (2.5) with $\tau \in \mathfrak{R}$ is called the Krein-Naimark formula.

**Definition 2.5.** Let $E_{A^+}$ denote the spectral family of $A^+$ given by the spectral theorem. For any real Borel set $\partial$, define

$$\sigma(\partial) := \langle \phi, E_{A^+}(\partial) \phi \rangle_{\mathcal{H}^+}.$$

We refer to $\sigma$ as to the spectral measure of $A^+$ associated with $\phi$. 

4
For $z \in \mathbb{C} \setminus \mathbb{R}$, one has
\[
\langle \phi, R(z)\phi \rangle_H = \langle \phi, R^+(z)\phi \rangle_{H^+} = \int_{\mathbb{R}} \frac{d\sigma(t)}{t-z}, \tag{2.6}
\]
where $R$ is given by Definition 2.4.

**Definition 2.6.** For any Borel set $\partial \subset \mathbb{R}$, we define
\[
F(\partial) := P^+E_A^+(\partial) \upharpoonright H
\]
and call it a *generalized spectral family* of the symmetric operator $A$. Also
\[
\nu(\partial) := \langle \phi, F(\partial)\phi \rangle_H.
\]
is the *generalized spectral measure* of $A$ associated with $\phi$.

Note that
\[
\sigma(\partial) = \langle \phi, F(\partial)\phi \rangle_H. \tag{2.7}
\]
Moreover, it follows from Definition 2.6 that $F = F^* \in \mathcal{B}(\mathcal{H})$. On the basis of [2, Appendix I, Thm. 2], the following result is proven:

**Proposition 2.7.** $F$ is a generalized spectral family of $A$ if and only if the operator-valued function $F(t) := F(-\infty,t)$ ($t \in \mathbb{R}$) satisfies, for any $h \in H$, the following conditions:

(i) The function $\langle h, F(t)h \rangle$ does not decrease when $t$ increases.

(ii) $F(t)h$ is left continuous.

(iii) $F(t)h \xrightarrow{t\to-\infty} 0$ and $F(t)h \xrightarrow{t\to\infty} h$.

(iv) If $f \in \text{dom}(A)$, then
\[
\|Af\|^2 = \int_{\mathbb{R}} t^2 d\langle f, F(t)f \rangle \quad \text{and} \quad Af = \int_{\mathbb{R}} t dF(t)f.
\]

The results referred above lead to the following assertion (cf. [2, Appendix 1, pp. 141–143])

**Proposition 2.8.** There is a bijection between $\Re$ and the set of all generalized resolutions of the identity of any symmetric operator with deficiency indices $n_+(A) = n_-(A) = 1$. The bijection is given by the combination of (2.5) and (2.6). Moreover, this same bijection gives a one-to-one map between $\Re \cup \infty$ and the resolutions of the identity corresponding to selfadjoint extensions of $A$. 

5
3. Regular symmetric operators and gauges

**Definition 3.1.** A closed symmetric nonselfadjoint operator is said to be completely nonselfadjoint if it is not a nontrivial orthogonal sum of a symmetric and a selfadjoint operators.

**Definition 3.2.** The complex number \( z \) is in \( \hat{\rho}(T) \) (the set of points of regular type of a closed operator \( T \)) when there exists \( c_z > 0 \) such that

\[
\|(T - zI)\phi\| \geq c_z \|\phi\| \quad \text{for all } \phi \in \text{dom}(T).
\]

The complement of \( \hat{\rho}(T) \) in \( \mathbb{C} \) is \( \text{spec}(T) \) and it is called the spectral kernel.

Observe that if \( T = T^* \), then \( \hat{\rho}(T) \) is the resolvent set of \( T \).

**Definition 3.3.** A closed operator \( T \) is regular when \( \hat{\rho}(T) = \mathbb{C} \).

In other words, \( T \) is regular when every point of the complex plane is a point of regular type.

A regular, closed symmetric operator is necessarily completely nonselfadjoint since regularity implies that the spectral kernel is empty and, therefore, the operator cannot have selfadjoint parts. On the other hand, there are completely nonselfadjoint operators that are not regular [31, Sec. 2].

**Definition 3.4.** Let \( S(\mathcal{H}) \) denote the set of regular, closed symmetric operators in \( \mathcal{H} \) with deficiency indices \( n_+(A) = n_-(A) = 1 \).

The next assertion is well known for densely defined symmetric operators. The proof for the general case can be found in [30, Prop. 2.4].

**Proposition 3.5.** Let \( A \) be in \( S(\mathcal{H}) \). The following assertions are true:

(i) The spectrum of every canonical selfadjoint extension of \( A \) consists solely of isolated eigenvalues of multiplicity one.

(ii) Every real number is part of the spectrum of one, and only one, canonical selfadjoint extension of \( A \).

(iii) The spectra of the canonical selfadjoint extensions of \( A \) are pairwise interlaced.

Note that (i) above means that every selfadjoint extension of \( A \) is a simple operator [2, Sec. 69]. The last item of the previous assertion, together with the fact that under extensions the spectral kernel does not decrease, implies that regularity of \( A \) is equivalent to the fact that the spectra of any two selfadjoint extensions of \( A \) do not intersect.
For any \( A \in S(\mathcal{H}) \), let \( \mu \in \mathcal{H} \) be such that
\[
\mathcal{H} = \text{ran}(A - z_0I) + \text{span}\{\mu\},
\]
for some \( z_0 \in \mathbb{C} \). For this vector \( \mu \), consider the set
\[
\{ z \in \mathbb{C} : \mu \in \text{ran}(A - zI) \}.
\]
This is the set for which (3.1) fails to hold. The following result is proven in [29, Thm. 2.2]. It was first formulated by Krein without proof in [17, Thm. 8].

**Proposition 3.6.** For every \( A \in S(\mathcal{H}) \), there exists \( \mu \) satisfying (3.1) such that (3.2) does not intersect the real line.

**Definition 3.7.** We call the vector \( \mu \), whose existence is established in Proposition 3.6, a gauge of \( A \in S(\mathcal{H}) \).

Take notice that our definition of gauge differs from the one in [11] and [16].

**Lemma 3.8.** A gauge of \( A \in S(\mathcal{H}) \) is a generating vector (as defined in [2, Sec. 69]) for any canonical selfadjoint extension of \( A \).

**Proof.** Let \( A_\gamma \) be any canonical selfadjoint extension of \( A \) and \( \mu \) a gauge of \( A \). Since \( \mu \) is not in \( \text{ran}(A - xI) \) for any \( x \in \mathbb{R} \), \( \mu \) has a nonzero projection onto the one-dimensional space \( \ker(A^* - xI) \). In view of the fact that \( \ker(A_\gamma - xI) \) is contained in \( \ker(A^* - xI) \), it follows that \( \mu \) has a nonzero projection onto every eigenspace of \( A_\gamma \).

Thus, if \( A_\gamma \) is a canonical selfadjoint extension of \( A \in S(\mathcal{H}) \), then the spectral measure of \( A_\gamma \) associated with a gauge of \( A \) (see Definition 2.5) encodes all information on \( A_\gamma \).

The following assertion is stated in [17, Thm. 1] and proven in [11, Thm. 1.2.5].

