On SOCP/SDP formulation of the extended trust region subproblem

S. Fallahi *, M. Salahi† ‡, S. Ansary Karbasy§

Abstract

In this paper, we consider the extended trust region subproblem (eTRS ) which is the minimization of an indefinite quadratic function subject to the intersection of unit ball with a single linear inequality constraint. Using a variation of S-Lemma, we derive the necessary and sufficient optimality conditions for eTRS . Then an SOCP/SDP formulation is introduced for the problem. Finally, several illustrative examples are provided.

Keywords: Extended trust region subproblem, S-lemma, Semidefinite program, Second order cone program.

1 Introduction

Consider the following extended trust region subproblem eTRS

\[
\min \quad x^T Ax + 2a^T x \\
\|x\|^2 \leq 1 \\
b^T x \leq \beta
\]  (1)

where \( A^T = A \in \mathbb{R}^{n \times n} \) is indefinite, \( a, b \in \mathbb{R}^n \) and \( \beta \in \mathbb{R} \). Since \( A \) is indefinite, it is a nonconvex optimization problem and semidefinite programming (SDP) relaxation is not tight in general. When \( b = 0 \) and \( \beta = 0 \), then eTRS reduces to the well-known trust region subproblem (TRS ) which is the key subproblem in solving nonlinear optimization problems [4]. Although TRS is a nonconvex problem, it enjoys strong duality and exact SDP relaxation exists for it [5]. However, the following classical SDP relaxation is not exact for eTRS as it will be shown also in the numerical results section:

\[
\min \quad A \cdot X + 2a^T x \\
\text{trace}(X) \leq 1, \\
b^T x \leq \beta, \\
X \succeq xx^T. 
\]  (2)

First the authors in [11] have studied eTRS and proposed an exact SOCP/SDP formulation for it. Due to the importance of eTRS also in solving general nonlinear optimization problems, several variants of it have been the focus of current research [1, 2, 3, 6, 7, 9]. Beck and Eldar have studied eTRS under the condition that \( \dim(\text{Ker}(A - \lambda_1 I)) \geq 2 \) which is equivalent to

\[
\lambda_1 = \lambda_2, \tag{3}
\]

where \( \lambda_1 \) and \( \lambda_2 \) are the two smallest eigenvalues of \( A \). Under this condition, they have shown that the following optimality conditions are necessary and sufficient optimality conditions for eTRS:

\[
\begin{align*}
(i) \quad & 2(A + \lambda I)x = -(2a + \mu b), \\
(ii) \quad & (A + \lambda I) \succeq 0, \\
(iii) \quad & \lambda(\|x\|^2 - 1) = 0, \quad \mu(b^T x - \beta) = 0, \\
(iv) \quad & \lambda, \mu \geq 0.
\end{align*}
\]

Jeyakumar and Li in [7] have shown that \( \dim(\text{Ker}(A - \lambda_1 I_n)) \geq 2 \), together with the Slater condition ensures that a set of combined first and second-order Lagrange multiplier conditions are necessary and sufficient for the global optimality of eTRS and consequently for strong duality. In [6] the authors have improved the dimension condition by Jeyakumar and Li under which eTRS admits an exact semidefinite relaxation. They proposed the following condition

\[
\text{rank } ([A - \lambda_1 I_n \ b]) \leq n - 1. \tag{4}
\]

It should be noted that TRS has at most one local-nonglobal minimum (LNGM ) [8], which is a candidate for the optimal solution of eTRS if it is feasible. An efficient algorithm for computing LNGM is given in [10]. All the above rank conditions guarantee that the global solution of eTRS does not happen at the LNGM of TRS. Most recently in [2] the authors have studied eTRS and derived the SOCP/SDP reformulation given in [11] by different approach and extended it the cases where more than one linear constraint exist. In this paper, using a variation of S-Lemma, first we derive the necessary and sufficient optimality conditions for eTRS which leads us to an SOCP/SDP formulation of it. Then we prove that our derived formulation is the dual of the formulation presented in [2, 11]. Finally, we present several numerical examples illustrating various cases that may happen for the optimal solution of eTRS.

