September 5, 2018

Abstract

The semimartingale reflecting Brownian motion (SRBM) can be a heavy traffic limit for many server queueing networks. Asymptotic properties for stationary probabilities of the SRBM have attracted a lot of attention recently. However, many results are obtained only for the two-dimensional SRBM. There is only little work related to higher dimensional (≥ 3) SRBMs. In this paper, we consider a three dimensional SRBM: A three dimensional Brownian-driven tandem queue with intermediate inputs. We are interested in tail asymptotics for stationary distributions. By generalizing the kernel method and using couplings, we obtain exact tail asymptotics for the marginal stationary distribution of the buffer content in the third buffer and the joint stationary distribution.

Keywords: Brownian-driven tandem queue, stationary distribution, kernel method, exact tail asymptotics

1 Introduction

Since Harrison and Reiman \cite{10,11}, Varadhan and Williams \cite{28}, and Williams \cite{29,30} introduced the semimartingale reflecting Brownian motion, SRBM has received a lot of attention. Stationary properties of stationary distributions of SRBM when they exist, are important, especially in applications. However, except for a very limited number of special cases, a simple closed expression for the stationary distribution is not available. Hence, exact tail behaviour of stationary distributions becomes most important. Recently, many results about two-dimensional SRBM have been obtained. Harrison and Hasenbein \cite{12} presented sufficient and necessary conditions for the existence of a stationary distribution. Dai and Miyazawa \cite{5} studied exact tail asymptotics for the marginal distributions of SRBM by using a geometric method. Dai, Dawson and Zhao \cite{3} applied the kernel method to obtain exact tail asymptotics of the boundary measures of SRBM. Franceschi and Kurkova \cite{7} studied exact tail asymptotics of the stationary distribution along some path by analytic methods. Franceschi and Raschel \cite{8} studied exact tail behaviour of the boundary stationary distributions of SRBM by using the boundary value problems. However, we note that all aforementioned results are only for two-dimensional SRBM. In this paper, we will consider a three dimensional SRBM.

Miyazawa and Rolski \cite{21} generalized the result of Leshout and Mandjes \cite{19,20}, and studied a two-dimensional Lévy-driven tandem queue with an intermediate input. They obtained exact

\textsuperscript{[1]} School of Statistics, Shandong University of Finance and Economics, Jinan 250014, China.
\textsuperscript{[2]} School of Mathematics, Carleton University, Ottawa ON K1S5B6, CA
tail asymptotics for the Brownian inputs, while weaker tail asymptotic results were obtained for the general Lévy input. They also tried to discuss higher-dimensional cases. However only the stationary equation was obtained in terms of moment generating functions, and tail asymptotic properties for the marginal distributions were left for a future work. In this paper, we consider a three-dimensional Brownian-driven tandem queue with intermediate inputs. We derive exact tail asymptotics for the marginal stationary distribution of the third buffer content, since exact tail asymptotic results for the first two buffer content can be obtained directly from results for two-dimensional SRBM. We also note that all results related to exact tail asymptotics for stationary distributions of SRBM are only for marginal stationary distributions and boundary stationary distributions. There are no results referred in the literature on asymptotic properties for the joint stationary distribution of SRBM, which is also considered in this paper.

In this paper, we apply both the Kernel method and extreme value theory to study tail asymptotics. The kernel method has been systematically applied to study random walks in the quarter plane by Li and Zhao [18] and references therein. Key steps in applying the kernel method for random walks in the quarter plane are: (i) Establishing the fundamental form:

\[ h(x, y)\pi(x, y) = h_1(x, y)\pi_1(x) + h_2(x, y)\pi_2(y) + h_0(x, y)\pi_{0,0}, \]

where \( \pi(x, y) \), \( \pi_1(x) \) and \( \pi_2(y) \) are unknown generating functions for joint and two boundary probabilities, respectively. (ii) Finding a branch \( Y = Y_0(x) \) such that \( h(x, Y_0(x)) = 0 \), which leads to a relationship between the two unknown boundary generating functions:

\[ h_1(x, Y_0(x))\pi_1(x) + h_2(x, Y_0(x))\pi_2(Y_0(x)) + h_0(x, Y_0(x))\pi_{0,0} = 0; \quad (1.1) \]

(iii) Based on [13], carrying out a singularity analysis for \( \pi_1 \) and \( \pi_2 \), which leads to not only a decay rate, but also exact tail asymptotic properties of the boundary probabilities through a Tauberian-like theorem. In this paper, we will extend this method to study a three-dimensional SRBM. By using the kernel method, we can get exact tail asymptotics for the marginal stationary distributions.

In this paper, we also study asymptotic properties for the joint stationary distributions. However, we cannot use the kernel method to study tail behaviours of the joint stationary distribution, since the kernel method relies on the Tauberian-like Theorem, which is valid only for univariate functions. By using the kernel method, we can get tail equivalence for the marginal distributions, from which we will further study the tail dependence of the joint stationary distribution. Tail dependence describes the amount of dependence in the upper tail or lower tail of a multivariate distributions and has been widely used in extreme value analysis and in quantitative risk management. Once we get the dependence, we can study multivariate extreme value distribution of the joint stationary distribution. The extreme value distribution is very useful since from a sample of vectors of maximum, one can make inferences about the upper tail of the stationary distribution using multivariate extreme value theory. Based on the multivariate extreme distribution, by using copula, we can get tail behaviour of the joint stationary distributions.

