Dynamical systems for arithmetic schemes

Christopher Deninger

1 Introduction

In the present paper we construct infinite-dimensional continuous-time dynamical systems $X_0$ attached to integral normal schemes $\mathfrak{X}_0$ which are flat and of finite type over $\text{spec } \mathbb{Z}$. The closed points $x_0$ of $\mathfrak{X}_0$ correspond bijectively to compact packets $\Gamma_{x_0}$ of periodic orbits of length $\log N x_0$. Here $N x_0 = |\kappa(x_0)|$ is the norm of $x_0$, the number of elements in the (finite) residue field $\kappa(x_0)$ of $x_0$. If $p = \text{char } \kappa(x_0)$, then $\Gamma_{x_0}$ is fibred over the compact group

$$\text{Aut}(\mathfrak{F}^{x_0})/\text{Aut}(\mathfrak{F}_p) = \hat{\mathbb{Z}}(p)/p\hat{\mathbb{Z}},$$

with fibres the periodic orbits in $\Gamma_{x_0}$. Each periodic orbit of $X_0$ lies in exactly one packet $\Gamma_{x_0}$. There are no fixed points of the flow. The existence of periodic orbits rests on the existence of Frobenius elements for $x_0$ in the Galois group of the function field $K_0$ of $\mathfrak{X}_0$. The space $X_0$ carries a generalized 1-codimensional foliation such that the flow maps leaves to leaves. The existence of such systems $X_0$ for arithmetic schemes $\mathfrak{X}_0$ was predicted by earlier work, c.f. [Den00], [Den98], [Den01], [Den08]. Whether the particular dynamical systems constructed in this paper or suitable subsystems can be useful or require modification remains to be seen. Working with $X_0$ itself, the greatest difficulty is that $X_0$ is infinite dimensional instead of being $2 \dim \mathfrak{X}_0 + 1$-dimensional as suggested by arithmetic topology and the above references. There are many

*supported by CRC 878
natural questions about $X_0$ but we adress only the most basic one, namely the connectedness of $X_0$ in a natural topology, c.f. Corollary 16. We prove that $X_0$ has at most finitely many connected components and if $\mathfrak{X}_0 \otimes \mathbb{Q} \mathbb{Q}(\mu_\infty)$ is connected, then $X_0$ is connected. The proof uses de Jong’s theory of alterations if $\dim X_0 \geq 2$.

In [KS16] Kucharczyk and Scholze realize the absolute Galois groups of fields containing all roots of unity as covering groups on certain spaces. Part of the generic fibre of our space $\mathfrak{X}(\mathbb{C})$ is contained in one of their spaces.

I am deeply indebted to the CRCs 478 and 878 for their longterm support. Moreover I am very grateful to Umberto Zannier for the invitation to the Scuola Normale in Pisa where the construction of the dynamical systems was found. I also thank the HIM in Bonn for supporting a fruitful stay.

2 The $\mathcal{N}$- and $\mathbb{Q}^>0$-dynamical systems

Let $\mathfrak{X}_0$ be an arithmetic scheme by which we mean an integral normal scheme which is flat and of finite type over $\text{spec} \mathbb{Z}$. Let $K_0$ be the function field of $\mathfrak{X}_0$. Note that every open subscheme $\mathfrak{X}_0'$ of $\mathfrak{X}_0$ is again an arithmetic scheme with the same function field $K_0$. Our constructions depend on the choice of a radicially closed field extension $K$ of $K_0$ which is Galois over $K_0$. Radicially closed means that every equation $T^N - a$ for $a \in K$ decomposes into linear factors. Equivalently, $K^\times$ is divisible and $K$ contains all roots of unity. For example we can take an algebraic closure of $K_0$ or the maximal solvable extension of $K_0$ in an algebraic closure. Let $G$ be the Galois group of $K$ over $K_0$ and let $\mathfrak{X}$ be the normalization of $\mathfrak{X}_0$ in $K$. The group $G$ acts on $\mathfrak{X}$ over $\mathfrak{X}_0$. Let $\mathbb{C}$ be an algebraically closed field of characteristic zero. We are thinking of the complex numbers or of $\mathbb{C}_p$, the completion of an algebraic closure of $\mathbb{Q}_p$ for a prime number $p$.

**Proposition 1.** The natural morphism $\pi : \mathfrak{X} \to \mathfrak{X}_0$ induces a bijection $\mathfrak{X}(\mathbb{C})/G = \mathfrak{X}_0(\mathbb{C})$.

**Proof.** If $\mathfrak{X}_0 = \text{spec} R_0$ is affine we have $\mathfrak{X} = \text{spec} R$ where $R$ is the normalization of $R_0$ in $K$. Hence $R_0 = R^G$ and the claim is a special case of [KS16].
Lemma 4.9]. The general case follows because by construction \( \pi \) is integral and in particular affine: We have

\[
\mathfrak{X}(\mathbb{C}) = \bigcup_i \pi^{-1}(\mathfrak{X}_0^i(\mathbb{C}))
\]  

(1)

where \( \{ \mathfrak{X}_0^i \} \) is an open affine covering of \( \mathfrak{X}_0 \). Moreover \( \pi^{-1}(\mathfrak{X}_0^i(\mathbb{C})) = \mathfrak{X}_0^i(\mathbb{C}) \) where \( \mathfrak{X}_0^i \to \mathfrak{X}_0^i \) is the normalization of \( \mathfrak{X}_0^i \) in \( K \). Hence \( \pi^{-1}(\mathfrak{X}_0^i(\mathbb{C}))/G = \mathfrak{X}_0^i(\mathbb{C}) \) and therefore the map \( \mathfrak{X}(\mathbb{C})/G \to \mathfrak{X}_0(\mathbb{C}) \) is bijective. \( \square \)

A point of \( \mathfrak{X}_0(\mathbb{C}) \) consists of a scheme theoretic point \( x_0 \) of \( \mathfrak{X}_0 \) together with an embedding of its residue field \( \kappa(x_0) \) into \( \mathbb{C} \). Such field embeddings exist only if \( \text{char} \kappa(x_0) = \text{char} \mathbb{C} = 0 \). Hence \( \mathfrak{X}_0(\mathbb{C}) \) does not “see” the points \( x_0 \) in the fibres of \( \mathfrak{X}_0 \) over \( \text{spec} \mathbb{F}_p \). Moreover there is no Frobenius endomorphism of \( \mathfrak{X}_0(\mathbb{C}) \).

We propose generalizations of the notion of \( \mathbb{C} \)-valued point of \( \mathfrak{X}_0 \) which address these issues. There are several variants of the following construction. They depend on the choice of a suitable condition \( E \) on the characters \( P \times \) below.

**Definition 2.** a) Let \( \hat{\mathfrak{X}}(\mathbb{C}) \) be the set of pairs \( P = (x, P^x) \) where \( x \in \mathfrak{X} \) and \( P^x : \kappa(x)^\times \to \mathbb{C}^\times \) is a multiplicative homomorphism satisfying condition \( E \).

b) The group \( G \) acts on \( \hat{\mathfrak{X}}(\mathbb{C}) \) from the right by \( (x, P^x)^\sigma = (\sigma^{-1}(x), P^x \circ \sigma) \) for \( \sigma \in G \). We set \( \hat{\mathfrak{X}}_0(\mathbb{C}) := \hat{\mathfrak{X}}(\mathbb{C})/G \).

Here the strongest condition \( E \) for our purposes, \( E = E_{\text{fd}} \) requires \( \ker P^x \) to be finite. The weakest one, \( E = E_{\text{max}} \) requires that \( (\ker P^x)^{\text{tors}} \) is finite and that \( \text{im} P^x \subset \mu(\mathbb{C}) \) implies that \( \kappa(x)^\times \) is torsion. Other interesting conditions are \( E_{\text{fd}} \), resp. \( E_{\text{fd}_0} \), that \( (\ker P^x)^{\text{tors}} \) is finite, and \( \dim_Q(\ker P^x) \otimes \mathbb{Q} < \infty \) resp. \( \dim_Q((\ker P^x)_{|\kappa(x_0)^\times}) \otimes \mathbb{Q} < \infty \). Whenever we do not specify the condition \( E \), we assume the implications \( E_f \subset E \subset E_{\text{max}} \) and in particular that the groups \( (\ker P^x)^{\text{tors}} \) are finite. We have implications \( E_f \subset E_{\text{fd}} \subset E_{\text{fd}_0} \subset E_{\text{max}} \) and the corresponding dynamical systems satisfy the corresponding inclusions.

If \( \mathfrak{X}_0 = \text{spec} R_0 \) is affine, \( \mathfrak{X} = \text{spec} R \), we will identify \( \hat{\mathfrak{X}}(\mathbb{C}) \) with the set of multiplicative maps \( P : R \to \mathbb{C} \) with the following properties:

1) \( P(0) = 0, P(1) = 1 \).

2) \( p := P^{-1}(0) \) is additively closed and hence a prime ideal.
3) We have a factorization $P : R \to R/\mathfrak{p} \to \mathbb{C}$.

4) The unique extension of the multiplicative map $\overline{P} : (R/\mathfrak{p}) \setminus \{0\} \to \mathbb{C}^\times$ to a homomorphism $\overline{P}^\times : \kappa(p)^\times \to \mathbb{C}^\times$ satisfies condition $\mathcal{E}$.

We will identify the two points of view, writing $P = (p, \overline{P}^\times)$ and $p_P = p$ occasionally. Then we have $P^\sigma = (p, \overline{P}^\times)^\sigma$ where $P^\sigma = P \circ \sigma$.

There are many considerations in arithmetic geometry leading to relaxing the condition of additivity but keeping multiplicativity: For example the Teichmüller lift in Witt vector theory which is only multiplicative, the work on $\mathbb{F}_1$-geometry for which we refer to the survey [Lor18], ideas in arithmetic topology [Mor12] and its dynamical enhancement [Den02], and recently the work of Kucharczyk and Scholze [KS16].

We could have asked for $\overline{P}^\times$ to be injective like in the classical case where $P$ is also additive, but since we want an action by commuting Frobenius endomorphisms for all prime numbers $p$ we must at least allow finite kernels $\ker \overline{P}^\times$.

We now define the Frobenius actions. Let $\mathcal{N}$ be the multiplicative monoid of positive integers. For $\nu \in \mathcal{N}$ define a map $F_\nu : \mathfrak{X}(\mathbb{C}) \to \mathfrak{X}(\mathbb{C})$ by setting

$$F_\nu(x, \overline{P}^\times) = (x, \overline{P}^\times(\cdot)\nu) = (x, \overline{P}^{\times\nu}) .$$

For this to make sense we have to assume that condition $\mathcal{E}$ is such that $\overline{P}^\times(\cdot)\nu$ satisfies $\mathcal{E}$ if $\overline{P}^\times$ satisfies $\mathcal{E}$. This holds for $\mathcal{E} = E_f, E_{fd}, E_{fd_0}$ and $E_{\max}$. In the affine case where $P = (p, \overline{P}^\times)$ can be viewed as a multiplicative map $P : R \to \mathbb{C}$ we have

$$F_\nu(P)(r) = P(r^\nu) = P(r)^\nu \quad \text{for all } r \in R .$$

Letting $\nu \in \mathcal{N}$ act via $F_\nu$ we obtain a right action of $\mathcal{N}$ on $\mathfrak{X}(\mathbb{C})$ which commutes with the $G$-action. Hence we obtain self maps $F_\nu$ and an $\mathcal{N}$-action on the quotient $\mathfrak{X}_0(\mathbb{C}) = \mathfrak{X}(\mathbb{C})/G$.

Note that we have natural inclusions $\mathfrak{X}(\mathbb{C}) \subset \mathfrak{X}(\mathbb{C})$ and by Proposition 1 also $\mathfrak{X}_0(\mathbb{C}) \subset \mathfrak{X}_0(\mathbb{C})$. More generally, for any field $k$ with a multiplicative embedding $i : k^\times \hookrightarrow \mathbb{C}^\times$ we get a $G$-equivariant inclusion $i_* : \mathfrak{X}(k) \hookrightarrow \mathfrak{X}(\mathbb{C})$. If $a \in \mathfrak{X}(k)$ corresponds to a point $x \in \mathfrak{X}$ and an inclusion $\kappa(x) \hookrightarrow k$, we set $i_*(a) = (x, \overline{P}^\times)$.
where $\mathcal{P}^\times$ is the composition

$$\mathcal{P}^\times : \kappa(x)^\times \xrightarrow{\alpha} k^\times \xhookrightarrow{\iota} \mathbb{C}^\times.$$ 

If $k$ is algebraically closed, we have $\mathcal{X}(k)/G = \mathcal{X}_0(k)$ by [KS16] Lemma 4.9, and we obtain an inclusion $i_* : \mathcal{X}_0(k) \hookrightarrow \hat{\mathcal{X}}_0(\mathbb{C})$.

**Lemma 3.** Let $k$ be a countable field and let $\chi_\mu : \mu(k) \to \mathbb{C}^\times$ be a homomorphism. Then there is a homomorphism $\chi : k^\times \to \mathbb{C}^\times$ with $\chi|_{\mu(k)} = \chi_\mu$ and $\ker \chi = \ker \chi_\mu$. In particular there is an injective homomorphism $k^\times \hookrightarrow \mathbb{C}^\times$.

**Proof.** We may assume that $k$ is algebraically closed. The sequences

$$1 \to \mu(k) \to k^\times \to k^\times/\mu(k) \to 1 \quad \text{and} \quad 1 \to \mu(\mathbb{C}) \to \mathbb{C}^\times \to \mathbb{C}^\times/\mu(\mathbb{C}) \to 1$$

are both split since $\mu(k)$ and $\mu(\mathbb{C})$ are divisible. Choose splittings and consider the induced isomorphisms

$$k^\times \cong \mu(k) \times (k^\times/\mu(k)) \quad \text{and} \quad \mathbb{C}^\times \cong \mu(\mathbb{C}) \times (\mathbb{C}^\times/\mu(\mathbb{C})).$$

Here $k^\times/\mu(k)$ and $\mathbb{C}^\times/\mu(\mathbb{C})$ are uniquely divisible abelian groups and therefore $\mathbb{Q}$-vector spaces. We have

$$\dim_\mathbb{Q} k^\times/\mu(k) \leq \aleph_0 = \dim_\mathbb{Q} \overline{\mathbb{Q}}^\times/\mu(\overline{\mathbb{Q}}) \leq \dim_\mathbb{Q} \mathbb{C}^\times/\mu(\mathbb{C}).$$

Hence there is a $\mathbb{Q}$-linear injection from $k^\times/\mu(k)$ into $\mathbb{C}^\times/\mu(\mathbb{C})$. Together with $\chi_\mu$ and the above decompositions we obtain a homomorphism $\chi : k^\times \to \mathbb{C}^\times$ prolonging $\chi_\mu$ with $\ker \chi = \ker \chi_\mu$. \qed

For any point $x \in \mathcal{X}$ the residue field $k = \kappa(x)$ is countable. Using Lemma 3 it follows that the map

$$\text{pr}_x : \hat{\mathcal{X}}(\mathbb{C}) \longrightarrow \mathcal{X}, \ (x, \mathcal{P}^\times) \longmapsto x$$

is surjective. Hence the induced map of orbit spaces $\hat{\mathcal{X}}_0(\mathbb{C}) \to \mathcal{X}/G$ is surjective as well. The going-up theorem implies that the normalization map $\hat{\mathcal{X}} \to \hat{\mathcal{X}}_0$ and hence the induced map $\mathcal{X}/G \to \mathcal{X}_0$ are surjective as well. By composition we obtain a natural surjection

$$\text{pr}_{\mathcal{X}_0} : \hat{\mathcal{X}}_0(\mathbb{C}) \longrightarrow \mathcal{X}_0.$$
In conclusion we see that contrary to $X_0(C)$ the new set of points $\mathring{X}_0(C)$ carries information about all points of $\mathring{X}_0$.

Enlarging $\mathring{X}(C)$ and $\mathring{X}_0(C)$ we may extend the $\mathcal{N}$-action to an action by the multiplicative group $Q^{>0}$ of positive rational numbers. For $\nu \in \mathcal{N}$ and $x \in X$, the maps $(\cdot)^\nu : \mathcal{O}_{X,x} \to \mathcal{O}_{X,x}$ and hence also $(\cdot)^\nu : \kappa(x)^\times \to \kappa(x)^\times$ are surjective since by our assumptions, $K^\times$ is divisible and $\mathcal{O}_{X,x}$ is integrally closed in $K$. Thus the maps $F_\nu : \mathring{X}(C) \to \mathring{X}(C)$ and hence also $F_\nu : \mathring{X}_0(C) \to \mathring{X}_0(C)$ are injective. We therefore have to extend the backward orbits of the $\mathcal{N}$-operation. This is done by passing to the colimit over the set $\mathcal{N}$ ordered by divisibility, the transition maps being the $F_\nu$ for $\nu \in \mathcal{N}$. Thus we set 

$$\mathring{X}(C) = \text{colim}_\mathcal{N} \mathring{X}(C) \quad \text{and} \quad \mathring{X}_0(C) = \text{colim}_\mathcal{N} \mathring{X}_0(C).$$

The maps $F_\nu$ extend to bijections $F_\nu$ on $\mathring{X}(C)$ and $\mathring{X}_0(C)$ and using them the points of $\mathring{X}(C)$ can be written in the form $F_\nu^{-1}(P)$ for $P \in \mathring{X}(C)$ with $F_\nu^{-1}(P) = F_{\nu'}^{-1}(P')$ if and only if $F_{\nu'}(P) = F_{\nu}(P')$ in $\mathring{X}(C)$. Similar remarks apply to the points $F_\nu^{-1}(P_0)$ of $\mathring{X}_0(C)$, where $P_0 \in \mathring{X}_0(C)$. The actions of $\mathcal{N}$ on $\mathring{X}(C)$ and $\mathring{X}_0(C)$ extend uniquely to actions by $Q^{>0}$ on $\mathring{X}(C)$ and $\mathring{X}_0(C)$. Thus $q = \nu/\nu'$ with $\nu, \nu' \in \mathcal{N}$ acts by $F_q := F_{\nu} \circ F_{\nu}^{-1}$.