2 Global Optimality Conditions for eTRS

We define the dual cone of \( S \) as \( S^* = \{ y : \langle y, x \rangle \geq 0, \forall x \in S \} \). The following proposition which is variant of S-Lemma, plays a key role in the proof of the optimality conditions.

**Proposition 2.1.** Let \( f, g : \mathbb{R}^n \rightarrow \mathbb{R} \) be quadratic functions, \( g(x) = x^T A_g x + a_g^T x + c_g \), and let \( b \in \mathbb{R}^n \), and \( \beta \in \mathbb{R} \). Moreover, assume that \( g(x) \) is convex and there exists an \( \bar{x} \in \mathbb{R}^n \) such that \( b^T \bar{x} < \beta \) and \( g(\bar{x}) < 0 \). Then the following two statements are equivalent:

\( \text{Second order cone program/Semidefinite program} \)
1. The system

\[ f(x) < 0, \]
\[ g(x) \leq 0, \]
\[ b^T x \leq \beta, \]
\[ x \in \mathbb{R}^n \]

is not solvable.

2. There is a nonnegative multiplier \( y \geq 0 \), a scalar \( u_0 \in \mathbb{R} \) and vector \( u \in \mathbb{R}^n \) such that

\[ f(x) + yg(x) + (u^T x - u_0)(b^T x - \beta) \geq 0, \quad \forall x \in \mathbb{R}^n, \]
\[ u \in \{ x \in \mathbb{R}^n : x^T A_g x \leq 0, a_g^T x \leq 0 \}^*, \]
\[ \begin{pmatrix} u_0 \\ u \end{pmatrix} \in \left\{ \begin{pmatrix} x_0 \\ x \end{pmatrix} : x_0 = -1, g(x) \leq 0, c_g + a_g^T x \leq 0 \right\}^*. \]

Proof. See [11, Corollary 7]. \( \square \)

Corollary 2.1. When \( g(x) = \|x\|^2 - 1 \), then the second item in Proposition 1 is equivalent to

\[ f(x) + yg(x) + (u^T x - u_0)(b^T x - \beta) \geq 0, \quad \forall x \in \mathbb{R}^n, \]
\[ \begin{pmatrix} u_0 \\ u \end{pmatrix} \in L_{n+1}, \]

where \( L_{n+1} \) is the Lorentz cone defined as follows:

\[ L_{n+1} = \{ x = (x_0; \bar{x}) \in \mathbb{R}^{n+1} | \| \bar{x} \| \leq x_0 \}. \]

In the following theorem, we give the optimality conditions for eTRS . Our proofs follows the idea in [7].

Theorem 2.1. Suppose that the strict feasibility constraint holds for eTRS :

\[ \exists \hat{x} \in \mathbb{R}^n \text{ with } \| \hat{x} \|^2 - 1 < 0, \quad b^T \hat{x} - \beta < 0. \]

Moreover, let \( x^* \) be a feasible point for eTRS . Then \( x^* \) is a global minimizer of eTRS if, and only if, there exist \( \lambda_0 \in \mathbb{R}_+ \) and \( (-u_0, u) \in L_{n+1} \) such that the following conditions hold:

- (i) \( (2A + 2\lambda_0 I + bu^T + ub^T)x^* = -(2a - \beta u - bu_0) \),
- (ii) \( \lambda_0(\|x^*\|^2 - 1) = 0, (u^T x^* - u_0)(b^T x^* - \beta) = 0, \)
- (iii) \( (2A + 2\lambda_0 I + bu^T + ub^T) \succeq 0. \)

Proof. [Necessity] Let \( x^* \) be a global minimizer of eTRS . Then the following system of inequalities has no solution:

\[ x^T Ax + 2a^T x + \gamma < 0, \]
\[ \|x\|^2 - 1 \leq 0, \]
\[ b^T x \leq \beta, \]
where \( \gamma = -(x^T Ax^* + 2a^T x^*) \). Thus by Proposition 2.1 there exist \( \lambda_0 \geq 0 \) and a vector \((u_0; u) \in \mathbb{R}^{n+1}\) such that

\[
x^T Ax + 2a^T x + \gamma + \lambda_0(\|x\|^2 - 1) + (u^T x - u_0)(b^T x - \beta) \geq 0, \quad \forall x \in \mathbb{R}^n
\]

and \( u^T x - u_0 \geq 0, \quad \forall x \in \mathbb{R}^n : \|x\|^2 \leq \delta^2 \). Let \( x = x^* \), then we have

\[
\lambda_0(\|x^*\|^2 - 1) + (u^T x^* - u_0)(b^T x^* - \beta) \geq 0.
\]