In this paper, we study a three dimensional SRBM and anticipate the tools developed in this paper will be useful in analyzing the general \( d \)-dimensional case. The rest of this paper is organized as follows: In Section 2, a three-dimensional Brownian-driven tandem queue with intermediate inputs is introduced. To apply the kernel method for asymptotic properties for the marginal \( L_3 \), we study the kernel equation and the analytic continuation of moment generating functions in Section 3. We study some asymptotic properties of moment generating functions in Section 4. Asymptotic results for the marginal distributions are present in Section 5. In Section 6, we study asymptotic properties of the joint stationary distribution.

## 2 Model and Preliminaries

In this section, we introduce a three dimensional Brownian-driven tandem queue with intermediate inputs and establish a stationary equation satisfied by stationary probabilities. This tandem queue
has three nodes, numbered as 1, 2, 3, each of which has exogenous input process and a constant processing rate. Outflow from the node 1 goes to node 2, and the outflow from node 2 goes to node 3. Finally, outflow from node 3 leaves the system, see Fig. 1 below.

\[
\begin{pmatrix}
X_1(t) & c_1 t & X_2(t) & c_2 t & X_3(t) & c_3 t
\end{pmatrix}
\]

**Fig. 1** A tandem queue with 3 nodes.

We assume that the exogenous inputs are Brownian processes of the form:

\[X_i(t) = \lambda_i t + B_i(t), \quad i = 1, 2, 3,\]

where \(\lambda_i > 0\) is a nonnegative constant, and \(B_i(t)\) is a Brownian motion with variance \(\sigma_i^2\) and no drift. Without loss of generality, we assume that the correlation coefficients \(\rho_{B_i B_j} < 1, i, j = 1, 2, 3,\) where \(B(1) = (B_1, B_2, B_3)'.\) Denote the processing rate at node \(i\) by \(c_i > 0.\) Let \(L_i(t)\) be the buffer content at node \(i\) at time \(t \geq 0\) for \(i = 1, 2, 3,\) which are formally defined as

\[
L_1(t) = L_1(0) + X_1(t) - c_1 t + Y_1(t),
\]

\[
L_i(t) = L_i(0) + X_i(t) + c_{i-1} t - c_i t - Y_{i-1}(t) + Y_i(t), \quad i \geq 2,
\]

where \(Y_i(t)\) is a regulator at node \(i,\) that is, a minimal nondecreasing process for \(L_i(t)\) to be nonnegative. In fact, we can regard \((L_1(t), L_2(t), L_3(t))'\) as a reflection mapping from the net flow processes \((X_1(t) - c_1 t, X_2(t) - c_2 t, X_3(t) + c_2 t - c_3 t)'\) with the reflection matrix

\[
R = \begin{bmatrix}
1 & 0 & 0 \\
-1 & 1 & 0 \\
0 & -1 & 1
\end{bmatrix} = [R^1, R^2, R^3].
\]

Let \(L(t) = (L_1(t), L_2(t), L_3(t))'\) and \(B(t) = (B_1(t), B_2(t), B_3(t))'.\) Then

\[L(t) = B(t) + \Lambda t + RY(t) + L(0),\]

where \(\Lambda = (\lambda_1 - c_1, \lambda_2 + c_1 - c_2, \lambda_3 + c_2 - c_3)'\) and \(Y(t) = (Y_1(t), Y_2(t), Y_3(t))'.\)

Without any difficulty, we can obtain that the tandem queue has the stationary distribution if and only if

\[
\sum_{i=1}^{k} \lambda_i \leq c_k, \quad 1 \leq k \leq 3.
\]

Moreover, by Harrison and Williams [13], we can get that the stationary distribution of \(\{L(t)\}\) is unique. Throughout this paper, we denote this stationary distribution by \(\pi.\) In order to simplify the discussion, in this paper, we refine the stability condition (2.5) to assume that

\[\lambda_1 < c_1, \quad \text{and} \quad \lambda_i + c_{i-1} < c_i, \quad i = 2, 3.\]

**Remark 2.1** From the proofs of the main results of this paper, it is clear that under the more general stability condition (2.4), we can use the same argument to discuss tail asymptotics. The only difference is that we need to discuss possible relationships between the parameters \(\lambda_i\) and \(c_i, i = 1, 2, 3,\) before we use the arguments in the proofs in this paper. For each of the possible relationships, we repeat the method applied in this paper to study tail asymptotics.
We are interested in asymptotic tail behaviour of the stationary distribution. Recall that a positive function $g(x)$ is said to have exact tail asymptotic $h(x)$, if
\[ \lim_{x \to \infty} \frac{g(x)}{h(x)} = 1. \]
In this paper, our main aim is to find exact tail asymptotics for various stationary distributions. Moment generating function will play an important role in determining these exact tail asymptotics.