Note that the projections $\text{pr}_X$ and $\text{pr}_{X_0}$ above extend $Q^{>0}$-equivariantly to projections 

$$\text{pr}_X : \mathring{X}(C) \longrightarrow X \quad \text{and} \quad \text{pr}_{X_0} : \mathring{X}_0(C) \longrightarrow X_0.$$

Here we let $Q^{>0}$ act trivially on $X$ and $X_0$. The $\mathcal{N}$-equivariant $G$-action of $\mathring{X}(C)$ extends uniquely to a $Q^{>0}$-equivariant $G$-action on $\mathring{X}(C)$ and the natural $Q^{>0}$-equivariant projection 

$$\pi : \mathring{X}(C) \longrightarrow \mathring{X}_0(C)$$

extending the $\mathcal{N}$-equivariant projection 

$$\pi : \mathring{X}(C) \longrightarrow \mathring{X}_0(C)$$

induces a $Q^{>0}$-equivariant bijection: 

$$\pi : \mathring{X}(C)/G \sim \mathring{X}_0(C). \quad (2)$$
The fibres of \( \text{pr}_{\mathcal{X}_0} : \mathcal{X}_0(\mathbb{C}) \to \mathcal{X}_0 \) are \( \mathbb{Q}^>^0 \)-invariant. We will now analyze the structures of the \( \mathbb{Q}^>^0 \)-sets \( C_{\mathcal{X}_0} = \text{pr}^{-1}_{\mathcal{X}_0}(\mathcal{X}_0) \) in \( \mathcal{X}_0(\mathbb{C}) \) for the closed points \( \mathcal{X}_0 \) of \( \mathcal{X}_0 \).

In this case \( \kappa(\mathcal{X}_0) \) is a finite field and for every closed point \( \mathcal{x} \in \mathcal{X} \) over \( \mathcal{X}_0 \) the residue field \( \kappa(\mathcal{x}) \) is an algebraic closure of \( \kappa(\mathcal{X}_0) \) since \( K \) and hence \( \mathcal{O}_{\mathcal{X}_0} \), being integrally closed in \( K \) contain all roots of unity. The reduction map \( \mathcal{O}_{\mathcal{X}_0} \to \kappa(\mathcal{x}) \) induces an isomorphism

\[
i_{\mathcal{x}} : \mu(\text{pr})(\mathcal{K}) = \mu(\text{pr})(\mathcal{O}_{\mathcal{X}_0}) \cong \kappa(\mathcal{x})^\times \ . \tag{3}\]

Here \( p = \text{char} \kappa(\mathcal{X}_0) \) and \( \mu(\text{pr})(S) \) denotes the group of prime-to-\( p \) order roots of unity in a ring \( S \). Consider the commutative diagram where \( \text{pr} = \text{pr}_{\mathcal{X}} \) and \( \text{pr}_0 = \text{pr}_{\mathcal{X}_0} \)

\[
\begin{array}{ccc}
\mathcal{X} & \xrightarrow{\text{pr}} & \mathcal{X}_0(\mathbb{C}) \smallsetminus \mathcal{X}_0(\mathbb{C}) \\
\pi \downarrow & & \pi \downarrow \\
\mathcal{X}_0 & \xrightarrow{\text{pr}_0} & \mathcal{X}_0(\mathbb{C}) \smallsetminus \mathcal{X}_0(\mathbb{C}) .
\end{array}
\tag{4}
\]

The fibre \( \text{pr}^{-1}_0(\mathcal{X}_0) \) in \( \mathcal{X}_0(\mathbb{C}) \) is \( \mathcal{N} \)-invariant. Its extension to a \( \mathbb{Q}^>^0 \)-invariant subset of \( \mathcal{X}_0(\mathbb{C}) \) is the set

\[
C_{\mathcal{X}_0} = \text{pr}_0^{-1}(\mathcal{X}_0)\mathbb{Q}^>^0 = \bigcup_{\nu \in \mathcal{N}^\times} F^{-\nu} \text{pr}_0^{-1}(\mathcal{X}_0) \subset \mathcal{X}_0(\mathbb{C}) .
\]

The fibre \( \text{pr}_0^{-1}(\mathcal{X}_0) \) consists of the \( G \)-orbits of all pairs \( (\mathcal{x}, \mathcal{P}^\times) \) where \( \mathcal{x} \) is a closed point of \( \mathcal{X} \) over \( \mathcal{X}_0 \) and \( \mathcal{P}^\times : \kappa(\mathcal{x})^\times \to \mathbb{C}^\times \) satisfies condition \( \mathcal{E} \). Since \( \kappa(\mathcal{x})^\times \) is torsion this means that \( \ker \mathcal{P}^\times = (\ker \mathcal{P}^\times)^\text{tors} \) is finite or equivalently finite cyclic since finite subgroups of \( L^\times \) for a field \( L \) are cyclic. Given \( \mathcal{x} \) and using the isomorphism \( (2) \), any choice of isomorphisms \( \mu(\text{pr})(\mathcal{K}) \cong \mu(\text{pr})(\mathcal{C}) \) gives an element of \( \text{pr}_0^{-1}(\mathcal{X}_0) \). The structure of \( \text{pr}_0^{-1}(\mathcal{X}_0) \) and of \( C_{\mathcal{X}_0} \) as \( \mathcal{N} \)-resp. \( \mathbb{Q}^>^0 \)-sets is determined as follows. Fix a closed point \( \mathcal{x} \) over \( \mathcal{X}_0 \) and let \( G_\mathcal{x} \) be the stabilizer subgroup of \( \mathcal{x} \) in \( G \). It surjects onto \( \text{Gal}(\kappa(\mathbf{x})/\kappa(\mathcal{X}_0)) \), c.f. [Bou64, Chap.V, §2, n° 3, Proposition 6]. Because of \( (3) \), the group of automorphisms of the abelian group \( \kappa(\mathcal{x})^\times \) is given by \( \hat{\mathcal{Z}}^\times_{\mathcal{x}} \) where \( \hat{\mathcal{Z}}_{\mathcal{x}} = \prod_{l \neq p} \mathcal{Z}_l \). We have a natural inclusion

\[
\mathcal{N} \hat{\mathcal{Z}}_{\mathcal{x}}^\times = \text{Gal}(\kappa(\mathbf{x})/\kappa(\mathcal{X}_0)) \hookrightarrow \text{Aut}(\kappa(\mathcal{x})^\times) = \hat{\mathcal{Z}}_{\mathcal{x}}^\times . \tag{5}
\]
Here on the left, $N\mathbf{x}_0$ corresponds to the Frobenius automorphism $y \mapsto y^{N\mathbf{x}_0}$ in the Galois group. The monoid $\hat{\mathbb{Z}}'_p \times \mathcal{N}$ acts on the set $\mathcal{S}$ of homomorphisms $\bar{\mathcal{P}}^\times : \kappa(\mathbf{x})^\times \to \mathbb{C}^\times$ with finite cyclic kernel by pre-composition. Fix a multiplicative embedding $i : \kappa(\mathbf{x})^\times \hookrightarrow \mathbb{C}^\times$. It follows that we have a $\hat{\mathbb{Z}}'_p \times \mathcal{N}$-equivariant surjection:

$$\hat{\mathbb{Z}}'_p \times \mathcal{N} \twoheadrightarrow \mathcal{S}, (a, \nu) \mapsto i \cdot (a, \nu) := i \circ (\cdot)^a \circ (\cdot)^\nu. \quad (6)$$

Two elements $(a, \nu)$ and $(a', \nu')$ are in the same fibre of this map if and only if $\nu'/\nu = p^n$ for some $n \in \mathbb{Z}$ and $a = p^n a'$. Any closed point $\mathbf{y}$ in $\mathfrak{X}$ over $\mathbf{x}_0$ is conjugate to our chosen point $\mathbf{x}$ by an element of $G$. This follows from [1] and [Mat89 Theorem 5 vi)]. We have canonical $\mathcal{N}$-equivariant bijections

$$\text{pr}_0^{-1}(\mathbf{x}_0) = (\pi^{-1}(\text{pr}_0^{-1}(\mathbf{x}_0)))/G$$

$$= (\pi^{-1}(\pi^{-1}(\mathbf{x}_0)))/G$$

$$= \{ (\mathbf{y}, \bar{\mathcal{P}}^\times) \in \hat{\mathfrak{X}}(\mathbb{C}) \mid \pi(\mathbf{y}) = \mathbf{x}_0 \}/G$$

$$\cong \{ (\mathbf{x}, \bar{\mathcal{P}}^\times) \in \hat{\mathfrak{X}}(\mathbb{C}) \}/G_{\mathbf{x}_0}$$

$$\cong \mathcal{S}/\text{Gal}(\kappa(\mathbf{x})/\kappa(\mathbf{x}_0)).$$

Explicitly this gives the $\mathcal{N}$-equivariant bijection:

$$\mathcal{S}/N\mathbf{x}_0 \hat{\mathcal{P}} \sim \text{pr}_0^{-1}(\mathbf{x}_0), \bar{\mathcal{P}}^\times \text{ mod } N\mathbf{x}_0 \hat{\mathcal{P}} \mapsto \pi((\mathbf{x}, \bar{\mathcal{P}}^\times)) \quad \text{.} \quad (7)$$

Composing with $(6)$ we get the $\mathcal{N}$-equivariant surjection:

$$\left(\hat{\mathbb{Z}}'_p/N\mathbf{x}_0 \hat{\mathcal{P}} \right) \times \mathcal{N} \twoheadrightarrow \text{pr}_0^{-1}(\mathbf{x}_0), (\pi, \nu) \mapsto \pi((\mathbf{x}, i \circ (\cdot)^a \circ (\cdot)^\nu)) \quad \text{.} \quad (8)$$

Two elements $(\pi, \nu)$ and $(\pi', \nu')$ are in the same fibre if and only if $\nu'/\nu = p^n$ for some $n \in \mathbb{Z}$ and $\pi = p^n \pi'$. The later condition depends only on the class of $n$ mod deg $\mathbf{x}_0$. Passing to the $\mathbb{Q}^{>0}$-extensions i.e. to $\text{colim}_\mathcal{N}$ we obtain a $\mathbb{Q}^{>0}$-equivariant bijection:

$$\left(\hat{\mathbb{Z}}'_p/N\mathbf{x}_0 \hat{\mathcal{P}} \right) \times_{\mathbb{Q}^{>0}} \mathbb{Q}^{>0} \sim \mathcal{C}_{\mathbf{x}_0} \quad \text{.} \quad (9)$$

Here, for a right $\Gamma$-modul $A$ and a left $\Gamma$-module $B$ we write $A \times_\Gamma B$ for the quotient of $A \times B$ by the left $\Gamma$-action given by $\gamma(a, b) = (a\gamma^{-1}, \gamma b)$. The $\Gamma$-orbit of $(a, b)$ is denoted by $[a, b]$. It follows that all points $P_0 \in C_{\mathbf{x}_0}$ have isotropy subgroup $(\mathbb{Q}^{>0})P_0 = N\mathbf{x}_0 \hat{\mathcal{P}}$. Namely, the equation $[\pi, r]q = [\pi, r]$, i.e. $[\pi, rq] = [\pi, r]$ means that for some $n \in \mathbb{Z}$ we have $\pi = p^n \pi$ in $\hat{\mathbb{Z}}'_p/N\mathbf{x}_0 \hat{\mathcal{P}}$ and
\( rq = p^n r \). This is equivalent to \( p^n \in N x_0 \hat{\mathbb{Z}} \) and \( q = p^n \) i.e. to \( q \in N x_0 \hat{\mathbb{Z}} \). We may also write \( \mathfrak{m} \) as a \( Q_{>0} \)-equivariant bijection:

\[
(\hat{\mathbb{Z}}(p)/N x_0 \hat{\mathbb{Z}}) \times_{\mathbb{Z}/\deg x_0} (Q_{>0}/N x_0 \hat{\mathbb{Z}}) \sim C_{x_0}.
\]

(10)

It shows that \( C_{x_0} \) fibres over the compact group

\[
\hat{\mathbb{Z}}(p)/p \hat{\mathbb{Z}} = \text{Aut}(\mathbb{F}_p^\times)/\text{Aut}(\mathbb{F}_p)
\]

with fibres the \( Q_{>0} \)-orbits in \( C_{x_0} \). After this discussion of the \( Q_{>0} \)-sets \( C_{x_0} \), we mention one further item before proving the basic Theorem 4 below. The maps \( \mathfrak{m} \) and the fibration map are non-canonical and depend on our choices of \( x \) and \( i \). On the other hand, the projection

\[
C_{x_0} \rightarrow Q_{>0}/p \mathbb{Z}
\]

(11)

resulting from \( \mathfrak{m} \) is canonical, it maps the point \( \hat{\pi}(F^{-1}_p(x, \mathbb{F}_p^\times)) \) to the class of \( |\ker \mathbb{F}_p^\times|/\nu \mod p \mathbb{Z} \). More generally consider the map

\[
\rho : \hat{\mathfrak{X}}_0(\mathbb{C}) \rightarrow \mathcal{N}, \quad P_0 \mapsto |(\ker \mathbb{F}_p^\times)_{\text{tors}}| \quad \text{where} \quad P_0 = \hat{\pi}(F^{-1}_p(x, \mathbb{F}_p^\times)).
\]

(12)

For \( \nu \in \mathcal{N} \) let \( \nu_x \) be the prime-to-char \( \kappa(x) \) part of \( \nu \). If \( \text{char} \kappa(x) = 0 \) then \( \nu_x = \nu \). We have

\[
|(\ker \mathbb{F}_p^\times \circ (\ )^{\nu})_{\text{tors}}| = \nu_x |(\ker \mathbb{F}_p^\times)_{\text{tors}}|,
\]

or in other words

\[
\rho(F^{-1}_p(P_0)) = \nu_x \rho(P_0) \quad \text{for} \quad \nu \in \mathcal{N}.
\]

(13)

Recall the projection \( \text{pr}_{x_0} : \hat{\mathfrak{X}}_0(\mathbb{C}) \rightarrow \mathfrak{X}_0 \) and for a prime \( p \) set

\[
\hat{\mathfrak{X}}_0(\mathbb{C})_{\mathbb{F}_p} = \text{pr}_{x_0}^{-1}(\mathfrak{X}_0 \otimes \mathbb{F}_p).
\]

This is the set of points \( F^{-1}_p([x, \mathbb{F}_p^\times]) \) in \( \hat{\mathfrak{X}}_0(\mathbb{C}) \) with \( \kappa(x) \) of characteristic \( p \). Similarly,

\[
\hat{\mathfrak{X}}_0(\mathbb{C})_{\mathbb{Q}} = \text{pr}_{x_0}^{-1}(\mathfrak{X}_0 \otimes \mathbb{Q})
\]

is the set of points with \( \kappa(x) \) of characteristic zero. Formulas (12) and (13) show that \( \rho \) induces \( Q_{>0} \)-equivariant maps

\[
\rho : \hat{\mathfrak{X}}_0(\mathbb{C})_{\mathbb{F}_p} \rightarrow Q_{>0}/p \mathbb{Z}
\]

(14)
and
\[ \rho : \hat{X}_0(\mathbb{C})_Q \longrightarrow Q^{>0} \]  \hspace{1cm} (15)

We obtain a natural \( Q^{>0} \)-equivariant surjective map
\[ \rho : \hat{X}_0(\mathbb{C}) = \hat{X}_0(\mathbb{C})_{F_p} \longrightarrow Q^{>0} \prod_p \mathbb{Q}^{>0} / p\mathbb{Z} . \]  \hspace{1cm} (16)

The projection (11) is the restriction of \( \rho : \hat{X}_0(\mathbb{C})_{F_p} \rightarrow Q^{>0} / p\mathbb{Z} \) to \( C_{x_0} \subset \hat{X}_0(\mathbb{C})_{F_p} \).

Concerning the \( Q^{>0} \)-action on \( \hat{X}_0(\mathbb{C}) \) we have the following main result:

**Theorem 4.** The following decomposition holds, where \( x_0 \) runs over the closed points of \( \hat{X}_0 \)
\[ \{ P_0 \in \hat{X}_0(\mathbb{C}) \mid (Q^{>0})_{P_0} \neq 1 \} = \bigcup_{x_0} C_{x_0} . \]  \hspace{1cm} (17)

For any point \( P_0 \in C_{x_0} \) the isotropy group of \( P_0 \) is \( (Q^{>0})_{P_0} = N_{x_0} \).

