AUTOMORPHISMS OF POINTLESS SURFACES

CONSTANTIN SHRAMOV AND VADIM VOLOGODSKY

Abstract. For a geometrically rational surface $X$ over an arbitrary field of characteristic different from 2 and 3 that contains all roots of 1, we show that either $X$ is birational to a product of a projective line and a conic, or the group of birational automorphisms of $X$ has bounded finite subgroups. As a key step in the proof, we show boundedness of finite subgroups in any anisotropic reductive algebraic group over a perfect field that contains all roots of 1. Also, we provide applications to Jordan property for groups of birational automorphisms.

1. Introduction

The group of birational automorphisms Bir($X$) of an algebraic variety $X$ can be rather difficult to understand. However, in many cases the structure of its finite subgroups is more accessible. An amazing example of this phenomenon is provided by the following theorem. We shall say that a field $K$ contains all roots of 1, if, for every positive integer $n$, the polynomial $x^n - 1$ splits completely in $K[x]$.

Theorem 1.1 ([BZ17a, Corollary 4.11]). Let $K$ be a field of characteristic zero that contains all roots of 1. Let $C$ be a conic over $K$. Assume that $C$ is not rational, i.e., that $C(K) = \emptyset$. Then every non-trivial element of finite order in Aut($C$) has order 2, and every finite subgroup of Aut($C$) has order at most 4.

In this paper we study finite subgroups of the group of birational automorphisms of geometrically rational surfaces and certain higher-dimensional varieties. A group $\Gamma$ is said to have bounded finite subgroups, if there exists a constant $B = B(\Gamma)$ such that, for any finite subgroup $G \subset \Gamma$, one has $|G| \leq B$. If this is not the case, we say that $\Gamma$ has unbounded finite subgroups.
One of the important results concerning boundedness of finite subgroups of birational automorphism groups is the following theorem proved by Yu. Prokhorov and C. Shramov.

**Theorem 1.2** ([PS18, Theorem 1.6]). Let \( \mathbb{K} \) be a field of characteristic zero that contains all roots of 1, and let \( X \) be a geometrically rational surface over \( \mathbb{K} \). Assume that \( X \) is not rational but has a \( \mathbb{K} \)-point. Then the group \( \text{Bir}(X) \) has bounded finite subgroups.

The first main result of the present paper is the following.

**Theorem 1.3.** Let \( \mathbb{K} \) be a field that contains all roots of 1. Assume that either \( \text{char} \mathbb{K} \) is different from 2 and 3, or \( \mathbb{K} \) is a perfect field of characteristic 3. Let \( X \) be a geometrically rational surface over \( \mathbb{K} \). Then the group \( \text{Bir}(X) \) has bounded finite subgroups if and only if \( X \) is not birational to \( \mathbb{P}^1 \times C \), where \( C \) is a conic.

According to a theorem of Lang and Nishimura, if a smooth projective variety \( X \) over a field \( \mathbb{K} \) has a \( \mathbb{K} \)-point, then the same is true for any smooth projective variety \( X' \) which is birational to \( X \); see for instance [Kol96, Proposition IV.6.2]. It follows that if a smooth projective variety \( X \) is birational to \( \mathbb{P}^1 \times Y \), for some smooth projective variety \( Y \), then \( X \) has a \( \mathbb{K} \)-point if and only if \( Y \) has a \( \mathbb{K} \)-point. Thus, Theorem 1.3 is a generalization of Theorem 1.2.

In Example 9.8 and Lemma 4.14(ii) we show that the group \( \text{Bir}(X) \) may have unbounded finite subgroups if the assumptions on the characteristic of \( \mathbb{K} \) in Theorem 1.3(ii) are dropped. However, in small characteristics we can still prove a weaker result stated in Theorem 1.4 below.

Given an integer \( m > 0 \), we say that a group \( \Gamma \) has \( m \)-bounded finite subgroups if there exists a constant \( B = B(\Gamma) \) such that, for any finite subgroup \( G \subset \Gamma \), one has \( |G'| \leq B \), where \( |G'| \) is the largest factor of \( |G| \) which is coprime to \( m \). We say that \( \Gamma \) has 0-bounded subgroups if it has bounded subgroups in the usual sense.

**Theorem 1.4.** Let \( \mathbb{K} \) be a field of characteristic 2 or 3 that contains all roots of 1, and let \( X \) be a geometrically rational surface over \( \mathbb{K} \). Then the group \( \text{Bir}(X) \) has char \( \mathbb{K} \)-bounded finite subgroups if and only if \( X \) is not birational to \( \mathbb{P}^1 \times C \), where \( C \) is a conic.

Given a geometrically rational surface \( X \) it could be hard to decide whether it is birational to \( \mathbb{P}^1 \times C \), for some conic \( C \), or not. However, in some cases, one can show that \( X \) is not birational to \( \mathbb{P}^1 \times C \) by analyzing the kernel of the pullback homomorphism \( \text{Br}(\mathbb{K}) \rightarrow \text{Br}(X) \) of the Brauer groups. Using this approach we obtain the following corollary of Theorems 1.3 and 1.4.

**Corollary 1.5.** Let \( \mathbb{K} \) be a field that contains all roots of 1, and let \( X \) be one of the following

- a Severi–Brauer surface over \( \mathbb{K} \) without \( \mathbb{K} \)-points;
- a product of two non-rational non-isomorphic conics;
- a smooth quadric \( X \) in \( \mathbb{P}^3 \) with no \( \mathbb{K} \)-points and \( \text{Pic}(X) \cong \mathbb{Z} \).

Then the group \( \text{Bir}(X) \) has char \( \mathbb{K} \)-bounded finite subgroups. Moreover, if either the characteristic of \( \mathbb{K} \) is different from 2 and 3 or \( \mathbb{K} \) is a perfect field of characteristic 3 then the group \( \text{Bir}(X) \) has bounded finite subgroups.

Note that a smooth quadric surface with Picard group different from \( \mathbb{Z} \) is isomorphic to the product \( C \times C \), where \( C \) is a conic (see Lemma 7.3(ii)). The latter is birationally equivalent to \( \mathbb{P}^1 \times C \).
The key step in the proof of Theorem 1.3 is a certain general property of linear algebraic groups, see Theorem 1.6 below. To state the result we must recall a bit of terminology.

A linear algebraic group is said to be anisotropic if it does not contain a subgroup isomorphic to $\mathbb{G}_m$. A connected semi-simple algebraic group $\Gamma$ is said to be simply connected if every central isogeny $\tilde{\Gamma} \to \Gamma$, where $\tilde{\Gamma}$ is a connected semi-simple group, is necessarily an isomorphism. Recall that every connected semi-simple group $\Gamma$ admits a universal cover which is a pair consisting of a connected semi-simple simply connected group $\Gamma$ and a central isogeny $\pi: \tilde{\Gamma} \to \Gamma$. The group scheme theoretic kernel of $\pi$ is called the algebraic fundamental group of $\Gamma$ and denoted by $\pi_1(\Gamma)$. This is a finite group scheme whose order $|\pi_1(\Gamma)|$ equals the order of the topological fundamental group of the connected semi-simple group over $\mathbb{C}$ constructed from the the root datum of $\Gamma_{\bar{\mathbb{C}}}$.

Let $H$ be a quasi-simple algebraic group over an algebraically closed field (that is, $H$ has no proper infinite normal closed subgroups). One defines the set $T(H)$ of torsion primes of $H$ to be the empty set if $H$ has type $A_n$ or $C_n$. If $H$ has type $B_n$, $D_n$, or $G_2$, we set $T(H) = \{2\}$; if $H$ has type $F_4$, $E_6$, or $E_7$, we set $T(H) = \{2, 3\}$; if $H$ has type $E_8$, we set $T(H) = \{2, 3, 5\}$. Given any connected semi-simple algebraic group $\Gamma$ over a field $K$ we say that a prime $p$ is a torsion prime of $\Gamma$ if $p$ is a torsion prime for some quasi-simple direct factor of $\tilde{\Gamma}_{\bar{K}}$, where $\tilde{\Gamma}$ is the universal cover of $\Gamma$.

The second main result of our paper is the following.

**Theorem 1.6.** Let $r$ and $n$ be positive integers. Then there exists a constant $L = L(r, n)$ with the following property. Let $K$ be a field that contains all roots of 1, and let $\Gamma$ be an anisotropic linear algebraic group over $K$ such that the number of connected components of $\Gamma$ is at most $r$ and the rank of $\Gamma$ is at most $n$. Let $G$ be a finite subgroup of $\Gamma(K)$. The following assertions hold.

(i) If $\Gamma$ is reductive and $K$ is perfect, then $|G| \leq L$.

(ii) Suppose that $\Gamma$ is an arbitrary linear algebraic group. If $\text{char } K > 0$, denote by $|G'|$ the largest factor of $|G|$ which is coprime to $\text{char } K$; otherwise put $|G'| = |G|$. Then $|G'| \leq L$. In particular, the group $\Gamma(K)$ has char $K$-bounded finite subgroups.

(iii) Assume that $\Gamma$ is connected, semi-simple, and char $K = p > 0$ is not a torsion prime for $\Gamma$. Write $|\pi_1(\Gamma)| = lp^m$, for some non-negative integers $m$ and $l$ such that $l$ is coprime to $p$. Then $G$ is a semi-direct product $G = H \rtimes S$ of its normal subgroup $H$ whose order is coprime to $p$ and is less than or equal to $L$, and an abelian $p$-group $S$ of exponent less than or equal to $p^m$.

As an application of Theorem 1.6, we obtain the following result. Recall that the irregularity of a smooth projective variety $X$ is defined to be $h^1(O_X)$. Abusing the terminology a little bit, we define the irregularity of singular projective varieties in the same way.

**Theorem 1.7.** Let $K$ be a perfect field that contains all roots of 1, and let $S$ a variety over its algebraic closure $\bar{K}$. Let $\pi: X \to S$ be a projective morphism such that every fiber of $\pi$ is an integral scheme and its irregularity equals 0. Then there exists a constant $B = B(X)$ with the following property. Suppose that $Y$ is a variety over $K$ such that $Y_{\bar{K}}$ is isomorphic to the fiber $X_s$, for some $s \in S(\bar{K})$, and $Y$ is not birational to $\mathbb{P}^1 \times Y'$, for any variety $Y'$ defined over $K$. Then every finite subgroup of $\text{Aut}(Y)$ has order at most $B$. 

3
Applying a result of C. Birkar on the boundedness of Fano varieties [Bir16, Theorem 1.1], we obtain the following.

**Corollary 1.8.** Let $\mathbb{K}$ be a field of characteristic zero that contains all roots of 1. Then, for every $\varepsilon > 0$ and a positive integer $n$, there exists a constant $B(\varepsilon, n)$ with the following property. Suppose that $Y$ is a Fano variety of dimension $n$ over $\mathbb{K}$ with $\varepsilon$-log canonical singularities which is not birational to $\mathbb{P}^1 \times Y'$, for any variety $Y'$. Then the orders of finite subgroups of $\text{Aut}(Y)$ are bounded by $B(\varepsilon, n)$.

A particular case of Corollary 1.8 for automorphism groups of flag varieties was established in [G18].

One can apply Theorem 1.6 to study the automorphism groups of Severi–Brauer varieties. For a Severi–Brauer variety $X$ associated to a central simple algebra $A$ over a perfect field $\mathbb{K}$ that contains all roots of 1, Theorem 1.6 implies that $\text{Aut}(X)$ has bounded finite subgroups if and only if $A$ is a division algebra; see Remark 1.7 for details. The following proposition, which we prove directly, amplifies this observation.

**Proposition 1.9.** Let $\mathbb{K}$ be a field that contains all roots of 1. Let $X$ be a Severi–Brauer variety of dimension $n - 1$ over $\mathbb{K}$, and let $A$ be the corresponding central simple algebra. Assume that the characteristic $\text{char}\, \mathbb{K}$ of $\mathbb{K}$ does not divide $n$. The following assertions hold.

(i) The group $\text{Aut}(X)$ has bounded finite subgroups if and only if $A$ is a division algebra; in particular, if $n$ is a prime number, then $\text{Aut}(X)$ has bounded finite subgroups if and only if $X(\mathbb{K}) = \emptyset$, i.e., $X$ is not isomorphic to $\mathbb{P}^{n-1}$.

(ii) Suppose that $A$ is a division algebra. Let $g \in \text{Aut}(X)$ be an element of finite order, and $G \subset \text{Aut}(X)$ be a finite subgroup. Then $g^n = 1$ and $|G| \leq n^{2n-1}$.

(iii) Suppose that $\text{char}\, \mathbb{K} = 0$, $n = 3$, and $X(\mathbb{K}) = \emptyset$. Let $G \subset \text{Aut}(X)$ be a finite subgroup. Then $|G| \leq 27$.

In particular, if $\mathbb{K}$ is a perfect field that contains all roots of 1, then Proposition 1.9 applies to all Severi–Brauer varieties over $\mathbb{K}$; indeed, in this case $\text{char}\, \mathbb{K}$ cannot divide the dimension of a division algebra over $\mathbb{K}$, see Remark 1.6 below. In the case of an arbitrary field whose characteristic divides the dimension of the division algebra, the structure of finite subgroups of the corresponding automorphism group is still rather simple, cf. Theorem 1.6 (iii).

**Proposition 1.10.** Let $\mathbb{K}$ be a field of characteristic $p > 0$ that contains all roots of 1. Let $A$ be a division algebra over $\mathbb{K}$ of dimension $n^2$, and let $X$ be a corresponding Severi–Brauer variety. Write $n = n'p^m$ for some non-negative integers $m$ and $n'$ such that $n'$ is coprime to $p$. Then every finite subgroup $G \subset \text{Aut}(X)$ is a semi-direct product $G = H \rtimes S$ of its normal subgroup $H$ whose order is coprime to $p$ and is less than or equal to $n'^{2(n-1)}$, and an abelian $p$-group $S$ of exponent less than or equal to $p^m$.

As another application of Theorem 1.6 one can prove that the automorphism group of a smooth quadric $Q$ over a field $\mathbb{K}$ of characteristic different from 2 that contains all roots of 1 has bounded finite subgroups if and only if $Q(\mathbb{K}) = \emptyset$. In the case when $\mathbb{K}$ has zero characteristic, this result was proved earlier in [BZ17a, §4]. We find explicit bounds for orders of finite automorphism groups of quadrics over appropriate fields, thus generalizing the results of [BZ17a, §4] and making them more precise.
Proposition 1.11. Let $K$ be a field that contains all roots of 1. Assume that char $K \neq 2$ or $K$ is perfect. Let $n \geq 3$ be an integer, and let $Q \subset \mathbb{P}^{n-1}$ be a smooth quadric hypersurface over $K$. The following assertions hold.

(i) The group $\text{Aut}(Q)$ has bounded finite subgroups if and only if $Q(K) = \emptyset$.

(ii) If $n$ is odd and $Q(K) = \emptyset$, then every non-trivial element of finite order in the group $\text{Aut}(Q)$ has order 2, and every finite subgroup of $\text{Aut}(Q)$ has order at most $2^{n-1}$.

(iii) If $n$ is even and $Q(K) = \emptyset$, then every non-trivial element of finite order in the group $\text{Aut}(Q)$ has order 2 or 4, and every finite subgroup of $\text{Aut}(Q)$ has order at most $8^{n-1}$.

(iv) If $n = 4$ and $Q(K) = \emptyset$, then every finite subgroup of $\text{Aut}(Q)$ has order at most 32.

In particular, we see from Proposition 1.9(ii) or Proposition 1.11(ii) that Theorem 1.1 actually holds over any perfect field, and also over any field of characteristic different from 2 (we will use this in the proof of our Theorem 1.3). Note that over a non-perfect field of characteristic 2 this is not the case: for every conic over any infinite field of characteristic 2, its automorphism group has unbounded finite subgroups; see Lemma 4.14(ii) below for details. Note also that one cannot drop the assumption on the existence of roots of 1 in Theorem 1.1, as well as in Propositions 1.9 and 1.11. Indeed, the conic over the field of real numbers defined by the equation $x^2 + y^2 + z^2 = 0$ has automorphisms of arbitrary finite order.

Next, we provide explicit bounds for orders of finite subgroups in the automorphism groups of smooth del Pezzo surfaces.

Proposition 1.12. Let $K$ be a field that contains all roots of 1. Let $X$ be a smooth del Pezzo surface over $K$ with $K_X^2 \geq 6$ such that $X$ is not birational to $\mathbb{P}^1 \times C$, where $C$ is a conic. Let $G$ be a finite subgroup of $\text{Aut}(X)$. The following assertions hold.

(i) If either char $K$ is different from 2 and 3, or $K$ is perfect, then $|G| \leq 432$.

(ii) If char $K$ is equal to 2 or 3, then $|G|' \leq 432$, where $|G|'$ is the largest factor of $|G|$ coprime to char $K$.

We point out that if char $K$ is equal to 2 or 3, the bound provided by Proposition 1.12 can be improved using a more accurate case-by-case study, see Remark 7.10. Also, we remind the reader that for a smooth del Pezzo surface $X$ of degree $K_X^2 \leq 5$ over an arbitrary field the group $\text{Aut}(X)$ is finite, and there is are explicit upper bounds for its order; see Remark 7.9 for details.

Similarly to [BZ17a], where Theorem 1.1 was applied to study groups of birational self-maps of conic bundles over non-uniruled varieties, we will apply Theorem 1.3 to higher dimensional varieties whose maximal rationally connected fibration has relative dimension 2, see Proposition 10.6 below.

The plan of our paper is as follows. In §2 we prove Theorem 1.6 in the case when $\Gamma$ is a torus. The proof is based on the Minkowski theorem on finite subgroups of $\text{GL}_n(\mathbb{Z})$ and elementary Galois theory.

In §3 we study finite subgroups of linear algebraic groups and prove Theorem 1.6. The idea of the proof is the following. According to a result of Borel and Tits, for every connected anisotropic reductive group $\Gamma$ over a perfect field $K$, every element $g \in \Gamma(K)$ is contained in $T(K)$, for some torus $T \subset \Gamma$. Using the results of §2 we bound the order of $g$. On the other hand, choosing a faithful representation of $\Gamma$ we get an
embedding $\Gamma(\mathbb{K}) \subset \text{GL}_N(\mathbb{K})$ for some positive integer $N$. This, together with a Burnside type result due to [HP76] (see Theorem 3.6 below), proves that $\Gamma(\mathbb{K})$ has bounded finite subgroups.

In §4 we describe automorphism groups of Severi–Brauer varieties and prove Propositions 1.9 and 1.10. In §5 we prove assertions (i)–(iii) of Proposition 1.11. In §6 we discuss automorphism groups of varieties with zero irregularity and prove Theorem 1.7. In §7 we study groups acting on del Pezzo surfaces, prove Proposition 1.12, and complete the proof of Proposition 1.11. In §8 we study groups acting on conic bundles. The results of this section are summarized in Proposition 8.12 that plays a key role in the proof of Theorem 1.3.

In §9 we prove Theorems 1.3 and 1.4 and Corollary 1.5; we also provide a counterexample to Theorem 1.3 over a perfect field of characteristic 2. The strategy of our proof of Theorem 1.3 is the following. For every finite subgroup $G \subset \text{Bir}(X)$, there exists a smooth projective surface $Y$ birational to $X$ such that the induced action of $G$ on $Y$ is regular, that is, one has $G \subset \text{Aut}(Y)$. We may assume that $Y$ is $G$-minimal. According to a well known classification result (see [Isk80, Theorem 1G]), the surface $Y$ is either a del Pezzo surface or a $G$-conic bundle. In the former case the order of $G$ is bounded by universal constants from Proposition 1.12 and Remark 7.9. We remark that if $\mathbb{K}$ is perfect then instead of detailed analysis of the automorphism groups of del Pezzo surfaces from Proposition 1.12 and Remark 7.9 we could refer to Theorem 1.7; it is well known that smooth del Pezzo surfaces over $\overline{\mathbb{K}}$ form finitely many families. This approach does not work for conic bundles. One reason for this is that we do not have an a priori bound for the Picard number of $Y_{\overline{\mathbb{K}}}$, where $Y$ is a conic bundle appearing as a $G$-minimal model of $X$. The trick here that we borrow from [PS18] is based on Proposition 8.12 and a deep result of Iskovskikh, see Theorem 8.13.

Finally, in §10 we derive some consequences of Theorem 1.3 for birational automorphism groups of higher dimensional varieties, and prove Jordan property for some of these groups.

Throughout the paper by $\overline{\mathbb{K}}$ we denote an algebraic closure of a field $\mathbb{K}$, and by $\mathbb{K}^{\text{sep}}$ we denote a separable closure of $\mathbb{K}$ (recall that $\mathbb{K}^{\text{sep}} = \overline{\mathbb{K}}$ provided that $\mathbb{K}$ is perfect; we prefer to use the notation $\overline{\mathbb{K}}$ in this case). Given a variety $X$ or a morphism $\phi$ defined over $\mathbb{K}$, for an arbitrary field extension $K \supset \mathbb{K}$ we denote by $X_K$ and $\phi_K$ the corresponding scalar extensions to $K$, and by $X(K)$ we denote the set of $K$-points of $X$. Abusing notation a bit, we write $\mathbb{P}^n$ for a projective space over a field $\mathbb{K}$, and similarly write $\mathbb{G}_m$ and $\mathbb{G}_a$ for the multiplicative and additive groups, respectively.

