JACOBI SUMS OF ORDER $2\ell^2$

Md. Helal Ahmed and Jagmohan Tanti

Abstract

Let $\ell \geq 3$ and $p$ be primes, $q = p^r$, $r \in \mathbb{Z}^+$, $q \equiv 1 \pmod{2\ell^2}$ and $\mathbb{F}_q$ a field with $q$ elements. In this paper we establish the congruences for Jacobi sums of order $2\ell^2$ and also explore here to express these Jacobi sums in terms of Dickson-Hurwitz sums. These expressions and congruences are useful in algebraic characterizations of the Jacobi sums of order $2\ell^2$.

Keywords: Jacobi sums; Dickson-Hurwitz sums; Congruences; Cyclotomic field.

Mathematics Subject Classification 2010: Primary 11T24, Secondary 11T22.

1 Introduction

Let $e \geq 2$ be an integer, $p$ a rational prime, $q = p^r$, $r \in \mathbb{Z}^+$ and $q \equiv 1 \pmod{e}$. Let $\mathbb{F}_q$ be a finite field of $q$ elements. We can write $q = p^r = ek + 1$ for some $k \in \mathbb{Z}^+$. Let $\gamma$ be a generator of the cyclic group $\mathbb{F}_q^*$ and $\zeta_e = \exp(2\pi i / e)$. Define a multiplicative character $\chi_e : \mathbb{F}_q^* \to \mathbb{Q}(\zeta_e)$ by $\chi_e(\gamma) = \zeta_e$ and extend it on $\mathbb{F}_q$ by putting $\chi_e(0) = 0$. For integers $0 \leq i, j \leq e - 1$, the Jacobi sum $J_e(i, j)$ is define by

$$J_e(i, j) = \sum_{v \in \mathbb{F}_q} \chi_e^i(v)\chi_e^j(v + 1).$$

However in the literature a variation of Jacobi sums are also considered and is defined by

$$J_e(\chi_e^i, \chi_e^j) = \sum_{v \in \mathbb{F}_q} \chi_e^i(v)\chi_e^j(1 - v),$$

but are related by $J_e(i, j) = \chi_e^i(-1)J_e(\chi_e^i, \chi_e^j)$.

The Problem of congruences of Jacobi sums of order $e$ concerns to determine an element modulo an appropriate power of $(1 - \zeta_e)$ in $\mathbb{Z}[\zeta_e]$, which is coprime to $e$ and this plays a vital role to determine the element uniquely along with some other elementary conditions.

For some small values of $e$ the study of congruences of Jacobi sums is available in the literature. For example Dickson \cite{Dickson} obtained the congruences $J_q(1, n) \equiv -1 \pmod{(1 - \zeta_l)^2}$ for $1 \leq n \leq l - 1$. Parnami,

\[ J_{2l}(1, n) \equiv -\zeta_l^m(n+1)(1 - \zeta_l^2), \]

where \(n\) is an odd integer such that \(1 \leq n \leq 2l - 3\) and \(m = \text{ind}_l 2\). Also in 1983, Katre and Rajwade [7] obtained the congruence of Jacobi sum of order 9, i.e.,

\[ J_9(1, 1) \equiv -1 - (\text{ind} \ 3)(1 - \omega)(1 - \zeta_9^4), \]

where \(\omega = \zeta_9^3\). In 1986, Ihara [5] showed that if \(k > 3\) is an odd prime power, then

\[ J_k(i, j) \equiv -1 \ (\text{mod} \ (1 - \zeta_k^3)). \]

Evans ([4], 1998) used simple methods to generalize this result for all \(k > 2\). Congruences for the Jacobi sums of order \(l^2\) (\(l\) odd prime) were obtained by Shirolkar and Katre [10]. They showed that

\[ J_{l^2}(1, n) \equiv \begin{cases} -1 + \sum_{i=3}^{l} c_{i, n}(\zeta_{l^2} - 1)^i(1 - \zeta_{l^2})^{i+1} & \text{if } \gcd(l, n) = 1, \\ -1 \ (\text{mod} \ (1 - \zeta_{l^2})^{l+1}) & \text{if } \gcd(l, n) = l. \end{cases} \]