**Proof.** Replacing \( P_0 \in \hat{X}_0(\mathbb{C}) \) with \( F_\nu(P_0) \) for some \( \nu \in \mathcal{N} \) does not change the isotropy subgroup. Hence it is sufficient to determine the points \( P_0 \in \hat{X}_0(\mathbb{C}) \) whose isotropy subgroup is non-trivial. The points \( P_0 \) in \( \hat{X}_0(\mathbb{C}) \) have the form
\[ P_0 = \hat{\pi}(x, \overline{\kappa}^x) = (x, \overline{\kappa}^x) \mod G, \]  \hspace{1cm} \( \overline{\kappa}^x : \kappa(x)^x \rightarrow \mathbb{C}^x \) is a homomorphism satisfying \( \mathcal{E} \) and hence \( \mathcal{E}_{\text{max}} \). For \( q = \nu/\nu' \in Q^{>0} \) with \( \nu, \nu' \in \mathcal{N} \), the condition \( q \in (Q^{>0})_{P_0} \) means that \( F_q(P_0) = P_0 \) i.e. \( F_\nu(P_0) = F_{\nu'}(P_0) \). This is equivalent to the existence of some \( \sigma \in G \) with \( \sigma x = x \) and
\[ \overline{\kappa}^x(y') = \overline{\kappa}^x(\sigma(y)^{\nu'}) \]  \hspace{1cm} for all \( y \in \kappa(x)^x \). \hspace{1cm} (18)

Here \( \sigma \) is the automorphism of \( \kappa(x) \) over \( \kappa(x_0) \) induced by \( \sigma \) where \( x_0 = \pi(x) \). Condition (18) means that the subgroup
\[ H = \{ y^{\sigma}(-y') \mid y \in \kappa(x)^x \} \]

is contained in the kernel of \( \overline{\kappa}^x \). According to the next lemma, \( \kappa(x)^x / H \) is a torsion group if \( q \neq 1 \).

**Lemma 5.** For \( \nu \neq \nu' \) the following map is surjective
\[ \bigcup_{i \geq 1} \mu_{\nu - \nu'}(K) \longrightarrow \kappa(x)^x / H , \zeta \mapsto (\zeta \mod m_x) H \]  \hspace{1cm} (19)
Here \( m_x \) is the maximal ideal in \( \mathcal{O}_{X,x} \).

The proof of the lemma will be given below. For \( q \neq 1 \), using the lemma, it follows that \((\ker \overline{P}^\times) \otimes \mathbb{Q} = \kappa(x)^\times \otimes \mathbb{Q} \) and hence that \( \text{im} \overline{P}^\times \) is torsion. Since condition \( \mathcal{E} \) implies \( \mathcal{E}_{\text{max}} \), it follows that \( \kappa(x)^\times \) is torsion. By the structure theory of fields we conclude that \( \kappa(x) \subset \overline{\mathbb{F}}_p \) for some \( p \). But then the point \( x \) must be closed and \( \kappa(x) = \overline{\mathbb{F}}_p \). Moreover, \( x_0 = \pi(x) \) is a closed point of \( X_0 \) and \( \kappa(x_0) \) is finite. It follows that \( P_0 \in \text{pr}_0^{-1}(x_0) \subset C_{x_0} \). The remaining assertions in the theorem have already been shown in our discussion of \( C_{x_0} \). In particular, we have \( q \in \mathcal{N}_{x_0}^Z \). Thus, modulo the lemma, Theorem 4 is proved.

**Proof of Lemma**

Fix \( c \in \kappa(x)^\times \) and choose \( i \geq 1 \) such that \( \overline{\sigma}^i(c) = c \). The \( N \)-th power map is surjective on \( \kappa(x) \) for every \( N \geq 1 \). Thus, since \( \nu \neq \nu' \) there is some \( z \in \kappa(x)^\times \), such that \( z^{\nu - \nu'} = c \).

We find \( \overline{\sigma}^i(z)^{\nu - \nu'} = \overline{\sigma}^i(c) = c = z^{\nu - \nu'} \).

Hence we have \( \overline{\sigma}(z) = \eta z \) for some \( \eta \in \mu_{\nu - \nu'}(\kappa(x)) \). This implies:

\[
\frac{z^{\nu i}}{\overline{\sigma}(z)^{\nu i}} = \frac{z^{\nu i}}{\eta^{\nu i} z^{\nu i}} = \eta^{-\nu i} z^{\nu - \nu'} = \eta^{-\nu i} c.
\]

In the commutative group ring \( \mathbb{Z}\langle \overline{\sigma} \rangle \) of the cyclic group \( \langle \overline{\sigma} \rangle \) generated by \( \overline{\sigma} \) we have

\[
\nu - \nu' \overline{\sigma} = \omega(\nu - \nu' \overline{\sigma})
\]

for \( \omega = \sum_{\alpha=0}^{i-1} \nu^{i-1-\alpha} \nu' \alpha \overline{\sigma} = \mathbb{Z}\langle \overline{\sigma} \rangle \).

The group ring \( \mathbb{Z}\langle \overline{\sigma} \rangle \) acts on \( \kappa(x)^\times \). Setting \( y = z^\omega \) we obtain:

\[
\frac{y^{\nu'}}{\overline{\sigma}(y)^{\nu'}} = y^{\nu - \nu' \overline{\sigma}} = z^{\omega(\nu - \nu' \overline{\sigma})} = z^{\nu - \nu' \overline{\sigma}} = \frac{z^{\nu i}}{\overline{\sigma}(z)^{\nu i}}.
\]

This implies that \( \eta^{-\nu i} c = \frac{y^{\nu'}}{\overline{\sigma}(y)^{\nu'}} \in H \).
Thus we have
\[ cH = \zeta H, \]
for \( \zeta = \eta^\nu \in \mu_{\nu,\nu'}(\kappa(x)) \). This implies the Lemma and hence Theorem 4. \( \square \)

**Remark 6.** For conditions \( \mathcal{E} \subset \mathcal{E}_{fd_0} \) the proof of Theorem 4 does not require Lemma 3. As before (18) implies \( H \subset \ker \overline{\mathcal{T}}^x \) and hence \( H \cap \kappa(x_0)^x \subset \ker \overline{\mathcal{T}}^x |_{\kappa(x_0)^x} \). Since \( \overline{\sigma} \) acts trivially on \( \kappa(x_0)^x \), we have
\[ (\kappa(x_0)^x)^{\nu-\nu'} := \{ y^{\nu-\nu'} \mid y \in \kappa(x_0)^x \} \subset H \cap \kappa(x_0)^x \subset \ker \overline{\mathcal{T}}^x |_{\kappa(x_0)^x}. \]
Because \( \overline{\mathcal{T}}^x \) satisfies \( \mathcal{E}_{fd_0} \) it follows that \( \dim_{\mathbb{Q}}((\kappa(x_0)^x)^{\nu-\nu'} \otimes \mathbb{Q}) < \infty \). If \( q \neq 1 \) i.e. \( \nu \neq \nu' \) this implies that \( \dim_{\mathbb{Q}} \kappa(x_0)^x \otimes \mathbb{Q} < \infty \). Since \( \kappa(x_0) \) is the residue field of a point on a scheme of finite type over \( \mathbb{Z} \) it follows that \( \kappa(x_0) \) is a finite field and that \( x_0 \) is a closed point of \( \mathfrak{X}_0 \). We now finish the proof as before.

The condition that \( (\ker \overline{\mathcal{T}}^x)_{\text{tors}} \) is finite seems to be fundamental, in particular for the later connectedness results. However by itself it is not enough to ensure that Theorem 4 holds. It does force the points \( P_0 \in \mathfrak{X}_0(\mathbb{C}) \) over characteristic zero points of \( \mathfrak{X}_0 \) to have trivial stabilizer \( (\mathbb{Q}^>0)_{P_0} = 1 \). However over all positive characteristic points of \( \mathfrak{X}_0 \) it allows points \( P_0 \) with \( (\mathbb{Q}^>0)_{P_0} \neq 1 \) whereas we want this to happen only over the closed points of \( \mathfrak{X}_0 \):

**Theorem 7.** Define \( \dot{\mathfrak{X}}(\mathbb{C}) \) etc as before under the only condition that all the groups \( (\ker \overline{\mathcal{T}}^x)_{\text{tors}} \) are finite. For \( P_0 \in \dot{\mathfrak{X}}_0(\mathbb{C}) \) let \( x_0 = \text{pr}^0_0(P_0) \in \mathfrak{X}_0 \). Then the following assertions hold:

a) If \( (\mathbb{Q}^>0)_{P_0} \neq 1 \) then the characteristic \( p \) of \( \kappa(x_0) \) is positive and \( (\mathbb{Q}^>0)_{P_0} \subset \mathbb{N}_{\kappa(x_0)} \). Here \( \mathbb{N}_{\kappa(x_0)} = |\kappa(x_0) \cap \overline{\mathbb{F}}_p| \) where \( \overline{\mathbb{F}}_p \) is the algebraic closure of \( \mathbb{F}_p \) in \( \kappa(x) \).

b) For any point \( x_0 \in \mathfrak{X}_0 \) with \( p = \text{char} \kappa(x_0) > 0 \) there exist points \( P_0 \in \text{pr}^0_0^{-1}(x_0) \) with \( (\mathbb{Q}^>0)_{P_0} \neq 1 \).

**Proof.** For \( \nu \neq \nu' \), the union of the groups \( \mu_{\nu,\nu'}(K) \) for \( i \geq 1 \) is a subgroup of \( \mu(K) \) since \( \nu^i - \nu'^i \) divides \( \nu^{ki} - \nu'^{ki} \) for \( k \geq 1 \). We may assume that in \( q = \nu/\nu', \nu \neq \nu' \) the integers \( \nu, \nu' \in \mathcal{N} \) are coprime. Let \( \mu_{(\nu\nu')}(K) \) be the group of roots of unity in \( K \) whose orders are prime to \( \nu \) and \( \nu' \). Then we have
\[ \mu_{(\nu\nu')}(K) = \bigcup_{i \geq 1} \mu_{\nu,\nu'}(K). \]  
(20)
Namely, if a prime number \( l \) divides \( \nu^i - \nu' \), then it must be prime to \( \nu \) and \( \nu' \) because otherwise it would divide them both. Hence the right hand side is contained in \( \mu_{(\nu \nu')}(K) \). Now assume that \( \zeta \) has order \( N \) where \( N \) is prime to \( \nu \) and \( \nu' \). Then for \( i = \varphi(N) = |(\mathbb{Z}/N)^\times| \), the classes \( \nu \) and \( \nu' \) in \((\mathbb{Z}/N)^\times\) satisfy \( \nu^i = \nu'^i \) which means that \( N \) divides \( \nu^i - \nu'^i \). Thus \( \zeta \in \mu_{\nu^i - \nu'^i}(K) \) and the reverse inclusion follows. Together with the lemma it follows that \( \mu_{\nu \nu'}(K) \) maps to 1 in \( \kappa(x)^\times / H \) for all prime divisors \( l \) of \( \nu \nu' \). Since \( \P^\times \) factors over \( \kappa(x)^\times / H \), we see that

\[
\text{Im} \left( \mu_{\nu \nu'}(K) \rightarrow \kappa(x)^\times \right) \subset (\ker \P^\times)_{\text{tors}}.
\]

is finite. It follows that \( \nu \nu' > 1 \) can have only one prime divisor, namely \( l = p = \text{char} \kappa(x) \). Note here that the image of \( \mu_{\nu \nu'}(K) \) in \( \kappa(x)^\times \) is trivial. Since \( \nu \neq \nu' \) are coprime it follows that \( \nu = p^n \) and \( \nu' = 1 \) or \( \nu = 1 \) and \( \nu' = p^n \) for some \( n \geq 1 \). Thus we have \( q = \nu / \nu' \in p\mathbb{Z} \). We now assume that \( \nu = p^n, \nu' = 1 \), the following argument being similar in the case \( \nu = 1, \nu' = p^n \).

We know that the group

\[
\{ \zeta^{p^n} \sigma(\zeta)^{-1} \mid \zeta \in \mu_{\nu}(K) \} \hookrightarrow \text{H}_{\text{tors}}, \quad \zeta \mapsto \zeta \mod m_x
\]

is finite since \( \text{H}_{\text{tors}} \subset (\ker \P^\times)_{\text{tors}} \). Hence the map \( p^n - \sigma : \mu_{\nu} \rightarrow \mu_{\nu} \) has finite image. The same is therefore true for its Pontrjagin dual map \( p^n - a : \hat{\mathbb{Z}}(p) \rightarrow \hat{\mathbb{Z}}(p) \). Here \( \sigma \) acts on \( \mu_{\nu} \) by \( \zeta \mapsto \zeta^a \) for some \( a \in \hat{\mathbb{Z}}(p) \) where \( \hat{\mathbb{Z}}(p) = \prod_{l \neq p} \mathbb{Z}_l \).

Writing \( a = (a_l) \) it follows that all maps \( p^n - a_l : \mathbb{Z}_l \rightarrow \mathbb{Z}_l \) for \( l \neq p \) have finite image. This implies \( a_l = p^n \) for all \( l \) and hence \( a = p^n \) in \( \hat{\mathbb{Z}}(p) \). Since \( \sigma \) is trivial on \( \kappa(x_0) \) and hence on \( \kappa(x_0) \cap \mathbb{F}_p \) it follows that the index \( (\kappa(x_0) \cap \mathbb{F}_p : \mathbb{F}_p) \) divides \( n \) i.e. that \( q = \nu / \nu' = p^n \in N_{x_0} \).

b) For a point \( x_0 \in \mathcal{X}_0 \) of positive characteristic \( p = \text{char} \kappa(x_0) \) let spec \( R_0 \) be an open affine subscheme of \( \mathcal{X}_0 \) containing \( x_0 \). Then the open affine subscheme spec \( R \) of \( \mathcal{X} \) contains the points \( x \in \mathcal{X} \) over \( x_0 \). Choose such an \( x \) and let \( p \) be the corresponding prime ideal in \( R \) and let \( p_0 = p \cap R_0 \) be the prime ideal of \( R_0 \) corresponding to \( x_0 \). Let \( \sigma \in \text{Gal}(\mathbb{F}_p / \kappa(p_0) \cap \mathbb{F}_p) \) be the Frobenius automorphism \( y \mapsto y^{p_0} \). Lift \( \sigma \) to an automorphism \( \sigma \) of \( \kappa(p) \) over \( \kappa(p_0) \). According to [Bou74, Chap. V, §2, n° 3, Proposition 6] there is an extension of \( \sigma \) to an automorphism \( \sigma \in G = \text{Gal}(\mathcal{K} / K_0) \) with \( \sigma(x) = x \). Consider the subgroup

\[
H = \{ y^{N_{x_0}} \sigma(y)^{-1} \mid y \in \kappa(x)^\times \} \subset \kappa(x)^\times.
\]

By Lemma 4 the natural map

\[
\mu_{\nu}(K) \cong \mu(\kappa(p)) \rightarrow \kappa(p)^\times / H
\]

13
is surjective. We now show that it is an isomorphism. Its kernel consists of elements \( \zeta = y^{N_0}\sigma(y)^{-1} \in \mu(\kappa(p)) \) for some \( y \in \kappa(p)^\times \). Choose some \( N \geq 1 \) prime to \( p \) with \( \zeta^N = 1 \). For \( z = y^N \) we then have \( \sigma(z) = z^{N_0} \). Letting \( i \) be such that \( \sigma(z) = z \) we see that \( z \) is an \( (N_0^i - 1) \)-th root of unity in \( \kappa(p)^\times \). Hence \( z \) and therefore also \( y \) lie in \( \mu(\kappa(p)) = \mathbb{F}_p^\times \). But then, by the choice of \( \sigma \) we have \( \sigma(y) = y^{N_0} \) and therefore \( \zeta = 1 \). Using the isomorphism \( \mu(p)(K) \overset{\sim}{\longrightarrow} \kappa(p)^\times / H \), any character \( \chi : \mu(p)(K) \rightarrow \mu(\mathbb{C}) \) with finite kernel gives a character \( \overline{\mathcal{F}}^\times : \kappa(x)^\times \rightarrow \mu(\mathbb{C}) \subset \mathbb{C}^\times \) with \( \overline{\mathcal{F}}^\times (H) = 1 \) i.e. with \( \overline{\mathcal{F}}^\times (y^{N_0}) = \overline{\mathcal{F}}^\times (\sigma(y)) \) for all \( y \in \kappa(x)^\times \). Moreover, by construction \( (\ker P)_{\text{tors}} \) is finite. This gives the desired point \( P_0 = (x, \overline{\mathcal{F}}^\times) \mod G \) over \( x_0 \) with \( F_{N_0}(P_0) = P_0 \).

\[ \square \]

3 The \( \mathbb{R}^{>0} \)-dynamical system

In this section we assume that \( \mathbb{C} \) is the field of complex numbers.

Let \( \mathbb{R}^{>0} \) be the group of positive real numbers under multiplication and consider the suspension

\[ X_0 = \hat{X}_0(\mathbb{C}) \times_{\mathbb{Q}^{>0}} \mathbb{R}^{>0} \, . \]

It is the quotient of \( \hat{X}_0(\mathbb{C}) \times \mathbb{R}^{>0} \) by the left \( \mathbb{Q}^{>0} \)-action given by

\[ q(P_0, u) := (P_0q^{-1}, qu) = (F_{q}^{-1}(P_0), qu) \quad \text{for } q \in \mathbb{Q}^{>0} \, . \]

The \( \mathbb{Q}^{>0} \)-orbit of \( (P_0, u) \) is denoted by \( [P_0, u] \). The group \( \mathbb{R}^{>0} \) acts on \( X_0 \) via the second factor:

\[ [P_0, u] \cdot v = [P_0, uv] \quad \text{for } v \in \mathbb{R}^{>0} \, . \]

We may also view \( X_0 \) as a continuous time dynamical system by letting \( t \in \mathbb{R} \) act by \( e^t \). We write \( \phi^t \) for this action i.e. \( \phi^t([P_0, u]) = [P_0, ue^t] \). Dynamical systems of this type can be studied with the methods of [Far04]. For a closed point \( x_0 \) of \( \hat{X}_0 \) set

\[ \Gamma_{x_0} = C_{x_0} \times_{\mathbb{Q}^{>0}} \mathbb{R}^{>0} \subset X_0 \, . \]

The \( \mathbb{Q}^{>0} \)-bijection \( (10) \) induces an \( \mathbb{R}^{>0} \)-bijection

\[ \left( \hat{\mathcal{Z}}_{(p)}^\times / N_{x_0}^\times \right) \times_{\mathbb{Q}^{>0} / \deg x_0} \mathbb{R}^{>0} / N_{x_0}^\times \sim \Gamma_{x_0} \, . \]

Thus all \( \mathbb{R}^{>0} \)-orbits in \( \Gamma_{x_0} \) are circles \( \mathbb{R}^{>0} / N_{x_0}^\times \) and \( \Gamma_{x_0} \) fibres over \( \hat{\mathcal{Z}}_{(p)}^\times / p\hat{\mathcal{Z}} = \text{Aut}(\overline{\mathcal{F}}^\times_p) / \text{Aut}(\overline{\mathcal{F}}_p) \) with fibres the \( \mathbb{R}^{>0} \)-orbits in \( \Gamma_{x_0} \).
The next result is an immediate consequence of Theorem 1.