Now as \( x^* \) is feasible for eTRS and \( \lambda_0 \geq 0 \), \((u^T x^* - u_0) \geq 0\), it follows that

\[
\lambda_0(\|x^*\|^2 - 1) = 0, \quad (u^T x^* - u_0)(b^T x^* - \beta) = 0.
\]

Let

\[
h(x) = x^T Ax + 2a^T x + \lambda_0(\|x\|^2 - 1) + (u^T x - u_0)(b^T x - \beta),
\]

then obviously \( x^* \) is a global minimizer of \( h \), and so \( \nabla h(x^*) = 0 \) and \( \nabla^2 h(x^*) \geq 0 \) i.e.,

\[
(2A + 2\lambda_0 I + bu^T + ub^T)x^* = -(2a - \beta u - bu_0),
\]

\[
(2A + 2\lambda_0 I + bu^T + ub^T) \succeq 0.
\]

Thus all conditions (i), (ii) and (iii) hold. 

[Sufficiency] If the optimality conditions hold, then from (ii) we see that

\[
h(x) = x^T Ax + 2a^T x + \lambda_0(\|x\|^2 - 1) + (u^T x - u_0)(b^T x - \beta)
\]

is convex. Moreover, from condition (i), we have \( \nabla h(x^*) = 0 \), therefore, \( x^* \) is a global minimizer of \( h \). Thus for given \( \lambda_0 \) and \((u_0; u) \) in the optimality conditions and for any feasible solution of eTRS , we have

\[
x^T Ax + 2a^T x \geq x^T Ax + 2a^T x + \lambda_0(\|x\|^2 - 1) + (u^T x - u_0)(b^T x - \beta),
\]

\[
\geq x^T Ax^* + 2a^T x^* + \lambda_0(\|x^*\|^2 - 1) + (u^T x^* - u_0)(b^T x^* - \beta)
\]

\[
= x^T Ax^* + 2a^T x^*.
\]

This implies that \( x^* \) is a global minimizer of eTRS . \hspace{1cm} \Box

**Theorem 2.2.** Suppose that there exists \( \bar{x} \in \mathbb{R}^n \) with \( \|\bar{x}\|^2 - 1 < 0 \) and \( b^T \bar{x} - \beta < 0 \). Then, we have

\[
\min \left\{ x^T Ax + 2a^T x : \|x\|^2 \leq 1, b^T x \leq \beta \right\}
\]

\[
= \max_{\lambda_0 \geq 0, (u_0; u) \in S} \min_x \left\{ x^T Ax + 2a^T x + \lambda_0(\|x\|^2 - 1) + (u^T x - u_0)(b^T x - \beta) \right\},
\]

where

\[
S = \left\{ (u_0; u) \left| (u^T x - u_0) \geq 0, \quad \forall x : \|x\|^2 \leq 1 \right. \right\}
\]

and the maximum is attained.
Proof. It is easy to see that, for every feasible point of eTRS, and every $\lambda_0 \geq 0$ and $(u_0, u) \in S$,

$$x^T Ax + 2a^T x \geq x^T Ax + 2a^T x + \lambda_0(\|x\|^2 - 1) + (u^T x - u_0)(b^T x - \beta).$$

Therefore

$$\min \left\{ x^T Ax + 2a^T x : \|x\|^2 \leq 1, b^T x \leq \beta \right\}$$

$$\geq \max_{\lambda_0 \geq 0, (u_0, u) \in S} \min_x \left\{ x^T Ax + 2a^T x + \lambda_0(\|x\|^2 - 1) + (u^T x - u_0)(b^T x - \beta) \right\}.$$

To show the reverse inequality, let $x^*$ be a global minimizer of eTRS, then there exists $\lambda_0 \in \mathbb{R}_+$ and $(u_0, u) \in S$ such that the following condition holds:

- $(2A + 2\lambda_0 I + bu^T + ub^T)x^* = -(2a - \beta u - bu_0)$,
- $\lambda_0(\|x^*\|^2 - 1) = 0$ and $(u^T x^* - u_0)(b^T x^* - \beta) = 0$,
- $(2A + 2\lambda_0 I + bu^T + ub^T) \geq 0$.