**Proposition 3.9.** Let \( \mu \) be a gauge of \( A \in S(\mathcal{H}) \) and \( a, b \in \mathbb{R} \) such that \( a < b \). If \( F \) is a generalized spectral family of \( A \), then
\[
F([a,b])\phi = \int_a^b \frac{\langle \psi(t), \phi \rangle}{\langle \psi(t), \mu \rangle} dF(t)\mu
\]
for any \( \phi \in \mathcal{H} \) and \( \psi \) given in (2.4).

4. Extremality of measures

**Definition 4.1.** Let \( A \) be in \( S(\mathcal{H}) \) and \( \mu \) be a gauge of \( A \). Denote by \( \mathcal{V}_\mu(A) \) the set of all measures given by (2.7) with \( \phi = \mu \) and \( F \) being a generalized
spectral family of $A$. Inside $\mathcal{V}_\mu(A)$, we single out the set of extremal measures $\mathcal{V}_\mu^{\text{ext}}(A)$ which corresponds to measures given by (2.7) with $\phi = \mu$ when $F$ is the spectral family of a canonical selfadjoint extension of $A$.

In the context of this definition, Proposition 2.8 implies the following.

**Corollary 4.2.** For any given gauge $\mu$ of $A \in \mathcal{S}(\mathcal{H})$, there is a bijection between $\mathfrak{R}$ and $\mathcal{V}_\mu(A)$. Moreover, this bijection gives a one-to-one mapping between $\mathbb{R} \cup \{\infty\}$ and $\mathcal{V}_\mu^{\text{ext}}(A)$.

The bijection referred above depends on the choice of $A_\infty$ (see Section 2), but regardless of this choice, all measures arising from spectral families corresponding to canonical selfadjoint extensions of $A$ are obtained when $\tau$ runs through $\mathbb{R} \cup \{\infty\}$. Note that, as a consequence of Proposition 3.5, one has:

**Corollary 4.3.** Let $\mu$ be a gauge of $A \in \mathcal{S}(\mathcal{H})$. All measures in $\mathcal{V}_\mu^{\text{ext}}(A)$ are discrete and their supports are pairwise disjoint. For any $x \in \mathbb{R}$, there is a measure $\sigma \in \mathcal{V}_\mu^{\text{ext}}(A)$ such that $\sigma\{x\} > 0$.

The next assertion can be found in [11, Ch. 2, Sec. 7.1] and the first part of it in [2, Appendix I, Sec. 4] (cf. [16, Thm. 6] and [15]).

**Theorem 4.4.** Consider $A \in \mathcal{S}(\mathcal{H})$. Given $\tau \in \mathfrak{R}$, let $R_\tau(z)$ be a generalized resolvent as in (2.5). If $\mu$ is a gauge for $A$, then

$$\langle \mu, R_\tau(z)\mu \rangle = -\frac{\tau(z)A(z) - C(z)}{\tau(z)B(z) - D(z)},$$

where $A(z), B(z), C(z), D(z)$ are meromorphic functions on $\mathbb{C}$, analytic on $\mathbb{R}$.

**Proof.** Reasoning as in [11, Ch. 42, Sec. 7.1], one obtains the stated formula by inserting (2.5) into $\langle \mu, R_\tau(z)\mu \rangle$ and considering the functions:

$$A(z) := -\frac{\langle \mu, R_\infty(z)\mu \rangle}{\langle \psi(\overline{z}), \mu \rangle},$$

$$B(z) := \frac{1}{\langle \psi(\overline{z}), \mu \rangle},$$

$$C(z) := -Q(z)A(z) - \langle \mu, \psi(z) \rangle,$$

$$D(z) := -Q(z)B(z),$$

where $\psi$ is given in (2.4). One verifies from their definition that $A(z), B(z), D(z)$ can be analytically extended to any point $z$ outside the set given in (3.2). The function $C(z)$ has a priori poles in $\text{spec}(A_\infty)$, but by an argument along the lines of [11, Ch. 2 Secs. 7.3 and 7.4], one concludes that $C(z)$ can be analytically extended to any point $z$ outside the set given in (3.2).
Remark 4.5. For Jacobi operators, the functions $A(z), B(z), C(z), D(z)$ coincide with the ones given in [1, Eq. 2.28] and [32, Thm. 4.9]. Note that [32, Eq. 4.36] is actually an expression for the function $\langle \mu, R_{-1/\tau}(z)\mu \rangle$ and $-1/\tau$ is also a Herglotz function.

The next theorem is proven by repeating the proof of [32, Thm. 4.17]. Note that, by Theorem 4.4, the functions $A(z), B(z), C(z), D(z)$ have the same analytic properties on the real axis as the corresponding functions in [32, Thm. 4.17].

**Theorem 4.6.** Let $\mu$ be a gauge of $A \in S(\mathcal{H})$ and $\lambda$ a real number. If $\sigma \in \mathcal{V}_\mu(A) \setminus \mathcal{V}_\mu^{\text{ext}}(A)$ is such that $\sigma\{\lambda\} > 0$, then there exists $\bar{\sigma} \in \mathcal{V}_\mu^{\text{ext}}(A)$ such that $\bar{\sigma}\{\lambda\} > \sigma\{\lambda\}$.

5. A generalization of the moment problem

**Definition 5.1.** A Hilbert space of entire functions $\mathcal{B}$ is a dB space if and only if, for any function $f(z)$ in $\mathcal{B}$, the following conditions holds:

(A1) For all $w \in \mathbb{C}$, the linear functional $f(\cdot) \mapsto f(w)$ is continuous;

(A2) for every non-real zero $w$ of $f(z)$, the function $f(z)(z-w)(z-w)^{-1}$ belongs to $\mathcal{B}$ and has the same norm as $f(z)$;

(A3) the function $f^\#(z) := \overline{f(z)}$ also belongs to $\mathcal{B}$ and has the same norm as $f(z)$.

Alternatively, a dB space can be defined in terms of a Hermite-Biehler function, that is, an entire function $e(z)$ such that $|e(z)| > |e(\overline{z})|$ for all $z \in \mathbb{C}^+$. In that case, the dB space is sometimes denoted $\mathcal{B}(e)$ and one has

$$\langle f, g \rangle_{\mathcal{B}} = \int_{\mathbb{R}} \frac{f(x)g(x)}{|e(x)|^2} dx. \quad (5.1)$$

(cf. [7, Sec. 19], [28, Thm. 2.2], [31]). We note that a given dB space can be obtained by many Hermite-Biehler functions (in fact, an infinite number of them); see [6, Thm. 1]. In this work, we consider dB spaces generated by Hermite-Biehler functions $e(z)$ having the additional property

$$e(x) \neq 0 \quad \forall x \in \mathbb{R}. \quad (5.2)$$

**Definition 5.2.** Given a dB space $\mathcal{B}$, the operator $S$ of multiplication by the independent variable is defined by

$$\text{dom}(S) = \{ f(z) \in \mathcal{B} : zf(z) \in \mathcal{B} \}; \quad (Sf)(z) = zf(z), \quad f(z) \in \text{dom}(S).$$
It is noteworthy that the operator $S$ is in $S(\mathcal{B})$ as long as $e(z)$ satisfies (5.2) (cf. [13, Prop. 4.2, Cor. 4.7]). On the other hand, to any operator $A$ in the class $S(\mathcal{H})$, there corresponds a dB space such that the operator of multiplication in it is unitarily equivalent to $A$. To elucidate this, we introduced below the so-called functional model for operators in $S(\mathcal{H})$.