**Theorem 8.** The following decomposition holds, where \( x_0 \) runs over the closed points of \( \mathcal{X}_0 \)
\[
\{ x_0 \in X_0 \mid (\mathbb{R}^>0)_{x_0} \neq 1 \} = \bigsqcup_{x_0} \Gamma_{x_0}.
\]

For any point \( x_0 \in \Gamma_{x_0} \) the isotropy group of \( x_0 \) is \((\mathbb{R}^>0)_{x_0} = N_{x_0}Z\).

The theorem asserts that the closed points \( x_0 \) of \( X_0 \) correspond bijectively to the compact “packets” \( \Gamma_{x_0} \) of periodic orbits of length \( \log N_{x_0} \) in the \( \mathbb{R} \)-dynamical system \( X_0 \). Any periodic orbit \( \gamma \) in \( X_0 \) is contained in \( \Gamma_{x_0} \) for a uniquely determined closed point \( x_0 \) of \( X_0 \). In our previous analogies between arithmetic schemes and foliated dynamical systems, we assumed that the closed points should correspond bijectively to the periodic orbits. This point of view was suggested by analytic results for path-connected phase spaces. The correspondence in Theorem 8 is a little bit more involved.

We now introduce topologies on our spaces. We begin with the case of an affine arithmetic scheme \( \mathcal{X}_0 = \text{spec} R_0 \) and write \( \mathcal{X} = \text{spec} R \). Viewing \( \mathcal{X}(\mathbb{C}) \) as a set of multiplicative maps \( P : R \to \mathbb{C} \) we give \( \mathcal{X}(\mathbb{C}) \) the topology of pointwise convergence. It is the subspace topology induced by the Tychonov topology of \( \mathbb{C}^R = \prod_R \mathbb{C} \) on \( \mathcal{X}(\mathbb{C}) \) via the inclusion \( \mathcal{X}(\mathbb{C}) \subset \mathbb{C}^R, P \mapsto (P(r))_{r \in R} \). Since \( R \) is countable, \( \mathcal{X}(\mathbb{C}) \) is a metrizable topological space.

**Lemma 9.** For affine arithmetic schemes \( \mathcal{X}_0 \), the natural surjective map
\[
\text{pr}_\mathcal{X} : \mathcal{X}(\mathbb{C}) \twoheadrightarrow \mathcal{X}, \ (x, \overrightarrow{P^x}) \mapsto x \quad \text{or} \quad P \mapsto p = P^{-1}(0)
\]
is continuous.

**Proof.** A closed subset \( A \) of \( \mathcal{X} \) has the form \( A = \{ p \supset I \} \) for some ideal \( I \) in \( R \). Consider a convergent sequence \( P_n \to P \) in \( \mathcal{X}(\mathbb{C}) \) where \( P_n \in \text{pr}_\mathcal{X}^{-1}(A) \) for all \( n \), i.e. \( p_n = P_n^{-1}(0) \supset I \). Since \( P_n(r) \to P(r) \) for all \( r \in R \), it follows that \( P(r) = 0 \) for \( r \in I \) and hence \( p = P^{-1}(0) \supset I \) i.e. \( P \in \text{pr}_\mathcal{X}^{-1}(A) \). Hence \( \text{pr}_\mathcal{X}^{-1}(A) \) is closed and therefore \( \text{pr}_\mathcal{X} \) is continuous. \( \Box \)
Let \( \mathfrak{X}_0 = \text{spec } R_0 \subset \mathfrak{X}_0 = \text{spec } R_0 \) be the inclusion of an open affine (hence arithmetic) subscheme of \( \mathfrak{X}_0 \). Then we have \( R_0 \subset R_0' \subset K_0 \). Let \( \mathfrak{X}' = \text{spec } R' \) be the normalization of \( \mathfrak{X}_0' \) in \( K \). It is an open subscheme of \( \mathfrak{X} = \text{spec } R \) and there is a commutative diagram

\[
\begin{array}{ccc}
\mathfrak{X}' & \subset & \mathfrak{X} \\
\pi' \downarrow & & \downarrow \pi \\
\mathfrak{X}_0' & \subset & \mathfrak{X}_0.
\end{array}
\]

We have \( R \subset R' \subset K \). Moreover there is a commutative diagram

\[
\begin{array}{ccc}
\hat{\mathfrak{X}}'(\mathbb{C}) & \subset & \hat{\mathfrak{X}}(\mathbb{C}) \\
\hat{\mathfrak{X}}' & \subset & \hat{\mathfrak{X}}.
\end{array}
\]

The inclusion map \( \hat{\mathfrak{X}}'(\mathbb{C}) \subset \hat{\mathfrak{X}}(\mathbb{C}) \) sends \( (x, P^x) \) to \( (x, P^x) \) or in terms of multiplicative maps, \( P' \) is sent to \( P'|_R \). It follows that the inclusion is continuous.

**Lemma 10.** The space \( \hat{\mathfrak{X}}'(\mathbb{C}) \) is an open subspace of \( \hat{\mathfrak{X}}(\mathbb{C}) \).

**Proof.** The inclusion being continuous it remains to show that it is an open map. Let \( O \subset \hat{\mathfrak{X}}'(\mathbb{C}) \) be an open subset. The set \( O \) is open in \( \hat{\mathfrak{X}}(\mathbb{C}) \) if

\[
A' = (\hat{\mathfrak{X}}(\mathbb{C}) \setminus \hat{\mathfrak{X}}'(\mathbb{C})) \cup A \quad \text{with } A = \hat{\mathfrak{X}}'(\mathbb{C}) \setminus O
\]

is closed in \( \hat{\mathfrak{X}}(\mathbb{C}) \). Since \( \hat{\mathfrak{X}}'(\mathbb{C}) = \text{pr}^{-1}_X(\mathfrak{X}') \) is open in \( \hat{\mathfrak{X}}(\mathbb{C}) \) by Lemma 9 it suffices to show that \( \overline{A} \subset A' \), where \( \overline{A} \) is the closure of \( A \) in \( \hat{\mathfrak{X}}(\mathbb{C}) \). So, let \( P_n \in A \subset \hat{\mathfrak{X}}(\mathbb{C}) \) be a sequence with \( P_n \to P \in \hat{\mathfrak{X}}(\mathbb{C}) \). The inclusion \( \hat{\mathfrak{X}}'(\mathbb{C}) \subset \hat{\mathfrak{X}}(\mathbb{C}) \) is given by the restriction \( P' \mapsto P'|_R \). Hence \( P_n = P'_n|_R \) for a sequence of points \( P'_n \in A \subset \hat{\mathfrak{X}}'(\mathbb{C}) \). If \( P \notin \hat{\mathfrak{X}}'(\mathbb{C}) \), then \( P \in A' \) and we are done. If \( P \in \hat{\mathfrak{X}}'(\mathbb{C}) \) then \( P = P'|_R \). For the multiplicative maps \( P'_n, P' : R' \to \mathbb{C} \) we have \( P'_n(r) \to P'(r) \) for each \( r \in R \) as \( n \to \infty \). Let \( p' = P'^{-1}(0) \subset R' \) and \( p = P^{-1}(0) \subset R \) be the prime ideals belonging to \( P' \) resp. \( P \). We have \( p = p' \cap R \). Since \( \mathfrak{X}' = \text{spec } R' \subset \mathfrak{X} = \text{spec } R \) is an open immersion, the local rings of \( \mathfrak{X}' \) in \( p' \)
and \( \mathfrak{X} \) in \( p \) are canonically isomorphic. Thus the inclusion \( R \subset R' \) induces a commutative diagram:

\[
\begin{array}{ccc}
R_p & \longrightarrow & R'_p \\
\downarrow P & & \downarrow P' \\
\mathbb{C} & & \,
\end{array}
\]

Here \( P, P' \) also denote the unique multiplicative extensions of \( P \) and \( P' \) to \( R_p \) resp. \( R'_p \). We have \( R' \subset R'_p = R_p \). Given \( r' \in R' \) write \( r' = r/s \) with \( r \in R, s \in R \setminus p \). Since \( P_n(s) \rightarrow P(s) \neq 0 \) for \( n \rightarrow \infty \) we have \( P_n(s) \neq 0 \) for \( n \geq n_0(s) \). Pointwise convergence \( P_n \rightarrow P \) on \( R \) gives:

\[
P'_n(r') = P_n(r)/P_n(s) \rightarrow P(r)/P(s) = P'(r')
\]

for \( n \rightarrow \infty \). Thus we have \( P'_n \rightarrow P' \) pointwise on \( R' \) and therefore \( P' \in A \subset A' \) since \( P_n \in A \) and \( A \) is closed in \( \mathfrak{X}'(\mathbb{C}) \). Hence we have shown that \( \overline{A} \subset A' \).

Now let \( \mathfrak{X}_0 \) be any arithmetic scheme. For any affine open (and hence arithmetic) subscheme \( \mathfrak{X}_0' \) of \( \mathfrak{X}_0 \) consider the inclusion \( \mathfrak{X}'(\mathbb{C}) \subset \mathfrak{X}(\mathbb{C}) \) mapping \( (s', P') \) to \( (s', P') \) via the identification \( O_{\mathfrak{X}', s'} = O_{\mathfrak{X}, s'} \). We give \( \mathfrak{X}(\mathbb{C}) \) the topology for which \( O \subset \mathfrak{X}(\mathbb{C}) \) is open if and only if \( O \cap \mathfrak{X}'(\mathbb{C}) \) is open in \( \mathfrak{X}'(\mathbb{C}) \) for any \( \mathfrak{X}_0' \). Given any covering \( \{ \mathfrak{X}_0' \}_{i \in I} \) of \( \mathfrak{X}_0 \) by affine open subschemes \( \mathfrak{X}_0' \), the set \( O \) is open if and only if \( O \cap \mathfrak{X}_i(\mathbb{C}) \) is open for all \( i \). To see the non-trivial direction, one covers \( \mathfrak{X}_0' \cap \mathfrak{X}_0' \) by open affine subschemes \( \mathfrak{X}_0' \) and notes that \( \mathfrak{X}_i(\mathbb{C}) \) is an open subspace of \( \mathfrak{X}_i(\mathbb{C}) \) and \( \mathfrak{X}'(\mathbb{C}) \) by Lemma 10. Thus, if \( O \cap \mathfrak{X}_i(\mathbb{C}) \) is open in \( \mathfrak{X}_i(\mathbb{C}) \) for all \( i \), it follows that \( O \cap \mathfrak{X}_i(\mathbb{C}) \) is open in \( \mathfrak{X}_i(\mathbb{C}) \) and hence in \( \mathfrak{X}'(\mathbb{C}) \). Hence

\[
O \cap \mathfrak{X}'(\mathbb{C}) = \bigcup_{i,j} O \cap \mathfrak{X}_i(\mathbb{C})
\]

is open in \( \mathfrak{X}'(\mathbb{C}) \). We equip \( \mathfrak{X}_0(\mathbb{C}) = \mathfrak{X}(\mathbb{C})/G \) with the quotient topology. Using Lemma 9 one sees that

\[
\text{pr}_{\mathfrak{X}} : \mathfrak{X}(\mathbb{C}) \rightarrow \mathfrak{X} \quad \text{and hence also} \quad \text{pr}_{\mathfrak{X}_0} : \mathfrak{X}_0(\mathbb{C}) \rightarrow \mathfrak{X}_0
\]

are continuous.
Lemma 11. For any arithmetic scheme $\mathfrak{X}_0$, the group $G$ acts by homeomorphisms on $\hat{\mathfrak{X}}(\mathbb{C})$ and the injective maps $F_\nu : \hat{\mathfrak{X}}(\mathbb{C}) \to \hat{\mathfrak{X}}(\mathbb{C})$ for $\nu \in \mathcal{N}$ are continuous, closed and open. In particular $F_\nu(\hat{\mathfrak{X}}(\mathbb{C}))$ is closed and open in $\hat{\mathfrak{X}}(\mathbb{C})$.

Proof. We first assume that $\mathfrak{X}_0 = \text{spec } R_0$ is affine. Consider the equations

$$F_\nu(\hat{\mathfrak{X}}(\mathbb{C})) = \{ P \in \hat{\mathfrak{X}}(\mathbb{C}) \mid P(\mu_\nu(K)) = 1 \} \subset \hat{\mathfrak{X}}(\mathbb{C}) ,$$

and

$$\hat{\mathfrak{X}}(\mathbb{C}) \setminus F_\nu(\hat{\mathfrak{X}}(\mathbb{C})) = \bigcup_{\chi \neq 1} \{ P \in \hat{\mathfrak{X}}(\mathbb{C}) \mid P|_{\mu_\nu(K)} = \chi \} .$$

Here $\chi$ is in the finite group $\text{Hom}(\mu_\nu(K), \mathbb{C}^\times)$. It follows that $F_\nu(\hat{\mathfrak{X}}(\mathbb{C}))$ is both closed and open in $\hat{\mathfrak{X}}(\mathbb{C})$. Now let $A$ be a closed subset of $\hat{\mathfrak{X}}(\mathbb{C})$. If $P_n \in F_\nu(A)$ and $P_n \to P$ in $\hat{\mathfrak{X}}(\mathbb{C})$, it follows from (21) that $P \in F_\nu(\hat{\mathfrak{X}}(\mathbb{C}))$. Writing $P_n = F_\nu(Q_n)$ and $P = F_\nu(Q)$ it follows that $Q_n(r) \to Q(r)$ for any $r \in R$ since any $r$ has the form $r = s^\nu$ for some $s \in R$. Since $A$ is closed we see that $Q \in A$ and hence $P \in F_\nu(A)$. Thus $F_\nu(A)$ is closed. The continuity of $F_\nu$ being clear, it follows that $F_\nu$ induces a homeomorphism onto its image $F_\nu(\hat{\mathfrak{X}}(\mathbb{C}))$. Since $F_\nu(\hat{\mathfrak{X}}(\mathbb{C}))$ is open in $\hat{\mathfrak{X}}(\mathbb{C})$, it follows that the map $F_\nu : \hat{\mathfrak{X}}(\mathbb{C}) \to \hat{\mathfrak{X}}(\mathbb{C})$ is also open. If $\mathfrak{X}_0$ is an arbitrary arithmetic scheme and $\mathfrak{X}_0' \subset \mathfrak{X}_0$ an affine open (hence arithmetic) subscheme, we have

$$F_\nu(Z) \cap \hat{\mathfrak{X}}'(\mathbb{C}) = F_\nu(Z \cap \hat{\mathfrak{X}}'(\mathbb{C})) ,$$

for any subset $Z \subset \hat{\mathfrak{X}}(\mathbb{C})$ since $F_\nu(x, P^\times) = (x, F_\nu(P^\times))$. If $Z$ is closed (open) in $\hat{\mathfrak{X}}(\mathbb{C})$, then by definition of the topology of $\hat{\mathfrak{X}}(\mathbb{C})$, the set $Z \cap \hat{\mathfrak{X}}'(\mathbb{C})$ is closed (open) in $\hat{\mathfrak{X}}'(\mathbb{C})$. From the affine case we know that $F_\nu(Z \cap \hat{\mathfrak{X}}'(Z))$ is closed (open) in $\hat{\mathfrak{X}}'(\mathbb{C})$. Since this holds for all $\mathfrak{X}_0'$, using (22) it follows that $F_\nu(Z)$ is closed (open) in $\hat{\mathfrak{X}}(\mathbb{C})$.

Remark. We have

$$\bigcap_{\nu \in \mathcal{N}} F_\nu(\hat{\mathfrak{X}}(\mathbb{C})) = \emptyset .$$

Namely, any point $(x, P^\times) \in \hat{\mathfrak{X}}(\mathbb{C})$ in the intersection would satisfy $P^\times|_{\mu(\kappa(x))} = 1$, contradicting the finiteness of $(\ker P^\times)_{\text{tors}}$.  

18
Recall that the maps $F_\nu$ extend to bijections $F_\nu : \hat{\mathcal{X}}(\mathbb{C}) \to \hat{\mathcal{X}}(\mathbb{C})$. We give 
\[
\hat{\mathcal{X}}(\mathbb{C}) = \text{colim}_N \hat{\mathcal{X}}(\mathbb{C})
\]
the inductive limit topology. It is the finest topology such that for all \( \nu \in \mathcal{N} \) the inclusions
\[
F_\nu^{-1} \mid_{\hat{\mathcal{X}}(\mathbb{C})} : \hat{\mathcal{X}}(\mathbb{C}) \hookrightarrow \hat{\mathcal{X}}(\mathbb{C})
\]  
are continuous. Thus $Z \subset \hat{\mathcal{X}}(\mathbb{C})$ is closed, resp. open if and only if $F_\nu(Z) \cap \hat{\mathcal{X}}(\mathbb{C})$ is closed, resp. open in $\hat{\mathcal{X}}(\mathbb{C})$ for all $\nu \in \mathcal{N}$.