We see that

$$h(x) = x^T Ax + 2a^T x + \lambda_0(\|x\|^2 - 1) + (u^T x - u_0)(b^T x - \beta),$$

is convex, $\nabla h(x^*) = 0$ and $\nabla^2 h(x^*) \geq 0$. Therefore, $x^*$ is a global minimizer of $h$ i.e.,

$$x^T Ax + 2a^T x + \lambda_0(\|x\|^2 - \delta^2) + (u^T x - u_0)(b^T x - \beta) \geq x^T Ax^* + 2a^T x^* + \lambda_0(\|x^*\|^2 - 1) + (u^T x^* - u_0)(b^T x^* - \beta)$$

$$= x^T Ax^* + 2a^T x^*.$$

Therefore

$$\min \left\{ x^T Ax + 2a^T x : \|x\|^2 \leq 1, b^T x \leq \beta \right\}$$

$$\leq \max_{\lambda_0 \geq 0, (u_0, u) \in S} \min_x \left\{ x^T Ax + 2a^T x + \lambda_0(\|x\|^2 - 1) + (u^T x - u_0)(b^T x - \beta) \right\}.$$

As we see, in general strong duality does not hold for eTRS which is the reason to rank conditions given in \cite{1,4,7} to guarantee it.

**Corollary 2.2.** If $u = 0$ and $u_0 \neq 0$, then strong duality holds for eTRS.

**Proof.** It follows from the previous theorem. \qed

Form Theorem 2.2, we further have

$$\max_{\lambda_0 \geq 0, (u_0, u) \in S} \min_x \left\{ x^T Ax + 2a^T x + \lambda_0(\|x\|^2 - 1) + (u^T x - u_0)(b^T x - \beta) \right\}$$

$$= \max_z \left( \begin{array}{cc} -\lambda_0 + \beta u_0 - z & \frac{1}{2} (2a - \beta u - bu_0)^T \\ \frac{1}{2} (2a - \beta u - bu_0) & A + \lambda_0 I + \frac{1}{2} (bu^T + ub^T) \end{array} \right) \geq 0,$$

(5)

$$||u|| \leq -u_0,$$

$$\lambda_0 \geq 0,$$

5
which is an SOCP/SDP formulation for $e$TRS. In what follows, we show that this formulation is the dual of the SOCP/SDP formulation given in [2, 11]. Consider the Lagrange function of (5): 

$$
L(Y, v, u, u_0, \lambda_0, z) = z + \left( -\lambda_0 + \beta u_0 - z \right) \left( A + \lambda_0 I + \frac{1}{2} \left( bu^T + ub^T \right) \right) \bullet Y + v^T \left( -u_0 \right)
$$

where $Y \succeq 0$ and $||\bar{v}|| \leq v_0$. Let also 

$$
Y = \begin{pmatrix} \alpha & x^T \\ x & X \end{pmatrix}.
$$

Thus the Lagrangian can be written as 

$$
L(Y, v, u, u_0, \lambda_0, z) = z + \left( A + \lambda_0 I + \frac{1}{2} \left( bu^T + ub^T \right) \right) \bullet X + (2a - \beta u - bu_0)^T x
$$

$$
+ \alpha (-\lambda_0 + \beta u_0 - z) + \bar{v}^T u - v_0 u_0
$$

$$
= A \bullet X + 2a^T x + (1 - \alpha) z + \lambda_0 (\text{trace}(X) - \alpha) + (X b - \beta x + \bar{v})^T u
$$

$$
+ (-b^T x - v_0 + \beta) u_0.
$$

Therefore, the Lagrangian dual becomes

$$
\min_{\alpha \geq 0, ||v|| \leq v_0} \max_{\lambda_0 \geq 0, ||u|| \leq -u_0} L(Y, v, u, u_0, \lambda_0, z)
$$