2. Tori

In this section we study elements of finite order in algebraic tori.

The following result is a famous theorem of Minkowski, see [Min1887] or [Ser07 Theorem 1].
Theorem 2.1. For any positive integer \( n \), the group \( \text{GL}_n(\mathbb{Z}) \) has bounded finite subgroups.

Theorem 2.1 tells us that there is a constant \( \Upsilon(n) < \infty \) equal to the maximal order of a finite subgroup in \( \text{GL}_n(\mathbb{Z}) \).

Remark 2.2. One can deduce Theorem 2.1 from the following assertion: for every integer \( m > 2 \), the kernel of the reduction homomorphism \( \text{GL}_n(\mathbb{Z}) \to \text{GL}_n(\mathbb{Z}/m\mathbb{Z}) \) is torsion free. In particular, one has \( \Upsilon(n) \leq |\text{GL}_n(\mathbb{Z}/3\mathbb{Z})| \). However, in general this bound is not sharp. However, for small \( n \) one can find the precise value of the constant \( \Upsilon(n) \). For instance, we have \( \Upsilon(1) = 2 \), \( \Upsilon(2) = 12 \), and \( \Upsilon(3) = 48 \), see e.g. \cite[§1.1]{Ser07} or \cite[§1]{Tah71}.

The following is the main technical result of this section.

Lemma 2.3. Let \( n \) and \( d > \Upsilon(n) \) be positive integers. Let \( K \) be a field such that the characteristic of \( K \) does not divide \( d \), and \( K \) contains a primitive \( d \)-th root of 1. Let \( T \) be an \( n \)-dimensional algebraic torus over \( K \) such that \( T(K) \) contains a point of order \( d \). Then \( T \) contains a subtorus isomorphic to \( \mathbb{G}_m \).

Proof. Let \( \tilde{T} = \text{Hom}(\mathbb{G}_m, T_{K^{\text{sep}}}) \) be the lattice of cocharacters of \( T \). Recall (see \cite[§8.12]{Bor91}) that the functor \( T \mapsto \tilde{T} \) induces an equivalence between the category of algebraic tori over \( K \) and the category of free abelian groups of finite rank equipped with an action of the Galois group \( \text{Gal}(K^{\text{sep}}/K) \) such that the image of the homomorphism \( \text{Gal}(K^{\text{sep}}/K) \to \text{Aut}(\tilde{T}) \) is finite. Denote this image by \( \Gamma \).

The group of \( d \)-torsion elements of \( T(K^{\text{sep}}) \) is isomorphic, as a Galois module, to \( \tilde{T} \otimes \mu_d \), where \( \mu_d \) is the group of \( d \)-th roots of unity in \( K^{\text{sep}} \). Since \( K \) contains a primitive \( d \)-th root of 1, the Galois module \( \mu_d \) is the trivial module \( \mathbb{Z}/d\mathbb{Z} \), so that the Galois module \( \tilde{T} \otimes \mu_d \) is isomorphic to \( \tilde{T}/d\tilde{T} \). Hence, a point \( x \in T(K) \) of order \( d \) can be viewed as a \( \text{Gal}(K^{\text{sep}}/K) \)-invariant element \( \overline{v} \in \tilde{T}/d\tilde{T} \) of order \( d \) (so that \( m\overline{v} \neq 0 \) for \( m < d \)). Let \( v \in \tilde{T} \) be any preimage of \( \overline{v} \) under the projection \( \tilde{T} \to \tilde{T}/d\tilde{T} \), and let

\[
\gamma = \sum_{\gamma \in \Gamma} \gamma(v).
\]

Since \( \overline{v} \) is \( \text{Gal}(K^{\text{sep}}/K) \)-invariant, the image of \( \gamma \) in \( \tilde{T}/d\tilde{T} \) is equal to \( |\Gamma|\overline{v} \). By assumption, the latter is not equal to 0. Hence \( \gamma \neq 0 \). On the other hand, it is clear that \( \gamma \) is a \( \text{Gal}(K^{\text{sep}}/K) \)-invariant element of \( \tilde{T} \). By the above mentioned equivalence of categories, \( \gamma \) gives rise to a non-zero homomorphism \( \mathbb{G}_m \to T \) whose image is the required subtorus. □

Remark 2.4. J.-L. Colliot-Thélène pointed out to us that the proof of Lemma 2.3 can be reformulated in the following way. The short exact sequence of \( \Gamma \)-modules

\[
0 \longrightarrow \tilde{T} \longrightarrow \tilde{T}/d\tilde{T} \longrightarrow \tilde{T}/d\tilde{T} \longrightarrow 0
\]

gives rise to the long exact sequence of cohomology groups

\[
\ldots \to H^0(\Gamma, \tilde{T}) \to H^0(\Gamma, \tilde{T}/d\tilde{T}) \to H^1(\Gamma, \tilde{T}) \to \ldots
\]

If \( H^0(\Gamma, \tilde{T}) = 0 \) then the second map in (2.5) is injective. On the other hand, the group \( H^1(\Gamma, \tilde{T}) \) is annihilated by \( |\Gamma| \) (see e.g. \cite[Proposition IV.6.3]{CF67}). It follows that the group \( H^0(\Gamma, \tilde{T}/d\tilde{T}) \) of \( d \)-torsion points of \( T(K) \) is also annihilated by \( |\Gamma| \).

Lemma 2.3 immediately implies the following result.
Corollary 2.6. Let $\mathbb{K}$ be a field that contains all roots of 1, and let $T$ be an anisotropic $n$-dimensional torus over $\mathbb{K}$. Then every element of finite order in $T(\mathbb{K})$ has order at most $\Upsilon(n)$, and every finite subgroup in $T(\mathbb{K})$ has order at most $\Upsilon(n)^n$. Moreover, every element of finite order and every finite subgroup of $T(\mathbb{K})$ has order coprime to the characteristic of $\mathbb{K}$.

Proof. Note that if char $\mathbb{K} = p$ is positive, then $T$ does not contain elements of order $p$, because there are no such elements even in $T(\mathbb{K})^{sep} \cong \mathbb{G}_m^n$. Thus, if there is an element of finite order $d$ in $T(\mathbb{K})$, then $d$ is coprime to $p$, so that $d \leq \Upsilon(n)$ by Lemma 2.3. It remains to notice that every finite subgroup of $T(\mathbb{K})$ is an abelian group generated by at most $n$ elements, and thus has order at most $\Upsilon(n)^n$. □

Remark 2.2 and Corollary 2.6 immediately imply the following (well-known) assertion.

Lemma 2.7. Let $\mathbb{K}$ be a field that contains all roots of 1, and let $T$ be a one-dimensional torus over $\mathbb{K}$ that is different from $\mathbb{G}_m^n$. Then every non-trivial finite subgroup of $T(\mathbb{K})$ has order 2.

Lemma 2.7 implies the following assertion that is in some sense analogous to Theorem 1.1.

Corollary 2.8 (cf. [BZ17b, Lemma 3.3]). Let $\mathbb{K}$ be a field that contains all roots of 1. Let $O_1, O_2 \in \mathbb{P}^1(\mathbb{K}^{sep})$ be two distinct points that form a $\text{Gal}(\mathbb{K}^{sep}/\mathbb{K})$-orbit (so that $\{O_1, O_2\}$ is a closed point of $\mathbb{P}^1$ whose residue field $\mathbb{K}_{O_1, O_2}$ is a separable quadratic extension of $\mathbb{K}$). Consider the affine curve

$$U = \mathbb{P}^1 - \{O_1, O_2\}$$

defined over $\mathbb{K}$. Let $G$ be a finite group acting by automorphisms of $U$. Then every non-trivial element of $G$ has order 2, and $|G| \leq 4$.

Proof. Let $T$ be the one-dimensional torus that corresponds to the quadratic field extension $\mathbb{K} \subset \mathbb{K}_{O_1, O_2}$. Then $T(\mathbb{K})$ is isomorphic to the group of all automorphisms $\phi$ of $\mathbb{P}^1$ such that $\phi^{\mathbb{K}^{sep}}$ preserves both points $O_1$ and $O_2$. Therefore, we have $\text{Aut}(U) \cong T(\mathbb{K}) \rtimes \mathbb{Z}/2\mathbb{Z}$, where $\mathbb{Z}/2\mathbb{Z}$ acts on $T(\mathbb{K})$ carrying every element of $T(\mathbb{K})$ to its inverse. Let $g \in T(\mathbb{K}) \rtimes \mathbb{Z}/2\mathbb{Z}$ be an element of finite order. If $g \in T(\mathbb{K})$, then $g^2 = 1$ by Lemma 2.7. Otherwise, write $g = t\sigma$, where $t \in T(\mathbb{K})$ and $\sigma$ is the non-trivial element of $\mathbb{Z}/2\mathbb{Z}$. We have that

$$g^2 = t\sigma t\sigma = tt^{-1} = 1.$$

Finally, by Lemma 2.7 we have $|G \cap T(\mathbb{K})| \leq 2$, so $|G| \leq 4$. □

Now we will provide more precise bounds for the possible finite orders of elements and subgroups of two-dimensional tori that will be used in §7. Note that there is an explicit classification of two-dimensional tori (see [Vos65]), but we will not use it. Our approach here is similar to the proof of Lemma 2.3 but instead of the bounds on the orders of finite subgroups of $\text{GL}_n(\mathbb{Z})$ we use the bounds on the orders of elements of $\text{GL}_2(\mathbb{Z})$ together with the following simple observation that is specific to rank 2.

Lemma 2.9. Put $\Lambda = \mathbb{Z}^2$, and let $\Gamma \subset \text{GL}(\Lambda)$ be a finite subgroup. Suppose that every element of $\Gamma$ has a non-zero invariant vector in $\Lambda$. Then $\Gamma$ has a non-zero invariant vector in $\Lambda$. 8
Proof. Let \( \gamma \) be an element of \( \Gamma \). Since \( \gamma \in \text{GL}(\Lambda) \cong \text{GL}_2(\mathbb{Z}) \), its determinant is \( \pm 1 \). Since one of the eigen-values of \( \gamma \) equals 1, the other eigen-value equals \( \pm 1 \). Since \( \gamma \) is of finite order, this implies that \( \gamma^2 = 1 \). Hence the group \( \Gamma \) is abelian, and thus there are two non-proportional vectors \( v_1 \) and \( v_2 \) in \( \Lambda \) that generate one-dimensional \( \Gamma \)-invariant sublattices. If there exist two non-trivial elements \( \gamma_1 \) and \( \gamma_2 \) in \( \Gamma \) such that \( \gamma_i v_i = -v_i \), then it is easy to see that there is an element \( \gamma' \) in \( \Gamma \) such that \( \gamma' v_i = -v_i \) for both \( i = 1, 2 \). This means that \( \gamma' \) acts on \( \Lambda \) by multiplication by \( -1 \), which is impossible because \( \gamma' \) must have a non-zero invariant vector by assumption. Therefore, one of the vectors \( v_1 \) and \( v_2 \) is invariant with respect to the whole group \( \Gamma \). \( \square \)

Lemma 2.10. Put \( \Lambda = \mathbb{Z}^2 \), and let \( \Gamma \subset \text{GL}(\Lambda) \) be a finite subgroup. Let \( d > 6 \) be an integer. Suppose that there is a \( \Gamma \)-invariant vector \( v \) in \( \Lambda \) (mod \( d \)) such that \( mv \neq 0 \) for \( m < d \). Then there is a non-zero \( \Gamma \)-invariant vector in \( \Lambda \).

Proof. Let \( \gamma \) be an element of the group \( \Gamma \), and \( r \) be the order of \( \gamma \). It is easy to check that \( r \in \{1, 2, 3, 4, 6\} \), see for instance \([\text{Tah71}, \S1]\).

Suppose that \( \gamma \) has no non-zero invariant vectors in \( \Lambda \). Then the matrix \( \gamma^{-1} \) is invertible in \( \text{GL}_2(\mathbb{Q}) \). Since we know that \( \gamma^r - 1 = 0 \), this implies that the matrix
\[
\delta = \gamma^{r-1} + \ldots + \gamma + 1 \in \text{Mat}_2(\mathbb{Z}) \subset \text{Mat}_2(\mathbb{Q})
\]
is the zero matrix, where \( \text{Mat}_2 \) denotes the ring of \( 2 \times 2 \)-matrices. Thus
\[
\delta_d = \delta \quad (\text{mod } d)
\]
is a zero matrix as well. Write
\[
0 = \delta_d v = (\gamma^{r-1} + \ldots + \gamma + 1) v \quad (\text{mod } d) = rv,
\]
which is a contradiction since \( r \leq 6 < d \).

Therefore, we see that every element of \( \Gamma \) has an invariant vector in \( \Lambda \). Now it remains to apply Lemma 2.9. \( \square \)

Lemma 2.11. Let \( \mathbb{K} \) be a field that contains all roots of 1, and let \( T \) be an anisotropic two-dimensional torus over \( \mathbb{K} \). Then every element of finite order in \( T(\mathbb{K}) \) has order at most 6, and every finite subgroup of \( T(\mathbb{K}) \) has order at most 36.

Proof. As in the proof of Lemma 2.3, we put \( \tilde{T} = \text{Hom}(\mathbb{G}_m, T_\mathbb{K}) \) and let \( \Gamma \) be the image of the Galois group \( \text{Gal}(\bar{\mathbb{K}}/\mathbb{K}) \) in \( \text{Aut}(\tilde{T}) \). Then \( \Gamma \) is a finite subgroup of \( \text{Aut}(\tilde{T}) \cong \text{GL}_2(\mathbb{Z}) \).

Suppose that \( T(\mathbb{K}) \) has an element of finite order \( d > 1 \). We note that \( d \) is coprime to the characteristic of the field \( \mathbb{K} \). As in the proof of Lemma 2.3, we see that \( \tilde{T}/d\tilde{T} \) has a \( \Gamma \)-invariant vector \( v \) such that \( mv \neq 0 \) for \( m < d \). By Lemma 2.10, if \( d > 6 \), then there is a non-zero \( \Gamma \)-invariant vector in \( \tilde{T} \). Hence there is an embedding \( \mathbb{G}_m \hookrightarrow T \). Since the latter is not the case by assumption, we conclude that \( d \leq 6 \). As in the proof of Corollary 2.6, we observe that every finite subgroup of \( T \) is an abelian group generated by at most two elements, and thus has order at most 36. \( \square \)

Remark 2.12. The proofs of Lemmas 2.10 and 2.11 also imply that an anisotropic two-dimensional torus over \( \mathbb{K} \) does not have elements of order 5.
3. Linear algebraic groups

In this section we study finite subgroups of linear algebraic groups and prove Theorem 1.6.

Recall that a linear algebraic group $\Gamma$ over a field $K$ is a smooth closed subgroup scheme of $GL_N$ over $K$. In particular, the group $\Gamma(K)$ of its $K$-points has a faithful finite-dimensional representation in a $K$-vector space. We refer the reader to [Bor91] and [Spr98] for the basics of the theory of linear algebraic groups.

Similarly to the case of an algebraically closed field, many properties of linear algebraic groups are determined by their maximal tori. Note that in general a linear algebraic group $\Gamma$ over a non-algebraically closed field $K$ may contain non-isomorphic maximal tori, but their dimension still equals the dimension of maximal tori in $\Gamma_{\overline{K}}$, see [Spr98, Theorem 13.3.6(i)] and [Spr98, Remark 13.3.7]; this dimension is called the rank of $\Gamma$.

Recall that an element $\gamma \in \Gamma(K)$ is called semi-simple if its image in $GL_N(K)$ is diagonalizable over an algebraic closure $\overline{K}$ of $K$. The notion of a semi-simple element is intrinsic, that is, it does not depend on the choice of $N$ and an embedding $\Gamma \hookrightarrow GL_N(K)$, see [Spr98, §2.4]. The main tool that will allow us to apply the results of §2 is the following theorem.

**Theorem 3.1** (see [Spr98, Corollary 13.3.8(i)]). Let $\Gamma$ be a connected linear algebraic group over a field $K$, and let $\gamma \in \Gamma(K)$ be a semi-simple element. Then there exists a torus $T \subset \Gamma$ such that $\gamma$ is contained in $T(K)$.

**Corollary 3.2.** Let $\Gamma$ be a connected linear algebraic group over a field $K$, and let $\gamma \in \Gamma(K)$ be a finite order element whose order is coprime to the characteristic of $K$. Then there exists a torus $T \subset \Gamma$ such that $\gamma$ is contained in $T(K)$.

For anisotropic reductive groups over perfect fields and for simply connected semi-simple anisotropic groups over arbitrary fields whose characteristic is large enough, one has a stronger result.

**Theorem 3.3** (see [BT71, Corollary 3.8] and [Tit86, Corollary 2.6]). Let $\Gamma$ be a connected anisotropic reductive linear algebraic group over $K$. Assume, in addition, that either $K$ is perfect, or $\Gamma$ is semi-simple, simply connected, and $\text{char} K = p > 0$ is not a torsion prime for $\Gamma$. Then, for every element $\gamma \in \Gamma(K)$, there exists a torus $T \subset \Gamma$ such that $\gamma$ is contained in $T(K)$.

**Corollary 3.4.** Under the assumptions of Theorem 3.3 the order of every finite order element of $\Gamma(K)$ is coprime to the characteristic of $K$.

**Proof.** By Theorem 3.3 it suffices to prove the assertion in the case when $\Gamma$ is a torus, in which case it is given by Corollary 2.6. □

Note that over fields of positive characteristic non-reductive algebraic groups may have unbounded finite subgroups. For instance, the $p$-torsion subgroup of $\mathbb{G}_a$ over an infinite field of characteristic $p$ is an infinite-dimensional vector space over the field $\mathbb{F}_p$ of $p$ elements. However, this example is in a certain sense the only source of unboundedness for unipotent groups.

**Lemma 3.5.** Let $K$ be a field, and let $\Gamma$ be a unipotent group over $K$. Then $\Gamma(K)$ does not contain elements of finite order coprime to the characteristic of $K$. 10
Theorem 3.6. Let \( n \) and \( d \) be positive integers, and let \( \mathbb{K} \) be a field. Let \( G \subset GL_n(\mathbb{K}) \) be a finite subgroup. If \( \text{char } \mathbb{K} \neq 0 \), denote by \( |G|' \) the largest factor of \( |G| \) which is coprime to \( \text{char } \mathbb{K} \); otherwise put \( |G|' = |G| \). Suppose that for every \( g \in G \), whose order is coprime to the characteristic of \( \mathbb{K} \), one has \( g^d = 1 \). Then \( |G|' \leq d^n \).

Proof. Without loss of generality we may assume that \( \mathbb{K} \) is algebraically closed. In this case the assertion of the lemma follows from a similar assertion for \( G_a \) together with Lie–Kolchin theorem (see e.g. [Bor91, Corollary 10.5]), which implies that any unipotent group over an algebraically closed field can be obtained as a consecutive extensions of groups isomorphic to \( G_a \).

We will need the following auxiliary fact about orders of finite groups with given exponents.

**Theorem 3.6** (see [HP76, Theorem 1]). Let \( n \) and \( d \) be positive integers, and let \( \mathbb{K} \) be a field. Let \( G \subset GL_n(\mathbb{K}) \) be a finite subgroup. If \( \text{char } \mathbb{K} > 0 \), denote by \( |G|' \) the largest factor of \( |G| \) which is coprime to \( \text{char } \mathbb{K} \); otherwise put \( |G|' = |G| \). Suppose that for every \( g \in G \), whose order is coprime to the characteristic of \( \mathbb{K} \), one has \( g^d = 1 \). Then \( |G|' \leq d^n \).

Now we prove Theorem 1.6.

**Proof of Theorem 1.6.** Clearly, we may assume that \( \Gamma \) is connected. Note that assertion (i) follows from assertion (ii) and Corollary 3.4.