**Proposition 12.**  
a) $\hat{\mathcal{X}}(\mathbb{C})$ is a closed and open subspace of $\hat{\mathcal{X}}(\mathbb{C})$.  
b) $F_q : \hat{\mathcal{X}}(\mathbb{C}) \to \hat{\mathcal{X}}(\mathbb{C})$ is a homeomorphism for every $q \in \mathbb{Q}^>0$.  
c) The group $G$ acts by homeomorphisms on $\hat{\mathcal{X}}(\mathbb{C})$.

**Proof.**  
a) By (23) for $\nu = 1$, the inclusion $\hat{\mathcal{X}}(\mathbb{C}) \subset \hat{\mathcal{X}}(\mathbb{C})$ is continuous. We show that it is a closed (open) map. Thus let $Z \subset \hat{\mathcal{X}}(\mathbb{C})$ be closed (open). Then $F_\nu(Z) \cap \hat{\mathcal{X}}(\mathbb{C}) = F_\nu(Z)$ is closed (open) in $\hat{\mathcal{X}}(\mathbb{C})$ for every $\nu$ by Lemma 11. Hence $Z$ is closed (open) in $\hat{\mathcal{X}}(\mathbb{C})$.
b) If $O \subset \hat{\mathcal{X}}(\mathbb{C})$ is open, then for all $\mu \in \mathcal{N}$,  
\[
F_\mu(F_\nu(O)) \cap \hat{\mathcal{X}}(\mathbb{C}) = F_{\mu \nu}(O) \cap \hat{\mathcal{X}}(\mathbb{C})
\]  
is open in $\hat{\mathcal{X}}(\mathbb{C})$ by definition. Hence $F_\nu(O)$ is open in $\hat{\mathcal{X}}(\mathbb{C})$ as well. On the other hand  
\[
F_\mu(F_\nu^{-1}(O)) \cap \hat{\mathcal{X}}(\mathbb{C}) = F_\nu^{-1}(F_\mu(O)) \cap \hat{\mathcal{X}}(\mathbb{C}) = (F_\nu \mid_{\hat{\mathcal{X}}(\mathbb{C})})^{-1}(F_\mu(O)).
\]  
The map  
\[
F_\nu \mid_{\hat{\mathcal{X}}(\mathbb{C})} : \hat{\mathcal{X}}(\mathbb{C}) \to \hat{\mathcal{X}}(\mathbb{C}) \subset \hat{\mathcal{X}}(\mathbb{C})
\]  
is continuous and we have seen that $F_\mu(O)$ is open. Hence the subsets in (24) are open for every $\mu$ and therefore $F_\nu^{-1}(O)$ is open. In conclusion, $F_\nu$ is a homeomorphism for every $\nu \in \mathcal{N}$ and therefore also for every $\nu \in \mathbb{Q}^>0$. Assertion c) is clear.

We give $\hat{\mathcal{X}}_0(\mathbb{C}) = \hat{\mathcal{X}}(\mathbb{C})/G$ the quotient topology. The projections  
\[
\hat{\pi} : \hat{\mathcal{X}}(\mathbb{C}) \to \hat{\mathcal{X}}_0(\mathbb{C}) \quad \text{and} \quad \hat{\pi} : \hat{\mathcal{X}}(\mathbb{C}) \to \hat{\mathcal{X}}_0(\mathbb{C})
\]  

19
are continuous and open. Moreover the projections
\[\text{pr}_X : \check{\mathfrak{X}}(\mathbb{C}) \longrightarrow \mathfrak{X} \quad \text{and} \quad \text{pr}_{X_0} : \check{\mathfrak{X}}_0(\mathbb{C}) \longrightarrow \mathfrak{X}_0\]
are continuous. It suffices to show that \(\text{pr}_X\) is continuous, i.e. that
\[\text{pr}_X \circ (F^{-1}_\nu |_{\check{\mathfrak{X}}(\mathbb{C})}) : \check{\mathfrak{X}}(\mathbb{C}) \longrightarrow \mathfrak{X}\]
is continuous for each \(\nu \in \mathcal{N}\). Since \(\text{pr}_X = \text{pr}_X \circ F_\nu\), this follows from the continuity of \(\text{pr}_X : \check{\mathfrak{X}}(\mathbb{C}) \rightarrow \mathfrak{X}\) which was noted before Lemma 11.

**Theorem 13.** Let \(\mathfrak{X}_0\) be an arithmetic scheme. Let \(\eta = \text{spec} K\) and \(\eta_0 = \text{spec} K_0\) be the generic points of \(\mathfrak{X}\) resp. \(\mathfrak{X}_0\). Then \(\text{pr}_X^{-1}(\eta)\) and \(\text{pr}_X^{-1}(\eta_0)\) are dense in \(\check{\mathfrak{X}}(\mathbb{C})\) resp. \(\check{\mathfrak{X}}_0(\mathbb{C})\).

**Proof.** It suffices to show that \(\text{pr}_X^{-1}(\eta)\) is dense in \(\check{\mathfrak{X}}(\mathbb{C})\). Since \(\text{pr}_X^{-1}(\eta)\) and \(\check{\mathfrak{X}}(\mathbb{C})\) are \(\mathbb{Q}^>0\)-invariant and since \(\check{\mathfrak{X}}(\mathbb{C})\) is covered by the \(\mathbb{Q}^>0\)-translates of the subspace \(\check{\mathfrak{X}}(\mathbb{C})\), it is enough to show that \(\text{pr}^{-1}(\eta)\) is dense in \(\check{\mathfrak{X}}(\mathbb{C})\) where
\[\text{pr} := \text{pr}_X |_{\check{\mathfrak{X}}(\mathbb{C})} : \check{\mathfrak{X}}(\mathbb{C}) \longrightarrow \mathfrak{X} .\]

For a covering of \(\mathfrak{X}_0\) by open affine arithmetic subschemes \(\mathfrak{X}_0^\iota\), the space \(\check{\mathfrak{X}}(\mathbb{C})\) is covered by the open subspaces \(\check{\mathfrak{X}}_0^\iota(\mathbb{C})\) and each of them contains \(\text{pr}^{-1}(\eta)\). Hence it suffices to show that \(\text{pr}^{-1}(\eta)\) is dense in \(\check{\mathfrak{X}}(\mathbb{C})\) if \(\mathfrak{X}_0 = \text{spec} R_0\) is affine. We will first do this in case the chosen radicially closed field \(K\) is an algebraic closure of \(K_0\). Let \(\text{Hom}_E(K^\times, \mathbb{C}^\times)\) be the set of homomorphisms \(\chi : K^\times \rightarrow \mathbb{C}^\times\) satisfying condition \(E\). We have an identification
\[\text{Hom}_E(K^\times, \mathbb{C}^\times) \xrightarrow{\sim} \text{pr}^{-1}(\eta) , \chi \mapsto (\eta, \chi) .\]

We will also view \(\chi\) as a multiplicative map \(\chi : R \rightarrow \mathbb{C}\) by extending \(\chi |_{R_0}\) by \(\chi(0) = 0\) to \(R\). Now let \(P = (p, \overline{P}^\times)\) be a point of \(\check{\mathfrak{X}}(\mathbb{C})\). We have to show that every neighborhood of \(P\) contains a point from \(\text{pr}^{-1}(\eta)\). Since \(P(0) = 0 = \chi(0)\), this means that given any finite subset \(T \subset R \setminus 0\) and some \(\epsilon > 0\) there is an element \(\chi \in \text{Hom}_E(K^\times, \mathbb{C}^\times)\) such that
\[|\chi(r) - P(r)| < \epsilon \quad \text{for all} \ r \in T . \quad (25)\]
We will actually find some $\chi$ with finite kernel i.e. satisfying condition $E_f \subset E$. We first define a character $\chi_\mu : \mu(K) \to \mathbb{C}^\times$, which will be the restriction of $\chi$ to $\mu(K)$. If the characteristic $p$ of $\kappa(p)$ is zero we have $\mu(K) \hookrightarrow \kappa(p)^\times$ and we set
\[
\chi_\mu(\zeta) = P(\zeta) = \overline{P}(\zeta \mod p) \quad \text{for} \ \zeta \in \mu(K).
\]
If $p$ is non-zero, we have a direct product decomposition
\[
\mu(K) = \mu(p)(K) \cdot \mu_p^\infty(K)
\]
and it suffices to define $\chi_\mu$ on each factor. We set
\[
\chi_\mu(\zeta) = P(\zeta) = \overline{P}(\zeta \mod p) \quad \text{for} \ \zeta \in \mu(p)(K),
\]
noting the inclusion $\mu(p)(K) \hookrightarrow \kappa(p)^\times$. On $\mu_p^\infty(K)$ the map $P$ is identically 1 and we cannot set $\chi_\mu = P$ because then $\chi_\mu$ and hence $\chi$ would have a kernel with infinite torsion. Instead we choose some $M \geq 0$ which is bigger than the $p$-valuations of the orders of all the roots of unity in the finite set $T$. Fix an isomorphism $\iota : \mu^\infty_p(K) \cong \mu^\infty_p(\mathbb{C})$ and set
\[
\chi_\mu(\zeta) = \iota(\zeta^M) \quad \text{for} \ \zeta \in \mu_p^\infty(K).
\]
(26) In both cases $p = 0$ and $p \neq 0$ the so defined character $\chi_\mu : \mu(K) \to \mathbb{C}^\times$ has a finite kernel and we have
\[
\chi_\mu(\zeta) = P(\zeta) \quad \text{for all} \ \zeta \in \mu(K) \cap T.
\]
(27) At a later stage we may have to increase the chosen $M$. The characters $\chi$ that we construct are of the following type. Since $\mu(K)$ is divisible the sequence of abelian groups
\[
1 \to \mu(K) \to K^\times \to K^\times/\mu(K) \to 1
\]
splits. Let $\alpha : K^\times \to \mu(K)$ and $\beta : K^\times/\mu(K) \to K^\times$ be corresponding splittings i.e. $\alpha(\zeta) = \zeta$ for $\zeta \in \mu(K)$ and $\beta(\overline{x}) = x\alpha(x)^{-1}$ where we set $\overline{x} = x \mod \mu(K)$. Note that $\alpha(\beta(\overline{x})) = 1$. Set $\mathbb{Z}(1) = 2\pi i\mathbb{Z}$ and $\mathbb{Q}(1) = 2\pi i\mathbb{Q}$ inside of $\mathbb{C}$ and choose a complement $\mathbb{C}'$ to $\mathbb{Q}(1)$ as $\mathbb{Q}$-vector spaces, i.e. $\mathbb{C} = \mathbb{Q}(1) \oplus \mathbb{C}'$. Then the homomorphism
\[
\mu(\mathbb{C}) \times \mathbb{C}' \to \mathbb{C}^\times, (\zeta, z) \mapsto \zeta \exp z
\]
is injective. Our characters $\chi$ are defined by composition

$$K^\times \xrightarrow{\sim} \mu(K) \times K^\times / \mu(K)$$

$$\chi \downarrow \downarrow \quad (\chi_\mu, \chi')$$

$$\mathbb{C}^\times \xrightarrow{\sim} \mu(C) \times C'$$

Here $\chi' : K^\times / \mu(K) \to \mathbb{C}'$ is an injective linear map of $\mathbb{Q}$-vector spaces to be constructed and the top horizontal map sends $x$ to $(\alpha(x), \varpi)$. Explicitly, we have:

$$\chi(x) = \chi_\mu(\alpha(x)) \exp \chi'(\varpi) \quad \text{for } x \in K^\times .$$

It is then immediate that

$$\chi|_{\mu(K)} = \chi_\mu \quad \text{and} \quad \ker \chi = \ker \chi_\mu \text{ is finite}.$$

In defining $\chi'$, so that the resulting character $\chi$ is close to $P$ on $T$, the elements $t \in T \cap p$ are the problematic ones since $P(t) = 0$. The naive approach which works for $t \in T \setminus p$, using linear algebra after tensoring with $\mathbb{Q}$ runs into the problem that $\frac{0}{0}$ is not defined. Let $K_1$ be the finite extension of $K_0$ generated by $T$ and let $R_1 = R \cap K_1$ be the integral closure of $R_0$ in $K_1$. Since $\mathbb{Z}$ is universally Japanese, $R_1$ is a finite $R_0$-algebra and in particular of finite type over $\mathbb{Z}$. As an integral Noetherian scheme, $\mathfrak{X}_1 = \text{spec } R_1$ has an alteration, cf. [dJ96]. This is a proper, dominant hence surjective morphism $f : \mathcal{Z} \to \mathfrak{X}_1$ from an integral regular scheme $\mathcal{Z}$ whose function field $L$ is a finite extension of $K_1$. Let $z \in \mathcal{Z}$ be a point with $f(z) = p_1 := p \cap R_1$. Then we have inclusions, where $\mathcal{O}_z = \mathcal{O}_{\mathcal{Z}, z}$,

$$\mathcal{O}_z \subseteq L \bigcup R_1 \subset p_1 \cap R_1 \subset K_1 .$$

Since we supposed that $K = \overline{K}_0$ was an algebraic closure of $K_0$ we may assume that $L \subset K$ in this diagram. Let $m_z$ be the maximal ideal in the local ring $\mathcal{O}_z$. The map $R_{1, p_1} \subset \mathcal{O}_z$ is local, i.e.

$$p_1 R_{1, p_1} = m_z \cap R_{1, p_1}$$

and hence $p_1 = m_z \cap R_1$. By the Auslander–Buchsbaum theorem, the regular, Noetherian local ring $\mathcal{O}_z$ is a unique factorization domain. We therefore have a decomposition of multiplicative monoids

$$\mathcal{O}_z \setminus 0 = \mathcal{O}_z^\times \oplus \pi_1^{n_0} \oplus \pi_2^{n_0} \oplus \ldots$$
Here $\pi_1, \pi_2, \ldots$ are a complete set of pairwise non-associated prime elements of $\mathcal{O}_z$. If $T \cap p = T \cap p_1 \subset m_2$ is non-empty we can write its elements $s_1, \ldots, s_m$ in the form

$$s_i = u_i \pi_1^{\nu_{i1}} \cdots \pi_N^{\nu_{in}} \quad \text{for } 1 \leq i \leq m.$$  

(30)

Here $N \geq 1$, $\nu_{ij} \geq 0$ and for each $i$ there is some $1 \leq j \leq N$ with $\nu_{ij} > 1$. Moreover $u_i \in \mathcal{O}_z^*$ for $1 \leq i \leq m$. We will come back to this expression later. If $T \setminus p = T \setminus p_1$ is non-empty its elements $t_1, \ldots, t_n$ lie in $R_{1,p_1}^\times \subset \mathcal{O}_z^\times$. Note that $P$ restricts to a homomorphism $R_{1,p_1}^\times \to \mathbb{C}^\times$ since on $R_{1,p_1}^\times$ it is the composition

$$R_{1,p_1}^\times \subset R_p^\times \longrightarrow \kappa(p)^\times \longrightarrow \mathbb{C}^\times.$$  

Let $\Gamma$ be the subgroup of $R_{1,p_1}^\times /\mu(K_1) \subset K^\times /\mu(K)$ generated by $\overline{t}_1, \ldots, \overline{t}_n$. Since $\Gamma$ is finitely generated and torsion-free, it is free of some rank $l \geq 1$. Let $\gamma_1, \ldots, \gamma_l$ be a $\mathbb{Z}$-basis of $\Gamma$. Then we have

$$\overline{t}_i = \gamma_1^{k_{i1}} \cdots \gamma_l^{k_{il}} \quad \text{for some } k_{ij} \in \mathbb{Z} \text{ and } 1 \leq i \leq n.$$  

Setting $\xi_i = \beta(\gamma_i) \in K^\times$, it follows that

$$t_i = \zeta_i \xi_1^{k_{i1}} \cdots \xi_l^{k_{il}} \quad \text{for some } \zeta_i \in \mu(K) \text{ and } 1 \leq i \leq n.$$  

We do not know if $\xi_i \in R_{1,p_1}^\times$, but since $\xi_i$ differs from an element of $R_{1,p_1}^\times$ only by a root of unity, we know that $P(\xi_j) \neq 0$ for all $1 \leq j \leq l$. We need $\chi_\mu$ and $P$ to agree on all $\zeta_i$ for $1 \leq i \leq n$. This will be the case if the integer $M \geq 0$ in (26) is bigger than the $p$-valuations of the orders of all the roots of unity $\xi_i$ for $1 \leq i \leq n$. Choosing some $M$ that satisfies this condition as well, $\chi_\mu$ is finally defined. We have

$$P(t_i) = P(\xi_i)P(\xi_1)^{k_{i1}} \cdots P(\xi_l)^{k_{il}} = \chi_\mu(\xi_i)P(\xi_1)^{k_{i1}} \cdots P(\xi_l)^{k_{il}}.$$  

Thus, if $\chi'$ is defined in such a way, that for the corresponding $\chi$ the values $P(\xi_j)$ and $\chi(\xi_j)$ are very close to each other, it will follow that $P(t_i)$ and

$$\chi_\mu(\xi_1)\chi(\xi_1)^{k_{i1}} \cdots \chi(\xi_l)^{k_{il}} = \chi(\zeta_i^{k_{i1}} \cdots \zeta_l^{k_{il}}) = \chi(t_i)$$  

are very close for $1 \leq i \leq n$. We have

$$\chi(\xi_j) = \chi_\mu(\alpha(\xi_j)) \exp \chi'(\overline{t}_j) = \exp \chi'(\gamma_j).$$  