In this paper, we determine the congruences (mod \((1 - \zeta_{2l^2})^{l+1}\)) for Jacobi sums of order \(2l^2\) and also calculate their coefficients in terms of Dickson-Hurwitz sums. We split the problem into two cases:

**Case 1.** \(n\) is odd. This case splits into three sub-cases:

**Subcase i.** \(n = l^2\).

**Subcase ii.** \(n = dl\), where \(1 \leq d \leq 2l - 1\), \(d\) is an odd and \(d \neq l\).

**Subcase iii.** \(\gcd(n, 2l^2) = 1\).

**Case 2.** \(n\) is even. In this case the Jacobi sums \(J_{2l^2}(1, n)\) can be calculated using the relation

\[ J_{2l^2}(1, n) = \chi_{2l^2}(-1)J_{2l^2}(1, 2l^2 - n - 1) \]

(which has been shown in the next section).

This paper has been organized in the following pattern. Section 2, discussess some properties of Jacobi sums, Dickson-Hurwitz sums and relations among them. These properties are used to evaluate the congruences of Jacobi sums and their expressions in terms of Dickson-Hurwitz sums. In Section 3, we prove some Lemma’s, which are needed for the proofs of congruences for Jacobi sums. Section 4 is assigned to discuss the main results, i.e. to determine Jacobi sums of order \(2l^2\) in terms of the coefficients of Dickson-Hurwitz sums and to calculate the congruences for Jacobi sums of order \(2l^2\).
2 Preliminaries

Let $\zeta = \zeta_{2l^2}$ and $\chi = \chi_{2l}$ then $\chi^2 = \chi_{l^2}$ is a character of order $l^2$ and $\zeta_l = \zeta^2$ is a primitive $l^2$th root of unity. The Jacobi sums $J_{l^2}(i,j)$ and $J_{2l^2}(i,j)$ of order $l^2$ and $2l^2$ respectively are defined as in the previous section. We also have $\zeta = -\zeta_{(l^2+1)/2}$.

2.1 Properties of Jacobi sums

In this subsection we discuss some properties of Jacobi sums.

Proposition 1. If $m + n + s \equiv 0 \pmod{e}$ then

$$J_e(m, n) = J_e(s, n) = \chi_e^s(-1)J_e(s, m) = \chi_e^s(-1)J_e(n, m) = \chi_e^m(-1)J_e(m, s) = \chi_e^m(-1)J_e(n, s).$$

In particular,

$$J_e(1, m) = \chi_e(-1)J_e(1, s) = \chi_e(-1)J_e(1, e - m - 1).$$

Proposition 2. Let $J_e(0, j) = \begin{cases} -1 & \text{if } j \not\equiv 0 \pmod{e}, \\ q - 2 & \text{if } j \equiv 0 \pmod{e}. \end{cases}$

$$J_e(i, 0) = -\chi_i^1(-1) i \text{ if } i \not\equiv 0 \pmod{e}.$$

Proposition 3. Let $m + n \equiv 0 \pmod{e}$ but not both $m$ and $n$ zero (mod $e$). Then $J_e(m, n) = -1$.

Proposition 4. For $(k, e) = 1$ and $\sigma_k$ a $\mathbb{Q}$ automorphism of $\mathbb{Q}(\zeta_e)$ with $\sigma_k(\zeta_e) = \zeta_k^e$, we have $\sigma_kJ_e(m, n) = J_e(mk, nk)$. In particular, if $(m, e) = 1$, $m^{-1}$ denotes the inverse of $m$ (mod $e$) then $\sigma_mJ_e(m, n) = J_e(1, nm^{-1})$.

Proposition 5. $J_{2l^2}(2m, 2s) = J_e(m, n)$.