We first introduce moment generating functions for stationary distributions. Let $L = (L_1, L_2, L_3)'$ be the stationary random vector with the stationary distribution $\pi$. The moment generating function $\phi(\cdot)$ for $L$ is given by:
\[ \phi(x, y, z) = \mathbb{E}\left[ e^{xL_1 + yL_2 + zL_3} \right], \quad \text{for any } (x, y, z)' \in \mathbb{R}^3. \] (2.7)

We apply the kernel method to study tail asymptotics for stationary distributions. In order to apply the kernel method, we need establish a relationship between the moment generating function $\phi(\cdot)$ for the stationary distribution and the moment generating functions for the boundary measures defined below. For any Borel set $A \subset \mathcal{B}(\mathbb{R}^3)$, we define the boundary measures $V_i(\cdot)$, $i = 1, 2, 3$, by
\[ V_i(A) = \mathbb{E}_\pi \left[ \int_0^1 I_{\{L(u) \in A\}} dY_i(u) \right]. \] (2.8)
Moreover, due to Harrison and Williams [14], we obtain that the density functions for $V_i$, $i = 1, 2, 3$, exist. Then, their moment generating functions are defined by
\[ \phi_i(x, y, z) = \int_{\mathbb{R}^3} e^{<\vec{x}, \theta>} V_i(d\theta) = \mathbb{E}_\pi \left[ \int_0^1 e^{<\vec{x}, L(t)>} dY_i(t) \right], \quad i = 1, 2, 3, \] (2.9)
where $\vec{x} = (x, y, z)' \in \mathbb{R}^3$.

Next, we establish the relationship between these moment generating functions. In fact, there is a nice connection during them. The following lemma is due to Konstantopoulos, Last and Lin [14].

**Lemma 2.1** [14, Theorem 4] For each $(x, y, z)' \in \mathbb{R}^3$ with $\phi(x, y, z) < \infty$ and $\phi_i(x, y, z) < \infty$, $i = 1, 2, 3$, we have
\[ H(x, y, z)\phi(x, y, z) = H_1(x, y)\phi_1(x, y, z) + H_2(y, z)\phi_2(x, y, z) + H_3(z)\phi_3(x, y, z), \] (2.10)
where
\[ H(x, y, z) = -\frac{1}{2} \left( \sigma_1^2 x^2 + \sigma_2^2 y^2 + \sigma_3^2 z^2 \right) + (c_1 - \lambda_1)x + (c_2 - \lambda_2 - c_1)y + (c_3 - \lambda_3 - c_2)z, \] (2.11)
\[ H_1(x, y) = x - y, \] (2.12)
\[ H_2(y, z) = y - z, \] (2.13)
\[ H_3(z) = z. \] (2.14)

From Lemma 2.1 we can prove the following lemma.

**Lemma 2.2** For $1 \leq k \leq 3$, we have
\[ \phi_k(0, 0, 0) = \mathbb{E}_\pi [Y_k(1)] = c_k - \sum_{i=1}^k \lambda_i > 0. \] (2.15)
Proof: From (2.9), we get that (2.10) makes sense for $x \in \mathbb{R}^3 \setminus \mathbb{R}_+^3$. Let $x = (0, x_k, 0)'$ with $x_k < 0$. From (2.10), we get

$$
\left((c_k - \lambda_k - c_{k-1})x_k - \frac{1}{2}\sigma_k^2 x_k^2\right)\phi(0, x_k, 0) = -x_k\phi_{k-1}(0, x_k, 0) + x_k\phi_k(0, x_k, 0),
$$
i.e.,

$$
\left((c_k - \lambda_k - c_{k-1}) - \frac{1}{2}\sigma_k^2 x_k\right)\phi(0, x_k, 0) = -\phi_{k-1}(0, x_k, 0) + \phi_k(0, x_k, 0),
$$
where $c_0 = 0$ and $\phi_0 = 0$. Letting $x_k$ go to 0 in (2.16), we get that the left-hand side of equation (2.16) equals to

$$
c_k - \lambda_k - c_{k-1}
$$
(2.16)
since $\phi(0, 0, 0) = 1$. Hence,

$$
(c_k - \lambda_k - c_{k-1}) + \phi_{k-1}(0, 0, 0) = \phi_k(0, 0, 0). \tag{2.17}
$$
Let $k = 1$. Then, one can easily get that

$$
\phi_1(0, 0, 0) = c_1 - \lambda_1. \tag{2.18}
$$
By (2.17) and (2.18), we can get the lemma holds. \qed

In general, it is difficult or impossible to obtain the explicit expression for the stationary distribution $\pi$ or its moment generating function. However in some special cases, it becomes possible. For example, if there are no intermediate inputs, that is $X_k = 0$, $k = 2, 3$, Miyazawa and Rolski [21] obtained an explicit expression of $\phi(\theta)$. For a general case, our focus is on its tail asymptotics. There are a few available methods for studying tail asymptotics, for example, in terms of large deviations and boundary value problems. In this paper, we study tail asymptotics of the marginal distribution $P(L_3 < x)$ via the kernel method introduced by Li and Zhao [17] and asymptotic properties of the joint stationary distribution by extreme value theory and copula.

At the end of this section, we present a technical lemma, which plays an important role in finding the tail asymptotics of the marginal distribution $P(L_3 < x)$.