Note here that $\alpha(\xi_j) = \alpha(\beta(\gamma_j)) = 1$. Choose $z_j \in \mathbb{C}$ with $\exp z_j = P(\xi_j)$ and choose $\mathbb{Q}$-linearly independent complex numbers $w_1, \ldots, w_l \in \mathbb{C}'$ such that each
$w_j$ is very close to $z_j$ for each $j$. Note that $C'$ is dense in $C$ since it has to contain two $\mathbb{R}$-linearly independent vectors. We obtain an injective $\mathbb{Q}$-linear map

$$\chi' : \Gamma \otimes \mathbb{Q} \hookrightarrow C'$$

by setting $\chi'(\gamma_j) = w_j$ for $1 \leq j \leq l$. Then $P(\xi_j)$ and $\chi(\xi_j)$ will be close to each other as desired. We extend $\chi'$ from $\Gamma \otimes \mathbb{Q} \subset (R_1^x \otimes (\mu(K_1)) \otimes \mathbb{Q} \subset (\mathcal{O}_x^x / \mu(L)) \otimes \mathbb{Q}$ to an injective $\mathbb{Q}$-linear map

$$\chi' : (\mathcal{O}_x^x / \mu(L)) \otimes \mathbb{Q} \hookrightarrow C'. $$

The isomorphism (29) gives a decomposition of $\mathbb{Q}$-vector spaces

$$(L^x / \mu(L)) \otimes \mathbb{Q} = ((\mathcal{O}_x^x / \mu(L)) \otimes \mathbb{Q}) \oplus \pi_1^0 \oplus \pi_2^0 \oplus \ldots$$

The values of $\chi'$ on the first summand on the right are already determined. In the formula resulting from (30),

$$\pi_i = \pi_1^{\nu_1} \cdots \pi_N^{\nu_N} \text{ in } L^x / \mu(L)$$

the values $\chi'(\pi_i)$ are therefore given. We extend $\chi'$ to a $\mathbb{Q}$-linear injection

$$\chi' : (L^x / \mu(L)) \otimes \mathbb{Q} \hookrightarrow C'$$

in such a way that the values $\text{Re} \chi'(\pi_1), \ldots, \text{Re} \chi'(\pi_N)$ are close to $-\infty$. Then the real parts of

$$\chi'(\pi_i) = \chi'(\pi_i) + \sum_{j=1}^{N} \nu_{ij} \chi'(\pi_j)$$

will be close to $-\infty$ as well. It is decisive here that all $\nu_{ij} \geq 0$ and for each $i$ there is an index $j$ with $\nu_{ij} \geq 1$. In this way we can make

$$|\chi(s_i)| = |\chi_\mu(\alpha(s_i))| \text{exp Re } \chi'(\pi_i) = \text{exp Re } \chi'(\pi_i)$$

as small as we wish and hence $\chi(s_i)$ as close to $P(s_i) = 0$ as desired. Having made the necessary choices to ensure that (25) will hold, we now choose any extension of $\chi'$ from $(L^x / \mu(L)) \otimes \mathbb{Q}$ to a $\mathbb{Q}$-linear injection $\chi' : K^x / \mu \hookrightarrow C'$. Note that $K^x / \mu$ is a $\mathbb{Q}$-vector space. Hence we have found a character $\chi \in \text{Hom}_{\mathbb{Q}}(K^x, \mathbb{C}^x)$ satisfying (25). Thus we are done in the case where $K = \overline{K_0}$. In fact, we have shown that the characters $\chi$ with finite kernel in $\text{pr}_x^{-1}(\eta)$ are
dense in the system $\hat{X}(C)$ of Theorem 9 where we only assume $(\ker P^\times)_{\text{tors}}$ to be finite. We now prove this stronger statement in case $K$ is any radically closed Galois extension of $K_0$. This will imply the theorem for such $K$. For $\hat{X}(C)$ constructed as in Theorem 7 using $K_0$ resp. $K$ we write $\hat{X}_{K_0}(C)$ and $\hat{X}_K(C)$. We claim that the natural map

$$\text{res} : \hat{X}_{K_0}(C) \longrightarrow \hat{X}_K(C), \quad \text{res}(P) = P|_R$$

is continuous and surjective. Since res maps $\text{pr}^{-1}(\eta_{K_0})$ to $\text{pr}^{-1}(\eta_K)$ the proven denseness of $\text{pr}^{-1}(\eta_{K_0})$ in $\hat{X}_{K_0}(C)$ will then imply denseness of $\text{pr}^{-1}(\eta_K)$ in $\hat{X}_K(C)$. If $P_n \to P$ then $\text{res} P_n \to \text{res} P$ by the definition of pointwise convergence. The spaces being metrizable it follows that res is continuous. Let $(p, P^\times)$ be a point of $\hat{X}_K(C)$. Let $\mathcal{R}_0$ be the integral closure of $R_0$ in $K_0$. The extension $\mathcal{R}_0 \supset R$ is integral and hence there is a prime ideal $p$ of $R_0$ with $p = R \cap \mathcal{R}$. We have an exact sequence

$$1 \longrightarrow \kappa(p)^\times \longrightarrow \kappa(\mathcal{R})^\times \longrightarrow \mathcal{L} \longrightarrow 1.$$  \hspace{1cm} (31)

It splits because $\kappa(p)^\times$ is divisible. Moreover the quotient $\mathcal{L}$ is uniquely divisible, since $\kappa(\mathcal{R})^\times$ is divisible and $\mu(\kappa(p)) = \mu(\kappa(\mathcal{R}))$. Consider the map $P^\times : \kappa(p)^\times \to \mathbb{C}^\times$. The subgroup $\exp^{-1}(\text{im } P^\times)$ generates a $\mathbb{Q}$-vector space $V$ in $\mathbb{C}$ of at most countable dimension. Hence there is a $\mathbb{Q}$-linear injection $\omega$ of the $\mathbb{Q}$-vector space $\mathcal{L}$ into $\mathbb{C}$ whose image meets $V$ only in 0. The resulting homomorphism

$$P^\times : \kappa(\mathcal{R})^\times \cong \kappa(p)^\times \times \mathcal{L} \xrightarrow{\text{id-exp}} \mathbb{C}^\times \times \mathbb{C} \xrightarrow{\omega \times \exp} \mathbb{C}^\times$$

prolongs $P^\times$ and the torsion subgroup of $\ker P^\times = \ker P^\times$ is finite. Explicitly

$$P^\times(x) = P^\times(\alpha_p(x)) \exp \omega(x).$$

Here $\alpha_p : \kappa(\mathcal{R})^\times \to \kappa(p)^\times$ is a chosen splitting of (31). Hence res is surjective.

We now investigate connectedness properties of our spaces. Let $V$ be a countable $\mathbb{Q}$-vector space and let $H = \text{Hom}(V, \mathbb{C}^\times)$ be the set of group homomorphisms $\varphi : V \to \mathbb{C}^\times$. We give $H$ the topology of pointwise convergence i.e. the subspace topology of the inclusion

$$H \subset \prod_{v \in V} \mathbb{C}^\times, \quad \varphi \mapsto (\varphi(v))_{v \in V}.$$
Let $H_{\text{inj}} \subset H$ be the subspace of injective $\varphi$'s.

**Lemma 14.** For any $\varphi_0, \varphi_1 \in H$ and neighborhoods $U_0$ of $\varphi_0$ and $U_1$ of $\varphi_1$ there are $\psi_0, \psi_1 \in H_{\text{inj}}$ with $\psi_0 \in U_0$ and $\psi_1 \in U_1$ that can be connected by a continuous path in $H_{\text{inj}}$.

**Proof.** Choose a finite set $\emptyset \neq S \subset V$ and some $\varepsilon > 0$ such that

$$U_i' := H \cap \left( \prod_{s \in S} U_s(\varphi_i(s)) \times \prod_{s \in V \setminus S} \mathbb{C}^\times \right) \subset U_i \quad \text{for } i = 0, 1.$$ 

The open sets $U_i'$ are non-empty since $\varphi_i \in U_i'$ for $i = 0, 1$. Choose a $\mathbb{Z}$-basis $b = \{v_1, \ldots, v_n\}$, $n \geq 0$ of the finitely generated torsion free (hence free) subgroup of $V$ generated by $S$. For small enough $\delta > 0$ any $\varphi \in H$ with $\varphi(v) \in U_\delta(\varphi_0(v))$ for $v \in b$ satisfies $\varphi(s) \in U_\delta(\varphi_0(s))$ for all $s \in S$, and similarly for $\varphi_1$ instead of $\varphi_0$. This implies that for small $\delta > 0$ and $i = 0, 1$

$$\varphi_i \in U_i'' := H \cap \left( \prod_{v \in b} U_\delta(\varphi_i(v)) \times \prod_{v \in V \setminus b} \mathbb{C}^\times \right) \subset U_i' \subset U_i.$$

Choose a $\mathbb{Q}$-vector space complement $\mathbb{C}_0 \subset \mathbb{C}$ to the countable $\mathbb{Q}$-vector space generated by $\exp^{-1}(\text{im} \varphi_0)$. Then $\mathbb{C}_0$ is dense in $\mathbb{C}$ since it has to contain two $\mathbb{R}$-linear independent vectors. Hence there is an injective $\mathbb{Q}$-linear map $\psi'_0 : V \to \mathbb{C}_0 \subset \mathbb{C}$ such that $\exp \psi'_0(v) \in U_\delta(\varphi_0(v))$ for all $v \in b$. Since $2\pi i \mathbb{Z} = \exp^{-1}(1) \subset \exp^{-1}(\text{im} \varphi_0)$ we have $2\pi i \mathbb{Q} \cap \mathbb{C}_0 = 0$ and hence $\psi_0 = \exp \circ \psi'_0 \in U_0 \cap H_{\text{inj}}$. Similarly we find an injective $\mathbb{Q}$-linear map $\psi'_1 : V \to \mathbb{C}_1 \subset \mathbb{C}$ with $2\pi i \mathbb{Q} \cap \mathbb{C}_1 = 0$ such that $\psi_1 = \exp \circ \psi'_1 \in U_1 \cap H_{\text{inj}}$. For a continuous path $\alpha : [0, 1] \to \mathbb{C}$ with $\alpha(0) = 0, \alpha(1) = 1$ set

$$\psi'_t = (1 - \alpha(t)) \psi'_0 + \alpha(t) \psi'_1 \quad \text{and} \quad \psi_t = \exp \circ \psi'_t \in H.$$

We want $\psi_t$ to be in $H_{\text{inj}}$ for all $0 \leq t \leq 1$. This means that $\psi_t(v) \neq 1$ or equivalently $\psi'_t(v) \notin 2\pi i \mathbb{Z}$ for all $0 \neq v \in V$ and $0 \leq t \leq 1$. In other words, $\alpha$ has to avoid the set

$$\Omega = \{ z \in \mathbb{C} \mid (1 - z)\psi'_0(v) + z\psi'_1(v) \in 2\pi i \mathbb{Z} \text{ for some } 0 \neq v \in V \}.$$

For $0 \neq v \in V$ with $\psi'_0(v) = \psi'_1(v)$ we have

$$(1 - z)\psi'_0(v) + z\psi'_1(v) = \psi'_0(v) \notin 2\pi i \mathbb{Z}$$

For $0 \neq v \in V$ with $\psi'_0(v) \neq \psi'_1(v)$ we have

$$(1 - z)\psi'_0(v) + z\psi'_1(v) \neq \psi'_0(v)$$

Therefore, we obtain a continuous path $\psi_t$ satisfying $\psi_0 = \exp \circ \psi'_0 \in U_0 \cap H_{\text{inj}}$ and $\psi_1 = \exp \circ \psi'_1 \in U_1 \cap H_{\text{inj}}$.
by the construction of $\psi'$. Hence $\Omega$ consists of the complex numbers

$$z = (2\pi i \nu - \psi'_0(v))/(\psi'_1(v) - \psi'_0(v))$$

with $\nu \in \mathbb{Z}$ and $0 \neq v \in V$ with $\psi'_0(v) \neq \psi'_1(v)$. Thus $\Omega \subset \mathbb{C}$ is countable. By construction, $\alpha(0) = 0$ and $\alpha(1) = 1$ are not in $\Omega$. The complement of any countable set in $\mathbb{C}$ is path connected. In fact, given two points $z_1 \neq z_2$ in the complement, for all but countably many slopes the lines through them lie in the complement. Taking two such lines through $z_1$ resp. $z_2$ which intersect we get a path from $z_1$ to $z_2$. Hence a path $\alpha$ avoiding $\Omega$ exists. The corresponding continuous path $t \mapsto \psi_t$ joins $\psi_0$ with $\psi_1$ in $H_{\text{inj}}$. 

We call a topological space $Z$ almost path-connected if for any two points $z_0, z_1 \in Z$ and any two neighborhoods $U_0$ of $z_0$ and $U_1$ of $z_1$ there are two points $\tilde{z}_0 \in U_0$ and $\tilde{z}_1 \in U_1$ and a continuous map $\gamma : [0, 1] \to Z$ with $\gamma(0) = \tilde{z}_0$ and $\gamma(1) = \tilde{z}_1$. The continuous image of an almost path connected space is again almost path connected. An almost path connected space $Z$ is connected. If not, there would be a decomposition $Z = U_0 \cup U_1$ into non-empty disjoint open subsets and a continuous map $\gamma : [0, 1] \to Z$ with $\gamma([0, 1]) \cap U_i \neq \emptyset$ for $i = 0, 1$. Then $\gamma^{-1}(U_0)$ and $\gamma^{-1}(U_1)$ would be non-empty disjoint open subsets covering $[0, 1]$. This is a contradiction.

Let $X_0$ be an arithmetic scheme. The group $\mathbb{Q}_{>0}$ acts on $\check{X}_0(\mathbb{C})$ via the homeomorphisms $F_q$ for $q \in \mathbb{Q}_{>0}$. We give

$$X_0 = \check{X}_0(\mathbb{C}) \times_{\mathbb{Q}_{>0}} \mathbb{R}_{>0}$$

the quotient topology of $\check{X}_0(\mathbb{C}) \times \mathbb{R}_{>0}$. Then the $\mathbb{R}_{>0}$-action

$$X_0 \times \mathbb{R}_{>0} \longrightarrow X_0, \quad ([P_0, u], v) \longmapsto [P_0, uv]$$

is continuous. The continuous projection

$$\check{X}_0(\mathbb{C}) \times \mathbb{R}_{>0} \longrightarrow X_0$$

is open since $\mathbb{Q}_{>0}$ acts by homeomorphisms on the left. Set

$$d_\mu = (K_0 \cap \mathbb{Q}(\mu(K)) : \mathbb{Q}).$$

Then $d_\mu = 1$ if and only if $K_0$ is disjoint from the maximal cyclotomic extension of $\mathbb{Q}$ in $K$. Consider:

$$X_{00_0} = \text{pr}_{X_0}(\eta_0) \times_{\mathbb{Q}_{>0}} \mathbb{R}_{>0} \subset X_0.$$
Theorem 15. The space $X_{0_n}$ has $d_\mu$ connected components. Each of them is almost path-connected.