Let \( \Gamma \) be an arbitrary linear algebraic group of rank \( n \), and let \( \gamma \in \Gamma(\mathbb{K}) \) be an element of finite order coprime to char \( \mathbb{K} \). Then, by Corollary 3.2, the element \( \gamma \) is contained in some subtorus of \( \Gamma \). Thus, it follows from Corollary 2.6 that the order of \( \gamma \) is bounded by some constant that depends only on \( n \). In other words, there exists a constant \( d(n) \), such that for every connected linear algebraic group of rank \( n \) and every element \( \gamma \in \Gamma(\mathbb{K}) \) of order coprime to char \( \mathbb{K} \), one has

\[
\gamma^{d(n)} = 1.
\]

Let \( \Gamma_\mathbb{K} \) be the algebraic group over \( \overline{\mathbb{K}} \) obtained from \( \Gamma \) by the base change, and let \( \Delta_\mathbb{K} \) be the unipotent radical of \( \Gamma_\mathbb{K} \). (Note that unless \( \mathbb{K} \) is perfect the group \( \Delta_\mathbb{K} \) need not be defined over \( \mathbb{K} \).) Then \( \Gamma_\mathbb{K}/\Delta_\mathbb{K} \) is a reductive linear algebraic group over \( \mathbb{K} \). Moreover, the group \( \Gamma_\mathbb{K}/\Delta_\mathbb{K} \) has the same rank as \( \Gamma_\mathbb{K} \) (which is equal to the rank of \( \Gamma \)). Indeed, the rank of a unipotent algebraic group is zero. Hence, the rank of \( \Gamma_\mathbb{K}/\Delta_\mathbb{K} \) is greater than or equal to the rank of \( \Gamma_\mathbb{K} \). On the other hand, by [Bor91, Theorem 10.6(4)], every extension of a torus by a unipotent group admits a section, which means that the rank of \( \Gamma_\mathbb{K} \) is greater than or equal to the rank of the quotient \( \Gamma_\mathbb{K}/\Delta_\mathbb{K} \). By a theorem of Chevalley (see [Spr98, Theorem 9.6.2]) there are only finitely many isomorphism classes of connected reductive groups of given rank over an algebraically closed field. Every such group is linear, that is, it admits a faithful finite-dimensional representation. Applying this to \( \Gamma_\mathbb{K}/\Delta_\mathbb{K} \), we infer that there exists a constant \( N(n) \), which depends only on \( n \), such that, for every connected linear algebraic group \( \Gamma \) of rank \( n \), the group \( (\Gamma_\mathbb{K}/\Delta_\mathbb{K})(\mathbb{K}) \) admits a faithful representation in an \( N(n) \)-dimensional vector space over \( \mathbb{K} \):

\[
(\Gamma_\mathbb{K}/\Delta_\mathbb{K})(\mathbb{K}) \hookrightarrow GL_{N(n)}(\mathbb{K}).
\]

Composing this embedding with the projection \( \Gamma(\mathbb{K}) \to (\Gamma_\mathbb{K}/\Delta_\mathbb{K})(\mathbb{K}) \) we construct a homomorphism

\[
\phi: \Gamma(\mathbb{K}) \to GL_{N(n)}(\mathbb{K}),
\]

whose kernel is contained in \( \Delta_\mathbb{K}(\mathbb{K}) \). By Lemma 3.5, every element of finite order in \( \Delta_\mathbb{K}(\mathbb{K}) \) has order divisible by char \( \mathbb{K} \). This means that the image \( \phi(G) \) of a finite subgroup \( G \subset \Gamma(\mathbb{K}) \) in \( GL_{N(n)}(\mathbb{K}) \) has order divisible by the largest factor \( |G|' \) of \( |G| \) coprime
to char $\mathbb{K}$; in particular, if char $\mathbb{K} = 0$, then $G$ projects isomorphically to $(\Gamma_\mathbb{K}/\Delta_\mathbb{K})(\mathbb{K})$. Theorem 3.6 applied to $\phi(G)$ gives us a bound $|G'| \leq L(1, n)$, where

$$L(1, n) = d(n)^{N(n)}.$$ 

This proves assertion (ii).

For the proof of assertion (iii), observe that since the group scheme $\pi_1(\Gamma)$ is commutative, we have that $\pi_1(\Gamma) \cong Z \times Z'$, where $Z$ is a group scheme of order $p^m$ and $Z'$ is a group scheme whose order is coprime to $p$. The central extensions

$$Z' \to \tilde{\Gamma} \to \tilde{\Gamma}/Z',$$
$$Z \to \tilde{\Gamma}/Z' \to \Gamma$$

give rise to the exact sequences of groups

$$Z'(\mathbb{K}) \to \tilde{\Gamma}(\mathbb{K}) \to (\tilde{\Gamma}/Z')(\mathbb{K}) \to H^1_{fl}(\text{spec } \mathbb{K}, Z'),$$
$$Z(\mathbb{K}) \to (\tilde{\Gamma}/Z')(\mathbb{K}) \to \Gamma(\mathbb{K}) \to H^1_{fl}(\text{spec } \mathbb{K}, Z),$$

where the groups on the right stand for cohomology of $Z'$ and $Z$ regarded as sheaves for the fppf topology on $\text{spec } \mathbb{K}$, and $H^1_{fl}$ denotes the first cohomology group for the fppf topology (see, for example, [Mil80, §III.4]). Set $H = G \cap \ker N$. By Corollary 3.4 the group $\tilde{\Gamma}(\mathbb{K})$ has no elements of order $p$. Since the multiplication by $p$ is invertible in $Z'$, the same is true for $H^1_{fl}(\text{spec } \mathbb{K}, Z')$. Hence $H$ has no elements of order $p$. Thus, by assertion (ii) the order of $H$ is less than or equal to $L(1, n) = d(n)^{N(n)}$. On the other hand, by construction $H$ is a normal subgroup of $G$, and $G/H$ is a subgroup of $H^1_{fl}(\text{spec } \mathbb{K}, Z)$. The latter is an abelian group annihilated by $p^m$. Hence, the same is true for $G/H$. Finally, since $H$ has no elements of order $p$, a $p$-Sylow subgroup of $G$ projects isomorphically to $G/H$. Thus, the group $G$ is isomorphic to a semi-direct product of $H$ and $G/H$. 

\[ \square \]

4. **Severi–Brauer varieties**

In this section we describe automorphism groups of Severi–Brauer varieties and prove Propositions 1.9 and 1.10. We refer the reader to [Ar82] for the definition and basic facts concerning Severi–Brauer varieties.

Let $A$ be a central simple algebra of dimension $n^2$ over an arbitrary field $\mathbb{K}$, and $X$ be the corresponding Severi–Brauer variety of dimension $n - 1$. As usual, for a field extension $K \supseteq \mathbb{K}$ we denote by $A^*(K)$ the multiplicative group of invertible elements in $A \otimes_\mathbb{K} K$. In particular, one has $A^*(\mathbb{K}_{sep}) = \text{GL}_n(\mathbb{K}_{sep})$. If $A$ is a division algebra, then $A^*(\mathbb{K})$ consists of all non-zero elements of $A(\mathbb{K})$.

The following fact is well known to experts (cf. Theorem E on page 266 of [Ch44], or [Ar82, §1.6.1]), but for the reader’s convenience we provide a proof.

**Lemma 4.1.** One has $\text{Aut}(X) \cong A^*(\mathbb{K})/\mathbb{K}^*$. 

**Proof.** Recall that the scheme $X$ represents the functor that takes a scheme $S$ over $\mathbb{K}$ to the set of right ideals $I$ in the sheaf of algebras $A \otimes_\mathbb{K} \mathcal{O}_S$ which are locally free of rank $n$ as $\mathcal{O}_S$-modules and are locally direct summands, that is, $I \oplus J = A \otimes_\mathbb{K} \mathcal{O}_S$ for some ideal $J$. The action of the group $A^*(\mathbb{K})$ on $A$ by conjugation induces an action of $A^*(\mathbb{K})$ on the above functor and thus, by Yoneda Lemma, on $X$. Obviously, the action of the central subgroup $\mathbb{K}^* \subset A^*(\mathbb{K})$ is trivial on $A$ and on $X$. This gives a homomorphism of groups

$$\xi_{\mathbb{K}}: A^*(\mathbb{K})/\mathbb{K}^* \to \text{Aut}(X).$$
Recall that $X_{K^{sep}} \cong \mathbb{P}^{n-1}_{K^{sep}}$ is the Severi–Brauer variety associated with the split central simple algebra $A \otimes_K K^{sep}$ over $K^{sep}$. Let $\Gamma = \text{Gal}(K^{sep}/K)$. We have a commutative diagram

$$
\begin{array}{ccc}
A^*(K)/K^* & \xrightarrow{\xi_K} & \text{Aut}(X) \\
\downarrow & & \downarrow \\
(A^*(K^{sep})/(K^{sep})^*)^\Gamma & \xrightarrow{\xi_{K^{sep}}} & (\text{Aut}(X_{K^{sep}}))^\Gamma
\end{array}
$$

Here, for a group $C$ with an action of $\Gamma$, we write $C^\Gamma$ for the subgroup of $\Gamma$-invariant elements. The homomorphism

$$
\xi_{K^{sep}}: A^*(K^{sep})/(K^{sep})^* \to \text{Aut}(X_{K^{sep}}) \cong \text{PGL}_n(K^{sep})
$$

is an isomorphism. Thus, the lower horizontal arrow in the diagram is also an isomorphism. In addition, the vertical arrows are injections. Hence, to complete the proof it suffices to show that the morphism

$$
A^*(K)/K^* \to (A^*(K^{sep})/(K^{sep})^*)^\Gamma
$$

is surjective. Indeed, the exact sequence of groups with $\Gamma$-action

$$
1 \to (K^{sep})^* \to A^*(K^{sep}) \to A^*(K^{sep})/(K^{sep})^* \to 1
$$

gives rise to the exact sequence of Galois cohomology groups

$$
1 \to K^* \to A^*(K) \to (A^*(K^{sep})/(K^{sep})^*)^\Gamma \to H^1(\Gamma, K^*).
$$

The latter cohomology group vanishes by Hilbert’s Theorem 90, and the assertion of the lemma follows. \hfill \Box

**Remark 4.2.** The above argument can be restated as follows: let $A^*$ be the algebraic group whose $S$-points are invertible elements in the algebra $A \otimes_K \mathcal{O}_S$. There is a natural embedding $\mathbb{G}_m \to A^*$ and the quotient group scheme is identified with the group scheme $\text{Aut}(X)$. Hilbert’s Theorem 90 implies that the group of $K$-points of the quotient $A^*/\mathbb{G}_m$ is $A^*(K)/K^*$.

**Lemma 4.3.** Let $K$ be a field that contains all roots of 1. Let $A$ be a central simple algebra of dimension $n^2$ over a field $K$, and let $x$ be an element of $A^*(K)$ whose image in $A^*(K)/K^*$ has finite order. Then the minimal polynomial $f(y) \in K[y]$ of $x$ has the form

$$
f(y) = \prod_i (y^r - a_i),
$$

for some positive integer $r$ that divides $n$ and some $a_i \in K$. In particular, if $A$ is a division algebra, then the order of the image of $x$ in $A^*(K)/K^*$ divides $n$.

**Proof.** We know that for some positive integer $m$, the element $a = x^m$ is contained in $K^*$. We claim that there exists a positive integer $r$ dividing $m$ such that every irreducible factor of the polynomial $y^m - a \in K[y]$ has the form $y^r - b$ for some $b \in K$. To show this, let $\alpha$ be a root of $y^m - a$ in $\overline{K}$, and let $r$ be the minimal positive integer such that $b = \alpha^r$ is contained in $K$. Clearly, $r$ divides $m$. We need to check that the polynomial $y^r - b$ is irreducible in $K[y]$. Consider the extension $F = K(\alpha) \supset K$. Since $K$ contains all roots of 1, the extension $F$ is the splitting field of the polynomial $y^r - b$.

If the characteristic of $K$ does not divide $r$, then $F$ is separable over $K$. We have an injective (Kummer) homomorphism $\text{Gal}(F/K) \to \mu_r$ to the cyclic group of $r$-th roots of 1.
which sends \( g \in \text{Gal}(F/\mathbb{K}) \) to \( \frac{2(\alpha)}{\alpha} \). If \( \mu_r \subset \mu_p \) is its image, then \( \alpha'^r \) is invariant under the action of the Galois group and, thus, belongs to \( \mathbb{K} \). Therefore, one has \( r = r' = [F : \mathbb{K}] \). This implies that \( y^r - b \) is irreducible in \( \mathbb{K}[y] \).

If \( \mathbb{K} \) has positive characteristic \( p \) which divides \( r \), write \( r = p^km \) with \( m \) coprime to \( p \). The subfield \( \mathbb{K}(\alpha^pk) \subset F \) is the splitting field of the separable polynomial \( y^m - b \), which, by the previous argument, is irreducible over \( \mathbb{K} \). On the other hand, \( \mathbb{K}(\alpha^m) \subset F \) is the splitting field of the polynomial

\[
y^p - b = (y - \alpha^m)^p^k
\]

which is also irreducible over \( \mathbb{K} \). Since the extension \( \mathbb{K} \subset \mathbb{K}(\alpha^pk) \) is separable and the extension \( \mathbb{K} \subset \mathbb{K}(\alpha^m) \) is purely inseparable, the degree of their composite is equal to the product

\[
[\mathbb{K}(\alpha^pk) : \mathbb{K}] \cdot [\mathbb{K}(\alpha^m) : \mathbb{K}] = r.
\]

Hence, the degree of \( F \) over \( \mathbb{K} \) is at least \( r \), and therefore \( y^r - b \) is irreducible in \( \mathbb{K}[y] \).

Since the minimal polynomial \( f(y) \) of \( x \) divides \( y^m - a \), each of its irreducible factors also has the form \( y^r - b \) for some integer \( r \) which divides \( m \) and \( b \in \mathbb{K} \) such that \( b^m = a \). We need to show that \( r \) divides \( n \). Consider the subalgebra

\[
R = \mathbb{K}[x] \subset A.
\]

By definition of the minimal polynomial, the algebra \( R \) is isomorphic to the quotient \( \mathbb{K}[y]/(f(y)) \). If \( y^r - b \) is an irreducible factor of \( f(y) \) then, using the assumption that \( \mathbb{K} \) contains all roots of 1 and the Chinese Remainder theorem, we see that there exists an integer \( e \) and a unital monomorphism

\[
\mathbb{K}[y]/(y^r - b^e) \hookrightarrow R.
\]

If the characteristic of \( \mathbb{K} \) does not divide \( r \), then by Hensel’s lemma the projection

\[
\mathbb{K}[y]/(y^r - b^e) \to \mathbb{K}[y]/(y^r - b)
\]

splits, and thus \( A \) contains a subfield isomorphic to \( \mathbb{K}[y]/(y^r - b) \). On the other hand, the degree \( [F : \mathbb{K}] \) of any subfield \( F \subset A \) divides \( n \). Indeed, the central simple algebra \( \mathbb{A} \otimes_{\mathbb{K}} F \) over \( F \) acts on the \( F \)-vector space \( A \). Hence, \( [F : \mathbb{K}] = \dim_F A \) is divisible by \( n \). Therefore, we see that \( r \) divides \( n \).

If \( \text{char} \mathbb{K} = p \) divides \( r \), write \( r = p^km \) with \( m \) coprime to \( p \). Then \( R \) contains a subfield isomorphic to \( \mathbb{K}[z]/(z^m - b) \). Therefore, \( m \) divides \( n \). Next, the algebra \( \mathbb{A} \otimes_{\mathbb{K}} \mathbb{K}_{\text{sep}} \) splits and thus has a representation of dimension \( n \) over \( \mathbb{K}_{\text{sep}} \). On the other hand, \( R \otimes_{\mathbb{K}} \mathbb{K}_{\text{sep}} \) contains a subalgebra of the form \( \mathbb{K}_{\text{sep}}[u]/((u^{p^k} - b)^e) \). Since the polynomial \( u^{p^k} - b \) remains irreducible over \( \mathbb{K}_{\text{sep}} \), the dimension of any representation of \( R \otimes_{\mathbb{K}} \mathbb{K}_{\text{sep}} \) in a \( \mathbb{K}_{\text{sep}} \)-vector space is divisible by \( p^k \). In particular, \( n \) is divisible by \( p^k \).

If \( A \) is a division algebra, then the minimal polynomial of any of its elements is irreducible and the last assertion of the lemma follows. \( \square \)

**Remark 4.4.** T. Bandman and Yu. Zarhin proved in [BZ17b, Theorem 3.4] a special case of Lemma 4.3 for \( A = \text{Mat}_n(\mathbb{K}) \) and \( \text{char} \mathbb{K} = 0 \).

Theorem 3.5 implies the following result about orders of finite groups with given exponents.
Lemma 4.5. Let $n$ and $d$ be positive integers, and let $K$ be a field such that $\text{char } K$ does not divide $d$. If $\text{char } K > 0$, denote by $n'$ the largest factor of $n$ which is coprime to $\text{char } K$; otherwise put $n' = n$. Let $G \subset \text{PGL}_n(K)$ be a finite subgroup. Suppose that for every $g \in G$ one has $g^d = 1$. Then

$$|G| \leq (n'd)^{n-1}.$$ 

Moreover, if $n = d = 3$ and $\text{char } K = 0$, then

$$|G| \leq 27.$$ 

Proof. We can assume that the field $K$ is algebraically (or separably) closed. Let $\tilde{G} \subset \text{SL}_n(K)$ be the preimage of $G$ with respect to the natural projection $\varphi: \text{SL}_n(K) \to \text{PGL}_n(K)$. The kernel of $\varphi$ is a cyclic group of order $n'$ that consists of scalar matrices. Thus, for every $g \in \tilde{G}$, one has $g^{n'd} = 1$ and $|\tilde{G}| = n'|G|$. Let $\mu_{n'd} \subset \text{GL}_n(K)$ be the subgroup of scalar matrices whose order divides $n'd$. Consider the subgroup $\hat{G} \subset \text{GL}_n(K)$ generated by $\tilde{G}$ and $\mu_{n'd}$. The order of any of its elements still divides $n'd$. Thus, by Theorem 3.6, we have

$$|\hat{G}| \leq (n'd)^n.$$ 

On the other hand, we also have

$$|\hat{G}| = n'd|G|,$$

and the first assertion of the lemma follows.

If $n = d = 3$, then $|G| = 3^r$ for some $r$, so that the second assertion of the lemma follows from the classification of finite subgroups of $\text{PGL}_3(K)$ over a field of characteristic zero, see [Bli17, Chapter V].

Now we are ready to prove Proposition 1.9.

Proof of Proposition 1.9. Suppose that $A$ is a division algebra. Let $g \in \text{Aut}(X)$ be an element of finite order. We claim that $g^n = 1$. Indeed, by Lemma 4.1 the element $g$ corresponds to some invertible element $x$ of $A$ (defined up to $K^*$). Since $A$ is a division algebra, the minimal polynomial of $x$ must be irreducible over $K$. By Lemma 4.3, the minimal polynomial of $x$ has the form $y^r - a$ for some $a \in K^*$ and some positive integer $r$ which divides $n$.

Furthermore, one has

$$G \subset \text{Aut}(X) \subset \text{Aut}(X_{K^{sep}}) \cong \text{PGL}_n(K^{sep}).$$

Therefore, by Lemma 4.5 we have $|G| \leq n^{2(n-1)}$ in general, and also $|G| \leq 27$ in the case when $\text{char } K = 0$ and $n = 3$. Moreover, every central simple algebra of dimension $n^2$ is a division algebra provided that $n$ is a prime number. This proves assertions (ii) and (iii).

Now suppose that $A$ is not a division algebra. Then

$$A \cong D \otimes_K \text{Mat}_m(K)$$

for some $2 \leq m \leq n$, where $\text{Mat}_m(K)$ denotes the algebra of $m \times m$-matrices. Thus $A$ contains $\text{Mat}_m(K)$ as a subalgebra. Since the field $K$ contains roots of $1$ of arbitrarily large degree, we see from Lemma 4.1 that the group $\text{Aut}(X)$ contains elements of arbitrarily large finite order. This completes the proof of assertion (i).
Remark 4.6. Let $\mathbb{K}$ be a perfect field of positive characteristic $p$, and let $A$ be a division algebra of dimension $n^2$ over $\mathbb{K}$. Then $p$ does not divide $n$. Indeed, the Frobenius morphism $\text{Fr}: \mathbb{K}^* \to \mathbb{K}^*$ is an isomorphism and, hence, the Brauer group $\text{Br}(\mathbb{K}) \cong H^2(\text{Gal}(\mathbb{K}/\mathbb{K}), \mathbb{K}^*)$ of $\mathbb{K}$ has no $p$-torsion elements and it is $p$-divisible. Therefore, our claim follows from the fact that, over any field, the dimension of a central division algebra and the order of its class in the Brauer group have the same prime factors (see for instance [Lieb08, Lemma 2.1.1.3]).

Remark 4.7. Let $A$ be a central simple algebra over a field $\mathbb{K}$. Denote by $A^*$ the algebraic group whose $S$-points are invertible elements in the algebra $A \otimes_{\mathbb{K}} \mathcal{O}_S$. We have a natural embedding $\mathbb{G}_m \hookrightarrow A^*$ induced by the homomorphism $\mathcal{O}_S^* \hookrightarrow (A \otimes_{\mathbb{K}} \mathcal{O}_S)^*$. The quotient group scheme $A^*/\mathbb{G}_m$ is anisotropic if and only if $A$ is a division algebra (see, for instance, [Bor91, §23.1]). In particular, if $\mathbb{K}$ is perfect, then Proposition 1.9(i) follows from Theorem 1.6 applied to the reductive group $A^*/\mathbb{G}_m$.