Proposition 6. Let $m, n, s$ be integers such that $m + n \not\equiv 0 \pmod{2l^2}$ and $m + s \not\equiv 0 \pmod{2l^2}$. Then

$$J_{2l^2}(m, n)J_{2l^2}(m + n, s) = \chi^m(-1)J_{2l^2}(m, s)J_{2l^2}(n, s + m).$$

Proposition 7. \[J_{2l^2}(1, n)J_{2l^2}(1, n)^{-1} = \begin{cases} q & \text{if } n \not\equiv 0 \pmod{2l^2}, \\ 1 & \text{if } n \equiv 0 \pmod{2l^2}. \end{cases}\]

Proof. The proofs of 1 - 5 follow directly using the definition of Jacobi sums (see [2]). The proofs of 6 and 7 are analogous to the proofs in the $2l$ and $l$ cases respectively (see [1], [9]).

Remark 1: The Jacobi sums of order $2l^2$ can be determined from the Jacobi sums of order $l^2$. The Jacobi sums of order $2l^2$ can also be obtained from $J_{2l^2}(1, n)$, $1 \leq n \leq 2l^2 - 3$ for $n$ odd.

Remark 2: The Jacobi sums of order $2l^2$ can be determined from the Jacobi sums of order $l^2$. The Jacobi sums of order $2l^2$ can also be obtained from $J_{2l^2}(1, n)$, $1 \leq n \leq 2l^2 - 3$ for $n$ odd.

Remark 3: The Jacobi sums of order $2l^2$ can be determined from the Jacobi sums of order $l^2$. The Jacobi sums of order $2l^2$ can also be obtained from $J_{2l^2}(1, n)$, $1 \leq n \leq 2l^2 - 3$ for $n$ odd.
2 ≤ n ≤ 2l^2 - 2 for n even). Further the Jacobi sums of order \( l^2 \) can be evaluated if one knows the Jacobi sums \( J_{l^2}(1, i) \), 1 ≤ i ≤ \( \frac{l^2 - 3}{2} \).

### 2.2 Dickson-Hurwitz sums

The Dickson-Hurwitz sums \( [10] \) of order \( e \) on \( \mathbb{F}_q \) are defined for \( i, j \) (mod \( e \)) by

\[
B_e(i, j) = \sum_{h=0}^{e-1} (h, i - jh)_e.
\]

For \( q = ek + 1 \) these satisfy the relations:

\[
B_e(i, j) = B_e(i, e - i - j), \quad B_e(0, 0) = k - 1, \quad B_e(i, 0) = k \quad \text{if } 1 \leq i \leq e - 1, \quad \sum_{i=0}^{e-1} B_e(i, j) = q - 2, \quad \text{and}
\]

for \( (j, e) = 1, \quad B_e(i, j, l, j) = B_e(i, j) \), where \( kk \equiv 1 \) (mod \( e \)).

Jacobi sums \( J_e(\chi_e, \chi'_e) \) and Dickson-Hurwitz sums are related by (for \( q = p \), see \( [3] \))

\[
\chi_e(-1)J_e(\chi_e, \chi'_e) = \chi'_e(-1)\chi_e(-1)J_e(1, j) = \sum_{i=0}^{e-1} B_e(i, j)\zeta_e^i.
\]

Thus if \( k \) is even or \( q = 2^r \) then \( J_e(1, j) = \sum_{i=0}^{e-1} B_e(i, j)\zeta_e^i \) \( [10] \). Further Shirolkar and Katre \( [10] \) calculated the coefficients of Jacobi sums of order \( l^2 \) in terms of Dickson-Hurwitz sums, which has been stated in the following proposition:

**Proposition 8.** \( J_{l^2}(1, n) = \sum_{i=0}^{l(l-1)-1} b_{i, n}\zeta_{l^2}^i \),

where \( b_{i, n} = B_{l^2}(i, n) - B_{l^2}(l(l-1) + j, n) \), 0 ≤ j ≤ l - 1, \( j \equiv i \) (mod \( l \)).

### 3 Congruences for Jacobi sums of order \( 2l^2 \)

The evaluation of congruences for the Jacobi sums of order \( l^2 \) has been done by Shirolkar and Katre \( [10] \) and has been stated in the following theorem.