Proof. Let $\text{Hom}_f(\mu(K), \mathbb{C}^\times) = \text{Hom}_f(\mu(K), S^1) \subset (S^1)^{\mu(K)}$ be the space of homomorphisms $\mu(K) \to \mathbb{C}^\times$ with finite kernel, equipped with the topology of pointwise convergence. Fix an isomorphism $i : \mu(K) \sim \to \mu(\mathbb{C})$ and consider the induced topological isomorphism

$$\hat{\mathbb{Z}} \sim \to \text{Hom}(\mu(K), \mathbb{C}^\times) = \text{Hom}(\mu(K), S^1)$$

$$a \mapsto \chi_a := (\zeta \mapsto i(\zeta)^a).$$

Here, if $\zeta$ is an $N$-th root of unity, $\zeta^a := \zeta^{aN}$ if $aN \mod N$ is the image of $a \in \hat{\mathbb{Z}}$ under the projection $\hat{\mathbb{Z}} \to \hat{\mathbb{Z}}/N\hat{\mathbb{Z}} = \mathbb{Z}/N$. The character $\chi_a$ is injective if and only if $a \in \hat{\mathbb{Z}}^\times$. In general, if $\ker \chi_a$ is finite, it is cyclic since $\mu(K) \subset K^\times$. For $|\ker \chi_a| = N$ let

$$\overline{\chi}_a : \mu(K)/\mu_N(K) \hookrightarrow \mathbb{C}^\times$$

be induced by $\chi_a$. Let $\chi$ be the composition

$$\chi : \mu(K) \leftrightarrow^{\sim^N} \mu(K)/\mu_N(K) \cong \mathbb{C}^\times,$$

i.e. $\chi = \overline{\chi}_a \circ (\cdot)^{-N}$. Then $\chi$ is injective and hence of the form $\chi = \chi_b$ for some $b \in \hat{\mathbb{Z}}^\times$. By construction we have $\chi_a = \chi^N$ and hence $a = Nb$. On the other hand, if $a$ has this form, then $\chi_a$ has finite kernel. Hence the isomorphism (32) restricts to a homeomorphism:

$$\mathcal{N}\hat{\mathbb{Z}}^\times \sim \to \text{Hom}_f(\mu(K), \mathbb{C}^\times).$$

Here $\mathcal{N}\hat{\mathbb{Z}}^\times \subset \hat{\mathbb{Z}}$ carries the subspace topology. Note that $\mathcal{N} \cap \hat{\mathbb{Z}}^\times = \{1\}$ in $\hat{\mathbb{Z}}$. Consider the restriction map

$$r : \text{Hom}_E(K^\times, \mathbb{C}^\times) \to \text{Hom}_f(\mu(K), \mathbb{C}^\times), \chi \mapsto \chi|_{\mu(K)}.$$

It is continuous for the topologies of pointwise convergence, and surjective by Lemma 3. Choose a splitting $\alpha : K^\times \to \mu(K)$ of the exact sequence

$$1 \to \mu(K) \to K^\times \to K^\times/\mu(K) \to 1.$$

Given a character $\chi_\mu \in \text{Hom}_f(\mu(K), \mathbb{C}^\times)$, the following map is a homeomorphism onto its image

$$f : r^{-1}(\chi_\mu) \hookrightarrow \text{Hom}(K^\times/\mu(K), \mathbb{C}^\times), \chi \mapsto \psi = \chi(\chi_\mu^{-1} \circ \alpha). (35)$$
Here we view \( \psi = \chi(\chi^{-1}_\mu \circ \alpha) \) which is trivial on \( \mu(K) \) as a character on \( K^\times/\mu(K) \). The inverse map \( f^{-1} \) defined on \( \text{im} f \) sends \( \psi : K^\times/\mu(K) \to \mathbb{C}^\times \) to the character \( \chi \) defined by \( \chi(x) = \psi(\overline{x}) \chi_\mu(\alpha(x)) \) for \( x \in K^\times \). The continuity of \( f \) and \( f^{-1} \) can be checked on pointwise convergent sequences of characters. Moreover, we claim that \( f \) restricts to a homeomorphism between the subspace of characters with finite kernels within \( r^{-1}(\chi_\mu) \) (recall \( \mathcal{E}_f \subset \mathcal{E} \)) and \( \text{Hom}_{\text{inj}}(K^\times/\mu(K), \mathbb{C}^\times) \). For this it suffices to check that the projection map \( \pi : K^\times \to K^\times/\mu(K) \) induces a \( \mathbb{Q} \)-linear isomorphism

\[
\pi \otimes \text{id} : \ker \chi \otimes \mathbb{Q} \to \ker \psi \otimes \mathbb{Q} , \quad x \otimes q \mapsto \overline{x} \otimes q .
\]

(36)

For \( x \in \ker \chi \) we have \( \psi(\overline{x}) = \chi^{-1}_\mu(\alpha(x)) \in \mu(\mathbb{C}) \). Hence \( \psi(\overline{x})^N = 1 \) for some \( N \geq 1 \), i.e. \( \overline{x}^N \otimes 1 = \overline{x} \otimes N \in \ker \psi \otimes \mathbb{Q} \), hence \( \overline{x} \otimes 1 \in \ker \psi \otimes \mathbb{Q} \). Thus we obtain the map \( \pi \otimes \text{id} \) of (36). If \( \overline{x} \otimes q \) is zero, either \( q = 0 \) or \( \overline{x} = 1 \) i.e. \( x \in \mu(K) \) i.e. \( x^N = 1 \) and hence \( x \otimes N = 0 \). In both cases \( x \otimes q = 0 \). Hence \( \pi \otimes \text{id} \) is injective. Given \( \overline{x} \in \ker \psi \) we have \( \chi(x) = \chi_\mu(\alpha(x)) \) and hence \( \chi(x)^N = 1 \) for some \( N \geq 1 \). Hence \( x^N \otimes 1 = x \otimes N \in \ker \chi \otimes \mathbb{Q} \) and hence \( x \otimes 1 \in \ker \chi \otimes \mathbb{Q} \). Thus \( x \otimes q \in \ker \chi \otimes \mathbb{Q} \) is mapped to \( \overline{x} \otimes q \) and therefore \( \pi \otimes \text{id} \) is surjective. Lemma [4] and the preceding facts about the map \( f \) in (35) show that the fibres of the restriction map \( r \) are almost path connected. We have:

\[
\text{pr}^{-1}(\eta) = \text{Hom}_\mathcal{N}(K^\times, \mathbb{C}^\times) \quad \text{where } \text{pr} := \text{pr}_x \big|_{\mathbb{C}(\mathcal{N})} .
\]

Using (33) we may therefore view \( r \) as an \( \mathcal{N} \)-equivariant continuous surjection with almost path-connected fibres

\[
r : \text{pr}^{-1}(\eta) \to \mathcal{N} \hat{\mathbb{Z}}^\times \subset \hat{\mathbb{Z}} .
\]

(37)

Passing to the colimit over \( \mathcal{N} \) we obtain a \( \mathbb{Q}^{\geq 0} \)-equivariant continuous surjection with almost path-connected fibres

\[
r : \text{pr}_X^{-1}(\eta) \to \mathbb{Q}^{\geq 0} \hat{\mathbb{Z}}^\times \subset \hat{\mathbb{Z}} \otimes \mathbb{Q} .
\]

(38)

Note that \( \mathbb{Q}^{\geq 0} \cap \hat{\mathbb{Z}}^\times = \{1\} \) in \( \hat{\mathbb{Z}} \otimes \mathbb{Q} \) and hence \( \mathbb{Q}^{\geq 0} \hat{\mathbb{Z}}^\times \cong \hat{\mathbb{Z}}^\times \times \mathbb{Q}^{\geq 0} \). The map (34) is \( G = \text{Gal}(K/K_0) \)-equivariant. Hence the maps (37) and (38) are \( G \)-equivariant as well. The \( G \)-action on the right is given by multiplication with the cyclotomic character \( \kappa \) of \( G \). Here, \( \kappa \) is the composition, where \( \mu = \mu(K) \):

\[
\kappa : G \to \text{Gal}(K_0(\mu)/K_0) = \text{Gal}(\mathbb{Q}(\mu)/K_0 \cap \mathbb{Q}(\mu)) \subset \text{Gal}(\mathbb{Q}(\mu)/\mathbb{Q}) = \hat{\mathbb{Z}}^\times .
\]
The quotient
\[ \hat{\mathbb{Z}}^\times / \kappa(G) = \text{Gal}(K_0 \cap \mathbb{Q}(\mu)/\mathbb{Q}) \]
has order \( d_\mu \). Passing to the orbit spaces mod \( G \) in (38) we obtain a map
\[ r_0 : \text{pr}_{X_0}(\eta_0) \rightarrow (\hat{\mathbb{Z}}^\times / \kappa(G)) \times \mathbb{Q}^>^0 \] (39)
whose fibres are continuous images of the fibres of \( r \) in (38) and are therefore almost path connected. Incidentally, note that the quotient topology on \( \text{pr}_{X_0}(\eta_0) = \text{pr}_{X}(\eta)/G \) equals the subspace topology within \( \check{X}_0(\mathbb{C}) \), the latter being equipped with the quotient topology via \( \check{X}(\mathbb{C}) = \check{X}(\mathbb{C})/G \).

For \( \pi \in \hat{\mathbb{Z}}^\times / \kappa(G) \) set
\[ \text{pr}_{X_0}(\eta_0) = r_0^{-1}(\{\pi\} \times \mathbb{Q}^>^0) \quad \text{and} \quad F = r_0^{-1}(\pi, 1) \subset \text{pr}_{X_0}(\eta_0) \pi . \]

Then \( F \) is almost path connected and
\[ \text{pr}_{X_0}(\eta_0) = \coprod_{q \in \mathbb{Q}^>^0} Fq . \]

Hence the continuous map
\[ F \times \mathbb{R}^>^0 \rightarrow (X_{0\eta_0})_\pi := \text{pr}_{X_0}(\eta_0) \pi \times \mathbb{R}^>^0 \quad (f, u) \mapsto [f, u] \]
is a bijection and therefore \( (X_{0\eta_0})_\pi \) is almost path connected. The composition
\[ X_{0\eta_0} = \text{pr}_{X_0}(\eta_0) \times \mathbb{R}^>^0 \xrightarrow{r_0 \times \text{id}} (\hat{\mathbb{Z}}^\times / \kappa(G)) \times \mathbb{R}^>^0 \rightarrow (\hat{\mathbb{Z}}^\times / \kappa(G)) \]
is continuous and its fibres are the spaces \( (X_{0\eta_0})_\pi \). Since the group \( \hat{\mathbb{Z}}^\times / \kappa(G) \) is finite and discrete, it follows that the connected components of \( X_{0\eta_0} \) are the \( d_\mu \) spaces \( (X_{0\eta_0})_\pi \) for \( \pi \in \hat{\mathbb{Z}}^\times / \kappa(G) \).

\[ \square \]

**Remark.** For \( K = \overline{K}_0 \), consider the map \( r \) of (34). Let \( \text{Hom}_{\text{inj}}(\mu(K), \mathbb{C}^\times) \) be the set of injective homomorphisms \( \mu(K) \hookrightarrow \mathbb{C}^\times \). Then the Galois group \( G \) acts without fixed points on
\[ r^{-1}(\text{Hom}_{\text{inj}}(\mu(K), \mathbb{C}^\times)) \subset \text{pr}^{-1}(\eta) . \]

This follows from [KS16] Lemma 4.12 (the condition \( F \ni \mu_\infty \) is not necessary).
Corollary 16. Let $X_0$ be an arithmetic scheme. The space $X_0 = \hat{X}_0(\mathbb{C}) \times_{\mathbb{Q}^+} \mathbb{R}^+ \setminus 0$ has at most $d_\mu$ connected components. In particular, $X_0$ is connected if $\hat{X}_0 \otimes \mathbb{Q}(\mu)$ is connected.

Proof. If $X_0$ has more than $d_\mu$ connected components, then there are non-empty disjoint open sets $O_i \subset X_0$ for $i = 1, \ldots, d_\mu + 1$ such that

$$X_0 = O_1 \cup \ldots \cup O_{d_\mu + 1}.$$ 

Then we have

$$X_{0Q} = (O_1 \cap X_{0Q}) \cup \ldots \cup (O_{d_\mu + 1} \cap X_{0Q}).$$

By Theorem 13, the open sets $O_i \cap X_{0Q}$ are non-empty and it would follow that $X_{0Q}$ had more than $d_\mu$ connected components, contradicting Theorem 15. The condition $d_\mu = 1$ means that $K_0 \cap \mathbb{Q}(\mu) = \mathbb{Q}$ i.e. that $\hat{X}_0 \otimes \mathbb{Q}(\mu)$ is connected.

Remarks. 1) Suspending the map $\rho$ in (16) we obtain a surjection

$$\rho \times_{\mathbb{Q}^+} \text{id} : X_0 \to S = \mathbb{R}^+ \bigcup_{p} \mathbb{R}^+ \setminus 0 / \mathbb{Z}.$$ 

Corollary 16 shows that the quotient topology on $S$ is not the disjoint union topology. In fact $\mathbb{R}^+$ is dense in $S$ by Theorem 13. The quotient topology of $S$ is more like the one of $\text{spec } \mathbb{Z}$ where the generic point is dense. In fact we have a commutative diagram of continuous maps

$$
\begin{array}{ccc}
X_0 & \xrightarrow{\rho \times_{\mathbb{Q}^+} \text{id}} & S \\
\downarrow & & \downarrow \\
\hat{X}_0(\mathbb{C}) / \mathbb{Q}^+ & \xleftarrow{\text{pr}_0} & \hat{X}_0(\mathbb{C}) / \mathbb{Q}^+ \\
\downarrow & & \downarrow \\
\text{spec } \mathbb{Z} & \xrightarrow{\text{pr}_0} & \hat{X}_0(\mathbb{C}) / \mathbb{Q}^+ \\
\end{array}
$$

Here $S \to \text{spec } \mathbb{Z}$ is defined by mapping $\mathbb{R}^+$ to $(0)$ and $\mathbb{R}^+ / \mathbb{Z}$ to $(p)$.

2) We may also describe $X_0$ using $\hat{X}_0(\mathbb{C})$ instead of $\hat{X}_0(\mathbb{C})$. For a (right) action of the monoid $\mathcal{N}$ on a set $Y$ we get an equivalence relation on $Y$ as follows: $y \sim y'$ if and only if there are $\nu, \nu' \in \mathcal{N}$ with $y \cdot \nu = y' \cdot \nu'$. Let $Y / \mathcal{N}$ denote the set of equivalence classes. Let $\nu \in \mathcal{N}$ act on $\hat{X}_0(\mathbb{C}) \times \mathbb{R}^+$ by setting $(P_0, u) \cdot \nu := (F_\nu(P_0), \nu^{-1} u)$. We equip

$$
\hat{X}_0(\mathbb{C}) \times_{\mathcal{N}} \mathbb{R}^+ \setminus 0 := (\hat{X}_0(\mathbb{C}) \times \mathbb{R}^+) / \mathcal{N}
$$
with the quotient topology. The space $\mathring{X}_0(\mathbb{C}) \times_{\mathcal{N}} \mathbb{R}^{>0}$ has a natural $\mathbb{R}^{>0}$-action by multiplication on the second factor. It is straightforward to check that the natural map

$$\mathring{X}_0(\mathbb{C}) \times \mathbb{R}^{>0} \longrightarrow \mathring{X}_0(\mathbb{C}) \times_{\mathbb{Q}^{>0}} \mathbb{R}^{>0}, \ (m, u) \mapsto [m, u]$$

induces an $\mathbb{R}^{>0}$-equivariant homeomorphism

$$\mathring{X}_0(\mathbb{C}) \times_{\mathcal{N}} \mathbb{R}^{>0} \cong \mathring{X}_0(\mathbb{C}) \times_{\mathbb{Q}^{>0}} \mathbb{R}^{>0}.$$

### 4 Functoriality and rational Witt vectors

We are interested in the functoriality of the association $X_0 \mapsto \mathring{X}_0(\mathbb{C})$. Let $f_0 : X_0 \to X'_0$ be a dominant morphism of arithmetic schemes. For all points $x_0$ of $X_0$ we have an inclusion of residue fields

$$f^\sharp_{x_0} : \kappa(f(x_0)) \hookrightarrow \kappa(x_0)$$

and for the generic point $\eta_0$ of $X_0$, since the image $f(\eta_0) = \eta'_0$ is the generic point of $X'_0$ we get an inclusion of function fields

$$f^\sharp_{\eta_0} : K'_0 \hookrightarrow K_0.$$

Let $K' = \overline{K}'_0$ and $K = \overline{K}_0$ be algebraic closures and fix an embedding $\tau : K' \hookrightarrow K$ prolonging $f^\sharp_{\eta_0}$. We obtain a commutative diagram

$$
\begin{array}{ccc}
\mathring{X} & \xrightarrow{f_\tau} & \mathring{X}' \\
\downarrow & & \downarrow \\
X_0 & \xrightarrow{f_0} & X'_0
\end{array}
$$

where $f_\tau$ is the induced morphism between the normalizations $\mathring{X}$ and $\mathring{X}'$ of $X_0$ in $K$ resp. of $X'_0$ in $K'$. For any point $x \in \mathring{X}$, the morphism $f_\tau$ gives an inclusion

$$f^\sharp_{\tau,x} : \kappa(f_\tau(x)) \hookrightarrow \kappa(x).$$
Given a multiplicative map \( \mathcal{P}^\times : \kappa(x)^\times \to \mathbb{C}^\times \) with kernel of class \( \mathcal{E} \) pullback by \( f_{\tau, x}^\sharp \) gives a multiplicative map
\[
f_{\tau}(\mathcal{P}^\times) := \mathcal{P}^\times \circ f_{\tau, x}^\sharp : \kappa(f_\tau(x)) \to \mathbb{C}^\times.
\]
The kernel of \( f_\tau(\mathcal{P}^\times) \) is contained in the one of \( \mathcal{P}^\times \) and hence it is of class \( \mathcal{E} \) as well. Thus we get an \( \mathcal{N} \)-equivariant map
\[
\hat{f}_\tau : \hat{\mathcal{X}}(\mathbb{C}) \to \hat{\mathcal{X}}'(\mathbb{C}), \ (x, \mathcal{P}^\times) \mapsto (f_\tau(x), f_\tau(\mathcal{P}^\times)).
\]
One can show that it induces an \( \mathcal{N} \)-equivariant map of orbit spaces
\[
\hat{f}_0 : \hat{\mathcal{X}}_0(\mathbb{C}) \to \hat{\mathcal{X}}'_0(\mathbb{C}),
\]
which is independent of the choice of \( \tau \). For \( \mathbb{C} \) the field of complex numbers, the maps \( \hat{f}_\tau \) and \( \hat{f}_0 \) are both continuous. From \( \hat{f}_0 \) we get maps \( \hat{f}_0 : \hat{\mathcal{X}}_0(\mathbb{C}) \to \hat{\mathcal{X}}'_0(\mathbb{C}) \) and \( f_0 : X_0 \to X'_0 \) which commute with the \( \mathbb{Q}^{>0} \)- resp. \( \mathbb{R}^{>0} \)-actions. Our constructions therefore give functors from the category of arithmetic schemes with dominant morphisms to the categories of \( \mathcal{N} \)- resp. \( \mathbb{Q}^{>0} \)- resp. \( \mathbb{R}^{>0} \)-dynamical systems with equivariant (continuous) maps.