An involution (conjugation) $J$ is an antilinear map satisfying

$$J^2 = I \quad \text{and} \quad \langle J\phi, J\psi \rangle = \langle \psi, \phi \rangle$$

for all $\phi, \psi \in \mathcal{H}$ [37, Eq. 8.1]. Fix an operator $A \in S(\mathcal{H})$ and let $J$ be an involution that commutes with the selfadjoint extensions of $A$ (there is always such involution because of [30, Prop. 2.3]). Consider a function $\xi_A : \mathbb{C} \to \mathcal{H}$ such that

(P1) $\xi_A(z)$ is zero-free, i.e. $\xi_A(z) \neq 0$ for all $z \in \mathbb{C}$, and entire,

(P2) $\xi_A(z) \in \ker(A^* - zI)$ for all $z \in \mathbb{C}$, and

(P3) $J\xi_A(z) = \xi_A(\overline{z})$ for every $z \in \mathbb{C}$.

Since $A \in S(\mathcal{H})$, one has $\dim \ker(A^* - zI) = 1$ for all $z \in \mathbb{C}$. Using this fact, one can prove the following assertion (see [30, Prop. 2.12 and Remark 2.13]).

**Lemma 5.3.** If $\xi_A^{(1)} : \mathbb{C} \to \mathcal{H}$ and $\xi_A^{(2)} : \mathbb{C} \to \mathcal{H}$ are two functions satisfying (P1), (P2), and (P3), then there exists a zero-free real entire function $g(z)$ such that $\xi_A^{(1)}(z) = g(z)\xi_A^{(2)}(z)$.

Pick a canonical selfadjoint extension $A_\gamma$ of $A \in S(\mathcal{H})$ and let $h_\gamma(z)$ be a real entire function whose zero set (counting multiplicities) equals $\text{spec}(A_\gamma)$ [23, Ch. 7, Sec. 2]. If one defines

$$\xi_A(z) := h_\gamma(z)V_{A_\gamma}(w, z)\psi_w,$$

where $\psi_w$ is in $\ker(A^* - wI)$ and $V_{A_\gamma}(w, z)$ is given by (2.1), then (5.3) will satisfy (P1) and (P2) (note that we have defined the function $h$ so that $\xi$ is analytically extended to the whole plane). By defining the involution so that it commutes with the canonical selfadjoint extensions of $A$ (see [30, Prop. 2.3]), the function (5.3) also satisfies (P3) (see [30, Prop. 2.3, Prop. 2.11]). Note that, since $h_\gamma(z)$ is defined up to a multiplying zero-free real entire function, Lemma 5.3 implies that (5.3) does not depend on the choice of the selfadjoint extension $A_\gamma$ nor on $w$ and, furthermore, every function $\xi_A : \mathbb{C} \to \mathcal{H}$ can be written as in (5.3).

Fix $A \in S(\mathcal{H})$ and any function $\xi_A : \mathbb{C} \to \mathcal{H}$ satisfying (P1), (P2), and (P3). Then define

$$(\Phi_A \varphi)(z) := \langle \xi_A(\overline{z}), \varphi \rangle, \quad \varphi \in \mathcal{H}.$$
Due to (P1), $\Phi_A$ linearly maps $\mathcal{H}$ onto a certain linear manifold $\Phi_A\mathcal{H}$ of entire functions. By \cite[Sec. 1]{34}, the complete nonselfadjointness condition

$$\bigcap_{z \in \mathbb{C} \setminus \mathbb{R}} \text{ran}(A-zI) = \{0\}$$

(see \cite[Chap. 1 Thm. 2.1]{11}), implies that $\Phi_A$ is injective. Clearly, the linear space $\Phi_A\mathcal{H}$ is turned into a Hilbert space by defining

$$\langle \Phi_A\eta, \Phi_A\varphi \rangle := \langle \eta, \varphi \rangle.$$  \hfill (5.4)

The resulting Hilbert space is a dB space which is denoted by $B_A$ \cite[Prop. 2.14]{30}.

**Remark 5.4.** If $A \in \mathcal{S}(\mathcal{H})$, then $\Phi_A A \Phi_A^{-1}$ is the multiplication operator $S$ in $B_A$. For any (canonical) selfadjoint extension $A_\gamma$ of $A$, $\Phi_A A_\gamma \Phi_A^{-1}$ is a (canonical) selfadjoint extension of the multiplication operator in $B_A$. Moreover, if $\mu$ is a gauge of $A$ and $m = \Phi \mu$, it can be proven from that

$$V_\mu(A) = V_m(S) \quad \text{and} \quad V_{\mu}^\text{ext}(A) = V_{m}^\text{ext}(S).$$

The reproducing kernel in the dB space $B_A$ is

$$k(z, w) = \langle \xi_A(z), \xi_A(w) \rangle .$$

Note that $k(z, w)$ is anti-entire with respect to its second argument.

**Remark 5.5.** It is not difficult to verify that $k(\cdot, w) \in \ker(S^* - \overline{w}I)$ for all $w \in \mathbb{C}$ and moreover

$$k(z, w) = h(\overline{w})V_{S_\gamma}(\overline{z}, \overline{w})k(z, v),$$

where $S_\gamma$ is a canonical selfadjoint extension of $S$ given in Definition 5.2 and $h(w)$ is a certain real entire function having zeros at $\text{spec}(S_\gamma)$ (cf. (2.4) and (5.3)).

**Lemma 5.6.** If $\mu$ is a gauge of $A \in \mathcal{S}(\mathcal{H})$, then the corresponding element $m(z)$ in $B_A$ has no zeros in $\mathbb{R}$. Moreover, if the function $m(z)$ in the dB space $B$ is such that $m(x) \neq 0$ for all $x \in \mathbb{R}$, then $m(z)$ is a gauge of the operator of multiplication $S$ in $B$.

**Proof.** By our definition of gauge,

$$\langle \xi(z), \mu \rangle \neq 0$$

for any $z \in \mathbb{R}$. The second part of the assertion follows from noticing that $k(\cdot, w) \in \ker(S^* - \overline{w}I)$ for all $w \in \mathbb{C}$. \hfill $\square$
The following definition is motivated by a (different) generalization of the moment problem discussed in [22].

**Definition 5.7.** Generalized moment problem: For a given dB space $\mathcal{B}$ find a Borel measure $\rho$ such that

$$\langle g, f \rangle_{\mathcal{B}} = \int_{\mathbb{R}} f(x) \overline{g(x)} d\rho(x)$$

for every $f, g \in \mathcal{B}$.

As (5.1) shows, the Lebesgue measure multiplied by $1/|e(\cdot)|^2$ is always a solution of the generalized moment problem for $\mathcal{B}(e)$. Below, it will be established that there are more than one solution to our generalized moment problem.