**Theorem 1.** Let \( l > 3 \) be a prime and \( p^r = q \equiv 1 \) (mod \( l^2 \)). If 1 ≤ n ≤ \( l^2 - 1 \), then a (determining) congruence for \( J_{l^2}(1, n) \) for a finite field \( \mathbb{F}_q \) is given by

\[
J_{l^2}(1, n) \equiv \begin{cases} 
-1 - \sum_{i=3}^{l-1} c_{i,n}(\zeta_{l^2} - 1)(\zeta_{l^2} - 1)^i \; \text{mod} \; (1 - \zeta_{l^2})^{l+1} & \text{if } \gcd(l, n) = 1, \\
-1 \; \text{mod} \; (1 - \zeta_{l^2})^{l+1} & \text{if } \gcd(l, n) = l,
\end{cases}
\]

where for 3 ≤ i ≤ l - 1, \( c_{i,n} \) and \( c_{i,n} = S(n) \) are as described in \( [10] \).

**Lemma 1.** Let \( p \geq 3 \) be a prime and \( q = p^r \equiv 1 \) (mod \( 2l^2 \)). If \( \chi \) is a nontrivial character of order \( 2l^2 \) on the finite field \( \mathbb{F}_q \), then

\[
J_{2l^2}(a, a) = \chi^a(4)J_{2l^2}(a, l^2).
\]
Lemma 2. Let \( l \geq 3 \) be a prime, \( q = p^r \equiv 1 \pmod{2l^2} \) and \( \gamma \) a generator of \( \mathbb{F}_q^* \) then

\[
J_{2l^2}(1,l^2) \equiv \zeta_{l^2}^{-w}(-1 + \sum_{i=3}^{l}(\zeta_{l^2} - 1)^i)(1 - \zeta_{l^2})^{l+1},
\]

where \( w = \text{ind}_2.2 \).

Proof. From Proposition 6, for \( m = 1, n = 1 \) and \( s = l^2 - 1 \), we have

\[
J_{2l^2}(1,1)J_{2l^2}(2,l^2 - 1) = \chi(1)J_{2l^2}(1,l^2 - 1)J_{2l^2}(1,l^2).
\]

By Proposition 1, we obtain \( \chi(-1)J_{2l^2}(1,l^2 - 1) = J_{2l^2}(1,l^2). \)

Now equation (1) becomes

\[
J_{2l^2}(1,1)J_{2l^2}(2,l^2 - 1) = J_{2l^2}(1,l^2)J_{2l^2}(1,l^2).
\]

Again by Proposition 5 and Theorem 1 we have

\[
J_{2l^2}(2,l^2 - 1) = J_{2l^2}(1,(l^2 - 1)/2) \equiv -1 + \sum_{i=3}^{l}(\zeta_{l^2} - 1)^i(1 - \zeta_{l^2})^{l+1}.
\]

For \( w = \text{ind}_2.2 \), from Lemma 1 we have

\[
J_{2l^2}(1,1) = \chi^{-1}(4)J_{2l^2}(1,l^2) = \zeta_{l^2}^{-w}J_{2l^2}(1,l^2).
\]

Employing (1) and (3) in (2), we get

\[
J_{2l^2}(1,l^2) \equiv \zeta_{l^2}^{-w}(-1 + \sum_{i=3}^{l}(\zeta_{l^2} - 1)^i)(1 - \zeta_{l^2})^{l+1}.
\]

Lemma 3. Let \( n \) be an odd integer such that \( 1 \leq n \leq 2l^2 - 1 \) and \( \gcd(n,2l^2) = 1 \), then

\[
J_{2l^2}(1,n) \equiv \zeta_{l^2}^{-w(n+1)}(-1 + \sum_{i=3}^{l}(\zeta_{l^2} - 1)^i)(-1 + \sum_{i=3}^{l}(\zeta_{l^2}^n - 1)^i)
\]