The restriction on the characteristic of $\mathbb{K}$ in Proposition 1.9 is essential for validity of the statement.

Example 4.8. Let $F$ be a field of characteristic $p > 0$, and let $\mathbb{K} = F(x, y)$ be the field of rational functions in two variables, so that $\mathbb{K}$ is a non-perfect field of characteristic $p$. Let $A$ be an algebra over $\mathbb{K}$ with generators $u$ and $v$ and relations

$$v^p = x, \quad u^p = y, \quad vu - uv = 1.$$

Then $A$ is a central division algebra of dimension $p^2$ over $\mathbb{K}$. This is a special case of the Azumaya property of the ring of differential operators in characteristic $p$ (see [BMR08, Theorem 2.2.3]), but can be also checked directly. The group $A^*(\mathbb{K})/\mathbb{K}^*$ contains $F(v)^*/F(v^p)^*$ as a subgroup. The latter is an infinite-dimensional vector space over the field $\mathbb{F}_p$ of $p$ elements. In particular, for $p = 2$ this construction provides an example of a conic $C$ over a non-perfect field of characteristic 2 such that $C$ is acted on by elementary 2-groups of arbitrarily large order.

Now we prove Proposition 1.10.

Proof of Proposition 1.10. By Lemma 4.1 we have $\text{Aut}(X) \cong A^*(\mathbb{K})/\mathbb{K}^*$. Recall the reduced norm homomorphism:

$$\text{Norm}: A^*(\mathbb{K}) \to \mathbb{K}^*.$$ 

One has $\text{Norm}(cx) = c^n \text{Norm}(x)$ for every $c \in \mathbb{K}^*$ and $x \in A^*(\mathbb{K})$. Hence, Norm induces a homomorphism

$$A^*(\mathbb{K})/\mathbb{K}^* \to \mathbb{K}^*/(\mathbb{K}^*)^n,$$

where $(\mathbb{K}^*)^n \subset \mathbb{K}^*$ is the subgroups of $n$-th powers. Composing homomorphism (4.9) with the projection $\mathbb{K}^*/(\mathbb{K}^*)^n \to \mathbb{K}^*/(\mathbb{K}^*)^p$,

we get

$$A^*(\mathbb{K})/\mathbb{K}^* \to \mathbb{K}^*/(\mathbb{K}^*)^n.$$ 

Let $\Gamma(A)$ be the kernel of homomorphism (4.10). We claim that the order of every element of $\Gamma(A)$ of finite order divides $n'$. Indeed, if $n = n'$, this follows from Proposition 1.9(ii). Hence, we may assume that $m > 0$. By Lemma 4.3 the order of every element of $\Gamma(A)$ of finite order divides $n$. Thus, it suffices to check that $\Gamma(A)$ has no elements of
order \( p \). Assuming the contrary, let \( g \in \Gamma(A) \) be an element of order \( p \), and let \( x \) be its preimage in \( A^*(\mathbb{K}) \). Then \( x^p = a \) for some \( a \in \mathbb{K}^* \). Since \( a \) does not belong to \( (\mathbb{K}^*)^p \), the image of \( a \) in \( \mathbb{K}^*/(\mathbb{K}^*)^p \) has order \( p^m \). On the other hand, we have \( \text{Norm}(x) = a^{\frac{1}{p}} \). Thus, \( \text{Norm}(x) \) is not equal to 1 in \( \mathbb{K}^*/(\mathbb{K}^*)^{p^m} \), that is, \( g \) does not belong to \( \Gamma(A) \), which gives a contradiction.

It follows that for every finite subgroup \( H \subset \Gamma(A) \), one has \( |H| \leq n^{2(n-1)} \). The proof repeats verbatim the proof of the corresponding estimate from Proposition 1.9(ii), using the above multiplicative bound on the orders of finite order elements of \( \Gamma(A) \).

Now let \( G \subset A^*(\mathbb{K})/\mathbb{K}^* \) be a finite subgroup. Set \( H = G \cap \Gamma(A) \). Then \( H \) is normal and the quotient \( G/H \) is a subgroup of \( \mathbb{K}^*/(\mathbb{K}^*)^{p^m} \). Moreover, a \( p \)-Sylow subgroup of \( G \) must project isomorphically to \( G/H \). Thus, \( G \) is isomorphic to a semi-direct product of \( H \) and \( G/H \).

**Remark 4.11.** Under the assumptions of Proposition 1.10 the fact that every finite subgroup of \( A^*(\mathbb{K})/\mathbb{K}^* \) is a semi-direct product of its abelian \( p \)-Sylow subgroup and a normal subgroup of bounded order is a special case of Theorem 1.6(iii) applied to the reductive group \( A^*/\mathbb{G}_m \). Indeed, the algebraic fundamental group of \( A^*/\mathbb{G}_m \) is isomorphic to the group scheme \( \mu_n = \ker(\mathbb{G}_m \rightarrow \mathbb{G}_m) \), which has order \( n \). Also, since \( A^*/\mathbb{G}_m \) has type \( A_{n-1} \), the set of torsion primes for \( A^*/\mathbb{G}_m \) is empty.

Later we will need the following generalization of Theorem 1.1.

**Corollary 4.12.** Let \( \mathbb{K} \) be a field that contains all roots of 1, and let \( C \) be a conic over \( \mathbb{K} \) with \( C(\mathbb{K}) = \emptyset \). Then every finite subgroup of \( \text{Aut}(C) \) is isomorphic to \((\mathbb{Z}/2\mathbb{Z})^n\) for some non-negative integer \( n \). Moreover, if \( \text{char} \mathbb{K} \neq 2 \) or \( \mathbb{K} \) is perfect then \( n \leq 2 \).

**Proof.** The first assertion follows from Proposition 1.10. Furthermore, if \( \mathbb{K} \) is perfect, then \( \text{char} \mathbb{K} \neq 2 \) by Remark 4.6. Thus, the second assertion follows from Proposition 1.9(iii).

We conclude this sections with a few further remarks on division algebras over a field of characteristic \( p \).

**Lemma 4.13.** Let \( A \) be a division algebra of dimension \( n^2 \) over a field \( \mathbb{K} \) of finite characteristic \( p \) that contains all roots of 1. Then the group \( A^*(\mathbb{K})/\mathbb{K}^* \) has bounded finite subgroups if and only if every element of \( v \in A \) is separable over \( \mathbb{K} \), that is, the field extension \( \mathbb{K}(v) \supset \mathbb{K} \) is separable.

**Proof.** If \( v \in A \) is not separable, then there exists a subfield

\[ \mathbb{K} \subset L \subset \mathbb{K}(v) \]

which is a purely inseparable extension of \( \mathbb{K} \) of degree \( p \). Then every non-trivial element of the group \( L^*/\mathbb{K}^* \) has order \( p \). Since \( |L^*/\mathbb{K}^*| = \infty \), we conclude that the group \( L^*/\mathbb{K}^* \subset A^*(\mathbb{K})/\mathbb{K}^* \) has unbounded finite subgroups.

Conversely, suppose that every element of \( A \) is separable over \( \mathbb{K} \). Denote by \( n' \) the largest factor of \( n \) which is coprime to \( \text{char} \mathbb{K} \). Then by Lemma 4.3, for every element \( v \in A^*(\mathbb{K}) \) whose image in \( A^*(\mathbb{K})/\mathbb{K}^* \) has finite order, one has \( v^{n'} \in \mathbb{K}^* \) (otherwise \( v^{n'} \) would be inseparable over \( \mathbb{K} \)). Hence, the assertion follows from Lemma 4.3.

There are examples of division algebras of dimension \( p^4 \) over a field \( \mathbb{K} \) of characteristic \( p \) such that all their elements are separable over \( \mathbb{K} \). On the other hand, we do not know if it is
true that every division algebra $A$ of dimension $p^2$ over a field $K$ of characteristic $p$ contains an element $v \in A$ which is inseparable over $K$. We refer the reader to [ABGV11 §1] and references therein for a further discussion of this problem.

The following result shows that the division algebra in Example 4.8 provides a universal example of a division algebra of dimension $p^2$ over a field of characteristic $p$ which contains an inseparable element.

(i) The following conditions are equivalent.

1. $A$ contains an element $v \in A$ which is inseparable over $K$.
2. $A$ is generated by two elements $v, u \in A$ such that $v^p, u^p \in K$ and $vu - uv = 1$.
3. $A$ contains a subfield $L \subset A$ that is a Galois extension of $K$ of degree $p$.

(ii) If $p = 2$ or $p = 3$, then every division algebra $A$ of dimension $p^2$ over a field $K$ of characteristic $p$ contains an element $v \in A$ which is inseparable over $K$. In particular, for every Severi–Brauer variety $X$ of dimension $p - 1$ over an infinite field $K$ of characteristic $p$, the group $\text{Aut}(X)$ has unbounded finite subgroups.

**Proof.** The equivalence of conditions (1) and (3) is due to Albert [Alb61 Theorem XI.4.4].

Let us show that condition (1) implies condition (2). Suppose that an element $v \in A$ is inseparable over $K$. Consider the linear map $\text{ad} v : A \to A$, which takes an element $w \in A$ to the commutator $vw - vw$. Since $v^p \in K$, we see that $(\text{ad} v)^p = \text{ad} v^p = 0$. On the other hand, the kernel of $\text{ad} v$ has dimension $p$ over $K$. Hence, the image of $\text{ad} v$ is equal to the kernel of $(\text{ad} v)^{p-1}$. In particular, the element 1 is in the image of $\text{ad} v$. Thus, there exists an element $u \in A$ such that $vu - uv = 1$. Let

$$y^p + a_{p-1}y^{p-1} + \ldots + a_0 \in K[y]$$

be the minimal polynomial for $u$. Applying the operator $\text{ad} v$ to the equality

$$u^p + a_{p-1}u^{p-1} + \ldots + a_0 = 0,$$

we compute that

$$(p - 1)a_{p-1}u^{p-1} + \ldots + 2a_2u + a_1 = 0,$$

which is impossible unless $a_{p-1} = \ldots = a_1 = 0$. Thus, we have $u^p \in K$.

To prove that condition (2) implies condition (3), assume that $v, u \in A$ are as in (2). Then one can easily check (or deduce from [BMR08 Lemma 1.3.1]) that

$$(uv)^p - uv = u^pv^p \in K.$$  

Thus, the subfield $K(uv) \subset A$ is a Galois extension of $K$.

Finally, assume that a subfield $L \subset A$ is a Galois extension of $K$. Its Galois group is a cyclic group of order $p$. Let $\sigma$ be its generator. By the Skolem–Noether theorem the action of $\sigma$ on $L$ extends to an inner automorphism of $A$ given by an element $v \in A$, that is, $vuv^{-1} = \sigma(u)$ for every $u \in L$. Then, since the normalizer of $L$ in $A$ is $L$ itself, we have that $v^p \in L$. Since $L$ is separable over $K$, the element $v^p$ is, in fact, contained in $K$. This completes the proof of assertion (i).

To prove assertion (ii), recall that every division algebra of dimension $p^2$ contains a subfield $L \subset A$ of degree $p$ over $K$, which is separable over $K$. If $p = 2$, then any such subfield is a Galois extension of $K$. For $p = 3$, existence of a subfield $L \subset A$ that is a
Galois extension $K$ of degree $p$ was proved in [Wed21]. The last assertion follows from Lemmas 4.1 and 3.13.

5. **Quadrics**

In this section we study automorphism groups of quadrics and prove assertions (i)–(iii) of Proposition 1.11.

Let $V$ be a finite-dimensional vector space over a field $K$, and let $q$ be a non-degenerate quadratic form on $V$. Recall that a quadratic form $q$ is said to be non-degenerate if the associated symmetric bilinear form

$$B_q: V \times V \to K, \quad B_q(v, w) = q(v + w) - q(v) - q(w),$$

is non-degenerate. If char $K = 2$ the form $B_q$ is also alternating. Hence, in this case the dimension of $V$ must be even.

Denote by $O(V, q)$ the orthogonal (linear algebraic) group corresponding to $q$. The following result is well know (see, for instance, [Bor91, §§22.4, 22.6]).

**Lemma 5.1.** The group $O(V, q)$ is reductive. It is anisotropic if and only if $q$ does not represent 0.

We will also need the following structural result on quadratic forms over a perfect field of characteristic 2 due to Arf ([Arf41]).

**Lemma 5.2.** Let $V$ be a finite-dimensional vector space over a perfect field $K$ of characteristic 2, and let $q$ be a non-degenerate quadratic form on $V$ (so that in particular $\dim V = 2k$ is even). Then, for some coordinates $x_1, \ldots, x_{2k}$ on $V$, the quadratic form $q$ is given by

$$(5.3) \quad q_a(x_1, \ldots, x_{2k}) = x_1^2 + x_1 x_2 + ax_2^2 + x_3 x_4 + \ldots + x_{2k-1} x_{2k},$$

where $a$ is an element of $K$. Moreover, two quadratic forms $q_a(x_1, \ldots, x_{2k})$ and $q_{a'}(x_1, \ldots, x_{2k})$ are equivalent if and only if $a$ and $a'$ have the same image in the cokernel of Artin–Schreier homomorphism

$$\mathbb{K} \to \mathbb{K}, \quad c \mapsto c^2 - c,$$

which is the Arf invariant of the quadratic form. In particular, if $\dim V > 2$ then every non-degenerate quadratic form on $V$ represents 0.

**Lemma 5.4** (cf. [GA13, Lemma 2.1]). Let $K$ be a field of characteristic $p > 2$. Let $V$ be a vector space over $K$, and let $q$ be a non-degenerate quadratic form on $V$. Assume that $q$ does not represent 0. Then the group of $K$-points of $O(V, q)$ has no elements of order $p$.

**Proof.** Assuming the contrary, let $g \in O(V, q)(K)$ be an element of order $p$. Viewing $g$ as a linear endomorphism of $V$, we have

$$g^p - 1 = (g - 1)^p = 0.$$ 

Applying the Jordan Normal Form theorem to $g - 1$, we can find linearly independent vectors $v_1, v_2 \in V$ such that $g(v_1) = v_1$ and $g(v_2) = v_1 + v_2$. Thus, we have

$$B_q(v_1, v_2) = B_q(g(v_1), g(v_2)) = B_q(v_1, v_1) + B_q(v_1, v_2).$$

Hence, we obtain $2q(v_1) = B_q(v_1, v_1) = 0$, that is, $q$ represents 0. □
Lemma 5.5 (cf. [BZ17a, Corollary 4.4]). Let $\mathbb{K}$ be a field that contains all roots of 1. Assume that $\text{char } \mathbb{K} \neq 2$ or $\mathbb{K}$ is perfect. Suppose that $q$ does not represent 0. Then every non-trivial element of finite order in $O(V, q)(\mathbb{K})$ has order 2, and every finite subgroup of $O(V, q)(\mathbb{K})$ is abelian of order less or equal to $2^{\dim V}$.

Proof. By Lemma 5.2 if $\mathbb{K}$ is perfect and $\text{char } \mathbb{K} = 2$, then we must have $\dim V = 2$. In this case, by Lemma 5.1, the group $O(V, q)$ is anisotropic and, thus, isomorphic to the product of an anisotropic torus of rank 1 and the finite group $\mathbb{Z}/2\mathbb{Z}$. Therefore, the assertion of the lemma follows from Lemma 2.7.

Now, assume that $\text{char } \mathbb{K} \neq 2$. Let $g \in O(V, q)(\mathbb{K})$ be an element of finite order. By Lemma 5.4, the order of $g$ is coprime to the characteristic of $\mathbb{K}$. Since $\mathbb{K}$ contains all roots of unity, it follows that every such element $g \in O(V, q)(\mathbb{K})$ viewed as a linear endomorphism of $V$ is diagonalizable in an appropriate basis for $V$. Moreover, since $q$ does not represent 0, the diagonal entries of the matrix of $g$ in this basis must be equal to $\pm 1$. Hence $g^2 = 1$. It follows that every finite subgroup $G \subset O(V, q)(\mathbb{K})$ is abelian, and $G$ is conjugate to a subgroup of the group of diagonal matrices in $\text{GL}(V)$. Hence, the order of $G$ is at most $2^{\dim V}$. □

Now we are ready to prove most of Proposition 1.11.

Proof of assertions (i)–(iii) of Proposition 1.11. Let $V$ be an $n$-dimensional vector space such that $\mathbb{P}^{n-1}$ is identified with the projectivization $\mathbb{P}(V)$, and let $q$ be a quadratic form corresponding to the quadric $Q$.

First, assume that $\mathbb{K}$ is a perfect field of characteristic 2. If $n$ is even, then the quadratic form is non-degenerate; indeed, otherwise its kernel $T$ would be at least two-dimensional, so that the singular locus of $Q$, which is $Q \cap \mathbb{P}(T)$, would be non-empty. Thus, by Lemma 5.2 one has $Q(\mathbb{K}) \neq \emptyset$. Moreover, writing $q$ in the form (5.3), we see that $\text{Aut}(Q)$ contains a subgroup isomorphic to $\mathbb{K}^*$. Hence, $\text{Aut}(Q)$ has unbounded finite subgroups. If $n$ is odd, the symmetric bilinear form $B_q: V \times V \to \mathbb{K}$ associated to $q$ has a one-dimensional kernel. In this case $q$ can be written as

$$q(x_1, \ldots, x_n) = x_1^2 + r(x_2, \ldots, x_n)$$

for some coordinates $x_1, \ldots, x_n$ on $V$ and some non-degenerate quadratic form $r$ in $n - 1$ variables. Applying Lemma 5.2 to $r$, we see that $Q(\mathbb{K}) \neq \emptyset$ and $\text{Aut}(Q)$ has unbounded finite subgroups. In fact, in this case $\text{Aut}(Q)$ is isomorphic to the group of linear transformations of the quotient $\tilde{V}$ of $V$ by $T$ which preserve the induced bilinear form $B_q$ on $\tilde{V}$, i.e., to the symplectic group $\text{Sp}(\tilde{V}, B_q)(\mathbb{K})$; see [Bor91] §22.6. We see that in the case when $\text{char } \mathbb{K} = 2$, assertion (i) holds, while the assumptions of assertions (ii), (iii), and (iv) do not hold.

From now on we assume that $\text{char } \mathbb{K} \neq 2$. The group $\text{Aut}(Q)$ is isomorphic to the group of $\mathbb{K}$-points of the group scheme quotient $\Gamma = O(V, q)/\mu_2$, where $\mu_2 \subset O(V, q)$ is the central subgroup of order 2. (More geometrically, $\text{Aut}(Q)$ can be identified with the group of automorphisms of the projective space $\mathbb{P}(V)$ that preserve $q$ up to a scalar multiple.) By Lemma 5.1, the group $\Gamma$ is anisotropic if and only if $Q(\mathbb{K}) = \emptyset$. The connected component of identity $\Gamma^0 \subset \Gamma$ is a connected semi-simple algebraic group. Moreover, the algebraic fundamental group of $\Gamma^0$ has order 2 if $n$ is odd and order 4 if $n$ is even. Also, note that no prime other than 2 is a torsion prime for $\Gamma^0$. Thus, assertion (i) of the proposition follows from Theorem 1.7(iii) applied to $\Gamma^0$. (It also follows that the group $\text{Aut}(Q)$ has no elements of order $\text{char } \mathbb{K}$; cf. Lemma 5.1.) The reader will see that
the argument we give below for the remaining assertions of the proposition also furnishes a direct proof of (i).

If $n$ is odd, then the embedding $\mu_2 \hookrightarrow O(V, q)$ splits, so that $\text{Aut}(Q)$ is isomorphic to the subgroup $\text{SO}(V, q)(K) \subset O(V, q)(K)$ of the orthogonal group that consists of matrices whose determinant is equal to 1. Thus, assertion (ii) follows from Lemma 5.5.

Suppose that $n$ is even. Then, using the exact sequence

\begin{equation}
0 \to \mu_2 \to O(V, q)(K) \to \text{Aut}(Q) \to K^*/(K^*)^2.
\end{equation}

and Lemma 5.5, we infer that every non-trivial element of $O(V, q)(K)$ divides 8, and the same is true for the subgroup $\hat{G} \subset \text{GL}(V)(\kbar)$ generated by $\hat{G}$ and scalar matrices whose orders divide 8. Thus, by Theorem 3.6, we have $|\hat{G}| \leq 8^n$. On the other hand, we know that $|\hat{G}| = 8|G|$. This proves assertion (iii).

Proposition 1.11(iii) implies that if $K$ is a field that contains all roots of 1 such that either $\text{char } K \neq 2$ or $K$ is perfect, and $Q$ is a smooth quadric surface over $K$ with $Q(K) = \emptyset$, then every finite subgroup of $\text{Aut}(Q)$ has order at most $8^3 = 512$. We will complete the proof of assertion (iv) of Proposition 1.11 by showing in Corollary 7.6 that this bound can be improved to 32.