$$
= \min_{\alpha \geq 0, ||v|| \leq v_0} \max_{\lambda_0 \geq 0, ||u|| \leq -u_0} A \bullet X + 2a^T x + (1 - \alpha) z + \lambda_0 (\text{trace}(X) - \alpha)
$$

$$
+ (X b - \beta x + \bar{v})^T u + (-b^T x - v_0 + \beta) u_0
$$

$$
= \min_{\alpha \geq 0, ||v|| \leq v_0} G(X, x, \alpha),
$$

where

$$
G(X, x, \alpha) = \max_{\lambda_0 \geq 0, ||u|| \leq -u_0} A \bullet X + 2a^T x + (1 - \alpha) z + \lambda_0 (\text{trace}(X) - \alpha)
$$

$$
+ (X b - \beta x + \bar{v})^T u + (-b^T x - v_0 + \alpha \beta) u_0.
$$

We further have

$$
G(X, x, \alpha) = \begin{cases} 
A \bullet X + 2a^T x, & \text{if } 1 - \alpha = 0, \text{ trace}(X) - \alpha \leq 0, \\
X b - \beta x + \bar{v} = 0, & -b^T x - v_0 + \beta \geq 0
\end{cases} \infty, \quad \text{o.w}
$$
Thus Lagrangian dual becomes
\[
\begin{align*}
\min & \ A \cdot X + 2a^T x \\
\text{subject to} & \ \text{trace}(X) - 1 \leq 0, \\
& \ Xb - \beta x + \bar{v} = 0, \\
& \ -b^T x - v_0 + \beta \geq 0, \\
& \ ||\bar{v}|| \leq v_0, \\
& \ X \succeq xx^T.
\end{align*}
\]

From (6) we have:
\[
\begin{align*}
\bar{v} &= \beta x - Xb, \\
v_0 &\leq -b^T x + \beta, \\
||\bar{v}|| &\leq v_0 \implies ||\bar{v}|| = ||\beta x - Xb|| \leq v_0 \leq -b^T x + \beta.
\end{align*}
\]

Therefore (6) can be written as follows:
\[
\begin{align*}
\min & \ A \cdot X + 2a^T x, \\
\text{subject to} & \ \text{trace}(X) \leq 1, \\
& \ ||\beta x - Xb|| \leq -b^T x + \beta, \\
& \ X \succeq xx^T.
\end{align*}
\]

This SOCP/SDP formulation is exactly the one given in [2] [11] but our derivation is completely different.

**Corollary 2.3.** If at the optimal solution of (7), \(X^* = x^*_{\text{socp/sdp}}(x^*_{\text{socp/sdp}})^T\), then \(x^*_{\text{socp/sdp}}\) is optimal for (7).

### 2.1 Rank one decomposition procedure

In order to derive an optimal solution for eTRS from the none-rank one solution of (7), here we give a rank one decomposition approach similar to the one in [12]. Let \(X^*\) be an optimal solution for (7) which is not rank one and consider the following notations:
\[
Y^* = \begin{pmatrix} 1 \\ x^*_{\text{socp/sdp}} \\ x^*_{\text{socp/sdp}} \end{pmatrix}, \quad J = \begin{pmatrix} 1 & 0 \\ 0 & -I_n \end{pmatrix}, \quad g = \begin{pmatrix} \beta \\ -b \end{pmatrix}.
\]

Obviously we have
\[
||\beta x^*_{\text{socp/sdp}} - X^*b|| \leq -b^T x^*_{\text{socp/sdp}} + \beta \iff \begin{pmatrix} \beta & -b^T x^*_{\text{socp/sdp}} \\ x^*_{\text{socp/sdp}} & -X^*b \end{pmatrix} = Y^*g \in L_{n+1},
\]
\[
\text{trace}(X^*) \leq 1 \iff J \cdot Y^* \succeq 0.
\]

**Lemma 2.1** ([12]). Let \(G\) be an arbitrary symmetric matrix and \(X\) be a positive semidefinite matrix with rank \(r\). Further suppose that \(G \cdot X \succeq 0\). Then there exists a rank-one decomposition for \(X\) such that
\[
X = \sum_{i=1}^{r} x_i x_i^T.
\]
and $x_i^T G x_i \geq 0$ for all $i = 1, \cdots, r$. If, in particular, $G \bullet X = 0$, then $x_i^T G x_i = 0$ for all $i = 1, \cdots, r$.