\[
\times (-1 + \sum_{i=3}^{l}(\zeta_{l^2}^{(1-l^2)/2} - 1)^i) \pmod{(1 - \zeta_{l^2})^{l+1}}.
\]
Proof. By Proposition 6, for \( m = 1 \) and \( s = l^2 - 1 \), we have
\[
J_{2l^2}(1,n)J_{2l^2}(1 + n, l^2 - 1) = \chi(-1)J_{2l^2}(1, l^2 - 1)J_{2l^2}(n, l^2).
\]
Applying Proposition 1 to get
\[
J_{2l^2}(1,n)J_{2l^2}(1 + n, l^2 - 1) = J_{2l^2}(1, l^2)J_{2l^2}(n, l^2).
\]
Applying \( \tau_n : \zeta_{2l^2} \to \zeta_{2l^2}^n \) (a \( \mathbb{Q} \) automorphism of \( \mathbb{Q}(\zeta_{2l^2}) \)) second term in RHS, we get
\[
J_{2l^2}(1,n)J_{2l^2}(1 + n, l^2 - 1) = \tau_n J_{2l^2}(1, l^2).
\]

Now as \( J_{2l^2}(1 + n, l^2 - 1)J_{2l^2}(1 + n, l^2 - 1) = q \), we have
\[
J_{2l^2}(1,n)J_{2l^2}(1 + n, l^2 - 1)J_{2l^2}(1 + n, l^2 - 1) = \tau_n J_{2l^2}(1, l^2)J_{2l^2}(1 + n, l^2 - 1). J_{2l^2}(1 + n, l^2 - 1).
\]
This implies
\[
J_{2l^2}(1,n) q = J_{2l^2}(1, l^2)\tau_n J_{2l^2}(1, l^2)J_{2l^2}(1 + n, l^2 - 1). \tag{5}
\]

From Proposition 5 and applying \( \sigma_n : \zeta_{2l^2} \to \zeta_{2l^2}^n \) (a \( \mathbb{Q} \) automorphism of \( \mathbb{Q}(\zeta_{2l^2}) \)), we get,
\[
J_{2l^2}(1 + n, l^2 - 1) = J_{2l^2}((-1 - n, 1 - l^2) = J_{2l^2}((-1 - n)/2, (1 - l^2)/2)
\]
\[
= \sigma_{(1-l^2)/2}(J_{2l^2}(1,1-n)).
\]

Now from Theorem 1 we get
\[
J_{2l^2}(1 + n, l^2 - 1) \equiv -1 + \sum_{i=3}^{l} c_i.n.(\zeta_{2l^2}^{1-l^2})^i - 1 \pmod{(1-\zeta_{2l^2})^{l+1}}. \tag{6}
\]

Employing (6) and Lemma 2 in (3), we get
\[
J_{2l^2}(1, n) \equiv \zeta_{2l^2}^{-w(n+1)}(-1 + \sum_{i=3}^{l} c_i.n.(\zeta_{l^2} - 1)^i)(-1 + \sum_{i=3}^{l} c_i.n.(\zeta_{2l^2} - 1)^i)
\]
\[
\times (-1 + \sum_{i=3}^{l} c_i.n.(\zeta_{2l^2}^{1-l^2})^i - 1) \pmod{(1-\zeta_{2l^2})^{l+1}}.
\]

\[\square\]

Lemma 4. Let \( d \neq 1, 1 \leq d \leq 2l - 1 \) be an odd positive integer, \( \gamma \) a generator of \( \mathbb{F}_q^* \), then
\[
J_{2l^2}(1, dl) \equiv -\zeta_{2l^2}^{-w(d+1)}(-1 + \sum_{i=3}^{l} c_i.n.(\zeta_{l^2} - 1)^i)(-1 + \sum_{i=3}^{l} c_i.n.(\zeta_{2l^2}^{1-d})^i - 1) \pmod{(1-\zeta_{2l^2})^{l+1}}.
\]

where \( w = \text{ind}_\gamma 2 \).