**Lemma 2.3** $\phi(0, 0, x)$ and $\phi_2(0, 0, x)$ have the same singularities.

**Proof:** Let $\theta = (0, 0, x)'$. Then,

$$
H(0, 0, x) = -\frac{1}{2}\sigma_3^2 x^2 + (c_3 - \lambda_3 - c_2)x. \tag{2.19}
$$
Note that for any $(x, y, z)'$, since $\Delta Y_3(t) > 0$ only if $L_3(t) = 0$, we have

$$
\phi_3(x, y, z) = \phi_3(x, y, 0).
$$
Then, by (2.10) and (2.15),

$$
H(0, 0, x)\phi(0, 0, x) = -x\phi_2(0, 0, x) + x\left(c_3 - \sum_{i=1}^{3} \lambda_i\right). \tag{2.20}
$$
From (4.11) below, we get that

$$
\phi_2(0, 0, \frac{2(c_3 - \lambda_3 - c_2)}{\sigma_3^2}) < +\infty.
$$
Letting $x = \frac{2(c_1 - \lambda_3 - c_2)}{\sigma_3^2}$ in (2.20), we obtain

\[-\phi_2(0, 0, \frac{2(c_3 - \lambda_3 - c_2)}{\sigma_3^2}) + (c_3 - \sum_{i=1}^{3} \lambda_i) = 0,\]

i.e.,

\[\phi_2(0, \frac{2(c_3 - \lambda_3 - c_2)}{\sigma_3^2}) = c_3 - \sum_{i=1}^{3} \lambda_i. \tag{2.21}\]

Therefore, by (2.20) and (2.21),

\[\phi(0, 0, x) = \phi_2(0, 0, \frac{2(c_3 - \lambda_3 - c_2)}{\sigma_3^2}) - \phi_2(0, 0, x)
- \frac{1}{2} \sigma_3^2 x + (c_3 - \lambda_3 - c_2). \tag{2.22}\]

By (2.21) and (2.22), one can easily get that $x = \frac{2(c_3 - \lambda_3 - c_2)}{\sigma_3^2}$ is a removable singularity of $\phi(0, 0, x)$. The proof of this lemma is completed.

\[\Box\]

3 Kernel Equation and Analytic Continuation

In this paper, we apply the kernel method to study tail asymptotics for the marginal stationary measure $\mathbb{P}(L_3 < x)$. In order to do it, we need the Tauberian-like Theorem (Theorem 5.1). For applying this theorem, we need to study the analytic properties of the moment generating function $\phi_2(x, y, z)$.

3.1. Kernel Equation and Branch Points

To study analytic properties of the moment generating functions, we first focus on the kernel equation and the corresponding branch points. For this purpose, we consider the kernel equation:

\[H(x, y, z) = 0, \tag{3.1}\]

which is critical in our analysis.

Since tail asymptotics for $\mathbb{P}(L_3 < z)$ is our focus, we first treat $z$ in $(x, y, z)' \in \mathbb{R}^3$ as a variable. Inspired by the procedure of applying the kernel method, for example, see Li and Zhao [17], we first construct the relationship between $z$ and $x, y$. The kernel equation in (3.1) defines an implicit function $z$ in variables $x$ and $y$ when we only consider non-negative values for $z$. For convenience, let $c_0 = 0$.

In view of the kernel method for the bivariate case, we locate the maximum $z_{\text{max}}$ of $z$ on $H(x, y, z) = 0$. In order to do it, taking the derivative with respect to $x$ at the both side of (3.1) yields

\[-x \sigma_1^2 - z \frac{\partial z}{\partial x} \sigma_3^2 + (c_3 - \lambda_3 - c_2) \frac{\partial z}{\partial x} + (c_1 - \lambda_1 - c_0) = 0,\]

i.e.,

\[-z \sigma_3^2 - \lambda_3 - c_2 + c_3 \frac{\partial z}{\partial x} + (-x \sigma_1^2 - \lambda_1 - c_0 + c_1) = 0. \tag{3.2}\]

Let

\[\frac{\partial z}{\partial x} = 0, \tag{3.3}\]
and solve the system of equations (3.2) and (3.3), we have
\[ x_{z_{\text{max}}} = \frac{c_1 - \lambda_1 - c_0}{\sigma_1^2}. \] (3.4)

Similarly, take the derivative with respect to \( y \),
\[ \frac{\partial z}{\partial y} = 0, \] (3.5)
to obtain
\[ y_{z_{\text{max}}} = \frac{c_2 - \lambda_2 - c_1}{\sigma_2^2}. \] (3.6)

It is easy to check that at the point \( (x_{z_{\text{max}}}, y_{z_{\text{max}}}) \), \( z \) attains the maximum value \( z_{\text{max}} \). From (3.4) and (3.6), we can get that on the point \( (x_{z_{\text{max}}}, y_{z_{\text{max}}}, z_{\text{max}}) \), the coordinates \( x \) and \( y \) satisfy
\[ x_{z_{\text{max}}} = k_1 y_{z_{\text{max}}}, \] (3.7)
where
\[ k_1 = \frac{(c_1 - \lambda_1 - c_0)\sigma_2^2}{(c_2 - \lambda_2 - c_1)\sigma_1^2}. \] (3.8)

**Remark 3.1** Without loss of generality, we assume that \( k_1 \neq 1 \) in the rest of this paper. For the special case \( k_1 = 1 \), the discussion can be carried out by using the same ideal which is much simpler than the general case due to the fact that when \( k_1 = 1 \), the term including \( k_1 - 1 \) in most equations will disappear.