Let us look at the affine case \( \mathcal{X}_0 = \text{spec} R_0 \). Here \( \hat{\mathcal{X}}(\mathbb{C}) \) consists of the multiplicative maps \( P : R \to \mathbb{C} \) described after Definition 2. Since \( P(0) = 0 \), the map \( P \) is uniquely determined by its restriction to \( R^\Diamond = R \setminus \{0\} \). Let \( \mathbb{Z} R^\Diamond \) denote the monoid algebra of \( (R^\Diamond, \cdot) \). The multiplicative map \( P : R^\Diamond \to \mathbb{C} \) extends uniquely to a ring homomorphism \( P : \mathbb{Z} R^\Diamond \to \mathbb{C} \). This gives an inclusion
\[
\hat{\mathcal{X}}(\mathbb{C}) \subset \text{Hom}(\mathbb{Z} R^\Diamond, \mathbb{C}) = (\text{spec} \mathbb{Z} R^\Diamond)(\mathbb{C}).
\]
Passing to the orbit spaces under the \( G \)-action, we get an inclusion
\[
\hat{\mathcal{X}}_0(\mathbb{C}) \subset (\text{spec} \mathbb{Z} R^\Diamond)(\mathbb{C})/G = (\text{spec} (\mathbb{Z} R^\Diamond)^G)(\mathbb{C}).
\]
Here we used [KS16, Lemma 4.9]. For a review of the rational Witt vectors of a ring, we refer to [KS16, 4.1]. Arguing as in [KS16, Remark 4.3], one sees that there is a canonical isomorphism
\[
W_{\text{rat}}(R_0) = (\mathbb{Z} R^\Diamond)^G.
\]
Hence we find that

\[ \mathfrak{X}_0(\mathbb{C}) \subset (\text{spec } \mathcal{W}_{\text{rat}}(R_0))(\mathbb{C}) . \quad (40) \]

Let \( \mathfrak{X}'_0 = \text{spec } R'_0 \) be another affine arithmetic scheme. A morphism \( f_0 : \mathfrak{X}_0 \to \mathfrak{X}'_0 \) corresponds to a ring homomorphism \( f'_0 : R'_0 \to R_0 \). If \( f_0 \) is dominant, then using the above maps \( f_0 \) we get a commutative diagram

\[
\begin{array}{ccc}
\mathfrak{X}_0(\mathbb{C}) & \xrightarrow{f_0} & (\text{spec } \mathcal{W}_{\text{rat}}(R_0))(\mathbb{C}) \\
\downarrow & & \downarrow \quad (\text{spec } f'_0)(\mathbb{C}) \\
\mathfrak{X}'_0(\mathbb{C}) & \xrightarrow{f'_0} & (\text{spec } \mathcal{W}_{\text{rat}}(R'_0))(\mathbb{C}) .
\end{array}
\]

The vertical arrow on the right exists for all morphisms \( f_0 \). One should clarify under which conditions it maps \( \mathfrak{X}_0(\mathbb{C}) \) to \( \mathfrak{X}'_0(\mathbb{C}) \).

According to (40) we have a ring homomorphism

\[ W_{\text{rat}}(R_0) \longrightarrow C^0(\mathfrak{X}_0(\mathbb{C}), \mathbb{C}) . \quad (41) \]

Namely, the element \( \psi_0 \in W_{\text{rat}}(R_0) = (\mathbb{Z} R^\circ)^{G} \) is sent to the function \( \psi_0 \) mapping \( P_0 \in \mathfrak{X}_0(\mathbb{C}) \) to \( P_0(\psi_0) := P(\psi_0) \). Here \( P_0 = P \mod G \) for a multiplicative map \( P : R \to \mathbb{C} \). Viewing \( P \) as a ring homomorphism \( P : \mathbb{Z} R^\circ \to \mathbb{C} \) we can evaluate \( P \) on \( \psi_0 \). The value \( P(\psi_0) \) depends only on the \( G \)-orbit \( P_0 \) of \( P \). It is clear that the map \( P_0 \mapsto \psi_0(P_0) := P_0(\psi_0) \) is continuous.

In particular, via the canonical multiplicative map \( R_0 \to W_{\text{rat}}(R_0) \) we get a multiplicative, and not additive map

\[ R_0 \longrightarrow C^0(\mathfrak{X}_0(\mathbb{C}), \mathbb{C}) . \]

It sends \( r_0 \in R_0 = R^G \) to the map

\[ r_0 : P_0 = P \mod G \mapsto P(r_0) . \]

Note that the map (41) is \( \mathcal{N} \)-equivariant if \( \nu \in \mathcal{N} \) acts by the \( \nu \)-th rational Witt vector Frobenius on the left and by \( F_{\nu}^* \) on the right.

**Proposition 17.** For the affine arithmetic scheme \( \mathfrak{X}_0 = \text{spec } R_0 \) consider the projection \( \text{pr}_{\mathfrak{X}_0} : \mathfrak{X}_0(\mathbb{C}) \to \mathfrak{X}_0 \). For an element \( r_0 \in R_0 \) let \( V_0(r_0) = \text{spec } R_0/r_0R_0 \subset \mathfrak{X}_0 \) be its zero-set in \( \mathfrak{X}_0 \). Then we have

\[ \{ P_0 \in \mathfrak{X}_0(\mathbb{C}) \mid r_0(P_0) = 0 \} = \text{pr}_{\mathfrak{X}_0}^{-1}(V_0(r_0)) . \]
Proof. We view $r_0$ as a function on $\mathfrak{X}(\mathbb{C})$ via $r_0(P) = P(r_0)$ and let $V(r_0) = \text{spec } R/r_0R \subset \mathfrak{X}$ be the zero-set of $r_0$ in $\mathfrak{X}$. Because of the commutative diagram (4) it suffices to show that

$$\{ P \in \mathfrak{X}(\mathbb{C}) \mid r_0(P) = 0 \} = \text{pr}^{-1}_X(V(r_0)) .$$

By definition, $\text{pr}_X(P) = p_{P} := P^{-1}(0)$. The equation $r_0(P) = 0$ is equivalent to $r_0 \in p_{P}$ i.e. to $p_{P} \in V(r_0)$, or $\text{pr}_X(P) \in V(r_0)$. $\square$

In particular, for $R_0$ the ring of integers in a number field $K_0$, an algebraic number $r_0 \in R_0$ viewed as a complex valued function on $\mathfrak{X}_0(\mathbb{C})$ has zeroes precisely in the $N$-orbits $\text{pr}_{X_0}^{-1}(p_0)$ for the prime divisors $p_0$ of $r_0$.

5 Miscellaneos remarks and questions

If the Hasse-Weil zeta function $X_0$ is to be the Ruelle zeta function of $X_0$, then the “Fuller indices” of the compact packets $\Gamma_{x_0}$ of periodic orbits for the closed points $x_0$ of $\mathfrak{X}_0$ all ought to be 1. Is there a natural extension of the Fuller index to spaces like $X_0$ which gives the value 1 to each $\Gamma_{x_0}$?

Given an arithmetic scheme $\mathfrak{X}_0$ there are natural flat complex line bundles $\mathfrak{L}(s)$ for $s \in \mathbb{C}$ on the associated $R^{>0}$-dynamical system $X_0 = \mathfrak{X}_0(\mathbb{C}) \times R^{>0}$. Let $\mathfrak{L}(s)$ be $\mathbb{C}$ as a vector space, and equipped with the $Q^{>0}$-action where $q \in Q^{>0}$ acts by multiplication with $q^s$. We get a left action of $Q^{>0}$ on $\mathfrak{X}_0(\mathbb{C}) \times R^{>0} \times \mathfrak{L}(s)$ by setting

$$q(P_0, u, z) := (F_q^{-1}(P_0), qu, qz) .$$

The quotient by $Q^{>0}$ is the total space of $\mathfrak{L}(s)$

$$\mathfrak{L}(s) = (\mathfrak{X}_0(\mathbb{C}) \times R^{>0} \times \mathfrak{L}(s))/Q^{>0} .$$

Together with the canonical projection

$$\pi : \mathfrak{L}(s) \longrightarrow X_0$$

we obtain the line bundle $\mathfrak{L}(s)$. For $s, s' \in \mathbb{C}$ we have canonical isomorphisms

$$\mathfrak{L}(s) \otimes \mathfrak{L}(s') = \mathfrak{L}(s + s') .$$
Similarly we obtain flat real resp. rational line bundles $\mathbb{R}(s)$ for $s \in \mathbb{R}$ and $\mathbb{Q}(s)$ for $s \in \mathbb{Q}$.

In view of the considerations in [Den00], [Den98], [Den01], [Den08], the cohomologies $H^i(X_0, \mathbb{L}(s))$ may contain interesting arithmetic information about $X_0$. Are the groups $H^i(X_0, \mathbb{Q}(n))$ related to motivic cohomology? We also draw attention to the foliation cohomologies $H^i(X_0, \mathcal{R})$ and $H^i(X_0, \mathcal{C})$ (or their maximal Hausdorff quotients) equipped with the induced $\mathbb{R}^{>0}$-action. Here $\mathcal{R}$ resp. $\mathcal{C}$ is the sheaf of germs of real resp. complex valued functions $f$ on $X_0$ such that the map $(P_0, u) \mapsto f([P_0, u])$ has continuous partial derivatives in $u \in \mathbb{R}^{>0}$ of all orders and locally constant in $P_0 \in \tilde{X}_0(\mathbb{C})$ if $u$ is fixed. Assume that $\mathbb{Q}^{>0}$ acts properly discontinuously on $\tilde{X}_0(\mathbb{C}) \times \mathbb{R}^{>0}$. We have not checked this yet but it seems possible since the stabilizers of $\mathbb{Q}^{>0}$ on $\tilde{X}_0(\mathbb{C})$ are trivial or of the form $N_{X_0} \mathbb{Z}$ and the quotient $\mathbb{R}^{>0}/N_{X_0} \mathbb{Z}$ is harmless. If $\theta = u \frac{\partial}{\partial u}$ denotes the infinitesimal generator of the $\mathbb{R}^{>0}$-action, we then obtain a short exact sequence of sheaves on $X_0$ for any $s \in \mathbb{C}$:

$$0 \longrightarrow \mathbb{C}(s) \longrightarrow \mathcal{C} \xrightarrow{\theta - s} \mathcal{C} \longrightarrow 0 \quad (42)$$

For surjectivity, given a local section $f$ of $\mathcal{C}$, choose some $u_0$ such that the following integral is locally defined:

$$g(P_0, u) = u^s \int_{u_0}^u f([P_0, v])v^{-s}dv.$$  

By proper discontinuity, it can be viewed as a local section of $\mathcal{C}$ on $X_0$ which satisfies $(\theta - s)g = f$. The short exact sequence (42) induces a long exact sequence

$$\ldots \longrightarrow H^i(X_0, \mathbb{L}(s)) \longrightarrow H^i(X_0, \mathcal{C}) \xrightarrow{\theta - s} H^i(X_0, \mathcal{C}) \longrightarrow \ldots \quad (43)$$

Here $\theta$ also denotes the map on cohomology induced by the sheaf map $\theta : \mathcal{C} \rightarrow \mathcal{C}$. On $H^i(X_0, \mathcal{C})$ it can be viewed as the infinitesimal generator of the induced $\mathbb{R}^{>0}$-action. Its spectrum could be interesting.

One prediction in [Den98] was that $X_0$ should have a “compactification” $\overline{X}_0$ corresponding to an Arakelov compactification $\overline{X}_0$ of $X_0$. The fixed points of the $\mathbb{R}$-action on $\overline{X}_0$ should be the set $\mathcal{X}_0(\mathbb{C})/F_\infty$ where $F_\infty : \mathcal{X}_0(\mathbb{C}) \rightarrow \mathcal{X}_0(\mathbb{C})$ is induced by complex conjugation on $\mathbb{C}$. In this context, we make the following observation. The isotropy groups in $\mathbb{Q}^{>0}$ of the classical points $\mathcal{X}_0(\mathbb{C}) \subset \tilde{X}_0(\mathbb{C})$
are trivial e.g. by Theorem 4. More precisely, for $P_0 \in \mathcal{X}_0(C)$ and $q \in \mathbb{Q}^\times$, $q \neq 1$ the point $F_q(P_0)$ is no-longer a classical point. Namely, for an inclusion of fields $i : \kappa(x) \subset \mathbb{C}$ the map $i \circ (\cdot)^\nu$ cannot be conjugate to $i' \circ (\cdot)^\nu$ for some other field embedding $i' : \kappa(x) \subset \mathbb{C}$ and $\nu, \nu' \in \mathcal{N}$ unless $\nu = \nu'$. Note here that $\nu = |\ker i \circ (\cdot)^\nu|_{\mathfrak{f}}$ for all $\mathfrak{f} \in \text{Aut}\kappa(x)$. Hence the map

$$\mathcal{X}_0(C) \times \mathbb{R}^{>0} \longrightarrow X_0 \ , \ (P_0, u) \longmapsto [P_0, u] = [P_0, 1] \cdot u$$

is an $\mathbb{R}^{>0}$-equivariant inclusion. Letting $F_\infty$ act on $\mathbb{R}$ by $F_\infty(t) = -t$ we have an $\mathbb{R}^{>0}$-equivariant isomorphism where $\mathbb{R}^{>0}$ acts on $\mathbb{R}^\times$ by multiplication:

$$\mathcal{X}(C) \times \mathbb{R}^{>0} \cong \mathcal{X}(C) \times_{F_\infty} \mathbb{R}^\times .$$

This gives an $\mathbb{R}^{>0}$-immersion:

$$\mathcal{X}(C) \times_{F_\infty} \mathbb{R}^\times \hookrightarrow \mathcal{X}(C) \times_{Q^{>0}} \mathbb{R}^{>0} \hookrightarrow X_0 .$$

It should extend to an $\mathbb{R}^{>0}$-immersion where $\mathbb{R} = \mathbb{R}^\times \cup \{0\}$

$$\mathcal{X}(C) \times_{F_\infty} R \hookrightarrow \mathcal{X}_0 .$$

The fixed point set of the $\mathbb{R}^{>0}$-action on the left is $\mathcal{X}(C) \times_{F_\infty} \{0\} = \mathcal{X}(C)/F_\infty$. Moreover for $z \in \mathcal{X}(C) \setminus \mathcal{X}(R)$ there are two orbits tending to the fixed point $[z, 0]$, namely $[z, \pm 1]u$ for $u \to 0^+$. For $z \in \mathcal{X}(R)$ there is one orbit with this property, namely $[z, 1]u$ for $u \to 0^+$. In the case $\mathcal{X} = \text{spec} \sigma_k$, where $k/\mathbb{Q}$ is a number field, we had seen this structure in the $\Gamma$-factors, c.f. [Den02, § 3]. Of course, it is unclear, why $X_0$ would not contain many more fixed points obtained in the same way from the points in $\mathcal{X}(C) \setminus \mathcal{X}$. The system $X_0$ may have to be replaced by a much smaller system:

Is there a sub-dynamical system $Y \subset X := \mathcal{X}(C) \times_{Q^{>0}} \mathbb{R}^{>0}$ which is invariant under the $G$-operation such that $\dim Y = 2d + 1$ where $d = \dim \mathcal{X}$ and such that $Y_0 = Y/G \subset X_0 = \mathcal{X}_0(C) \times_{Q^{>0}} \mathbb{R}^{>0}$ contains at least one periodic orbit in $\Gamma_{x_0}$ for every closed point $x_0$ of $\mathcal{X}$? If $d = 1$, is there such a $Y_0$ which is a Riemann surface lamination in the sense of [Ghy99]? What are the stabilizers in $G$ of the path connected components of $\mathcal{X}(C)$ and $X$? In case $d = 1$, and for suitable $Y$ are they fundamental groups of Riemann surfaces of infinite genus as in [Ghy99, Théorème 3.7]? In case $\mathcal{X}_0 = \text{spec} \mathbb{Z}$ and for prime numbers $p \neq l$ with $p \equiv l \equiv 1$ mod 4, can one define linking numbers between the periodic orbit packets $\Gamma_{(p)}$ and $\Gamma_{(l)}$ in $X_0$, which relate to the quadratic residue symbol

\[37\]
(p \mathcal{L}) = (1_p)? Is there a natural leafwise metric on $X_0$ or on a sub-dynamical system which transforms by the factor $u$ under the action of $u \in \mathbb{R}_{>0}$, i.e. by $e^t$ under the flow $\phi^t$? This may happen only on the level of cohomology. The complex points of a Shimura variety can be described group theoretically

$$\text{Sh}(G,X)(\mathbb{C}) = G(\mathbb{Q}) \setminus X \times G(\mathbb{A}_f)/\hat{\mathbb{Z}}(\mathbb{Q}).$$

Is there a group theoretical description of $\text{Sh}(G,X)_{\mathbb{Z}}(\mathbb{C})$?

For $\mathbb{C}_p = \hat{\mathbb{Q}}_p$, the $\mathbb{Q}_{>0}$-dynamical system $\hat{\mathfrak{X}}_0(\mathbb{C}_p)$ may be interesting for studying the arithmetic geometry of $\mathfrak{X}_0$ from a $p$-adic point of view. The constructions of $\hat{\mathfrak{X}}_0(\mathbb{C})$ and $\hat{\mathfrak{X}}_0(\mathbb{C}_p)$ are extrinsic in that they use the Galois action on the infinite ramified covering $\mathfrak{X}$ of $X_0$. There should be an intrinsic description of these systems and even of a more fundamental object $\hat{\mathfrak{X}}_0$ with $\mathbb{Q}^{>0}$-action whose $\mathbb{C}$- resp. $\mathbb{C}_p$-valued points would be $\hat{\mathfrak{X}}_0(\mathbb{C})$ resp. $\hat{\mathfrak{X}}_0(\mathbb{C}_p)$ but which exists also if $\mathfrak{X}_0$ is an $\mathbb{F}_p$-scheme. It might then be possible to take the $\mathbb{C}_\infty = \overline{\mathbb{F}}_p((t))$ points of $\hat{\mathfrak{X}}_0$ for the purposes of function field arithmetic.