The following case may occur:

**Case 1.** $Y^* g = 0$. From Lemma 2.1 there exists a rank one decomposition for $Y^*$ as follows:

$$Y^* = \sum_{i=1}^{r} (y_i^*)(y_i^*)^T,$$

where $r$ is the rank of $Y^*$ such $J \bullet [(y_i^*)(y_i^*)^T] \geq 0$ for all $i = 1, \ldots, r$. Moreover, $J \bullet [(y_i^*)(y_i^*)^T] = 0$ for all $i = 1, \ldots, r$ if $J \bullet Y^* = 0$. We may choose the sign of the $y_i^*$ to ensure that $y_i^* \in L_{n+1}$, $i = 1, \ldots, r$.

By linear independence of $y_i^*$'s, we get $g^T y_i^* = 0$, $i = 1, \ldots, r$. Let $y_i^* = \left( t_i^* / \bar{y}_i^* \right)$, $i = 1, \ldots, r$. Since $y_i^* \in L_{n+1}$ and $y_i^* \neq 0$, we have $t_i^* > 0$, $i = 1, \ldots, r$. Take any $1 \leq j \leq r$; it follows that

$$\left( 1 / \bar{y}_i^* / t_i^* \right) (1 \ [\bar{y}_i^* / t_i^*])^T$$

is optimal for (7).

**Case 2.** $J \bullet Y^* > 0$ and $Y^* g \neq 0$. Due to the complementarity condition, we must have $\lambda_0 = 0$. Let $y_g^* := Y^* g = \left( t_g^* / \bar{y}_g^* \right)$. Since $y_g^* \in L_{n+1}$ by feasibility, we know that $t_g^* > 0$. Moreover, $J \bullet [(y_g^*)(y_g^*)^T] = (t_g)^2 - ||\bar{y}_g^*||^2 \geq 0$, and $y_g^*(y_g^*)^T g = (g^T Y^* a) Y^* a \in L_{n+1}$. Therefore, $y_g^*(y_g^*)^T / (g^T)^2$ is optimal for (7) as it is feasible and satisfies the complementarity conditions.

**Case 3.** $J \bullet Y^* = 0$ and $Y^* g \neq 0$. Denote $y_g^* := Y^* g \neq 0$. Let $\tilde{Y} = Y^* - Y^* g g^T Y^* g / g^T Y^* g \geq 0$. It is easy to see that $\tilde{Y} g = 0$.

Case 3.1. $J \bullet [y_g^*(y_g^*)^T] = 0$. In this subcase, we have that $y_g^*(y_g^*)^T / (g^T)^2$ is optimal for (7).

Case 3.2. $J \bullet [y_g^*(y_g^*)^T] > 0$. In this subcase,

$$J \bullet \tilde{Y} = J \bullet Y^* - J \bullet [y_g^*(y_g^*)^T] / g^T Y^* g < 0. \quad (8)$$

Now let us decompose $\tilde{Y}$ as

$$\tilde{Y} = \sum_{i=1}^{s} \bar{y}_i \bar{y}_i^T,$$

where $s = \text{rank}(\tilde{Y}) > 0$. Since $\tilde{Y} g = 0$, we have $\bar{y}_i^T g = 0$, for all $i = 1, \ldots, s$. Choose $j$ such that

$$J \bullet \bar{y}_j (\bar{y}_j)^T < 0.$$

Such $j$ must exist due to (8). Consider the following quadratic equation:

$$J \bullet \left[ (y_g^* + \alpha \bar{y}_j) (y_g^* + \alpha \bar{y}_j)^T \right] = 0.$$

This equation has two distinct real roots with opposite signs. Choose the one such that the first component of $y_g^* + \alpha \bar{y}_j$ is positive. Denote

$$y_g^* + \alpha \bar{y}_j := \left( t^* / y^* \right).$$
In this case, since \( J \cdot \left[ y_g^* (y_g^*)^T \right] > 0 \) it follows that \( y_g^* \) is in the strict interior of the cone \( L_{n+1} \). Due to the complementarity, we must have \((u_g^*; u^*) = 0\). Let us consider the solution \( \left( \frac{1}{\bar{y}^*/t^*} \right) (1, (y^*/t^*)^T) \). It is easy to check that this solution is both feasible and complementary to the dual optimal solution \((\lambda_0^*; u_0^*; u^*)\), thus optimal for (7).