From the above arguments, we obtain the maximum \( z_{\text{max}} \) on the plane \( H(k_1 y, y, z) = 0 \). Now, we consider the new equation:
\[ H(k_1 y, y, z) = 0. \] (3.9)

From (2.6) and (3.1), we can easily know that (3.9) defines an ellipse. Thus, for fixed \( z \), there are two solutions to (3.9) for \( y \), which are given:
\[ Y_{\text{max},0}(z) = \frac{(c_1 - \lambda_1)k_1 + (c_2 - \lambda_2 - c_1) - \sqrt{\Delta(z)}}{(\sigma_1^2 k_1^2 + \sigma_2^2)}, \] and
\[ Y_{\text{max},1}(z) = \frac{(c_1 - \lambda_1)k_1 + (c_2 - \lambda_2 - c_1) + \sqrt{\Delta(z)}}{(\sigma_1^2 k_1^2 + \sigma_2^2)}. \] (3.10) (3.11)

where
\[ \Delta(z) = \left( (c_1 - \lambda_1)k_1 + c_2 - \lambda_2 - c_1 \right)^2 + 2\sigma_1^2 k_1^2 + \sigma_2^2 \left( -\frac{1}{2} \sigma_3^2 z^2 + (c_3 - \lambda_3 - c_2)z \right). \] (3.12)

Moreover, these two solution are distinct except \( \Delta(z) = 0 \). We call a point \( z \) a branch point if \( \Delta(z) = 0 \). For branch points, we have the following property.

**Lemma 3.1**

(i) \( \Delta(z) \) has two real zeros, one of which is \( z_{\text{max}} \), and the other is denoted by \( z_{\text{min}} \). Moreover, they satisfy
\[ z_{\text{min}} < 0 < z_{\text{max}}. \] (3.13)
(ii) $\Delta(z) > 0$ in $(z_{\text{min}}, z_{\text{max}})$ and $\Delta(z) < 0$ in $(-\infty, z_{\text{min}}) \cup (z_{\text{max}}, \infty)$.

**Proof:** From (3.12), we obtain

$$\Delta(0) = \left( \sum_{i=1}^{2} (c_i - \lambda_i - c_i - 1)k_i \right)^2 > 0,$$

where $k_2 = 1$. On the other hand,

$$\sum_{i=1}^{2} \sigma_i^2 k_i^2 > 0.$$  \hspace{1cm} (3.15)

From (3.14) and (3.15), we get (3.13).

By properties of quadratic functions, we can get that (ii) holds. The proof of the lemma is completed now. □

In order to use the Tauberian-like Theorem below, we consider the analytic continuation of the moment generating functions in the complex plane $C$. The function $\sqrt{\Delta(x)}$ plays an important role in the procedure of the analytic continuation. Hence, we first study its analytic continuation. By Lemma 3.1, $\sqrt{\Delta(x)}$ is well defined for $x \in [z_{\text{min}}, z_{\text{max}}]$. Moreover, it is a multi-valued function in the complex plane. For convenience, in the sequel, $\sqrt{\Delta(x)}$ denotes the principle branch, that is $\Delta(x) = \Delta(\text{Re}(x))$ for $x \in (z_{\text{min}}, z_{\text{max}})$. In the follow, we continue $\sqrt{\Delta(x)}$ to the cut plane $C \setminus \{ (-\infty, z_{\text{min}}] \cup [z_{\text{max}}, \infty) \}$.

**Lemma 3.2** $\sqrt{\Delta(x)}$ is analytic in the cut plane $C \setminus \{ (-\infty, z_{\text{min}}] \cup [z_{\text{max}}, \infty) \}$.

The proof of Lemma 3.2 is standard. For example, see Dai and Miyazawa [5], or Dai, Dawson and Zhao [3]. However, for the completeness of the paper, we provide a proof following the ideal used by Dai and Miyazawa [5].

**Proof:** Since $z_{\text{min}}$ and $z_{\text{max}}$ are two zeros of $\Delta(x) = 0$, we have

$$\Delta(x) = \left( \sum_{i=1}^{2} \sigma_i^2 k_i^2 \right) \sigma_3^2 (x - z_{\text{min}})(z_{\text{max}} - x).$$  \hspace{1cm} (3.16)

Next, we rewrite (3.16) in the polar form. Let $\omega_{\text{min}}(x)$ and $\omega_{\text{max}}(x)$ denote the principal arguments of $x - z_{\text{min}}$ and $z_{\text{max}} - x$, respectively. Therefore,

$$\omega_{\text{min}}(x), \omega_{\text{max}}(x) \in (-\pi, \pi].$$  \hspace{1cm} (3.17)

Hence, (3.16) can be rewritten as

$$\Delta(x) = \left[ (\sum_{i=1}^{2} \sigma_i^2 k_i^2) \sigma_3^2 \right] |x - z_{\text{min}}||z_{\text{max}} - x| \exp\{i(\omega_{\text{min}}(x) + \omega_{\text{max}}(x))\}. \hspace{1cm} (3.18)$$

Moreover for $\omega_{\text{min}}, \omega_{\text{max}} \in (-\pi, \pi]$, the functions $x - z_{\text{min}}$ and $z_{\text{max}} - x$ are analytic. Since $\sqrt{\Delta(x)}$ is the principle part, we have

$$\sqrt{\Delta(x)} = \sqrt{ \left( \sum_{i=1}^{2} \sigma_i^2 k_i^2 \right) \sigma_3^2 |x - z_{\text{min}}||z_{\text{max}} - x| \exp\left[ \frac{i(\omega_{\text{min}}(x) + \omega_{\text{max}}(x))}{2} \right] }.$$  \hspace{1cm} (3.19)

Thus, from (3.17) and (3.19), one can easily get that $\sqrt{\Delta(x)}$ is analytic in the cut plane. □