**Theorem 5.8.** Let $S$ be the operator of multiplication by the independent variable in a dB space $\mathcal{B}$ and $m$ be a function in $\mathcal{B}$ not vanishing in $\mathbb{R}$. If $\rho$ is a solution of the generalized moment problem for $\mathcal{B}$, then

$$\sigma(\partial) := \int_0 |m(x)|^2 d\rho(x)$$

is in $\mathcal{V}_m(S)$.

**Proof.** Fix $t \in \mathbb{R}$ and define

$$\Upsilon_t(f, g) := \int_{-\infty}^t f(x) \overline{g(x)} d\rho(x)$$

which is a sesquilinear form in $\mathcal{B} \times \mathcal{B}$. This form is bounded due to

$$\Upsilon_t(f, f) \leq \int_{\mathbb{R}} |f(x)|^2 d\rho(x) = \|f\|^2$$

and the polarization identity. By [4, Ch. 2, Sec. 4, Thm. 6] and the last corollary in [27, Sec. II.2], there is $F(t) \in B(\mathcal{B})$ such that

$$\langle g, F(t)f \rangle = \Upsilon_t(f, g).$$

It turns out that $F(t)$ corresponds to a generalized spectral family in the sense of Proposition 2.7. Indeed, (i)–(iii) are verified directly from the definition. As regards (iv), one verifies

$$\int_{\mathbb{R}} t d \langle g, F(t)f \rangle = \int_{\mathbb{R}} tf(t) \overline{g(t)} d\rho(t) = \langle g, \mathcal{S}f \rangle_{\mathcal{B}}$$

and

$$\int_{\mathbb{R}} t^2 d \langle f, F(t)f \rangle = \int_{\mathbb{R}} t^2 f(t) \overline{f(t)} d\rho(t) = \langle Sf, Sf \rangle_{\mathcal{B}}.$$
Thus, for any Borel set $\partial \subset \mathbb{R}$,

$$\mathcal{V}_m(S) \ni \langle m, F(\partial)m \rangle = \int_\partial |m(x)|^2 d\rho(x)$$

since $m$ is a gauge by Lemma 5.6.

**Lemma 5.9.** Let $m \in \mathcal{B}$ be such that $m(z) \neq 0$ when $z \in \mathbb{R}$ and $a, b \in \mathbb{R}$ such that $a < b$. If $F$ is a generalized spectral family of $S$, then

$$(F([a,b])f)(z) = \int_a^b \frac{f(t)}{m(t)}dF(t)m(z)$$

for any $f \in \mathcal{B}$.

**Proof.** According to Remark 5.5, since $m(z)$ is a gauge of $S$, the right-hand side of (3.3) in this case is

$$\int_a^b \frac{\langle k(\cdot,t), f(\cdot) \rangle_{\mathcal{B}}}{\langle k(\cdot,t), m(\cdot) \rangle_{\mathcal{B}}}dF(t)m(z).$$

The assertion then follows from Proposition 3.9.

**Theorem 5.10.** Let $S$ be the operator of multiplication by the independent variable in a $dB$ space $\mathcal{B}$ and $m$ be a function in $\mathcal{B}$ not vanishing in $\mathbb{R}$. If $\sigma \in \mathcal{V}_m(S)$, then

$$\rho(\partial) := \int_\partial \frac{d\sigma(x)}{|m(x)|^2}$$

is a solution of the generalized moment problem for $\mathcal{B}$.

**Proof.** By hypothesis

$$\sigma(\partial) = \langle m, F(\partial)m \rangle_{\mathcal{B}}$$

for any real Borel set $\partial$. It follows from Lemma 5.9 that

$$\langle g, F[a,b]f \rangle_{\mathcal{B}} = \int_a^b \frac{f(t)}{m(t)}d\langle g, F(t)m \rangle_{\mathcal{B}}$$

Also

$$\langle F(t)g, m \rangle_{\mathcal{B}} = \langle F(a)g, m \rangle_{\mathcal{B}} + \int_a^t \frac{g(x)}{m(x)}d\langle F(x)m, m \rangle_{\mathcal{B}}$$

Putting the last two equalities together, one obtains

$$\langle g, F[a,b]f \rangle_{\mathcal{B}} = \int_a^b \frac{f(t)g(t)}{|m(t)|^2}d\sigma(t) = \int_a^b f(t)g(t)d\rho(t)$$

For finishing the proof take the limit when $a \to -\infty$ and $b \to +\infty$. 

13
Lemma 5.11. Let $S$ be the operator of multiplication by the independent variable in a dB space $\mathcal{B}$ and $m$ be a function in $\mathcal{B}$ not vanishing in $\mathbb{R}$. If $S_\gamma$ is a selfadjoint extension of $S$ and

$$\sigma(\partial) := \langle m, E_\gamma(\partial)m \rangle$$

for any real Borel set $\partial$, where $E_\gamma$ is the spectral family of $S_\gamma$, then

$$(f(S_\gamma)m)(\lambda) = f(\lambda)m(\lambda)$$

for any $f$ in $L_2(\mathbb{R}, \sigma)$ and $\lambda \in \text{spec}(S_\gamma)$.

Proof. Using the spectral theorem,

$$(f(S_\gamma)m)(z) = \left(\int_{\mathbb{R}} f(t)dE_\gamma(t)m\right)(z) = \sum_{\lambda \in \text{spec}(S_\gamma)} f(\lambda)k(z,\lambda)\langle k(\cdot,\lambda),m \rangle_{\mathcal{B}}.$$

From the last expression the result follows due to the properties of the reproducing kernel.

Theorem 5.12. Let $S$, $\mathcal{B}$, and $m$ be as in the previous theorem. Assume that $\rho$ is a solution of the generalized moment problem and $\sigma$ is related to it as in Theorem 5.10. A necessary and sufficient condition for the measure $\sigma$ to be in $\mathcal{V}_{m}^{\text{ext}}(S)$ is that the map $\Psi$ between the spaces $\mathcal{B}$ and $L_2(\mathbb{R}, \rho)$ given by

$$\Psi f = f \upharpoonright_{\mathbb{R}}$$

is unitary.

Proof. Since $\rho$ is a solution of the generalized moment problem, $\Psi \mathcal{B}$ is contained in $L_2(\mathbb{R}, \rho)$, where $\Psi f = f \upharpoonright_{\mathbb{R}}$ and $\Psi$ is isometric. The hypothesis $\{f \upharpoonright_{\mathbb{R}} : f \in \mathcal{B}\} = L_2(\mathbb{R}, \rho)$ therefore means that $\Psi$ is unitary. Let $A_\rho$ be the operator of multiplication by the independent variable in $L_2(\mathbb{R}, \rho)$ defined in the maximal domain. Since $A_\rho$ is selfadjoint, the same holds for $\Psi^{-1}A_\rho \Psi$. If $f \in \text{dom}(S)$, then $\Psi f \in \text{dom}(A_\rho)$. Thus, $\Psi^{-1}A_\rho \Psi$ is a canonical selfadjoint extension of $S$. Denote $S_\gamma := \Psi^{-1}A_\rho \Psi$ and let $E_\gamma$ be the spectral family of $S_\gamma$. For any Borel set $\partial \subset \mathbb{R}$, define $\eta(\partial) := \langle m, E_\gamma(\partial)m \rangle$. By the canonical map (see [2, Sec. 69]),