Proof. From Proposition 6, for \( m = 1, n = dl \) and \( s = l^2 - 1 \), we have
\[
J_{2l^2}(1, dl)J_{2l^2}(1 + dl, l^2 - 1) = \chi(-1)J_{2l^2}(1, l^2 - 1)J_{2l^2}(dl, l^2).
\]
Applying Proposition 1, we get
\[ J_{2l^2}(1, d)J_{2l^2}(1 + dl, l^2 - 1) = J_{2l^2}(1, l^2)J_{2l^2}(dl, l^2). \]

Now as \( J_{2l^2}(1 + dl, l^2 - 1)J_{2l^2}(1 + dl, l^2 - 1) = q \), we have
\[ J_{2l^2}(1, dl)J_{2l^2}(1 + dl, l^2 - 1)J_{2l^2}(1 + dl, l^2 - 1) = J_{2l^2}(1, l^2)J_{2l^2}(dl, l^2)J_{2l^2}(1 + dl, l^2 - 1). \]
This implies
\[ J_{2l^2}(1, dl) q = J_{2l^2}(1, l^2)J_{2l^2}(dl, l^2)J_{2l^2}(1 + dl, l^2 - 1). \]

By Proposition 5, we get
\[ J_{2l^2}(1 + dl, l^2 - 1) = J_{2l^2}(-1 - dl, 1 - l^2) = J_{2l^2}((-1 - dl)/2, (1 - l^2)/2) = \sigma_{(-1-dl)/2}(J_{2l^2}(1, dl - 1)). \]

Now from Theorem \( \square \) we get
\[ J_{2l^2}(1 + dl, l^2 - 1) \equiv -1 + \sum_{i=3}^{l} c_{i, n}(\zeta_{l^2}(-1-\tilde{\alpha})/2 - 1)^i (\mod (1 - \zeta_{l^2})^{i+1}) \]

As \( \chi \) is of order \( 2l^2 \), \( \chi^l \) is of order \( 2l \), so for \( \eta_d : \zeta \mapsto \zeta^d \) (a \( \mathbb{Q} \) automorphism of \( \mathbb{Q}(\zeta_l) \)) and by Lemma 3 \( \square \), we obtain
\[ J_{2l^2}(dl, l^2) = J_{2l}(dl, l^2) = (\chi^l)^d(4)J_{2l}(d, d) = \chi^{ld}(2^2)\eta_d(J_{2l}(1, 1)) = \chi^{2ld}(2)\eta_d(J_{2l}(1, 1)). \]

Let \( w = \text{id}_{(2)} \), then we have
\[ \chi^{2ld}(2) = \chi^{2ld}(\gamma^w) = \chi^{2ldw}(\gamma) = \zeta_{2l^2}^{2ldw} = \zeta_{2l^2}^{dw}. \]

By Proposition 3 \( \square \), we get
\[ J_{2l}(1, l) \equiv -\zeta_{2l}^{-2w}(\mod (1 - \zeta_{2l})^2). \]

So
\[ \eta_d(J_{2l}(1, 1)) \equiv -\zeta_{2l}^{-2wd}(\mod (1 - \zeta_{2l})^2) \equiv -\zeta_{2l}^{-2wd}(\mod (1 - \zeta_{2l})^2). \]

Thus
\[ J_{2l^2}(dl, l^2) \equiv \zeta_{l^2}^{2wd}(-\zeta_{l^2}^{-2wd})(\mod (1 - \zeta_{l^2})^2) \equiv -\zeta_{l^2}^{-2wd}(\mod (1 - \zeta_{l^2})^2) \]
\[ \equiv -\zeta_{l^2}^{-2wdl}(\mod (1 - \zeta_{l^2})^2) \equiv -\zeta_{l^2}^{-2wdl}(\mod (1 - \zeta_{l^2})^2). \]

This implies
\[ J_{2l^2}(dl, l^2)(1 - \zeta_{l^2})^{l-1} \equiv -\zeta_{l^2}^{-2wdl}(1 - \zeta_{l^2})^{l-1}(\mod (1 - \zeta_{l^2})^{l+1}). \]

Employing \( \square \), \( \square \) and Lemma 2 \( \square \) in \( \square \), we get
\[ J_{2l^2}(1, dl) \equiv -\zeta_{l^2}^{-w(dl+1)}(-1 + \sum_{i=3}^{l} c_{i, n}(\zeta_{l^2} - 1)^i)(-1 + \sum_{i=3}^{l} c_{i, n}(\zeta_{l^2}(-1-\tilde{\alpha})/2 - 1)^i)(\mod (1 - \zeta_{l^2})^{l+1}). \]
4 Main Theorems