**Corollary 3.1** Both $Y_{\text{max},0}(x)$ and $Y_{\text{max},1}(x)$ are analytic in the cut plane $C \setminus \{ (-\infty, z_{\text{min}}] \cup [z_{\text{max}}, \infty) \}$. 
Symmetrically, we can treat the kernel equation \((3.9)\) as a quadratic function in \(z\), and obtain parallel results to those in Lemmas \(3.1\) and \(3.2\) and Corollary \(3.1\). We list them below. Before stating them, we first introduce the following notation. Define
\[
\Delta(y) = \left(c_3 - \lambda_3 - \lambda_2\right)^2 + 2\sigma_3^2 \left(y \sum_{i=1}^{2} \left(c_i - \lambda_i - c_{i-1}\right)k_i - \frac{1}{2}y^2 \sum_{i=1}^{2} \sigma_i^2 k_i^2\right).
\] (3.20)

For fixed \(y\), there are two solutions to \((3.9)\), which are given by
\[
Z_{\text{max},1}(y) = \left(\frac{c_3 - \lambda_3 - c_2 + \sqrt{\Delta(y)}}{\sigma_3}\right), \quad \text{and}
\]
\[
Z_{\text{max},0}(y) = \left(\frac{c_3 - \lambda_3 - c_2 - \sqrt{\Delta(y)}}{\sigma_3}\right).
\] (3.21) (3.22)

Similar to Lemmas \(3.1\) and \(3.2\) and Corollary \(3.1\), we have:

**Lemma 3.3**

(i) \(\Delta(y)\) has two real zeros, denoted by \(y^{\text{min}}\) and \(y^{\text{max}}\), respectively, satisfying
\[
y^{\text{min}} < 0 < y^{\text{max}}. \tag{3.23}\]

(ii) \(\Delta(y) > 0\) in \((y^{\text{min}}, y^{\text{max}})\) and \(\Delta(y) < 0\) in \((-\infty, y^{\text{min}}) \cup (y^{\text{max}}, \infty)\).

(iii) \(Z_{\text{max},0}(y)\) are analytic in the cut plane \(\mathbb{C} \setminus \{(-\infty, y^{\text{min}}] \cup [y^{\text{max}}, \infty)\}\).

In order to get the analytic continuation of the moment generating functions, we need some technical lemmas. Before we introduce these lemmas, we first present an important notation. Define
\[
\mathbb{G}_\delta(z_0) = \{z \in \mathbb{C} : z \neq z_0, |\text{arg}(z - z_0)| > \delta\} \cap \{z : |z| < z_0 + \epsilon\},
\]
where \(\text{arg}(z) \in (-\pi, \pi)\), \(\delta \geq 0\) and \(\epsilon > 0\).

For the function \(Y_{\text{max},0}(x)\), we have the following properties.

**Lemma 3.4** For \(Y_{\text{max},0}(x)\), we have

(i) \(\text{Re} \left( Y_{\text{max},0}(z) \right) \leq Y_{\text{max},0}(\text{Re}(z))\) for \(\text{Re}(z) \in (z^{\text{min}}, z^{\text{max}})\).

(ii) \(\text{Re}(Y_{\text{max},0}(z)) < y^{\text{max}}\) for \(z \in \mathbb{G}_{\delta_0}(z^{\text{max}}) \cap \{z \in \mathbb{C} : z^{\text{min}} < \text{Re}(z)\}\) with some \(\delta_0 \in [0, \frac{\pi}{2}]\).

**Proof:** It follows from \(3.10\) and \(3.16\) that
\[
\text{Re} \left( Y_{\text{max},0}(z) \right) - Y_{\text{max},0}(\text{Re}(z)) = \left[\sum_{i=1}^{2} \sigma_i^2 k_i^2 \left(\sqrt{(\text{Re}(z) - z^{\text{min}})(z^{\text{max}} - \text{Re}(z))} - \text{Re}\left(\sqrt{(z - z^{\text{min}})(z^{\text{max}} - z)}\right)\right)\right].\tag{3.24}\]

By \(3.24\), in order to prove case (i), we only need to show
\[
\sqrt{(\text{Re}(z) - z^{\text{min}})(z^{\text{max}} - \text{Re}(z))} - \text{Re}\left(\sqrt{(z - z^{\text{min}})(z^{\text{max}} - z)}\right) \leq 0. \tag{3.25}\]