3 Numerical examples

The aim of this section is to provide various examples explaining different cases that might occur for the optimal solution of eTRS.

Example 3.1. Consider the following example:

\[
A = \begin{pmatrix} -4 & 0 & 0 \\ 0 & 12 & 0 \\ 0 & 0 & 11 \end{pmatrix}, \quad a = \begin{pmatrix} -4 \\ 0 \\ 0 \end{pmatrix}, \quad b = \begin{pmatrix} 20 \\ 8 \\ -14 \end{pmatrix}, \quad \delta = 1, \ \beta = 5.
\]

We have \( \lambda_1 = -4 \) and \( \text{dim Ker } (A - \lambda_{\min}(A)I_n) = 1 \nleq 2 \), thus the dimension condition (4) fails to hold. Moreover, the new dimension condition given in [6] also fails to hold, since

\[
\text{rank } \left[ (A - \lambda_1 I_n \ b) \right] = \begin{pmatrix} 0 & 0 & 0 & 20 \\ 0 & 8 & 0 & 8 \\ 0 & 0 & 7 & -14 \end{pmatrix} = 3 \nleq 2.
\]

The optimal objective value of SDP relaxation (2) is \(-7.6827\). The global solution of TRS is \( x_g^* = [1, 0, 0]^T \) which is infeasible for eTRS and LNGM of TRS is \( x_i^* = [-1, 0, 0]^T \) which is feasible for eTRS with the objective value 4.0000. Moreover, for (7), the optimal solution is \( x_{socp/sdp}^* = [0.6266, -0.2169, 0.4140]^T \) and \( X^* = x_{socp/sdp}^* (x_{socp/sdp}^*)^T \). Thus \( x_{socp/sdp}^* \) is optimal for (11) with objective value -4.1329. As we see, the classical SDP relaxation (2) is not exact for this example and subsequently strong duality fails to hold. Also it is worth to note that at the optimal solution, the linear constraint is active while the trust region constraint is not active.

Example 3.2. Consider the following example:

\[
A = \begin{pmatrix} -4 & 0 & 0 \\ 0 & 5 & 0 \\ 0 & 0 & 3 \end{pmatrix}, \quad a = \begin{pmatrix} 0.5714 \\ 0 \\ 0 \end{pmatrix}, \quad b = \begin{pmatrix} -17 \\ 14 \\ -2 \end{pmatrix}, \quad \delta = 1, \ \beta = 4.4.
\]

We have \( \lambda_1 = -4 \) and \( \text{dim Ker } (A - \lambda_{\min}(A)I_n) = 1 \nleq 2 \), thus the dimension condition (4) fails to hold for this example as well. Also the new dimension condition [6] fails to hold here, since

\[
\text{rank } \left[ (A - \lambda_1 I_n \ b) \right] = \begin{pmatrix} 0 & 0 & 0 & -17 \\ 0 & 5 & 0 & 14 \\ 0 & 0 & 3 & -2 \end{pmatrix} = 3 \nleq 2.
\]

The global solution of TRS is \( x_g^* = [-1, 0, 0]^T \) which is infeasible for eTRS and LNGM of TRS is \( x_i^* = [1, 0, 0]^T \) which is feasible for eTRS with the objective value -2.4972. The
optimal objective value of SDP relaxation (2) is $-5.4326$ and the optimal objective value of SOCP/SDP formulation (7) is $-2.4972$ which is also the optimal objective value of (1). Moreover, for (7), the optimal solution is $x_{socp/sdp}^* = [1, 0, 0]^T$ and $X^* = x_{socp/sdp}^* (x_{socp/sdp}^*)^T$ and thus $x_{socp/sdp}^*$ is optimal for (1). Here also strong duality fails to hold like the previous example. Finally, at the optimal solution, the linear constraint is not active while the trust region constraint is active.