Theorem 2. Let \( p \) and \( l \geq 3 \) be primes, \( r \in \mathbb{Z}^+ \), \( q = p^r \equiv 1 (\text{mod } 2l^2) \) and \( \zeta \) a primitive \( 2l^2 \)-th root of unity. Then for \( 1 \leq n \leq 2l^2 - 3 \) the Jacobi sum \( J_{2l^2}(1, n) \) of order \( 2l^2 \) is given by

\[
J_{2l^2}(1, n) = \sum_{i=0}^{l(l-1)-1} d_{i,n} \zeta^{i},
\]

with

\[
d_{i,n} = B_{2l^2}(i, n) \mp B_{2l^2}(l(l-1) + j, n) - B_{2l^2}(l^2 + k, n) \pm B_{2l^2}(2\phi(l^2) + l) + j, n),
\]

where

\[
0 \leq j \leq l - 1, \; j \equiv i \pmod{2l^2}, \; k \equiv i \pmod{2l^2}, \; 0 \leq i, k \leq \phi(2l^2) - 1,
\]

sign’s are \( l \)’ periodic (i.e; sign’s are repeated after \( l \) terms).

Proof. Cyclotomic polynomial of order \( n = 2l^2 \) is

\[
\phi_n(x) = \sum_{i=0}^{l-1} (-x)^i = 1 - x^l + x^{2l} - x^{3l} + \cdots + x^{l(l-1)}
\]

So, we have

\[
1 - \zeta^l + \zeta^{2l} - \zeta^{3l} + \cdots + \zeta^{l(l-1)} = 0
\]

\[
\Rightarrow \zeta^{l(l-1)} = -1 + \zeta^l - \zeta^{2l} + \cdots + \zeta^{l(l-2)}.
\]

Every \( \zeta^i, l(l-1) \leq i \leq 2l^2 - 1 \) can be written as a linear combination of \( \zeta^i, 0 \leq i \leq l(l-1) - 1 \).

\[
J_{2l^2}(1, n) = \sum_{i=0}^{2l^2-1} B_{2l^2}(i, n) \zeta^i
\]

\[
= B_{2l^2}(0, n) + B_{2l^2}(1, n) \zeta + B_{2l^2}(2, n) \zeta^2 + \cdots + B_{2l^2}(l(l-1) - 1, n) \zeta^{l(l-1)-1} + B_{2l^2}(l(l-1), n)
\]

\[
(-1 + \zeta^l - \zeta^{2l} + \cdots + \zeta^{l(l-2)}) + B_{2l^2}(l(l-1) + 1, n)(-\zeta + \zeta^{l+1} - \zeta^{2l+1} + \cdots + \zeta^{l(l-2)+1}) + \cdots
\]

\[
+ B_{2l^2}(l(l-1) + l, n)(-\zeta^l + \zeta^{2l} - \zeta^{3l} + \cdots + \zeta^{l(l-2)+l}) + \cdots + B_{2l^2}(2l(l-1) + l - 1, n)
\]

\[
(-\zeta^{l(l-1)} - 1) + B_{2l^2}(2l(l-1) + l, n)(-\zeta^{l(l-1)}) + \cdots + B_{2l^2}(2l^2 - 1, n)(-\zeta^{l^2-1})
\]

\[
= B_{2l^2}(0, n) + B_{2l^2}(1, n) \zeta + B_{2l^2}(2, n) \zeta^2 + \cdots + B_{2l^2}(l(l-1) - 1, n) \zeta^{l(l-1)-1} + B_{2l^2}(l(l-1), n)
\]

\[
(-1 + \zeta^l - \zeta^{2l} + \cdots + \zeta^{l(l-2)}) + B_{2l^2}(l(l-1) + 1, n)(-\zeta + \zeta^{l+1} - \zeta^{2l+1} + \cdots + \zeta^{l(l-2)+1}) + \cdots
\]