We also note that \((\text{Re}(z) - z^{\text{min}})\) and \((z^{\text{max}} - \text{Re}(z))\) are real parts of \((z - z^{\text{min}})\) and \((z^{\text{max}} - z)\), respectively, since \(z^{\text{min}}\) and \(z^{\text{max}}\) are real. Therefore,
\[
(\text{Re}(z) - z^{\text{min}}) = |z - z^{\text{min}}| \cos(\omega_{\text{min}}(z)),
\]
\[
(z^{\text{max}} - \text{Re}(z)) = |z^{\text{max}} - z| \cos(\omega_{\text{max}}(z)).
\]
So,
\[
\sqrt{(Re(z) - z_{\min})(z_{\max} - Re(z))} = \sqrt{|z - z_{\min}| |z_{\max} - z| \left( \cos (\omega_{\min}(z)) \cos (\omega_{\max}(z)) \right)^{\frac{1}{2}}}.
\tag{3.26}
\]
Similarly, we have
\[
(z - z_{\min})(z_{\max} - z) = |z - z_{\min}| |z_{\max} - z| \exp \left\{ i(\omega_{\max}(z) + \omega_{\min}(z)) \right\}.
\]
Thus,
\[
\sqrt{(z - z_{\min})(z_{\max} - z)} = \sqrt{|z - z_{\min}| |z_{\max} - z|} \exp \left\{ i \frac{\omega_{\max}(z) + \omega_{\min}(z)}{2} \right\}.
\]
Hence,
\[
Re\left( \sqrt{(z - z_{\min})(z_{\max} - z)} \right) = \sqrt{|z - z_{\min}| |z_{\max} - z|} \cos \left\{ \frac{\omega_{\max}(z) + \omega_{\min}(z)}{2} \right\}.
\tag{3.27}
\]
Since for \(Re(z) \in (z_{\min}, z_{\max})\),
\[
\omega_{\max}(z) \in (-\frac{\pi}{2}, 0),
\tag{3.28}
\]
\[
\omega_{\min}(z) \in (0, \frac{\pi}{2}),
\tag{3.29}
\]
\[
\frac{\omega_{\max}(z) + \omega_{\min}(z)}{2} \in (-\frac{\pi}{4}, \frac{\pi}{4}).
\tag{3.30}
\]
From (3.26) to (3.30), in order to prove (3.25), we only need to prove
\[
\left( \cos (\omega_{\min}(z)) \cos (\omega_{\max}(z)) \right)^{\frac{1}{2}} \leq \cos \left( \frac{\omega_{\max}(z) + \omega_{\min}(z)}{2} \right),
\tag{3.31}
\]
which directly follows from Dai and Miyazawa [5].

Next, we prove case (ii). We first assume that \(z_{\min} < Re(z) < z_{\max}\). From (3.10) and Lemma 3.1, we have
\[
y^m := Y_{max,0}(z_{\max}) = \frac{\sum_{i=1}^{2} (\lambda_i - c_i - c_i - 1) k_i}{\sum_{i=1}^{2} \sigma_i^2 k_i^2},
\tag{3.32}
\]
since \(\Delta(z_{\max}) = 0\). From (3.32) and case (i), in order to prove the case (ii), we only need to show
\[
\frac{\sum_{i=1}^{2} (c_i - \lambda_i - c_i - 1) k_i}{\sum_{i=1}^{2} \sigma_i^2 k_i^2} \leq y^m.
\tag{3.33}
\]
On the other hand, it follows from (3.20) and Lemma 3.3 that
\[
2 \frac{\sum_{i=1}^{2} (\lambda_i - c_i - c_i - 1) k_i}{\sum_{i=1}^{2} \sigma_i^2 k_i^2} \leq y^m.
\tag{3.34}
\]
Hence, (3.33) follows from (3.34).

Finally, we assume that \(Re(z) \geq z_{\max}\). As \(\delta \to \frac{\pi}{2}\), we have that
\[
Re(z) \to z_{\max}.
\tag{3.35}
\]
It follows from Lemma 3.3, (3.34) and (3.35) that we can find \(\delta_0 \in (0, \frac{\pi}{2})\) such that case (ii) holds. The proof of the lemma is completed. \(\square\)
3.2. Analytic Continuation

The analytic continuation of the moment generating function $\phi_3(0, 0, z)$ plays an important role in our analysis, which is the focus in this subsection. In order to carry out this, we need the following technical lemma.

**Lemma 3.5** For the moment generating functions $\phi_i(\cdot), i = 1, 2, 3$, we have

(i) $\phi_1(0, y, z)$ is finite on some region $\{(y, z) : y < \epsilon, z < \epsilon\}$ with $\epsilon > 0$.

(ii) $\phi_2(0, 0, z)$ is finite on some region $\{z : z < \epsilon\}$ with $\epsilon > 0$.

(iii) $\phi_2(x, 0, z)$ is finite on some region $\{z : z < \epsilon, x < \epsilon\}$ with $\epsilon > 0$.

(iv) $\phi_3(0, y, 0)$ is finite on some region $\{y : y < \epsilon\}$ with $\epsilon > 0$.

**Proof:** We first prove case (i). In order to prove it, we first prove

\[ E \left[ \int_0^1 e^{yL_2(u)} dY_1(u) \right] < \infty \tag{3.36} \]

for some $y > 0$, and

\[ E \left[ \int_0^1 e^{zL_3(u)} dY_1(u) \right] < \infty \tag{3.37} \]

for some $z > 0$.

In fact,

\[ E \left[ \int_0^1 e^{yL_2(u)} dY_1(u) \right] = \phi_1(0, y, 0). \tag{3.38} \]

which suggests that we may restrict our analysis to the two-dimensional tandem queue $\{(L_1(t), L_2(t))'\}$ with the two nodes 1 and 2. We note that $(L_1(t), L_2(t))'$ is not affected by $L_3(t)$. Using the same method as in Dai, Dawson and Zhao [3], we can easily get (3.36).