$$L_2(\mathbb{R}, \eta) \ni f \mapsto \overline{f(S_\gamma)m} \in \mathcal{B}.$$

and for any function $f$ in $\mathcal{B}$ there is a function $\overline{f}$ in $L_2(\mathbb{R}, \eta)$ such that $f = \overline{f(S_\gamma)m}$. Thus

$$\int_{\mathbb{R}} f(t)\overline{g(t)}d\rho(t) = \int_{\mathbb{R}} \overline{f(t)g(t)}d\eta(t),$$

where $f$ and $g$ are the images of $\overline{f}$ and $\overline{g}$ under the canonical map. On the basis of Lemma 5.11, $f(t) = \overline{f(t)m(t)}$ and $g(t) = \overline{g(t)m(t)}$ with the equalities in the
Therefore

$$
\int_{\mathbb{R}} f(t)g(t)d\rho(t) = \int_{\mathbb{R}} f(t)g(t)\frac{d\eta(t)}{|m(t)|^2}.
$$

Since this equality holds for any element in $L_2(\mathbb{R}, \rho)$, one concludes that $\eta(\partial) = \sigma(\partial)$ for any real Borel set $\partial$ and hence $\sigma$ is extremal, i.e., $\sigma \in V_\text{ext}^m(S)$.

Let us prove the other direction. If $\sigma \in V_\text{ext}^m(S)$, then $\sigma$ is the spectral measure of a canonical selfadjoint extension of $S$ which is known to be simple. By the canonical map (see [2, Sec. 69]), $\mathcal{B}$ is unitarily equivalent to $L_2(\mathbb{R}, \sigma)$. In turn, since $m$ is zero-free on the real axis, $L_2(\mathbb{R}, \sigma)$ is unitarily equivalent to $L_2(\mathbb{R}, \rho)$. On the other hand, the Hilbert spaces $\mathcal{B}$ and $\Psi \mathcal{B} \subset L_2(\mathbb{R}, \rho)$ are unitarily equivalent due to the fact that $\rho$ is a solution of the moment problem. Whence $\Psi \mathcal{B}$ cannot be properly contained in $L_2(\mathbb{R}, \rho)$. \hfill \qed

**Definition 5.13.** A solution $\rho$ of the generalized moment problem for $\mathcal{B}$ is said to be extremal when the map $\Psi$ given in Theorem 5.12 is unitary.

Unlike the extremal measures (see Definition 4.1), the extremal solutions might not be finite. If $1 \in \mathcal{B}$, then the extremal solutions of the generalized moment problem for $\mathcal{B}$ are finite (see Example 7.1).

Let us denote by $\delta_x$ the measure

$$
\delta_x(\partial) := \begin{cases} 
1 & x \in \partial \\
0 & x \notin \partial,
\end{cases}
$$

where $\partial \subset \mathbb{R}$ is a real Borel set.

**Theorem 5.14.** Let $\mathcal{B}$ be a $dB$ space, $k(\cdot, w)$ its reproducing kernel, and $S_\gamma$ a canonical selfadjoint extension of the operator of multiplication $S$. The measure

$$
\rho_\gamma := \sum_{\lambda \in \text{spec}(S_\gamma)} \frac{\delta_\lambda}{k(\lambda, \lambda)}
$$

is an extremal solution of the generalized moment problem for $\mathcal{B}$.

**Proof.** Note that, since $S \in \mathcal{B}$, it follows from Proposition 3.5 that

$$
\{k(\cdot, \lambda)/ \|k(\cdot, \lambda)\|\}_{\lambda \in \text{spec}(S_\gamma)}
$$

is an orthonormal basis in $\mathcal{B}$. The fact that $\rho_\gamma$ is a solution of the generalized
moment problem follows from the polarization identity and
\[
\|f\|_B^2 = \sum_{\lambda \in \text{spec}(S)} \frac{|\langle k(\cdot, \lambda), f(\cdot) \rangle|^2}{\|k(\cdot, \lambda)\|^2}
\]
\[
= \sum_{\lambda \in \text{spec}(S)} \frac{|f(\lambda)|^2}{k(\lambda, \lambda)} = \|f\|_{L_2(\mathbb{R}, \rho_\gamma)}.
\]
To prove that \(\Psi\) is unitary, it suffices to show that the orthogonal system \(\{\Psi k(\cdot, \lambda)\}\) is a basis in \(L_2(\mathbb{R}, \rho_\gamma)\). If there is \(h\) in \(L_2(\mathbb{R}, \rho_\gamma)\) such that
\[
0 = \langle k(\cdot, \lambda), h(\cdot) \rangle_{L_2(\mathbb{R}, \rho_\gamma)} = \langle k(\cdot, \lambda), h(\cdot) \rangle_B
\]
for all \(\lambda \in \text{spec}(S_\gamma)\), then \(h\) has zero norm in \(B\) and therefore in \(L_2(\mathbb{R}, \rho_\gamma)\).

**Remark 5.15.** Assume that \(A \in \mathcal{S}(\mathcal{H})\) and take the measure \(\rho_\gamma\) as defined in Theorem 5.14 for the corresponding dB space \(B_A\). The multiplication by the independent variable in \(L_2(\mathbb{R}, \rho_\gamma)\) is unitarily equivalent to a canonical selfadjoint extension \(A_\gamma\) of \(A\). Note that one can write
\[
\rho_\gamma = \sum_{\lambda \in \text{spec}(S_\gamma)} \frac{\delta_\lambda}{\|\xi_A(\lambda)\|^2}.
\]
It is worth remarking that in the Sturm-Liouville theory (when \(A\) is associated with a regular Sturm-Liouville difference expression) the measure \(\rho_\gamma\) is usually called the spectral measure of the selfadjoint operator \(A_\gamma\) (see details in Example 7.2).

### 6. Mass-point perturbations of measures

**Lemma 6.1.** Let \(B\) be a dB space with inner product \(\langle \cdot, \cdot \rangle_B\). Given \(a > 0\) and \(\lambda \in \mathbb{R}\), define
\[
\langle g, f \rangle_\sim := \langle g, f \rangle_B + a g(\lambda) f(\lambda), \quad \text{for } f, g \in B.
\]
(6.1)

Then the linear manifold \(B\) equipped with the inner product \(\langle \cdot, \cdot \rangle_\sim\) is a dB space.

**Proof.** \(B\) is closed with respect to \(\langle \cdot, \cdot \rangle_\sim\). Indeed, let \(\{f_n\}_0^\infty \subset B\) be a \(\sim\)-Cauchy sequence. Since \(\|\cdot\|_\sim \geq \|\cdot\|_B\), \(\{f_n\}_0^\infty\) is also \(B\)-Cauchy. Then, there exists \(g \in B\) such that \(\|f_n - g\|_B \to 0\). Since \(\|f_n(\lambda) - g(\lambda)\|^2 \leq k(\lambda, \lambda) \|f_n - g\|_B^2\), one obtains
\[
\|f_n - g\|_\sim^2 \leq \|f_n - g\|_B^2 + ak(\lambda, \lambda) \|f_n - g\|_B^2,
\]
implying the assertion.
Now we prove (A1)–(A3) of Definition 5.1. Since
\[ |f(w) - g(w)|^2 = |\langle \cdot, w \rangle, f - g|^2 \leq k(w, w) \|f - g\|^2_B \leq k(w, w) \|f - g\|^2 \sim, \]
it follows that point evaluation is continuous with respect to the \( \sim \)-norm.