6. VARIETIES WITH ZERO IRREGULARITY

In this section we study automorphism groups of varieties with zero irregularity and prove Theorem 1.7. For any projective variety $X$ over a perfect field $K$ with zero irregularity, the connected component of identity $\text{Aut}^0(X) \subset \text{Aut}(X)$ of the group scheme of automorphisms of $X$ is a linear algebraic group, whereas the group of connected components $\text{Aut}(X)/\text{Aut}^0(X)$ can be very difficult to understand. For instance, there exists a surface $X$ that is a blow up of a $K3$ surface such that $\text{Aut}(X)$ is a discrete infinitely generated group, see [DO19]. However, for any normal projective variety $X$ over a field of characteristic zero the group $\text{Aut}(X)/\text{Aut}^0(X)$ has bounded finite subgroups, see [MZ18, Lemma 2.5]. Therefore, under these assumptions, the group $\text{Aut}(X)$ has bounded finite subgroups if and only if $\text{Aut}^0(X)(K)$ enjoys the same property. We expect that this result holds for any projective scheme over an arbitrary field.

Let us start with a few general auxiliary facts.

**Lemma 6.1.** Let $K$ be an arbitrary field. Let $G$ be an algebraic group over $K$ isomorphic either to $G_m$ or to $G_a$. Let $X$ be an irreducible variety over $K$ with a non-trivial action of $G$. Then $X$ is birational to $\mathbb{P}^1 \times Y$ for some variety $Y$.

**Proof.** The argument is contained in the proof of [BB73, Theorem 2], but we provide it here for the reader’s convenience. It follows from [Ros56, Theorem 2] that there is a dense open subscheme $U \subset X$ such that the geometric quotient

$$\pi: U \to Y = U/G$$

exists (we refer the reader to [Arz07, Theorem 2.3.10] for the proof translated into the scheme-theoretic language). In particular, the fiber $U_\eta$ of $\pi$ over the scheme-theoretic
generic point \( \eta \in Y \) is a torsor for the quotient of the group scheme \( \mathbb{G}_{\mathbb{K}(\eta)} \) by a closed (possibly non-reduced) group subscheme \( H \hookrightarrow \mathbb{G}_{\mathbb{K}(\eta)} \). Since the action of \( \mathbb{G} \) on \( X \) is non-trivial, one has \( H \neq \mathbb{G}_{\mathbb{K}(\eta)} \). Hence \( H \) is a finite group scheme. It is easy and well known that every finite group subscheme of \( \mathbb{G}_{m} \) has the form

\[
\mu_{n} = \ker(\mathbb{G}_{m} \longrightarrow \mathbb{G}_{m})
\]

for some positive integer \( n \). Also, every finite group subscheme of \( \mathbb{G}_{a} \) over a field of characteristic zero is trivial and every finite group subscheme of \( \mathbb{G}_{a} \) over a field of prime characteristic has the form \( \ker(\mathbb{G}_{a} \xrightarrow{F_{n}} \mathbb{G}_{a}) \), where \( F \) is the relative Frobenius morphism and \( n \) is a positive integer. In both cases we see that the quotient \( \mathbb{G}_{\mathbb{K}(\eta)}/H \) is isomorphic to \( \mathbb{G}_{\mathbb{K}(\eta)} \). By \cite{Ros56} Theorem 10 every \( \mathbb{G}_{\mathbb{K}(\eta)} \)-torsor is trivial, so that \( U_{\eta} \cong \mathbb{G}_{\mathbb{K}(\eta)} \) (see also \cite{Ros67} for a different proof of this statement). Now the assertion easily follows. \( \square \)

An alternative proof of Lemma 6.1 over algebraically closed fields can be found in \cite{Pop16}.

**Corollary 6.2.** Let \( X \) be an irreducible variety over a perfect field with a faithful action of a connected linear algebraic group \( \Gamma \). Suppose that \( \Gamma \) is not reductive. Then \( X \) is birational to \( \mathbb{P}^{1} \times Y \) for some variety \( Y \).

**Proof.** Since \( \Gamma \) is not reductive, its unipotent radical (that is, the largest normal unipotent connected closed subgroup of \( \Gamma \)) is non-trivial. Hence, it contains a subgroup isomorphic to \( \mathbb{G}_{a} \); this follows from the Lie–Kolchin theorem. Now the assertion follows from Lemma 6.1. \( \square \)

Given a scheme \( S \) and a locally free sheaf \( E \) on \( S \), we denote by \( \text{PGL}(E) \) the group scheme over \( S \) of projective linear automorphisms of \( E \), that is, the group scheme \( \text{Aut}(\text{Proj}(S^{*}E)) \) of automorphisms (over \( S \)) of the relative projective space. Thus, over an open subscheme \( U \subset S \), over which \( E \) is free of rank \( n \), the group scheme \( \text{PGL}(E) \) is isomorphic to \( \text{PGL}_{n}\times U \). The following observation is well known.

**Lemma 6.3.** Let \( S \) be a locally Noetherian scheme, and let \( \pi: X \to S \) be a flat projective morphism with geometrically connected fibers. Let \( \mathcal{L} \) be a line bundle over \( X \) that is very ample relative to \( S \). Assume that \( R^{m}\pi_{*}\mathcal{L} = 0 \), for every \( m > 0 \). Then the coherent sheaf \( E = \pi_{*}\mathcal{L} \) is locally free and the functor that carries an \( S \)-scheme \( T \) to the group of automorphisms \( \phi: X \times_{S} T \to X \times_{S} T \) over \( T \), such that Zariski locally over \( T \) the line bundle \( \phi^{*}\text{pr}_{X}^{*}\mathcal{L} \) is isomorphic to \( \text{pr}_{X}^{*}\mathcal{L} \), is representable by a closed group subscheme \( \text{Aut}(X, \mathcal{L}) \) of \( \text{PGL}(E) \).

**Proof.** The coherent sheaf \( E \) is locally free by the base change theorem (see e.g. \cite{Mum70} \S 5) and the vanishing of the higher direct images \( R^{m}\pi_{*}\mathcal{L} \). It also follows from the same theorem that, for every scheme \( T \) over \( S \) with a structure morphism \( g: T \to S \), we have

\[
g^{*}E \xrightarrow{\sim} \text{pr}_{T}^{*}\text{pr}_{X}^{*}\mathcal{L}.
\]

Let \( i: X \hookrightarrow \text{Proj}(S^{*}E) \) be the embedding defined by \( \mathcal{L} \). We claim that the functor carrying an \( S \)-scheme \( T \) to the subgroup \( \mathcal{G}(T) \subset \text{PGL}(E)(T) \) of automorphisms of \( \text{Proj}(S^{*}E) \times_{S} T \) preserving the closed subscheme

\[
X \times_{S} T \xrightarrow{i \times \text{Id}} \text{Proj}(S^{*}E) \times_{S} T
\]
is represented by a closed subgroup subscheme \( \mathcal{G} \) of \( \text{PGL}(\mathcal{E}) \). Indeed, the image of \( i \) is given by a sheaf \( I_\bullet \) of graded ideals in \( S^{\bullet} \mathcal{E} \). For sufficiently large \( m \), the \( \mathcal{O}_S \)-submodule \( I^m \subset S^m \mathcal{E} \) is locally a direct summand. Thus, \( I^m \) determines an \( S \)-point of the relative Grassmannian associated to \( S^m \mathcal{E} \). The group \( \mathcal{G}(\mathcal{T}) \) consists of the elements of \( \text{PGL}(\mathcal{E})(\mathcal{T}) \) which preserve \( I_m \subset S^m \mathcal{E} \) for all sufficiently large \( m \). Thus, our subgroup \( \mathcal{G} \subset \text{PGL}(\mathcal{E}) \) can be defined as the stabilizer of a point in the (infinite) product of relative Grassmann schemes \( \text{Gr}(S^m(\mathcal{E})) \) under the action of \( \text{PGL}(\mathcal{E}) \). Alternatively, \( \mathcal{G} \) can be described as the stabilizer in \( \text{PGL}(\mathcal{E}) \) of the point of the Hilbert scheme \( \text{Hilb}(\text{Proj}(S^{\bullet} \mathcal{E})) \) determined by the embedding \( i : X \hookrightarrow \text{Proj}(S^{\bullet} \mathcal{E}) \).

We claim that \( \mathcal{G} \) represents the functor defined in the assertion of the lemma, that is, one has \( \text{Aut}(X, \mathcal{L}) \cong \mathcal{G} \). Let \( \mathcal{T} \) and \( \phi \) be as in the assertion of the lemma, and let \( g : \mathcal{T} \to S \) be the structure morphism. Choose, Zariski locally on \( X \), a fiber is zero by our assumption. Therefore, the homomorphism from the Picard group of the \( \alpha \) Thus, \( \phi \) induces an automorphism of the \( \text{Pic}(X, \mathcal{L}) \) and is defined on the whole \( \mathcal{T} \). We leave it to the reader to check that the constructed morphism of functors is an isomorphism.

We will need the following boundedness result on the Picard groups.

**Lemma 6.4.** Let \( S \) be a Noetherian scheme, and let \( \pi : X \to S \) be a flat projective morphism with geometrically reduced and geometrically irreducible fibers. Suppose that for every point \( s \in S \) the irregularity of the fiber \( X_s \) is zero. Then the minimal number of generators of \( \text{Pic}(X_s) \) and the order of the torsion subgroup in \( \text{Pic}(X_s) \) are both bounded by a constant that depends only on \( X \).

**Proof.** Let \( \bar{s} \) be a geometric point of \( S \) lying over \( s \) (in particular, if the residue field of \( s \) is algebraically closed, then \( \bar{s} = s \)). Note that the pullback morphism \( \text{Pic}(X_s) \to \text{Pic}(X_\bar{s}) \) is injective (see for instance [Stack, Lemma 32.30.3]). Next, by a result of Grothendieck [Kle05, Theorem 9.4.8], the group \( \text{Pic}(X_s) \) can be identified with the group of closed points of the Picard group scheme \( \text{Pic}(X_s) \). By [Kle05, Theorem 9.5.11], the Lie algebra of \( \text{Pic}(X_s) \) is isomorphic to \( H^1(X_s, \mathcal{O}_{X_s}) \). The latter space is zero by our assumption. Therefore, the homomorphism from the Picard group of the fiber \( X_s \) to the group of connected components of the Picard scheme of the corresponding geometric fiber \( X_s \) is injective. Thus, our result follows from the boundedness of the order of the latter group [Kle71, Theorem 5.1].

In a particular case when \( S \) is a point, Lemma 6.4 gives a well-known assertion that the Picard group of a variety with zero irregularity is finitely generated.

The following assertion is mostly due to S. Meng and D.-Q. Zhang.

**Lemma 6.5** (cf. the proof of [MZ18, Lemma 2.5]). Let \( X \) be a geometrically reduced and geometrically irreducible projective variety over an arbitrary field. Suppose that the irregularity of \( X \) equals 0. Let \( \Gamma_{\text{Pic}} \) be the kernel of the action of \( \text{Aut}(X) \) on the Picard
group $\text{Pic}(X)$. Then there is a constant $\Xi$ that depends only on the (minimal) number of generators of $\text{Pic}(X)$ and the order of the torsion subgroup in $\text{Pic}(X)$, such that for every finite subgroup $G \subset \text{Aut}(X)$ the intersection $G \cap \Gamma_{\text{Pic}}$ has index at most $\Xi$ in $G$.

**Proof.** In our case $\text{Pic}(X)$ is a finitely generated abelian group by Lemma 6.4. Thus, Theorem 6.1 implies that the automorphism group of $\text{Pic}(X)$ has bounded finite subgroups. This means that the orders of all finite subgroups in the quotient group

$$\text{Aut}(X)/\Gamma_{\text{Pic}} \leftrightarrow \text{Aut}(\text{Pic}(X))$$

are also bounded by some constant $\Xi$ that depends only on $\text{Pic}(X)$. \hfill \Box

Now we are ready to prove Theorem 1.7.

**Proof of Theorem 1.7.** Since $S$ is Noetherian, arguing by induction it suffices to prove the theorem for the restriction of $\pi$ to a non-empty open subscheme of $S$. Thus, by generic flatness (see [Stack, Theorem 5.12]), we may assume that $\pi$ is flat. Choose a line bundle $L$ on $X$ that is very ample relative to $S$. Replacing if necessary $L$ by its power $L^N$, we may assume that the higher direct images $R^j\pi_*L$ vanish for all $j > 0$. Then, by Lemma 6.3 the coherent sheaf $E = \pi_*L$ is free of some rank $m$ over $\mathcal{O}_S$. Let

$$\text{Aut}(X, L) \subset \text{PGL}(E) \cong \text{PGL}_m \times S$$

be the closed subgroup scheme from Lemma 6.3. By generic flatness we may assume that $\text{Aut}(X, L)$ is flat over $S$. By [Stack, Lemma 36.25.7] the number of connected components of the fibers of the morphism $\text{Aut}(X, L) \to S$ is bounded. In fact, it follows from [Stack, Lemma 36.25.7] that after shrinking $S$ we have a short exact sequence

$$(6.6) \quad 1 \to \text{Aut}^\circ(X, L) \to \text{Aut}(X, L) \to \mathcal{C} \to 1,$$

where $\text{Aut}^\circ(X, L)$ is a flat group scheme with connected fibers and $\mathcal{C}$ is a finite étale group scheme over $S$.

Let $Y$ be a variety over $\mathbb{K}$ such that $Y_{\mathbb{K}} \cong X_s$, for some $s \in S(\mathbb{K})$. Since $Y_{\mathbb{K}}$ is projective, the variety $Y$ is projective as well. Pick a very ample line bundle $L$ over $Y$. We warn the reader that the pullback of $L$ to $X_s$ need not be isomorphic to $L_s$. Denote by $\text{Aut}(Y, L)$ the group scheme of automorphisms of the pair $(Y, L)$ and let $\text{Aut}^\circ(Y, L)$ be the connected component of the identity automorphism. Assuming that $Y$ is not birational to $\mathbb{P}^1 \times Y'$, the reduced subgroup $\text{Aut}^\circ(Y, L)_{\text{red}}$ is a connected anisotropic reductive group by Corollary 6.2 and Lemma 6.1. On the other hand, we claim that

$$(6.7) \quad \text{Aut}^\circ(Y, L)_{\mathbb{K}} \cong \text{Aut}^\circ(X, L)_s = \text{Aut}^\circ(X_s, L_s).$$

Indeed, since the group scheme $\text{Aut}^\circ(Y, L)_{\mathbb{K}}$ is connected and the Picard scheme of $X_s$ is discrete, we see that the action of $\text{Aut}^\circ(Y, L)_{\mathbb{K}}$ on $Y_{\mathbb{K}} = X_s$ induces the trivial action on the Picard scheme of $X_s$. This gives a morphism $\text{Aut}^\circ(Y, L)_{\mathbb{K}} \to \text{Aut}^\circ(X_s, L_s)$. Switching the roles of $Y_{\mathbb{K}}$ and $X_s$, we see that this morphism is an isomorphism. In particular, the rank of the reductive group $\text{Aut}^\circ(Y, L)_{\text{red}}$ is bounded by the dimension of fibers of the flat group scheme $\text{Aut}^\circ(X, L)$. Hence, by Theorem 1.7(i) the orders of finite subgroups of $\text{Aut}^\circ(Y, L)(\mathbb{K})$ are bounded by some constant which depends only on that dimension.

It remains to show that, for every finite subgroup $G \subset \text{Aut}(Y)$, the index of $G \cap \text{Aut}^\circ(Y, L)(\mathbb{K})$ in $G$ is bounded by some universal constant. This comes as follows. Let $\Gamma_{\text{Pic}}(X_s)$ be the kernel of the action of $\text{Aut}(X_s)$ on $\text{Pic}(X_s)$. Then $\Gamma_{\text{Pic}}(X_s)$ is a subgroup of $\text{Aut}(X, L)_s(\mathbb{K})$. In particular, by Lemmas 6.4 and 6.5 there exists a
constant Θ such that for every finite subgroup $G \subset \text{Aut}(\mathcal{X})$, the index of the intersection $G \cap \text{Aut}(\mathcal{X}, \mathcal{L})_s(\overline{K})$ in $G$ is at most Θ. Thus, using the exact sequence (6.6), one concludes that the index of $G \cap \text{Aut}^0(\mathcal{X}, \mathcal{L})_s(\overline{K})$ in $G$ is bounded by $|C|\Theta$, and so we win thanks to isomorphism (6.7).

7. Del Pezzo surfaces

In this section we study groups acting on del Pezzo surfaces and prove Proposition 1.12.

By a del Pezzo surface we always mean a smooth projective geometrically irreducible surface with an ample anticanonical divisor. By the degree of a del Pezzo surface $X$ we mean its anticanonical degree $K^2_X$. One has $1 \leq d \leq 9$.

**Lemma 7.1.** Let $K$ be any field. Let $X$ and $Y$ be del Pezzo surfaces over $K$ such that $X_K \cong Y_K$. Then we have $X_{K_{s\text{ep}}} \cong Y_{K_{s\text{ep}}}$.

**Proof.** First, we show that, for any del Pezzo surface $X$ over $K$, the group scheme $\text{Aut}(X)$ is smooth. Indeed, it suffices to check that $\text{Aut}(X)_K \cong \text{Aut}(X_K)$ is smooth. The Zariski tangent space to $\text{Aut}(X_K)$ at the identity is the vector space $H^0(X_K, T_{X_K})$ of global vector fields on $X_K$. Thus, smoothness of $\text{Aut}(X_K)$ is equivalent to the inequality

$$\dim H^0(X_K, T_{X_K}) \leq \dim \text{Aut}(X_K).$$

(Note that the opposite inequality

$$\dim H^0(X_K, T_{X_K}) \geq \dim \text{Aut}(X_K)$$

holds for trivial reasons.) Recall that every del Pezzo surface of degree $d$ over $\overline{K}$ is isomorphic either to $\mathbb{P}^1 \times \mathbb{P}^1$, or to the blow up of $\mathbb{P}^2$ in $9-d$ points in general position. If $X_K$ is a blow up of $\mathbb{P}^2$, then $H^0(X_K, T_{X_K})$ is identified with the space of vector fields on $\mathbb{P}^2$ vanishing at the points that are being blown up. In particular, if $d < 6$, then $H^0(X_K, T_{X_K}) = 0$, because the second Chern class of $T_{\mathbb{P}^2}$ equals 3, and so there are no vector fields on $\mathbb{P}^2$ vanishing at $9 - d > 3$ points. If $X_K$ is a blow up of $\mathbb{P}^2$ in at most 3 points, then up to a change of coordinates there is a unique choice of such triple of points (respectively, pair of points, or a point), and it is straightforward to check the inequality (7.2). Similarly, if $X_K \cong \mathbb{P}^1 \times \mathbb{P}^1$, the inequality (7.2) is obvious.

Now, given $X$ and $Y$ subject to the assumptions of the lemma, consider the scheme of isomorphisms $Z = \text{Iso}(X, Y)$. Being a torsor over a smooth group scheme $\text{Aut}(X)$ the scheme $Z$ is smooth over $K$. Hence, $Z$ has a $K_{s\text{ep}}$-point, which means that $X_{K_{s\text{ep}}} \cong Y_{K_{s\text{ep}}}$.

Now we deal with del Pezzo surfaces of degree 8. We will say that a del Pezzo surface $X$ of degree 8 over a field $K$ is of product type, if $X_K \cong \mathbb{P}^1 \times \mathbb{P}^1$.

Given a finite field extension $K \subset L$ and a scheme $Y$ over $L$ denote by $R_{L/K} Y$ its Weil restriction of scalars. Recall that $R_{L/K} Y$ is a scheme over $K$ which represents the functor sending a $K$-scheme $X$ to the set of morphisms $X_L = X \times \text{spec} L \to Y$ over $L$. In other words, the functor $R_{L/K}$ from the category of schemes over $L$ to the category of schemes over $K$ is right adjoint to the fiber product with spec $L$ (that is, to the functor of extension of scalars to $L$).

Assertion (i) of the following lemma is borrowed from (the proof of) [CTKM08, Proposition 5.2].
Lemma 7.3. Let \( \mathbb{K} \) be a field, and let \( X \) be a del Pezzo surface of degree \( K_X^2 = 8 \) of product type over \( \mathbb{K} \). The following assertions hold.

(i) The surface \( X \) is isomorphic either to the product \( C \times C' \) of two conics over \( \mathbb{K} \), or to \( R_{L/\mathbb{K}}Q \), where \( L \supset \mathbb{K} \) is a separable quadratic extension of \( \mathbb{K} \) and \( Q \) is a conic over \( L \).

(ii) The surface \( X \) is isomorphic to a quadric in \( \mathbb{P}^3 \) if and only if \( X \cong C \times C \) or \( X \cong R_{L/\mathbb{K}}C_L \), for some conic \( C \) over \( \mathbb{K} \).