\[
+ B_{2l^2}(l(l-1) + l, n)(-\zeta + \zeta^{2l} - \zeta^{3l} + \cdots + \zeta^{l(l-2)+l}) + \cdots + B_{2l^2}(2l(l-1) + l - 1, n)(-\zeta^{l(l-1)} - 1) + B_{2l^2}(2l(l-1) + l, n)
\]

\[
(-\zeta^{l(l-1)}) + \cdots + B_{2l^2}(2l^2 - 1, n)(-\zeta^{l^2-1})
\]
\[ \sum_{i=0}^{\ell(l-1)-1} d_{i,n} \zeta^i. \]

Here
\[ d_{i,n} = B_{2l^2}(i,n) \mp B_{2l^2}(l(l-1) + j,n) - B_{2l^2}((2l^2) + k,n) \pm B_{2l^2}((2\phi(2l^2) + l) + j,n), \]
where
\[ 0 \leq j \leq l - 1, \quad j \equiv i \pmod{2l^2}, \quad k \equiv i \pmod{2l^2}, \quad 0 \leq i, k \leq \phi(2l^2) - 1, \]
and sign's are 'l' periodic.

**Theorem 3.** Let \( l \geq 3 \) be a prime and \( q = p^r \equiv 1 \pmod{2l^2} \). If \( n, 1 \leq n \leq 2l^2 - 3 \) is an odd integer, then a congruence for \( J_{2l^2}(1,n) \) over \( \mathbb{F}_q \) is given by

\[
J_{2l^2}(1,n) \equiv \begin{cases} 
\zeta_{2l^2}^{-w}(-1 + \sum_{i=3}^{l} c_{i,n}(\zeta_{2l^2} - 1)i) \pmod{(1 - \zeta_{2l^2})^{l+1}}, & \text{if } n = l^2, \\
-\zeta_{2l^2}^{-w(dl+1)}(-1 + \sum_{i=3}^{l} c_{i,n}(\zeta_{2l^2} - 1)i)(-1 + \sum_{i=3}^{l} c_{i,n}(\zeta_{2l^2}^{(-1-dl)/2} - 1)i) \pmod{(1 - \zeta_{2l^2})^{l+1}}, & \text{if } d \neq l \text{ odd integer and } n = dl, \\
\zeta_{2l^2}^{-w(n+1)}(-1 + \sum_{i=3}^{l} c_{i,n}(\zeta_{2l^2} - 1)i)(-1 + \sum_{i=3}^{l} c_{i,n}(\zeta_{2l^2}^{n} - 1)i) \times (-1 + \sum_{i=3}^{l} c_{i,n}(\zeta_{2l^2}^{(1-l^2)/2} - 1)i) \pmod{(1 - \zeta_{2l^2})^{l+1}}, & \text{if } \gcd(n, 2l^2) = 1.
\end{cases}
\]

Where \( c_{i,n} \) are as described in the Theorem 1.

**Proof.** The proof of the theorem is immediate from the above-mentioned Lemma’s.

**Remark 2:** If \( n \) is even, \( 2 \leq n \leq 2l^2 - 2 \). The congruences for Jacobi sums \( J_{2l^2}(1,n) \) can be calculated using the relation \( J_{2l^2}(1,n) = \chi(-1) J_{2l^2}(1,2l^2 - n - 1) \). Also if \( d \) in the theorem is even then \( J_{2l^2}(1,d) = \chi(-1) J_{2l^2}(1,2l^2 - dl - 1) \) and \( 2l^2 - dl - 1 \) is odd. Thus the congruences for \( J_{2l^2}(1,n) \) gets completely determined and hence that of all Jacobi sums of order \( 2l^2 \). Further as \( 1 - \zeta_{2l^2} \) is a divisor of \( 1 - \zeta_{2l^2} \), the congruences remains same modulo \( (1 - \zeta_{2l^2})^{l+1} \).

**Future Scope:** The study of cyclotomic numbers of order \( 2l^2 \) and prime ideal decomposition of Jacobi sums of order \( 2l^2 \) are among the future scopes.