Example 3.3. Consider the following example where at optimality both constraints are active:

$$A = \begin{pmatrix} -4 & 0 & 0 \\ 0 & -8 & 0 \\ 0 & 0 & 2 \end{pmatrix}, \quad a = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}, \quad b = \begin{pmatrix} 4 \\ 15 \\ 18 \end{pmatrix}, \quad \delta = 1, \quad \beta = 4.$$

Here we have $\lambda_1 = -8$ and $\text{dim Ker} (A - \lambda_{\min} (A) I_n) = 1 \not\geq 2$, thus the dimension condition (3) fails to hold. Moreover, the new dimension condition of [6] also fails to hold, since

$$\text{rank} (\begin{bmatrix} A - \lambda_1 I_n & b \end{bmatrix}) = \begin{pmatrix} 4 & 0 & 0 & 4 \\ 0 & 0 & 0 & -15 \\ 0 & 0 & 10 & 18 \end{pmatrix} = 3 \not\geq 2.$$

The global solution of TRS is $x_g^* = [0, -1, 0]^T$ which is infeasible for eTRS and LNGM of TRS is $x_l^* = [0, 1, 0]^T$ which is feasible for eTRS with the objective value $-3.4286$. The optimal objective value of SDP relaxation (2) is $-11.0642$ and the optimal objective value of SOCP/SDP formulation (7) is $-9.7551$ which is also the optimal objective value of (1). The optimal solution of (7) is $x_{socp/sdp}^* = [-0.2885, -0.8567, -0.4276]^T$ and $X^* = x_{socp/sdp}^* (x_{socp/sdp}^*)^T$, thus $x_{socp/sdp}^*$ is optimal for (1).

In all three examples above, the optimal solution of (7) is rank one, thus we easily have the solution of (1). However, this is not the case in general as illustrated by the following example.

Example 3.4. Let

$$A = \begin{pmatrix} -4 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -3 \end{pmatrix}, \quad a = \begin{pmatrix} 0.5714 \\ 0 \\ 0 \end{pmatrix}, \quad b = \begin{pmatrix} -6 \\ -3 \\ 0 \end{pmatrix}, \quad \delta = 1, \quad \beta = 2.2.$$

We have $\lambda_1 = -4$ and $\text{dim Ker} (A - \lambda_{\min} (A) I_n) = 1 \not\geq 2$, thus the dimension condition (3) does not hold. Moreover, the new dimension condition [6] also fails to hold, since

$$\text{rank} (\begin{bmatrix} A - \lambda_1 I_n & b \end{bmatrix}) = \begin{pmatrix} 0 & 0 & 0 & -6 \\ 0 & 5 & 0 & -3 \\ 0 & 0 & 1 & 0 \end{pmatrix} = 3 \not\geq 2.$$

The global solution of TRS is $\bar{x}^* = [-1, 0, 0]^T$ which is again infeasible for eTRS and LNGM of TRS is $\bar{x} = [1, 0, 0]^T$ which is feasible for eTRS with the objective value $-2.8572$. The optimal objective value of SDP relaxation (2) is $-5.4354$ and the optimal objective value of SOCP/SDP formulation (7) is $-3.6121$ which is also the optimal objective value of (1). The optimal solution of (7) is

$$X^* = \begin{pmatrix} 0.1842 & -0.0537 & 0 \\ -0.053 & 0.0156 & 0 \\ 0 & 0 & 0.8001 \end{pmatrix}, \quad x_{socp/sdp}^* = \begin{pmatrix} -0.4292 \\ 0.1251 \\ 0 \end{pmatrix}.$$
which obviously $X^* \neq x^*_{socp/sdp}(x^*_{socp/sdp})^T$. By the rank-one decomposition procedure discussed in the previous section, one gets the optimal solution $x^* = [-0.4292, 0.1251, -0.8945]^T$ for (1).

4 Conclusions

In this paper, using a variant of S-Lemma, we presented the necessary and sufficient optimality conditions for the extended trust region subproblem that led us to an SOCP/SDP reformulation for it. Our derived formulation turned out to be the dual of the SOCP/SDP formulation given in [2, 11] but with a completely different approach. Extending this idea for several linear inequality constraints could be an interesting future research direction.