(iii) Let \( \text{Aut}^\circ(X) \subset \text{Aut}(X) \) be the subgroup that consists of all automorphisms of \( X \) which act trivially on \( \text{Pic}(X) \). Then \( \text{Aut}^\circ(X) \) has index at most 2 in \( \text{Aut}(X) \). That is, we have a left exact sequence

\[
1 \to \text{Aut}^\circ(X) \to \text{Aut}(X) \to \mathbb{Z}/2\mathbb{Z}.
\]

Moreover, one has that

\[
\text{Aut}(C) \times \text{Aut}(C') \xrightarrow{\sim} \text{Aut}^\circ(C \times C')
\]

for any conics \( C \) and \( C' \) over \( \mathbb{K} \), and

\[
\text{Aut}(Q) \xrightarrow{\sim} \text{Aut}^\circ(R_{L/\mathbb{K}}Q)
\]

for any conic \( Q \) over \( L \).

(iv) The homomorphism \( \text{Aut}(X) \to \mathbb{Z}/2\mathbb{Z} \) is surjective if and only if either \( X \cong C \times C \), where \( C \) is a conic over \( \mathbb{K} \), or \( X \cong R_{L/\mathbb{K}}Q \), where \( Q \) is a conic over \( L \) such that the Gal\((L/\mathbb{K})\)-conjugate conic \( Q' \) is isomorphic to \( Q \). The homomorphism \( \text{Aut}(X) \to \mathbb{Z}/2\mathbb{Z} \) is a split surjection, that is

\[
\text{Aut}(X) \cong \text{Aut}^\circ(X) \times \mathbb{Z}/2\mathbb{Z},
\]

if and only if \( X \) is a quadric.

Proof. By Lemma 7.1, we have that \( X_{\mathbb{K}^{\text{sep}}} \cong \mathbb{P}^1 \times \mathbb{P}^1 \). The action of the Galois group \( \text{Gal}(\mathbb{K}^{\text{sep}}/\mathbb{K}) \) on \( \text{Pic}(X_{\mathbb{K}^{\text{sep}}}) \cong \mathbb{Z} \oplus \mathbb{Z} \) is either trivial or factors through an order 2 quotient

\[
\text{Gal}(\mathbb{K}^{\text{sep}}/\mathbb{K}) \to \text{Gal}(L/\mathbb{K})
\]

which acts on \( \mathbb{Z} \oplus \mathbb{Z} \) by permuting the factors. In the first case the classes \((1,0)\) and \((0,1)\) define two morphisms \( X_{\mathbb{K}^{\text{sep}}} \to \mathbb{P}^1_{\mathbb{K}^{\text{sep}}} \), which descend to morphisms \( X \to C \) and \( X \to C' \) from \( X \) to some Severi–Brauer curves \( C \) and \( C' \). This yields an isomorphism \( X \cong C \times C' \). In the second case, we have that \( X_L \cong Q \times Q' \), where \( Q \) and \( Q' \) are Gal\((L/\mathbb{K})\)-conjugate conics. By adjunction, the projections \( Q \times Q' \to Q \) and \( Q \times Q' \to Q' \) yield the morphisms \( X \to R_{L/\mathbb{K}}Q \) and \( X \to R_{L/\mathbb{K}}Q' \), which are isomorphisms. This proves assertion (i).

A necessary and sufficient condition for \( X \) to be isomorphic to a quadric in \( \mathbb{P}^3 \) is that the Gal\((\mathbb{K}^{\text{sep}}/\mathbb{K})\)-invariant class

\[
(1,1) \in \text{Pic}(X_{\mathbb{K}^{\text{sep}}}) \cong \mathbb{Z} \oplus \mathbb{Z}
\]

is represented by a line bundle over \( X \). If \( X \cong C \times C \), the line bundle corresponding to the diagonal does the job. If \( X \cong R_{L/\mathbb{K}}C_L \), then the morphism \( C \to R_{L/\mathbb{K}}C_L \) defined by adjunction specifies a divisor of bidegree \((1,1)\) on \( X \). Conversely, let \( X \in \mathbb{P}^3 \) be a quadric. Let \( C \hookrightarrow X \) be a smooth hyperplane section of \( X \). If \( X \) is isomorphic to the product of two conics, then both conics must be isomorphic to \( C \). If \( X \cong R_{L/\mathbb{K}}Q \), then the morphism \( C_L \to Q \) given by adjunction is an isomorphism. This proves assertion (ii).
Let us prove assertion (iii). The subgroup Aut°(X) ⊂ Aut(X) has index at most 2 because this is true for X replaced by X_K ∼= P^1 × P^1. The claim that the morphism

\[ \text{Aut}(C) × \text{Aut}(C') \to \text{Aut}°(C × C') \]

is an isomorphism also follows by the base change to K. Finally, to show that

\[ \text{Aut}(Q) \to \text{Aut}°(R_L/K Q) \]

is an isomorphism we denote by Q' the Gal(L/K)-conjugate conic and observe that Aut(R_L/K Q) is isomorphic to the subgroup of

\[ \text{Aut}((R_L/K Q)_L) \cong \text{Aut}(Q × Q') \]

consisting of Gal(L/K)-invariant elements, and the assertion follows.

Let us prove the first part of assertion (iv) concerning the surjectivity of the map Aut(X) → Z/2Z. If X is the product of two conics, the proof is straightforward from the case of algebraically closed base field. If X ∼= R_L/K Q, then the claim follows from the description of Aut(R_L/K Q) given in the proof of assertion (iii).

For the second part of assertion (iv) we have to check that Aut(X) contains an involution which acts non-trivially on Pic(X_Ksep) if and only if X is a quadric. Let φ be such an involution. Using the base change to K, one checks that the fixed point subscheme of φ is a divisor of bidegree (1, 1). This implies that X is a quadric. Conversely, let X ∼= P^1 × P^1. In the latter case, the conic Q has an L-point by adjunction, so that Q is rational, and thus X is rational as well.

**Remark 7.4.** Proposition 5.2(2) from [Lied17](#) erroneously asserts that every del Pezzo surface of degree 8 with Picard group isomorphic to Z is a quadric in P^3.

One simple consequence of Lemma 7.3 is the following well known result.

**Corollary 7.5.** Let K be a field, and let X be a del Pezzo surface of degree 8 of product type over K. Suppose that X(K) ≠ ∅. Then X is rational.

**Proof.** By Lemma 7.3(i), the surface X is isomorphic either to a product C × C' of two conics, or to the Weil restriction of scalars R_L/K Q of a conic Q defined over a separable quadratic extension L of K. In the former case both conics C and C' have K-points, so that X ∼= P^1 × P^1. In the latter case, the conic Q has an L-point by adjunction, so that Q is rational, and thus X is rational as well.

Another result implied by Lemma 7.3 is as follows.

**Corollary 7.6.** Let K be a field that contains all roots of 1, and let X be a del Pezzo surface of degree 8 of product type over K. Suppose that X is not birational to P^1 × C, where C is a conic. Then every finite subgroup of Aut(X) is a 2-group. Moreover, if K is either a perfect field, or a field of characteristic different from 2, then every finite subgroup of Aut(X) has order at most 32.
Proof. We know from Lemma 7.3(i) that \( X \) is isomorphic either to a product of two conics, or to the Weil restriction of scalars \( R_{L/K} Q \) of a conic \( Q \) defined over a separable quadratic extension \( L \) of \( K \). In the former case the factors of \( X \) have no \( K \)-points, so that everything follows from Lemma 7.3(iii) and Corollary 4.12. In the latter case \( X \) has no \( K \)-points by Corollary 7.5. Thus the conic \( Q \) has no \( L \)-points by adjunction, and again everything is implied by Lemma 7.3(iii) and Corollary 4.12. □

In particular, Corollary 7.6 proves assertion (iv) of Proposition 1.11.

The following result is well known (see for instance [Lied17, Corollary 6.2]).

Lemma 7.7. Let \( K \) be a field, and let \( X \) be a del Pezzo surface over \( K \). Suppose that either \( X \) has degree 8 and is not of product type, or \( X \) has degree 7. Then \( X \) is rational.

Proof. Let \( X \) be such a surface. Using Lemma 7.1, it follows that \( X_{\overline{K}} \) is a blow up of \( \mathbb{P}^2 \) at one or two \( \mathbb{K}^{sep} \)-points. Thus, in both cases, \( X_{\overline{K}} \) contains a Galois-invariant \((-1)\)-curve. The image of this curve under the anticanonical embedding is a Galois-invariant line in the projective space. Therefore, this Galois-invariant \((-1)\)-curve contains a Galois-invariant point. Hence, \( X \) is a blow up of a del Pezzo surface \( X' \) of degree 9 or 8 at a \( \mathbb{K} \)-point. In the former case, \( X' \) is a Severi–Brauer surface with a \( \mathbb{K} \)-point, which implies that \( X' \cong \mathbb{P}^2 \). In the latter case, \( X' \) is a del Pezzo surface of product type with a \( \mathbb{K} \)-point which is rational by Corollary 7.5. □

Now we proceed to del Pezzo surfaces of degree 6 and less.

Lemma 7.8. Let \( K \) be any field that contains all roots of 1, and let \( X \) be a del Pezzo surface of degree 6 over \( K \). Suppose that \( X \) is not birational to \( \mathbb{P}^1 \times C \), where \( C \) is a conic. Then every finite subgroup of \( \text{Aut}(X) \) has order at most 432.

Proof. Consider the group scheme \( \text{Aut}(X) \). One has

\[
\text{Aut}(X)_{\overline{K}} \cong \text{Aut}(X_{\overline{K}}) \cong (\mathbb{G}_m \times \mathbb{G}_m) \rtimes D_{12},
\]

where \( D_{12} \) is the dihedral group of order 12, cf. [Dol12 Theorem 8.4.2]. Thus, the group scheme \( \text{Aut}(X) \) contains a two-dimensional torus \( T \) such that the quotient \( \text{Aut}(X)/T \) is a finite group scheme of order 12. If \( T \) contains a subtorus isomorphic to \( \mathbb{G}_m \), then \( X \) is birational to \( \mathbb{P}^1 \times C \) for some conic \( C \) by Lemma 6.1 which is not the case by assumption. Thus we see that \( T \) is anisotropic, so that every finite subgroup of \( T(\mathbb{K}) \) has order at most 36 by Lemma 2.11. Therefore, every finite subgroup of \( \text{Aut}(X) \) has order at most 12 \cdot 36 = 432. □

Remark 7.9. Let \( X \) be a del Pezzo surface of degree \( d \leq 5 \) over a field \( \mathbb{K} \). Then the group \( \text{Aut}(X) \) is finite. Moreover, in the case when \( \text{char} \mathbb{K} = 0 \), one has \( | \text{Aut}(X) | \leq 648 \).

To show this one can assume that \( \mathbb{K} \) is algebraically closed, and use an explicit classification of automorphism groups of del Pezzo surfaces of low degree, see [Doll12 §8.5.4], [Doll12 §8.6.4], [Doll12 §8.7.3], [Doll12 §8.8.4], and [Doll12 §9.5.3].

If \( \mathbb{K} \) is an arbitrary field, the known upper bound is much higher. Namely, one can check that \( | \text{Aut}(X) | \) is bounded by the order of the Weyl group \( W(E_8) \), that is, by the number 696,729,600, see [Doll12 Corollary 8.2.40] (where this is claimed for del Pezzo surfaces over fields of characteristic zero, but the proof does not depend on the characteristic). This bound is not sharp. However, over appropriate fields there exist del Pezzo surfaces of low degree with automorphism groups of rather large order. For instance,
the automorphism group of the Fermat cubic surface over an algebraically closed field of characteristic 2 has order 25920, see [DD17, Table 1].

Now we are ready to prove Proposition 1.12.

**Proof of Proposition 1.12.** As usual, we set \( d = K_2^2 \).

If \( d = 9 \), then \( X \) is a Severi–Brauer surface without \( K \)-points. If \( \text{char } K \neq 3 \) then by Proposition 1.9(ii) we have \( |G| \leq 81 \). If \( \text{char } K = 3 \) (in this case \( K \) must be non-perfect by Remark 4.6), then by Proposition 1.10 the group \( G \) is isomorphic to \((\mathbb{Z}/3\mathbb{Z})^n\) for some positive integer \( n \), so that \( |G'| = 1 \).

If \( 7 \leq d \leq 8 \), then it follows from Lemma 7.7 that \( d = 8 \) and \( X \) is of product type. Thus, by Corollary 7.6 we have \( |G| \leq 32 \) unless \( K \) is a non-perfect field of characteristic 2. If \( K \) is a non-perfect field of characteristic 2, again by Corollary 7.6 the group \( G \) is a 2-group, so that \( |G'| = 1 \).

Finally, if \( d = 6 \), then \( |G| \leq 432 \) by Lemma 7.8.\( \square \)

**Remark 7.10.** In the notation of Proposition 1.12, suppose that \( \text{char } K \) equals either 2 or 3. Then one can improve the bound for \( |G'| \) provided by Proposition 1.12(ii). Namely, if \( \text{char } K = 2 \), one can show that \( |G'| \leq 108 \). If \( \text{char } K = 3 \), then we have \( |G'| \leq 48 \).

8. Conic bundles

In this section we study groups acting on conic bundles. Our results are summarized in Proposition 8.12 that plays a key role in the proof of Theorem 1.3.

We begin by recalling some basic definitions concerning conic bundles; we refer the reader to [Isk80, §3] for the proofs. By a **conic bundle** we will mean a smooth geometrically irreducible surface \( X \) over a field \( K \) together with a proper surjective morphism \( \phi : X \to C \) to a smooth curve \( C \) whose fiber \( X_\eta \) over the scheme-theoretic generic point \( \eta \) of \( C \) is smooth and geometrically irreducible, and such that the anticanonical line bundle \( \omega_X^{-1} \) is very ample relative to \( C \). In other words, we have an embedding \( X \hookrightarrow \mathbb{P}_C(\phi_*\omega_X^{-1}) \), and an isomorphism between \( \omega_X^{-1} \) and the restriction of \( O_{\mathbb{P}_C(\phi_*\omega_X^{-1})}(1) \). It follows that all the fibers of \( \phi \) are geometrically reduced, the scheme-theoretic general fiber \( X_\eta \) is a conic over the field \( K(\eta) \) of rational functions on \( C \), and every singular geometric fiber is isomorphic to a pair of lines in \( \mathbb{P}^2 \) meeting at one point. The **singular locus** of \( \phi \), i.e., the closed subscheme of \( X \) defined by the sheaf of ideals \( \text{Ann}(\text{coker}(T_X \to \phi^*T_C)) \), where \( T_X \to \phi^*T_C \) is the differential of \( \phi \), is smooth of dimension zero over \( K \), which means reduced and supported on finitely many points with separable residue fields.

By the **discriminant locus** \( \Omega \subset C \) of \( \phi \) we mean the image of the singular locus of \( \phi \). This is a smooth zero-dimensional subscheme of \( C \). The smooth conic bundle \( X - \phi^{-1}(\Omega) \to C - \Omega \) is a Severi–Brauer scheme over \( C - \Omega \); the latter are in one-to-one correspondence with rank 4 Azumaya algebras over \( C - \Omega \). We denote by \( [X - \phi^{-1}(\Omega)] \in \text{Br}(C - \Omega) \) the class in the Brauer group of the Azumaya algebra corresponding to \( X - \phi^{-1}(\Omega) \).

We say that \( \phi : X \to C \) is **relatively minimal** if it does not admit a non-trivial factorization \( X \to Y \to C \), where \( Y \) is a smooth surface. If \( \phi \) is not relatively minimal and \( X \to Y \to C \) is a factorization as above, then \( Y \to C \) is also a conic bundle. A conic
bundle is relatively minimal if and only if the discriminant locus of \( \phi \) coincides with the discriminant locus of the class \([X_\eta] \in \text{Br}(\mathbb{K}(\eta))\), that is, the class \([X - \phi^{-1}(\Omega)] \in \text{Br}(C - \Omega)\) is not in the image of the (injective) restriction map \( \text{Br}(U) \to \text{Br}(C - \Omega)\), for any open \( U \subset C \) strictly larger than \( C - \Omega \). Also, \( \phi \) is relatively minimal if and only if \( \text{rk } \text{Pic}(X) - \text{rk } \text{Pic}(C) = 1 \).

For a scheme \( Y \) over \( \mathbb{K} \), we set

\[
\text{Br}^t(Y) = \ker \left( \text{Br}(Y) \to \text{Br}(Y_{\mathbb{K}^{\text{sep}}}) \right),
\]

where the homomorphism of the Brauer groups is induced by the projection \( Y_{\mathbb{K}^{\text{sep}}} \to Y \).

Given a positive integer \( l \), we write \( \text{Br}(Y)_l \) for the subgroup of \( l \)-torsion elements in \( \text{Br}(Y) \). Similarly, we write \( \text{Br}^t(Y)_l \) for the subgroup of \( l \)-torsion elements in \( \text{Br}^t(Y) \). Note that if the characteristic of \( \mathbb{K} \) does not divide \( l \) then \( \text{Br}^t(Y)_l = \text{Br}(Y)_l \).

**Lemma 8.1.** Let \( C \) be a smooth proper curve over a field \( \mathbb{K} \), and let \( \phi: X \to C \) be a conic bundle. Then \([X_\eta] \in \text{Br}^t(\mathbb{K}(\eta))_2\).

**Proof.** It suffices to check that if \( \mathbb{K} = \mathbb{K}^{\text{sep}} \), then every conic bundle \( \phi: X \to C \) has a section. To do this, we can assume that \( \phi \) is relatively minimal.

First, let us check that \( \phi \) is smooth over \( C \). Indeed, let \( X_c \) be a singular fiber. Then the residue field of the point \( c \in C \) is \( \mathbb{K} \), because the discriminant locus of \( \phi \) is smooth over \( \mathbb{K} \). Hence, \( X_c \) is a degree 2 curve in \( \mathbb{P}^2_{\mathbb{K}} \) whose base change to \( \bar{\mathbb{K}} \) is reducible. Therefore, \( X_c \) is itself reducible (see, for example, [Stack, Lemma 32.8.2]), i.e., a pair of lines in \( \mathbb{P}^2_{\bar{\mathbb{K}}} \) meeting at one point. Each of these lines is a \((-1)\)-curve on \( X \). It follows that \( \phi: X \to C \) is not relatively minimal.

Thus, \( \phi: X \to C \) is a Severi–Brauer curve over \( C \). Since \( \mathbb{K} = \mathbb{K}^{\text{sep}} \) is separably closed, the Brauer group of \( C \) is trivial by [Gr68, Corollary 5.7]. Thus, \( \phi \) has a section. \( \square \)

**Remark 8.2.** Lemma 8.1 shows that in characteristic 2 not every conic \( X_\eta \) over the scheme-theoretic generic point \( \eta \) of \( C \) can be extended to a conic bundle over \( C \). This seems to contradict [Isk80, Theorem 3(4)]; see also [Isk80, pp. 33–34], and especially formula (3.3) therein. For example, take \( \mathbb{K} = \mathbb{F}_2(a) \), where \( a \) is a transcendental variable, and consider the smooth conic bundle \( X_{\mathbb{A}^1} \to \mathbb{A}^1 \) given by equation

\[
ax^2 + xy + ty^2 + z^2 = 0
\]

in \( \mathbb{P}^2 \times \mathbb{A}^1 \), where \( t \) is the coordinate on \( \mathbb{A}^1 \) and \((x : y : z) \) are homogeneous coordinates on \( \mathbb{P}^2 \). The class

\[
[X_\eta] \in \text{Br}(\mathbb{A}^1) \subset \text{Br}(\mathbb{K}(t))
\]

is represented by the division algebra over \( \mathbb{K}(t) = \mathbb{F}_2(a, t) \) from Example 4.8 and, therefore, is not equal to 0. However, the Leray spectral sequence

\[
E_2^{ij} = H^i \left( \text{Gal}(\mathbb{K}^{\text{sep}}/\mathbb{K}), H^j(\mathbb{A}^1_{\mathbb{K}^{\text{sep}}, \text{et}}, \mathcal{O}_{\mathbb{A}^1_{\mathbb{K}^{\text{sep}}}}^*) \right)
\]

converging to \( H^n(\mathbb{A}^1_{\mathbb{K}^{\text{sep}}, \text{et}}, \mathcal{O}_{\mathbb{A}^1_{\mathbb{K}^{\text{sep}}}}^*) \) shows that \( \text{Br}^t(\mathbb{A}^1_{\mathbb{K}^{\text{sep}}}) = \text{Br}(\mathbb{K}) \). On the other hand, we have \( \text{Br}(\mathbb{K}) = 0 \) by Tsen’s theorem. This means that the group \( \text{Br}^t(\mathbb{A}^1_{\mathbb{K}^{\text{sep}}}) \) is trivial, and thus \([X_\eta] \not\in \text{Br}^t(\mathbb{K}(t))\). Since

\[
\text{Br}^t(\mathbb{A}^1_{\mathbb{K}^{\text{sep}}}) = \text{Br}^t(\mathbb{K}(t)) \cap \text{Br}(\mathbb{A}^1_{\mathbb{K}}) \subset \text{Br}(\mathbb{K}(t)),
\]

we conclude that \([X_\eta] \not\in \text{Br}^t(\mathbb{K}(t))\). Now Lemma 8.1 shows that \( X_{\mathbb{A}^1} \) and \( X_\eta \) do not extend to conic bundles over \( \mathbb{P}^1 \).
However, one can show that there is a one-to-one correspondence between relatively minimal conic bundles over $C$ with discriminant $\Omega$ and those Severi–Brauer schemes $X_{C-\Omega}$ of dimension 1 over $C - \Omega$ whose class in the Brauer group belongs to $\text{Br}(C - \Omega)$ and cannot be extended to a class in the Brauer group of a larger subscheme of $C$. We will not prove this claim here because we do not need it in the full generality, but we will check its special case in Lemma 8.3 below.