From the equality
\[ \|f\|^2\sim = \|f\|^2_B + a |f(\lambda)|^2 = \|f\|^2_B + a |f(x)|^2 = \|f\|^2 \sim, \]
it follows that the mapping \( f \mapsto f\# \) is a \( \sim \)-isometry in \( B \).

Finally, suppose \( w \in \mathbb{C} \setminus \mathbb{R} \) is a zero of \( f \in B \) and define \( g(z) := (z - \overline{w})(z - w)^{-1}f(z) \). Then, \( g \in B \) and
\[ \|g\|^2\sim = \|g\|^2_B + a \left| \frac{\lambda - \overline{w}}{\lambda - w} \right|^2 |f(x)|^2 = \|f\|^2_B + a |f(x)|^2 = \|f\|^2 \sim. \]

Lemma 6.1 has the following corollary.

**Corollary 6.2.** Let \( B \) be a dB space. If \( \rho \) is a solution of the generalized moment problem for \( B \), then
\[ \rho + a\delta_{\lambda}, \quad a > 0, \]
is a solution of the generalized moment problem for a dB space \( \tilde{B} \) having the same elements as \( B \) and with inner product given by (6.1).

**Proof.** The assertion follows from the equality
\[ \int_{\mathbb{R}} f(x)g(x)d(\rho + a\delta_{\lambda}) = \langle g, f \rangle_B + a \overline{g(\lambda)f(\lambda)}. \]

**Theorem 6.3.** Let \( S \) be the operator of multiplication by the independent variable in a dB space \( B \) and \( m \) be a function in \( B \) not vanishing in \( \mathbb{R} \). If \( \sigma \in V^\text{ext}_m(S) \), then
\[ \sigma + a |m(\lambda)|^2 \delta_{\lambda}, \quad a > 0, \quad \lambda \notin \text{supp}(\sigma), \]
is in \( V_m(\tilde{S}) \setminus V^\text{ext}_m(\tilde{S}) \), where \( \tilde{S} \) is the multiplication operator in the dB space \( \tilde{B} \) given in Corollary 6.2.

**Proof.** By hypothesis, \( \rho \) given in Theorem 5.10 is a solution of the generalized moment problem for \( B \). By Corollary 6.2, \( \rho + a\delta_{\lambda} \) is a solution of the generalized moment problem for \( B \) and Theorem 5.8 implies that
\[ \sigma + a |m(\lambda)|^2 \delta_{\lambda} \in V_m(\tilde{S}). \]
On the other hand, Corollary 4.3 yields a measure \( \sigma_{\lambda} \in V^\text{ext}_m(S) \) such that \( \sigma_{\lambda}\{\lambda\} > 0 \). The function \( \rho_{\lambda} \) related to \( \sigma_{\lambda} \) as in Theorem 5.10 is a solution of
the generalized moment problem for $\mathcal{B}$ and recurring again to Corollary 6.2, one concludes that $\rho_\lambda + a \delta_\lambda$ is a solution of the generalized moment problem for $\tilde{\mathcal{B}}$. Thus, in view of Theorem 5.8,

$$\sigma_\lambda + a |m(\lambda)|^2 \delta_\lambda \in \mathcal{V}_m(S).$$

Since $\lambda \in \text{supp}(\sigma_\lambda) \setminus \text{supp}(\sigma)$, one has

$$(\sigma_\lambda + a |m(\lambda)|^2 \delta_\lambda)\{\lambda\} > (\sigma + a |m(\lambda)|^2 \delta_\lambda)\{\lambda\} > 0.$$

Assume that $\sigma + a |m(\lambda)|^2 \delta_\lambda$ is extremal. If $\sigma_\lambda + a |m(\lambda)|^2 \delta_\lambda$ is extremal, then a contradiction arises from Corollary 4.3. If $\sigma_\lambda + a |m(\lambda)|^2 \delta_\lambda$ is not extremal, then, using Theorem 4.6, one obtains an extremal measure giving weight to $\lambda$.

**Corollary 6.4.** Let $A$ and $A'$ be in $\mathcal{S}(\mathcal{H})$ such that their corresponding $dB$ spaces have the same elements. If $\mu$ is a gauge for $A$ and $\sigma \in \mathcal{V}_\mu^\text{ext}(A)$, then, for any gauge $\nu$ of $A'$, $\sigma + b \delta_\lambda$ $(b > 0, \lambda \in \mathbb{R} \setminus \text{supp}(\sigma))$ is not in $\mathcal{V}_\nu^\text{ext}(A')$.

**Proof.** That $\sigma + b \delta_\lambda$ is not the spectral measure of any canonical selfadjoint extension of $A$ for any gauge $\nu$ of $A$ follows from Corollary 4.3 and the fact that the support of the measure does not depend on the gauge. By Theorem 5.10 and Remark 5.4,

$$\rho(\partial) := \int_{\partial} \frac{d\sigma(x)}{|n(x)|^2}$$

is a solution of the generalized moment problem for the $dB$ space $\mathcal{B}_A$ when $n = \Phi \nu$. If $A \neq A'$ and $\sigma + b \delta_\lambda$ is in $\mathcal{V}_\nu^\text{ext}(A')$, then writing $a := b / |n(\lambda)|^2$, one has again by Theorem 5.10 that $\rho + a \delta_\lambda$ is a solution of the generalized moment problem for $\mathcal{B}'$ and the inner products of $\mathcal{B}_A$ and $\mathcal{B}'$ are related as in (6.1). Theorem 6.3 and Remark 5.4 yield then a contradiction.

**Remark 6.5.** There is an alternative proof of Corollary 6.4. We present it below using the same notation introduced in the proof of the previous theorem. Assume that $\sigma + b \delta_\lambda$ is in $\mathcal{V}_\nu^\text{ext}(A')$, then by Theorems 5.10 and 5.12, one has, according to Definition 5.13, that $\rho + a \delta_\lambda$ is an extremal solution of the generalized moment problem for $\mathcal{B}'$. By the same token, $\rho$ is an extremal solution of the generalized moment problem for $\mathcal{B}_A$. Thus, Theorem 5.12 tells us that $\Phi$ is a unitary operator from $\mathcal{B}'$ onto $L_2(\mathbb{R}, \rho + a \delta_\lambda)$ and from $\mathcal{B}_A$ onto $L_2(\mathbb{R}, \rho)$. Note that

$$\text{supp}(\rho + a \delta_\lambda) = \text{supp}(\rho) \cup \{\lambda\}.$$ 

If $g$ is a function in $L_2(\mathbb{R}, \rho + a \delta_\lambda)$ such that $g(t) = 0$ for any $t \in \text{supp}(\rho)$ and $g(\lambda) \neq 0$, then $\|g\|_{L_2(\mathbb{R}, \rho + a \delta_\lambda)} > 0$. So $\Psi^{-1}g$ is a nonzero function in $\mathcal{B}$ and $\mathcal{B}_A$. On the other hand $\|g\|_{L_2(\mathbb{R}, \rho)} = 0$ which is not possible since $\Psi$ is an isometry.
Remark 6.6. Suppose that $\rho$ is the spectral measure (in the sense of Remark 5.15) of a Schrödinger operator $L$ with domain on $\mathbb{R}_+$ and $\tilde{\rho}$ is a point mass perturbation of $\rho$. According to the Gel’fand-Levitan theory [10] (see also [20, Chap. 2, Sec. 7]), there is a potential $q$ such that $L + q$ has $\tilde{\rho}$ as its spectral measure. In view of Corollary 6.4, if $L$ and $L + q$ have restrictions to operators in $\mathcal{S}(\mathcal{L}^2 (\mathbb{R}_+))$, then the dB spaces associated with $L$ and $L + q$ cannot have the same elements. See Example 7.2 below for results related to regular Schrödinger operators.