**Lemma 8.3.** Let $C$ be a smooth proper curve over a perfect field $\mathbb{K}$ of characteristic 2, and let $U \subset C$ a dense open subscheme. Then every conic bundle $\phi: X \to U$ over $U$ can be extended to a conic bundle over $C$.

**Proof.** It suffices to prove the following local statement: let $Y$ be a conic over the field of Laurent series $\mathbb{K}((t))$, where $\mathbb{K}$ is a perfect field of characteristic 2. Then $Y$ can be extended to a conic bundle over $\text{spec} \mathbb{K}[t]$, that is, there exists a connected regular closed subscheme $\bar{Y} \subset \mathbb{P}^2_{\mathbb{K}[t]}$ whose fiber over $\mathbb{K}((t))$ is $Y$.

To check the local statement recall that by a theorem of Witt (see, for example, [Gr68 p. 188]) the Brauer group of $\mathbb{K}((t))$ fits into the short exact sequence

$$0 \to \text{Br}(\mathbb{K}) \to \text{Br}(\mathbb{K}((t))) \to \text{Hom}(\text{Gal}(\overline{\mathbb{K}}/\mathbb{K}), \mathbb{Q}/\mathbb{Z}) \to 0.$$  

Since the multiplication by 2 is an isomorphism on $\text{Br}(\mathbb{K})$ (see Remark 4.6) we conclude that

$$\text{Br}(\mathbb{K}((t)))_2 \cong \text{Hom}(\text{Gal}(\overline{\mathbb{K}}/\mathbb{K}), \mathbb{Z}/2\mathbb{Z}).$$

The above isomorphism is compatible with algebraic extensions of $\mathbb{K}$, that is, for every extension $\mathbb{K} \subset \mathbb{L} \subset \overline{\mathbb{K}}$, we have a commutative diagram

$$\begin{array}{ccc}
\text{Br}(\mathbb{K}((t)))_2 & \cong & \text{Hom}(\text{Gal}(\overline{\mathbb{K}}/\mathbb{K}), \mathbb{Z}/2\mathbb{Z}) \\
\downarrow & & \downarrow \\
\text{Br}(\mathbb{L}((t)))_2 & \cong & \text{Hom}(\text{Gal}(\overline{\mathbb{K}}/\mathbb{L}), \mathbb{Z}/2\mathbb{Z})
\end{array}$$

where the left vertical arrow is the pullback homomorphism and the right vertical arrow is the restriction homomorphism. It follows that non-zero elements of $\text{Br}(\mathbb{K}((t)))_2$ are in one-to-one correspondence with quadratic extensions $\mathbb{K} \subset \mathbb{L} \subset \overline{\mathbb{K}}$ so that, for every such extension, there exists a unique non-zero class in $\text{Br}(\mathbb{K}((t)))_2$ which splits over $\mathbb{L}((t))$.

Now we claim that every conic over $\mathbb{K}((t))$ can be given in $\mathbb{P}^2_{\mathbb{K}((t))}$ by a homogeneous equation of the form

$$(8.4) \quad x^2 + xy + ay^2 + tz^2 = 0$$

for some $a \in \mathbb{K}$. Indeed, one can easily see that the above conic has no $\mathbb{K}((t))$-points if and only if the quotient ring $\mathbb{L} = \mathbb{K}[h]/(h^2 + h - a)$ is a field, and that in this case the conic has a point over $\mathbb{L}$. Hence, since every quadratic extension of $\mathbb{K}$ has the form $\mathbb{K}[h]/(h^2 - h - a)$ for some $a \in \mathbb{K}$, every class in $\text{Br}(\mathbb{K}((t)))_2$ is represented by a conic of the form (8.4), and this proves the claim.

It remains to observe that equation (8.4) defines a regular subscheme of $\mathbb{P}^2_{\mathbb{K}(t)}$. □

**Lemma 8.5.** Let $\phi: X \to C$ be a relatively minimal conic bundle over a field $\mathbb{K}$. Then, for every purely inseparable algebraic extension $\mathbb{K} \subset \mathbb{L}$, the conic bundle $\phi_\mathbb{L}: X_\mathbb{L} \to C_\mathbb{L}$ obtained from $\phi$ by the base change is relatively minimal.
Proof. A conic bundle $\phi \colon X \to C$ is relatively minimal if and only if, for every point $c \in C$, the fiber $X_c$ is irreducible. Now the claim follows from a general fact that, for an irreducible scheme $Y$ over a field $K'$ and a purely inseparable algebraic extension $K' \subset L'$, the scheme $Y_{L'}$ is irreducible (see, for example, [Stack, Lemma 10.45.7]). \qed

**Lemma 8.6.** Let $C$ be a smooth proper curve over a field $K$, and let $\phi \colon X \to C$ be a conic bundle. Suppose that $\phi_K \colon X_K \to C_K$ has a unique reducible fiber. Then $\phi \colon X \to C$ is not relatively minimal.

**Proof.** Assume that $\phi$ is relatively minimal. Replacing $K$ by its perfection (that is, by the maximal subfield of $\bar{K}$ which is purely inseparable over $K$) and using Lemma 8.5 we may assume that $K$ is perfect. By our assumptions the discriminant of $\phi$ consists of a single point $c$ whose residue field is $K$. Set $U = C - c$. We claim that the restriction morphism $\text{Br}(C) \to \text{Br}(U)$ is an isomorphism. This is well known, but we sketch the argument for the reader’s convenience.

By Tsen’s theorem the complexes $R\Gamma(C_{\text{ét}}, \mathcal{O}_{C_K}^*)$ and $R\Gamma(U_{\text{ét}}, \mathcal{O}_{U_K}^*)$ of sheaves for the étale topology on $\text{spec} K$ have non-trivial cohomology sheaves in degrees 0 and 1 only (see, for example, [Gr68, Theorem 1.1] and [Gr68, Proposition 2.1]). It follows that the restriction morphism

$$R\Gamma(C_{\text{ét}}, \mathcal{O}_{C_K}^*) \to R\Gamma(U_{\text{ét}}, \mathcal{O}_{U_K}^*)$$

together with the projection on the top cohomology group

$$R\Gamma(C_{\text{ét}}, \mathcal{O}_{C_K}^*) \to \text{Pic} C_K[-1]$$

composed with the degree map

$$\text{Pic} C_K[-1] \to \mathbb{Z}[-1]$$

induce a quasi-ismorphism

$$R\Gamma(C_{\text{ét}}, \mathcal{O}_{C_K}^*) \cong R\Gamma(U_{\text{ét}}, \mathcal{O}_{U_K}^*) \oplus \mathbb{Z}[-1].$$

Passing to the hypercohomology we conclude that, for every integer $i \geq 0$, one has

$$H^i(C_{\text{ét}}, \mathcal{O}_{C}^*) \cong H^i(U_{\text{ét}}, \mathcal{O}_{U}^*) \oplus H^{i-1}(\text{spec } K_{\text{ét}}, \mathbb{Z}).$$

Since $H^1(\text{spec } K_{\text{ét}}, \mathbb{Z}) = 0$ (see, for example, [Gr68, formula (2.5 bis)]), the claim follows.

Hence, the class $[X - \phi^{-1}(c)] \in \text{Br}(U)$ extends to a class in $\text{Br}(C)$. This contradicts the relative minimality of $\phi$. \qed

The following result is well-known at least if $K$ is perfect (see [Isk96, §4.7] or [Pro18, Proposition 5.2]), but we recall its proof for completeness.

**Lemma 8.7.** Let $C$ be a conic over a field $K$, and let $\phi \colon X \to C$ be a conic bundle such that $\phi_K$ has exactly two reducible fibers. Suppose that $\phi$ has no sections. Then $X$ is a del Pezzo surface with $K_X^2 = 6$.

**Proof.** By Lemma 8.5 the conic bundle $\phi_{K_{\text{sep}}} \colon X_{K_{\text{sep}}} \to C_{K_{\text{sep}}}$ has two reducible fibers over some $K_{\text{sep}}$-points of $C_{K_{\text{sep}}}$, and it is smooth over the complement to these points. Contracting one irreducible component of each reducible fiber on $X_{K_{\text{sep}}}$ we obtain a smooth conic bundle $\phi' \colon X' \to \mathbb{P}^1$ over $K_{\text{sep}}$. By Lemma 8.1 the conic bundle $\phi'$ has a section. Thus, we have

$$X' \cong \mathbb{F}_n = \mathbb{P} \left( \mathcal{O} \oplus \mathcal{O}(n) \right)$$
Lemma 8.7. Recall that the connected component of identity in the group scheme $\text{Aut}_{\overline{\mathbb{K}}} X$ that
diction. Thus, we see that $n \geq 1$ and at least one of the points $P_1$ and $P_2$ is contained in $D$, then $\overline{D}$ is the only section
of $\phi_{\overline{\mathbb{K}}} X$ with negative self-intersection; hence it is Galois-invariant, which gives a contradiction. Thus, we see that $n = 1$ and none of the points $P_1$ and $P_2$ is contained in $D$, which implies that $X_{\overline{\mathbb{K}}}$, and thus also $X$, is a del Pezzo surface.

Now suppose that $n = 0$. If $P_1$ and $P_2$ are contained in one section $D$ of $\phi_{\overline{\mathbb{K}}} X$ with self-intersection 0, then the proper transform of $D$ on $X_{\overline{\mathbb{K}}}$ is the only section of $\phi_{\overline{\mathbb{K}}} X$ with negative self-intersection, which gives a contradiction. Thus we conclude that $P_1$ and $P_2$ are contained in different sections of $\phi_{\overline{\mathbb{K}}} X$ with self-intersection 0, which implies that $X_{\overline{\mathbb{K}}}$, and thus also $X$, is a del Pezzo surface (cf. [Liedl17, Proposition 7.1(2)]).

The equality $K_X^2 = 6$ follows from Noether’s formula. □

Lemma 8.8. Let $\phi: X \to \mathbb{P}^1$ be a conic bundle over a field $\mathbb{K}$ and $\Omega$ its discriminant locus. Assume that $|\Omega(\mathbb{K})| = |\Omega(\mathbb{K})| = 2$, that is, $\phi$ has exactly two reducible fibers, and their images are points with residue field $\mathbb{K}$. Then $X$ is birational to the product $\mathbb{P}^1 \times C'$, for some conic $C'$ over $\mathbb{K}$.

Proof. We may assume that $\phi$ has no sections. Then $X$ is a del Pezzo surface of degree 6 by Lemma 8.7. Recall that the connected component of identity in the group scheme $\text{Aut}(X)$ of automorphisms of any degree 6 del Pezzo surface is a rank 2 torus $T$ (cf. the proof of Lemma 8.8). The morphism $\phi$ determines a character

$$\chi: T \to \mathbb{G}_m$$

as follows. Let $\{c_1, c_2\} \subset \mathbb{P}^1$ be the discriminant locus of $\phi$. Pick a rational function on $\mathbb{P}^1$ whose divisor is $[c_1] - [c_2]$, and let $f$ be its pullback to $X$. We claim that the divisor $(f)$ of the function $f$ is fixed under the action of $T$. Indeed, the pull back of $(f)$ to $X_{\overline{\mathbb{K}}}$ is supported on the union $Z_{\overline{\mathbb{K}}}$ of all six $(-1)$-curves on $X_{\overline{\mathbb{K}}}$. The subscheme $Z_{\overline{\mathbb{K}}}$ is fixed under the action the group scheme $\text{Aut}(X_{\overline{\mathbb{K}}})$. Thus, its connected subgroup $T_{\overline{\mathbb{K}}}$ fixes every irreducible component of $Z_{\overline{\mathbb{K}}}$ and, in particular, the pull back of $(f)$ to $X_{\overline{\mathbb{K}}}$. It follows that, for every smooth scheme $S$ over $\mathbb{K}$ and an $S$-point $v$ of $T$, we have that

$$\frac{v^*f}{f} \in \Gamma(X \times S, \mathcal{O}_{X \times S}^* \otimes \mathcal{O}_S) = \Gamma(S, \mathcal{O}_S^*).$$

We define the character (8.9) by the formula

$$v^*f = \chi(v)f, \quad v \in T.$$ 

We claim that $\chi$ is not identically equal to 1: otherwise, the action of $T$ on $X$ would preserve every fiber of $\phi$, which is impossible. Since the torus $T$ has a non-trivial character, it also has a subtorus isomorphic to $\mathbb{G}_m$ (see [Bor91 §8.12]). Thus, we get a faithful action of $\mathbb{G}_m$ on $X$. This completes the proof by Lemma 6.1. □

Given a conic bundle $\phi: X \to C$, denote by $\text{Bir}(X, \phi)$ the group consisting of pairs $(\sigma_X, \sigma_C)$, where $\sigma_X \in \text{Bir}(X)$ and $\sigma_C \in \text{Bir}(C) = \text{Aut}(C)$ such that $\phi \circ \sigma_X = \sigma_C \circ \phi$ as rational maps from $X$ to $C$. Note that $\text{Bir}(X, \phi)$ is a subgroup of $\text{Bir}(X)$. One can
consider Bir\((X, \phi)\) as the group of all birational automorphisms of \(X\) that respect the fibration \(\phi\).

We have a left exact sequence of groups
\[(8.10) \quad 1 \to \text{Aut}(X_\eta/\mathbb{K}(\eta)) \to \text{Bir}(X, \phi) \to \text{Aut}(C),\]
where \(\text{Aut}(X_\eta/\mathbb{K}(\eta))\) is the group of automorphisms of the conic \(X_\eta\) over \(\mathbb{K}(\eta)\) which is identified with the subgroup of Bir\((X, \phi)\) that consists of pairs \((\sigma_X, \text{Id}_C)\). Note that if \((\sigma_X, \sigma_C) \in \text{Bir}(X, \phi)\), then \(\sigma_C\) preserves the class \([X_\eta] \in \text{Br}(\mathbb{K}(\eta))\) and, in particular, it preserves the discriminant locus of this class. For example, if \(\phi: X \to C\) is a relatively minimal conic bundle with the discriminant locus \(\Omega\), then \(\Omega\) coincides with the discriminant locus of \([X_\eta]\), so that \(\sigma_C\) belongs to the automorphism group \(\text{Aut}(C - \Omega)\) of the affine curve \(C - \Omega\). (The latter group can be also identified with the stabilizer of \(\Omega\) in the group \(\text{Aut}(C)\).) Thus, \((8.10)\) actually gives a left exact sequence
\[(8.11) \quad 1 \to \text{Aut}(X_\eta/\mathbb{K}(\eta)) \to \text{Bir}(X, \phi) \to \text{Aut}(C - \Omega).\]

Now we can prove the main result of this section.

**Proposition 8.12.** For every non-negative integer \(m\) there exists a number \(d(m)\) with the following property. Let \(\mathbb{K}\) be any field containing all roots of 1, let \(C\) a conic over \(\mathbb{K}\), and let \(\phi: X \to C\) be a conic bundle that has not more than \(m\) reducible fibers over \(\bar{\mathbb{K}}\). Assume that \(X\) is not birational to \(\mathbb{P}^1 \times C'\), where \(C'\) is a conic. The following assertions hold.

(i) If \(\text{char} \mathbb{K} \neq 2\), then the order of every finite subgroup of Bir\((X, \phi)\) is at most \(d(m)\).
(ii) If \(\text{char} \mathbb{K} = 2\), then for every finite subgroup \(G \subset \text{Bir}(X, \phi)\), one has \(|G|' \leq d(m)\), where \(|G|'\) is the largest odd factor of \(|G|\).

**Proof.** Since \(X\) is not birational to the product of \(\mathbb{P}^1\) and a conic, we see that \(\phi\) does not have sections. If \(C\) is not rational then, using the exact sequence \((8.10)\) and Corollary 4.12, we have that, for every finite subgroup \(G \subset \text{Bir}(X, \phi)\), the number \(|G|'\) is equal to 1, and if \(\text{char} \mathbb{K} \neq 2\), then \(|G| \leq 16\).

Now assume that \(C \cong \mathbb{P}^1\). We may suppose that \(\phi\) is relatively minimal. Let \(\Omega\) be its discriminant locus. Set \(m' = |\Omega(\mathbb{K})|\).

Assume that \(m' = 0\). Then, since Br\((\mathbb{K}) \to \text{Br}(\mathbb{P}^1)\), we have that \(X_\eta \cong X_c \otimes \mathbb{K} \mathbb{K}(\eta)\), where \(c \in \mathbb{P}^1(\mathbb{K})\) is any point. Hence, \(X\) is birational to the product of \(\mathbb{P}^1\) and a conic \(X_c\) which we assumed to be not the case. Thus, by Lemma 8.6, we have that \(m' > 1\).

Assume that \(m' = 2\). Then, by Lemma 8.3 we have \(|\Omega(\mathbb{K})| = 1\), that is, \(\Omega\) consists of a single point whose residue field is a separable quadratic extension \(L \supseteq \mathbb{K}\). By Corollary 2.8 we have that every finite subgroup of Aut\((\mathbb{P}^1 - \Omega)\) is a 2-group of order at most 4. Hence, using the sequence \((8.11)\) and Corollary 4.12, we have that, for every finite subgroup \(G \subset \text{Bir}(X, \phi)\), the number \(|G|'\) is equal to 1, and if \(\text{char} \mathbb{K} \neq 2\) then \(|G| \leq 16\).

Finally, if \(m' > 2\) then
\[|\text{Aut}(\mathbb{P}^1 - \Omega)| \leq m'!\]
Thus, we have \(|G|' \leq m'!\), and if \(\text{char} \mathbb{K} \neq 2\), then
\[|G| \leq 4m'!\]
Summarizing, we find that \(d(m) = 16m!\) works in all cases.

We conclude this section by recalling that relatively minimal conic bundles with many geometrically reducible fibers are known to have few birational models.
**Theorem 8.13** (see [Isk96, Theorem 1.6(iii)]). Let $X$ and $X'$ be smooth projective geometrically rational surfaces over a field $K$. Let $X \to B$ and $X' \to B'$ be relatively minimal conic bundles. Suppose that $X$ and $X'$ are birational, and $K_X^2 \leq 0$. Then $K_{X'}^2 = K_X^2$.

**Remark 8.14.** Theorem 8.13 was proved in [Isk96] under the assumption that $K$ is perfect. However, the general case follows using Lemma 8.5.

### 9. Proof of the Main Theorem

In this section we prove Theorems [1.3 and 1.4] and Corollary [1.5] and provide a counterexample to Theorem 1.3 over a perfect field of characteristic 2. We start with Theorem 1.3.

**Proof of Theorem 1.3.** The proof is similar to that of Theorem 1.2, see [PS18, §2]. If $X$ is birational to $\mathbb{P}^1 \times C$, then the group Bir($X$) contains $K^*$ as a subgroup. Since $K$ contains all roots of 1 by assumption, we see that Bir($X$) contains cyclic subgroups of arbitrary finite order coprime to char $K$, and in particular Bir($X$) has unbounded finite subgroups (and also fails to have char $K$-bounded subgroups). Thus we will assume that $X$ is not birational to such a surface.

Let $G$ be a finite group acting by birational automorphisms of $X$. Replace $X$ with a surface $\tilde{X}$ birational to $X$ such that $G \subset \text{Aut}(\tilde{X})$, and then further replace $\tilde{X}$ with its $G$-minimal model $Y$. Therefore, $Y$ is either a $G$-del Pezzo surface, or a $G$-conic bundle over some conic $C$ (this means that $C$ can be equipped with an action of $G$, such that the morphism $\phi$ is $G$-equivariant), see [Isk80, Theorem 1G]. In the former case the order of $G$ is bounded by universal constants from Proposition 1.12(i) and Remark 7.9. Thus, we may assume that $Y$ has the structure $Y \to C$ of a $G$-conic bundle over a conic $C$. In particular, it follows that $G \subset \text{Bir}(Y, \phi)$. We can factor $\phi$ as $Y \to Y' \to C$, where $\phi': Y' \to C$ is a relatively minimal conic bundle. The action of $G$ on $Y$ need not descend to an action on $Y'$. However, we have that

$$G \subset \text{Bir}(Y', \phi') = \text{Bir}(Y, \phi).$$

On the other hand, by Theorem 8.13 the number of reducible fibers of $\phi'$ over $\overline{K}$ is bounded by some constant which depends on $X$ only. Thus, we are done by Proposition 8.12(i). \qed

The proof of Theorem 1.4 is identical to the proof of Theorem 1.3 except for the following. Let $|G'|$ be the largest factor of $|G|$ coprime to char $K$. If $Y$ is a del Pezzo surface, to show that $|G'|$ is bounded we apply Remark 7.9 together with Proposition 1.12(ii) instead of Proposition 1.12(i). If $Y$ is a $G$-conic bundle, we bound $|G|$ in the case char $K = 3$ using Proposition 8.12(i) as before, while in the case char $K = 2$ we bound $|G'|$ using Proposition 8.12(ii).

Now we prove Corollary 1.5.

**Proof of Corollary 1.5.** By Theorems 1.3 and 1.4 we have to prove that $X$ is not birational to the surface $\mathbb{P}^1 \times C$, where $C$ is a conic. By the theorem of Lang and Nishimura (see for instance [Ko96, Proposition IV.6.2]), since $X$ has no $K$-points, every smooth proper variety birational to $X$ has no $K$-points either. Thus, we may assume that $C(K) = \emptyset$. We complete the proof by computing a certain birational invariant for $X$ and for $\mathbb{P}^1 \times C$.

For every proper geometrically integral scheme $Y$ over a field $K$, one has an exact sequence

$$0 \to \text{Pic}(Y) \to (\text{Pic}(Y_{\overline{K}}))^{\text{Gal}(K^{sep}/K)} \to \text{Br}(K) \xrightarrow{\alpha_Y} \text{Br}(Y).$$

(9.1)
Composing \( \alpha_Y \) with the injection \( \text{Br}(Y) \hookrightarrow \text{Br}(\mathbb{K}(\eta)) \), where \( \mathbb{K}(\eta) \) is the field of rational functions on \( Y \), we obtain a homomorphism \( \text{Br}(\mathbb{K}) \rightarrow \text{Br}(\mathbb{K}(\eta)) \) induced by the embedding of the fields \( \mathbb{K} \hookrightarrow \mathbb{K}(\eta) \). This shows that \( \ker \alpha_Y \) is a birational invariant of \( Y \). We use exact sequence (9.1) to compute this invariant.

If \( Y = \mathbb{P}^1 \times C \) for some conic \( C \) with \( C(\mathbb{K}) = \varnothing \), then \( \ker \alpha_Y \) is generated by \([C] \in \text{Br}(\mathbb{K})\) and, thus, has order 2. If \( Y \) is a Severi–Brauer surface, then \( \ker \alpha_Y \) has order 3. If \( Y \) is a product of two non-isomorphic non-rational conics, then \( \ker \alpha_Y \) has order 4. If \( Y \) is a quadric surface with \( Y(\mathbb{K}) = \varnothing \) and \( \text{Pic}(Y) \cong \mathbb{Z} \), then \( \ker \alpha_Y \) is trivial. Indeed, in this case the group \((\text{Pic}(Y_{\mathbb{K}_{\text{sep}}}))_{\text{Gal}(\mathbb{K}_{\text{sep}}/\mathbb{K})}\) is generated by the class of a hyperplane section in \( \mathbb{P}^3 \), and thus the canonical map \( \text{Pic}(Y) \rightarrow (\text{Pic}(Y_{\mathbb{K}_{\text{sep}}}))_{\text{Gal}(\mathbb{K}_{\text{sep}}/\mathbb{K})} \) is an isomorphism. We conclude that surfaces of the latter three types cannot be birational to a product of \( \mathbb{P}^1 \) and a conic.

\[\square\]

Remark 9.2. To prove Corollary 1.5 in the case of Severi–Brauer surfaces one can give a geometric argument. Suppose that the group of birational automorphisms of \( X \) has unbounded finite subgroups. Then by Theorem 1.3 the surface \( X \) is birational to a surface \( Y \cong \mathbb{P}^1 \times C \) for some conic \( C \). Since \( \mathbb{P}^1 \) has a \( \mathbb{K} \)-point, and \( C \) has a point defined over a quadratic extension of \( \mathbb{K} \), we conclude that \( Y \) has a point defined over a quadratic extension of \( \mathbb{K} \) as well. Therefore, the same holds for \( X \) by the theorem of Lang and Nishimura. However, a Severi–Brauer surface with a point defined over a quadratic extension is isomorphic to \( \mathbb{P}^2 \), so we obtain a contradiction.

Note that there is a description of birational automorphism groups of Severi–Brauer surfaces via their generators and relations, see [IT91, §3]. We do not know whether it can be used to prove Corollary 1.5.

Below, we will give an example showing that Theorem 1.3 fails over perfect fields of characteristic 2. We start with the following general construction.

Lemma 9.3. Let \( \mathbb{K} \) be a perfect field of characteristic \( p > 0 \), let \( \Delta \subset \mathbb{P}^1(\mathbb{K}) \) be a finite subset consisting of more than one point, and let \( Y = \mathbb{P}^1 - \Delta \). Assume that \( \mathbb{K} \) admits a Galois extension of degree \( p \). Assume also that either \( p \neq 2 \), or the cardinality of \( \Delta \) is even. Then the following assertions hold.

(i) There exists an element \( \alpha \in \text{Br}(Y) \) of order \( p \) in the Brauer group of \( Y \) which is not contained in the image of the restriction map \( \text{Br}(\mathbb{P}^1 - \Delta') \rightarrow \text{Br}(Y) \), for any proper subset \( \Delta' \subset \Delta \).

(ii) For any \( \alpha \) as above, there exists an Azumaya algebra \( A \) over \( Y \) of rank \( p^2 \) whose class in the Brauer group \( \text{Br}(Y) \) is equal to \( \alpha \).

Proof. We compute \( \text{Br}(Y) \cong H^2(Y_{\text{et}}, \mathcal{O}^*_{Y}) \) using the Leray spectral sequence that converges to \( H^*(Y_{\text{et}}, \mathcal{O}^*_Y) \) and whose second page is given by \( H^i(\text{Gal}(\overline{\mathbb{K}}/\mathbb{K}), H^j(Y_{\overline{\mathbb{K}}_{\text{et}}}, \mathcal{O}^*_Y)) \). By Tsen’s theorem, we know that

\[ H^2(Y_{\overline{\mathbb{K}}_{\text{et}}}, \mathcal{O}^*_Y) \cong \text{Br}(Y_{\overline{\mathbb{K}}}) = 0. \]

In addition, one has \( H^1(Y_{\overline{\mathbb{K}}_{\text{et}}}, \mathcal{O}^*_Y) \cong \text{Pic}(Y_{\overline{\mathbb{K}}}) = 0 \). Hence, we conclude that

\[ \text{Br}(Y) \cong H^2(\text{Gal}(\overline{\mathbb{K}}/\mathbb{K}), \mathcal{O}^*(Y_{\overline{\mathbb{K}}})). \]

We have an exact sequence of Galois modules

\[ 0 \rightarrow \mathbb{K}^* \rightarrow \mathcal{O}^*(Y_{\overline{\mathbb{K}}}) \rightarrow \mathbb{Z}[\Delta] \rightarrow \mathbb{Z} \rightarrow 0, \]

\[ (9.4) \]
where \( \mathbb{Z}[\Delta] \) is the group of divisors on \( \mathbb{P}^1 \) supported on \( \Delta \), and the last morphism is the degree map. The sequence (9.4) splits as a sequence of Galois modules, that is, it is a direct sum of sequences of Galois modules of length 2. Since (9.4) splits, it remains exact (and split) after passing to Galois cohomology:

\[
0 \to \text{Br}(\mathbb{K}) \to \text{Br}(Y) \xrightarrow{\text{Res}} H^2(\text{Gal}(\overline{\mathbb{K}}/\mathbb{K}), \mathbb{Z}[\Delta]) \to H^2(\text{Gal}(\overline{\mathbb{K}}/\mathbb{K}), \mathbb{Z}) \to 0.
\]

Since \( H^i(\text{Gal}(\overline{\mathbb{K}}/\mathbb{K}), \mathbb{Q}) = 0 \) for every \( i > 0 \), we have

\[
H^2(\text{Gal}(\overline{\mathbb{K}}/\mathbb{K}), \mathbb{Z}) \cong \text{Hom}(\text{Gal}(\overline{\mathbb{K}}/\mathbb{K}), \mathbb{Q}/\mathbb{Z}).
\]

Thus, the above exact sequence takes the form

\[
0 \to \text{Br}(\mathbb{K}) \to \text{Br}(Y) \xrightarrow{\text{Res}} \bigoplus_{\Delta} \text{Hom}(\text{Gal}(\overline{\mathbb{K}}/\mathbb{K}), \mathbb{Q}/\mathbb{Z}) \xrightarrow{\Sigma} \text{Hom}(\text{Gal}(\overline{\mathbb{K}}/\mathbb{K}), \mathbb{Q}/\mathbb{Z}) \to 0.
\]

Tensoring this exact sequence by \( \mathbb{Z}/p\mathbb{Z} \) and using the vanishing of the \( p \)-torsion part of \( \text{Br}(\mathbb{K}) \) (see Remark 4.6), we find the following short exact sequence

\[
0 \to \text{Br}(Y)_p \xrightarrow{\text{Res}} \bigoplus_{\Delta} \text{Hom}(\text{Gal}(\overline{\mathbb{K}}/\mathbb{K}), \mathbb{Z}/p\mathbb{Z}) \xrightarrow{\Sigma} \text{Hom}(\text{Gal}(\overline{\mathbb{K}}/\mathbb{K}), \mathbb{Z}/p\mathbb{Z}) \to 0,
\]

where we write \( \text{Br}(Y)_p \) for the group of \( p \)-torsion elements in \( \text{Br}(Y) \). Since \( \mathbb{K} \) has a Galois extension of degree \( p \), the group \( \text{Hom}(\text{Gal}(\overline{\mathbb{K}}/\mathbb{K}), \mathbb{Z}/p\mathbb{Z}) \) is non-trivial (and, thus, it contains a cyclic subgroup of order \( p \)). Under our assumptions on \( p \) and the cardinality of \( \Delta \) we can find an element of

\[
\ker \Sigma \subset \bigoplus_{\Delta} \text{Hom}(\text{Gal}(\overline{\mathbb{K}}/\mathbb{K}), \mathbb{Z}/p\mathbb{Z})
\]

such that each of its components in \( \text{Hom}(\text{Gal}(\overline{\mathbb{K}}/\mathbb{K}), \mathbb{Z}/p\mathbb{Z}) \) is not equal to zero. Let \( \alpha \) be the corresponding element of \( \text{Br}(Y)_p \). The compatibility of all our constructions with the restriction map \( \text{Br}(\mathbb{P}^1 - \Delta') \to \text{Br}(Y) \) shows that \( \alpha \) is not contained in the image of such map. This proves assertion (i).

To prove assertion (ii), we recall from [OV07, Proposition 4.2] that for every smooth affine scheme \( Z \) over a perfect field \( \mathbb{K} \) of characteristic \( p > 0 \) there is a surjective homomorphism

\[
\Psi: H^0(Z, \Omega^1_Z) \to \text{Br}(Z)_p,
\]

which takes a differential form \( \omega = xdy \) to the class of the Azumaya algebra \( A_\omega \) generated over \( \mathcal{O}(Z) \) by elements \( v \) and \( u \) subject to the relations \( v^p = x, u^p = y \) and \( vu - uv = 1 \). This Azumaya algebra has rank \( p^2 \). Applying this to \( Z = Y \) and observing that every differential form on \( Y \) can be written as \( xdy \) for some regular functions \( x \) and \( y \) on \( Y \) (which holds since \( Y \) is one-dimensional and \( \Delta \neq \emptyset \)) we conclude that every \( p \)-torsion class in \( \text{Br}(Y) \) is represented by an Azumaya algebra of rank \( p^2 \). This completes the proof of assertion (ii).

\[\square\]

**Remark 9.5.** The Artin–Schreier short exact sequence

\[
0 \to \mathbb{Z}/p\mathbb{Z} \to \mathbb{K} \xrightarrow{\theta} \mathbb{K} \to 0,
\]

where the homomorphism \( \theta \) is defined by \( \theta(c) = c - c^p \), gives rise to an isomorphism

\[
\text{Hom}(\text{Gal}(\overline{\mathbb{K}}/\mathbb{K}), \mathbb{Z}/p\mathbb{Z}) \cong \text{coker} \theta.
\]
One can verify that the composition

$$H^0(Y, \Omega^1_Y) \xrightarrow{\Psi} \text{Br}(Y)_p \xrightarrow{\text{Res}} \bigoplus_{\Delta} \text{Hom}(\text{Gal}(\bar{K}/K), \mathbb{Z}/p\mathbb{Z}) \cong \bigoplus_{\Delta} \text{coker} \theta$$

carries a differential form $\omega$ to its residues (modulo the image of $\theta$) at all points of $\Delta$. This can be used to construct a class $\alpha$ and an Azumaya algebra $A$ satisfying the requirements of Lemma 9.3 explicitly. Namely, take an invertible function $f$ on $Y$ whose order at every point of $\Delta$ is not equal to 0 modulo $p$, and an element $t \in K$, which is not in the image of the Artin–Schreier homomorphism. Then the class

$$\Psi(t \frac{df}{f}) \in \text{Br}(Y)_p$$

satisfies the requirements of Lemma 9.3(i), and the Azumaya algebra $A$ satisfies the requirements of Lemma 9.3(ii).

Recall the following result.

**Theorem 9.6** (see [Isk96, §4]). Let $K$ be a field, and let $X$ be a smooth projective geometrically rational surface over $K$ with $X(K) \neq \emptyset$. Suppose that $X$ has a structure of a relatively minimal conic bundle and $K_X^2 \leq 4$. Then $X$ is not rational.

**Remark 9.7** (cf. Remark 8.14). Theorem 9.6 was proved in [Isk96] under the assumption that the field $K$ is perfect. The general case follows using Lemma 8.5.

Finally, we present a counterexample to Theorem 1.3 over a perfect field of characteristic 2.

**Example 9.8.** Let $k$ be an algebraically closed field of characteristic 2, and let

$$K = k(t^{2^{-\infty}}),$$

that is, $K$ is obtained from $k$ by adjoining all roots of a transcendental variable $t$ of degrees $2^r$, for all positive integers $r$. Then $K$ is a perfect field of characteristic 2, and it has a Galois extension of degree 2. Pick a subset $\Delta \subset \mathbb{P}^1(K)$ of 4 points. Set $Y = \mathbb{P}^1 - \Delta$, and let $X \to Y$ be the smooth conic bundle corresponding to the Azumaya algebra from Lemma 9.3(ii). By Lemma 8.3 there exists a conic bundle $\phi: \hat{X} \to \mathbb{P}^1$ that extends $X \to Y$. Then $\phi$ has degenerate fibers exactly over the points of $\Delta$. This means that $K_{\hat{X}}^2 = 4$. Also, we know that every fiber of $\phi$ has a $K$-point (see Remark 4.6), and thus $\hat{X}$ has a $K$-point. Hence, the surface $\hat{X}$ is not rational by Theorem 9.6(ii). On the other hand, the group of birational selfmaps of $\hat{X}$ contains an automorphism group of the scheme-theoretic general fiber $\hat{X}_y$ of $\phi$, which is a conic over a non-perfect field $K(\mathbb{P}^1)$ of characteristic 2. The latter automorphism group has unbounded finite subgroups by Lemma 4.14(ii). We conclude that the analog of Theorem 1.2 (and, thus, also Theorem 1.3) fails over perfect fields of characteristic 2.

**10. Jordan property**

In this section we apply Theorem 1.3 to study groups of birational automorphisms of higher-dimensional varieties. The group-theoretic property we will be interested in here is described as follows.
Definition 10.1 (see [Pop11, Definition 2.1]). A group $\Gamma$ is called Jordan if there is a constant $J$ such that for any finite subgroup $G \subseteq \Gamma$ there exists a normal abelian subgroup $A \subseteq G$ of index at most $J$.

The first result concerning Jordan property (and motivating the modern terminology) is an old theorem by C. Jordan that asserts this property for a general linear group over a field of characteristic zero (see e.g. [CR62, Theorem 36.13]).

J.-P. Serre noticed that Jordan property sometimes holds for groups of birational automorphisms.

Theorem 10.2 ([Ser09, Theorem 5.3]). The group of birational automorphisms of $\mathbb{P}^2$ over a field of characteristic zero is Jordan.

In [PS16 Theorem 1.8], Yu. Prokhorov and C. Shramov generalized Theorem 10.2 to the case of rationally connected varieties of arbitrary dimension over fields of characteristic zero (actually, their results were initially obtained modulo boundedness of terminal Fano varieties, which was recently proved by C. Birkar in [Bir16 Theorem 1.1]). Jordan property was also proved in many other cases for groups of birational automorphisms and for automorphism groups, see for instance [PS14, MZ18, BZ17a, BZ17b, PS17, Mun14, Mun16], and references therein. However, there are varieties whose groups of birational automorphisms are not Jordan.

Theorem 10.3 ([Zar14]). Let $A$ be a positive-dimensional abelian variety over an algebraically closed field of characteristic zero. Then the group of birational automorphisms of $A \times \mathbb{P}^1$ is not Jordan.

Recall that on any variety $X$ over a field of characteristic zero one can construct the maximal rationally connected fibration, which is a canonically defined rational map with rationally connected fibers and non-uniruled base (see [Kol96, §IV.5], [GHS03 Corollary 1.4]). The maximal rationally connected fibration is equivariant with respect to the whole group of birational automorphisms of $X$. Keeping in mind Theorem 10.3, it seems natural to try to understand the groups of birational automorphisms for varieties with maximal rationally connected fibration of small relative dimension; note that the case when the relative dimension is 0 (that is, the maximal rationally connected fibration is birational or, equivalently, the variety is not uniruled) is settled by [PS14, Theorem 1.8(ii)].

Theorem 10.4 ([BZ17a, Theorem 1.6]). Let $X$ be an irreducible variety over a field of characteristic zero, and let $\phi: X \dasharrow Y$ be its maximal rationally connected fibration. Suppose that the relative dimension of $\phi$ equals 1, and that $\phi$ has no rational sections. Then the group of birational automorphisms of $X$ is Jordan.

Theorem 10.5 ([PS18, Lemma 4.6]). Let $X$ be an irreducible variety over a field of characteristic zero, and let $\phi: X \dasharrow Y$ be its maximal rationally connected fibration. Suppose that the relative dimension of $\phi$ equals 2, and that $\phi$ has a rational section. Suppose also that $X$ is not birational to $Y \times \mathbb{P}^2$. Then the group of birational automorphisms of $X$ is Jordan.

Using Theorem 10.3, we obtain the following result that is somewhat similar to Theorems 10.4 and 10.5.

Proposition 10.6. Let $X$ be an irreducible variety over a field $k$ of characteristic zero, and let $\phi: X \dasharrow Y$ be its maximal rationally connected fibration. Suppose that the relative
dimension of $\phi$ equals 2, and that $\phi$ has no rational sections. Suppose also that $X$ is not birational to $Z \times \mathbb{P}^1$, where $Z$ is a conic bundle over $Y$. Then the group of birational automorphisms of $X$ is Jordan.

**Proof.** The proof is similar to those of Theorems 10.4 and 10.5, see [BZ17a §5] and [PS18 §4]. We may assume that the field $k$ is algebraically closed.

Let $S$ be the fiber of $\phi$ over the scheme-theoretic generic point of $Y$. Then $S$ is a geometrically rational surface defined over the field $K = k(Y)$, and $S$ has no $K$-points by assumption. Since $\phi$ is equivariant with respect to Bir($X$), we have an exact sequence of groups

$$1 \rightarrow \text{Bir}(X)_\phi \rightarrow \text{Bir}(X) \rightarrow \text{Bir}(Y),$$

where the action of Bir($X)_\phi$ is fiberwise with respect to $\phi$.

Our assumptions imply that $S$ is not birational to $\mathbb{P}^1 \times C$ over $K$, where $C$ is a conic. The group Bir($X)_\phi$ is isomorphic to the group Bir($S$), and thus has bounded finite subgroups by Theorem 1.3. On the other hand, the variety $Y$ is not uniruled. Thus the group Bir($Y$) is Jordan by [PS14, Theorem 1.8(ii)]. Moreover, there is a constant $R$ such that every finite subgroup in Bir($Y$) is generated by at most $R$ elements, see e.g. [PS14, Remark 6.9]. Therefore, the group Bir($X$) is Jordan by a simple group-theoretic argument, see [PS14, Lemma 2.8]. \qed

Note that if the field $k$ is algebraically closed, the assumptions of Proposition 10.6 imply that the dimension of $Y$ is at least 2 (so that the dimension of $X$ is at least 4) due to the theorem of Graber, Harris, and Starr, see [GHS03]. It would be interesting to describe more explicitly the varieties with maximal rationally connected fibration of relative dimension 2 whose birational automorphism groups are not Jordan, similarly to what was done in [PS18, Theorem 1.8]. Also, it would be interesting to try to generalize Theorem 1.3 to the case of threefolds, and to derive conclusions for birational automorphisms of varieties with maximal rationally connected fibration of relative dimension 3.