Corollary 6.7. Let $\rho$ be a solution of the generalized moment problem for a dB space $\mathcal{B}$. If there is a subset of

$$\{ f |_{\mathbb{R}} : f \in \mathcal{B} \}$$

such that it is dense in $L^2(\mathbb{R}, \rho)$, then this subset is not dense in $L^2(\mathbb{R}, \rho + a\delta_x)$, where $a > 0$ and $x \not\in \text{supp}(\rho)$.

Proof. Combine Theorems 5.12 and 6.3. \hfill \Box

7. Examples

7.1. The classical moment problem

According to [1, Thm. 2.1.1], for a given real sequence $\{s_k\}_{k=0}^\infty$, there exists a Borel measure $\rho$ such that

$$s_k = \int_{\mathbb{R}} t^k d\rho(t) \quad \text{for } k = 0, 1, \ldots$$

if and only if, for all $k \in \mathbb{N}$,

$$\det \begin{pmatrix} s_0 & \cdots & s_k \\ \vdots & \ddots & \vdots \\ s_k & \cdots & s_{2k} \end{pmatrix} > 0. \quad (7.1)$$

The measure is said to be a solution of the moment problem given by the sequence $\{s_k\}_{k=0}^\infty$. We refer to all sequences $\{s_k\}_{k=0}^\infty$ satisfying (7.1) and normalized so that $s_0 = 1$ as sequences of moments. To any sequence of moments there
corresponds one and only one Jacobi matrix
\[
\begin{pmatrix}
q_1 & b_1 & 0 & 0 & \cdots \\
b_1 & q_2 & b_2 & 0 & \\
0 & b_2 & q_3 & b_3 & \ddots \\
0 & 0 & b_3 & q_4 & \ddots \\
\vdots & \ddots & \ddots & \ddots & \ddots
\end{pmatrix}
\]  (7.2)

(see [1, paragraph after Eq. 1.8] and [32, p. 93]). Given a separable Hilbert space \(\mathcal{H}\) and an orthonormal basis \(\{\delta_k\}_{k=1}^{\infty}\), with any matrix (7.2), one can uniquely associate a closed symmetric operator [2, Sec. 47]. This operator, denoted by \(A\) and called Jacobi operator, has either deficiency indices \(n_+(A) = n_-(A) = 0\) or \(n_+(A) = n_-(A) = 1\) [3, Ch. 7, Thm. 1.1]. When the Jacobi operator has deficiency indices \((0, 0)\) the matrix (7.2) is said to be in the limit point case, otherwise the matrix (7.2) is said to be in the limit circle case. Due to the bijection between Jacobi matrices and sequences of moments, the limit point and limit circle dichotomy corresponds to the determinate and indeterminate dichotomy for sequences of moments.

It is established in [1, Ch. 4] that
\[
s_k = \langle \delta_1, A^k \delta_1 \rangle \quad \text{for} \ k = 0, 1, \ldots
\]  (7.3)

This shows that if \(A\) has deficiency indices \(n_+(A) = n_-(A) = 1\), then the spectral measures of canonical selfadjoint extensions are solutions of the moment problem, i.e., an indeterminate sequence of moments admits various solutions. According to [1, Cor. 2.2.4], when the deficiency indices \(n_+(A)\) and \(n_-(A)\) vanish, there are only one solution of the moment problem. This justifies the terminology.

A Jacobi operator \(A\) with deficiency indices \(n_+(A) = n_-(A) = 1\) is in \(S(\mathcal{H})\). Indeed, if one assume that \(\lambda \in \text{spec}(A)\), then, since the spectral kernel does not decrease under extensions, \(\lambda \in \text{spec}(A_\gamma)\) for any selfadjoint extension \(A_\gamma\) of \(A\). But the spectra of canonical selfadjoint extensions of \(A\) are disjoint (see the proof of [1, Thm. 4.2.4]).

For a Jacobi operator \(A \in S(\mathcal{H})\), the function \(\xi_A\) defined in Section 5 is given by \(\xi_A(z) = \sum_{k=1}^{\infty} P_{k-1}(z)\delta_k\), where \(P_k\) is the \(k\)-th orthogonal polynomial of the first kind associated with (7.2) (see [1, Ch. 1 Sec. 2, Ch. 4 Sec. 1] and [3, Ch. 7 Sec. 2]). Thus we have the unitary map
\[
\Phi_A : \mathcal{H} \to \mathcal{B}_A.
\]

Note first that, since the finite linear combinations of the basis \(\{\delta_k\}_{k=1}^{\infty}\) are
dense in $\mathcal{H}$, the polynomials are dense in $\mathcal{B}_A$. This is a peculiarity of dB spaces generated by Jacobi operators. Also,

$$(\Phi_A A\delta_1)(z) = \langle \xi_A(\overline{z}), A\delta_1 \rangle = \langle A^* \xi_A(\overline{z}), \delta_1 \rangle = \langle A \xi_A(\overline{z}), \delta_1 \rangle = z$$

since $\langle \xi_A(\overline{z}), \delta_1 \rangle = 1$. Thus

$$(\Phi_A A^k \delta_1)(z) = z^k \quad \text{for all } k \in \mathbb{N} \cup \{0\}. \quad (7.4)$$

**Theorem 7.1.** The measure $\rho$ is a solution of an indeterminate moment problem if and only if $\rho$ is a solution of the generalized moment problem for $\mathcal{B}_A$.

**Proof.** Assume that $\rho$ is a solution of the generalized moment problem for $\mathcal{B}_A$. Then, in view of (7.3) and (7.4), one has

$$s_k = \langle 1, z^k \rangle_{\mathcal{B}_A} = \int_{\mathbb{R}} t^k d\rho(t) \quad \text{for } k = 0, 1, \ldots$$

which means that $\rho$ is a solution of the moment problem given by $\{s_k\}_{k=0}^\infty$.

Now, suppose that $\rho$ is a solution of the moment problem given by $\{s_k\}_{k=0}^\infty$. Hence, by (7.3), one has

$$\int_{\mathbb{R}} t^k d\rho(t) = \langle \delta_1, A^k \delta_1 \rangle \quad \text{for } k = 0, 1, \ldots$$

One then verifies that if $R(t)$ is a polynomial, then

$$\int_{\mathbb{R}} R(t) d\rho(t) = \langle \delta_1, R(A) \delta_1 \rangle .$$

Thus

$$\int_{\mathbb{R}} |R(t)|^2 d\rho(t) = \langle R(A) \delta_1, R(A) \delta_1 \rangle .$$

But, due to (7.4),

$$\langle R(A) \delta_1, R(A) \delta_1 \rangle = \langle R, R \rangle_{\mathcal{B}_A}$$

For completing the proof one uses the fact that the polynomials are dense in $\mathcal{B}_A$ and the polarization identity.

We draw the reader’s attention to the fact that Theorem 6.3 in the context of the classical moment problem is [8, Prop. 4.1(a)] whose proof was communicated by A. Durán. Moreover, according to Corollary 6.7, the perturbations of the measure considered in Theorem 6.3 destroy the density of polynomials in $L^2$ spaces (cf. [8, Remark 4.2]).

**Remark 7.2.** If the sequence of moments yields an indeterminate moment problem, then all solutions are related to canonical and noncanonical self-adjoint extensions of a Jacobi operator $A$ in $\mathcal{S}(\mathcal{H})$. However, one can construct a
Jacobi matrix in the limit point case by an appropriate choice of the basis of representation of a canonical selfadjoint extension of \( A \). On the other hand, if the sequence of moments yields a determinate moment problem, then there is a unique Jacobi operator \( B \) whose spectral measure coincides with the unique solution of the problem. When the operator \( B \) has discrete spectrum, it can be seen as a selfadjoint extension of an operator \( \tilde{B} \) in \( S(\mathcal{H}) \). We note that \( \tilde{B} \) cannot correspond to a Jacobi operator.

### 7.2. Regular Schrödinger operators

Here, we consider symmetric operators arising from differential expressions

\[
\tau_q := -\frac{d^2}{dx^2} + q(x),
\]

where \( q \) is real-valued and belongs to \( L_1(0, b) \) with \( b > 0 \). Based on \( \tau_q \), we define a symmetric operator \( A \) in \( L_2(0, b) \) as follows:

\[
\text{dom}(A) := \{ \varphi \in L_2(0, b) : \tau_q \varphi \in L_2(0, b), \varphi'(0) = \varphi(b) = \varphi'(b) = 0 \} \quad \text{A}\varphi := \tau_q \varphi.
\]

The adjoint operator of \( A \) is

\[
\text{dom}(A^*) := \{ \varphi \in L_2(0, b) : \tau_q \varphi \in L_2(0, b), \varphi'(0) = 0 \}, \quad A^* \varphi := \tau_q \varphi.
\]

Note that \( A^{**} = A \), which means that \( A \) is closed (cf. [37, Thm. 8.25(b)]). By solving the equation

\[
(A^* \mp iI) \varphi = 0,
\]

one verifies that the deficiency indices are \( n_+(A) = n_-(A) = 1 \). Finally, the canonical selfadjoint extensions of \( A \) are given by (cf. [37, Thm. 8.26(a)])

\[
\text{dom}(A_\gamma) := \left\{ \varphi \in L_2(0, b) : \tau_q \varphi \in L_2(0, b), \begin{cases} \varphi'(0) = 0, \\ \varphi(b) \cos \gamma + \varphi'(b) \sin \gamma = 0 \end{cases} \right\} \quad A_\gamma \varphi := \tau_q \varphi.
\]

From these expressions, one can conclude that \( \gamma_1 \neq \gamma_2 \) implies the spec\((A_{\gamma_1})\) does not intersect spec\((A_{\gamma_2})\). Thus, the spectral kernel of \( A \) is empty. We have arrived at the conclusion that \( A \in S(L_2(0, b)) \).

Let \( \xi : \mathbb{R}_+ \times \mathbb{C} \to \mathbb{C} \) be the solution of the eigenvalue problem

\[
\tau_q \xi(x, z) = z \xi(x, z), \quad \xi(0, z) = 1, \quad \xi'(0, z) = 0.
\]

(The derivative is taken with respect to the first argument.) The function \( \xi(x, z) \)
is real entire for any fixed $x \in \mathbb{R}_+$ (see [21, Thm. 1.1.1] and [36, Thm. 9.1]). Also, $\xi(\cdot, z) \in L_2(0, b)$ for any $z \in \mathbb{C}$. Using [31, Sec. 4], one then establishes that $\xi(\cdot, z)$ is entire as an $L_2(0, b)$-valued map and satisfies (P1)–(P3) of Section 5. Thus, the space of functions

$$B_A := \Phi_A L_2(0, b)$$

with the inner product given by (5.4) is a dB space.

The solutions of the generalized moment problem for $B_A$ correspond to the generalized spectral measures of $A$. Let us consider here the extremal solutions of the generalized moment. According to Theorem 5.14 and Remark 5.15, any extremal solution is given by

$$\rho_\gamma = \sum_{\lambda \in \text{spec}(A_\gamma)} \frac{\delta_\lambda}{\|\xi(\cdot, \lambda)\|_{L_2(0, b)}^2},$$

(7.5)

where $A_\gamma$ is a selfadjoint extension of $A$. In the Sturm-Liouville theory $\rho_\gamma$ is usually said to be the spectral measure of the selfadjoint Schrödinger operator $A_\gamma$ (see [28, Eq. 3.2]).

**Proposition 7.3.** Let $A$ be the regular Schrödinger operator defined by $\tau_q$ and $A_\gamma$ an arbitrarily chosen selfadjoint extension of $A$ and $\rho_\gamma$ the corresponding spectral measure given in (7.5). If

$$\tilde{\rho} = \rho_\gamma + s\delta_\lambda$$

with $\lambda \not\in \text{spec}(A_\gamma)$ and $s > 0$, then

(a) there is no $\tilde{q} \in L_1(0, b)$ such that $\tilde{\rho}$ is the spectral measure corresponding to selfadjoint extensions of $A$ generated by $\tau_{\tilde{q}}$;

(b) The set of functions

$$\left\{ f(x) = \int_0^b \phi(t) \cos(\sqrt{\lambda} t) dt : \phi \in L_2(0, b), x \in \mathbb{R} \right\}$$

(7.6)

is a proper subset of $L_2(\mathbb{R}, \tilde{\rho})$.

**Proof.** The assertion (a) is a direct consequence of Corollary 6.4 after using the functional model given by $\Phi_A$. Let us prove (b). According to [28, Thm. 4.1], the set of functions in the dB space $B_A$ is given by

$$\left\{ f(z) = \int_0^b \phi(t) \cos(\sqrt{\lambda} t) dt : \phi \in L_2(0, b), z \in \mathbb{C} \right\}$$
for any function \( q \in L_1(0, b) \). The assertion then follows from Theorems 5.12 and 6.3.

**Remark 7.4.** Note that, in view of Theorem 5.12, any function in the set \((7.6)\) is a function in \( L_2(\mathbb{R}, \rho_\gamma) \) and for any element in \( L_2(\mathbb{R}, \rho_\gamma) \) there is a function in \((7.6)\) which belongs to the equivalence class of this element.