Next, we prove (3.37). Since $Y_1$ is a regulator,

\[ E \left[ \int_0^1 e^{zL_3(u)} dY_1(u) \right] = E \left[ \int_0^1 e^{xL_1(t) + 0L_2(t) + zL_3(u)} dY_1(u) \right] = \phi_1(x, 0, z). \tag{3.39} \]

By (3.10) and (3.39), we get that the left-hand side of (3.37) satisfies

\[ H(x, 0, z)\phi(x, 0, z) = x\phi_1(0, 0, z) - z\phi_2(x, 0, z) + z\phi_3(x, 0, 0). \tag{3.40} \]

Next, we study this system on the plane $y = 0$. We first consider the ellipse defined by

\[ H(x, 0, z) = 0. \tag{3.41} \]

For the point $(x, z)$ on this ellipse, we have

\[ x\phi_1(0, 0, z) - z\phi_2(x, 0, z) + z\phi_3(x, 0, 0) = 0. \tag{3.42} \]

For fixed $x$, we can find two solutions to (3.41) for $z$. Denote one of these two solutions by

\[ z_0(x) = \frac{(c_3 - \lambda_3 - c_2) - \sqrt{(c_3 - \lambda_3 - c_2)^2 + 2\sigma_3^2(-\frac{1}{2}\sigma_1^2x^2 + (c_1 - \lambda_1)x)}}{\sigma_3^2}. \tag{3.43} \]
Using the same method as in the proof of Lemma 3.1, we can get that $Z_0(x)$ is well-defined between $[x_{\min}, x_{\max}]$ with $x_{\min} < 0 < x_{\max}$ and
\[
\Delta_1(x_{\min}) = \Delta_1(x_{\max}) = 0,
\]
where
\[
\Delta_1(x) = (c_3 - \lambda_3 - c_2)^2 + 2\sigma_3^2(-\frac{1}{2}\sigma_2 x^2 + (c_1 - \lambda_1)x).
\]
Hence, from (3.42) and (3.43), we have
\[
x \phi_1(0, 0, Z_0(x)) - Z_0(x) \phi_2(x, 0, Z_0(x)) + Z_0(x) \phi_3(x, 0, 0) = 0, \tag{3.44}
\]
that is,
\[
Z_0(x) \phi_3(x, 0, 0) = Z_0(x) \phi_2(x, 0, Z_0(x)) - x \phi_1(0, 0, Z_0(x)). \tag{3.45}
\]
Hence, $Z_0(x) \phi_3(x, 0, 0)$ is finite if and only if the right-hand side of (3.45) is finite. On the other hand, from (3.43), we obtain that for $x \in [x_{\min}, 0)$,
\[
z = Z_0(x) > 0, \tag{3.46}
\]
and
\[
\phi_3(x, 0, 0) < \infty. \tag{3.47}
\]
From (3.46) and (3.47), we obtain that
\[
\phi_1(0, 0, Z_0(x)) < \infty, \tag{3.48}
\]
since $\infty > Z_0(x) \phi_2(x, 0, Z_0(x)) \geq 0$ and $-x \phi_1(0, 0, Z_0(x)) \geq 0$. Therefore (3.37) holds. Finally, we have
\[
\phi_1(0, y, z) = \mathbb{E} \left[ \int_0^1 e^{yL_2(u) + zL_3(u)} dY_1(u) \right] \\
\leq \frac{1}{2} \left( \mathbb{E} \left[ \int_0^1 e^{yL_2(u)} dY_1(u) \right] + \mathbb{E} \left[ \int_0^1 e^{zL_3(u)} dY_1(u) \right] \right). \tag{3.49}
\]
Combing (3.36), (3.37) and (3.49), we get that for some $y > 0$ and $z > 0$
\[
\phi_1(0, y, z) < \infty.
\]
Next, we prove case (ii). Since
\[
\phi_2(0, 0, z) = \mathbb{E} \left[ \int_0^1 e^{0L_1(u) + zL_3(u)} dY_2(u) \right], \tag{3.50}
\]
we can consider the problem on the plane $x = 0$. It follows from (2.10) that
\[
H(0, y, z) \phi(0, y, z) = -y \phi_1(0, y, z) + (y - z) \phi_2(0, 0, z) + z \phi_3(0, y, 0). \tag{3.51}
\]
Then,
\[
H(0, y, z) = 0 \tag{3.52}
\]
defines an ellipse. For every fixed $y$, define
\[
Z_0(y) = \frac{(c_3 - \lambda_3 - c_2) - \sqrt{(c_3 - \lambda_3 - c_2)^2 + 2\sigma_3^2\left(-\frac{1}{2}\sigma_2 y^2 + (c_2 - \lambda_2 - c_1)y\right)}}{\sigma_3^2}. \tag{3.53}
\]
Then, (3.53) is a solution to equation (3.52). Similar to Lemma 3.1, \( \tilde{Z}_0(y) \) is well-defined on some region \([a, b]\) with \( a < 0 \) and \( b > 0 \). It follows from (3.51) and (3.53) that

\[
(y - \tilde{Z}_0(y)) \phi_2(0, 0, z) = y \phi_1(0, y, \tilde{Z}_0(y)) - \tilde{Z}_0(y) \phi_3(0, y, 0).
\]  
(3.54)

Furthermore, from (3.53), we obtain that for \( y \in \{ y : a < y < 0 \} \)

\[
\tilde{Z}_0(y) > 0.
\]  
(3.55)

Hence, by case (i) and (3.55), we can choose \( y < 0 \) such that \( z = \tilde{Z}_0(y) > 0 \) and,

\[
\phi_1(0, y, \tilde{Z}_0(y)) < \infty.
\]  
(3.56)

It is also worthy noting that for \( y < 0, \)

\[
\phi_3(0, y, 0) < \infty.
\]  
(3.57)

Case (ii) now follows from (3.56) to (3.57).

Finally, we can show cases (iii) and (iv) to complete the proof of the lemma. \( \square \)

For the continuation of the function \( \phi_2(0, 0, z) \), we need another technical tool.

Lemma 3.6 Let \( f(x_1, x_2) \) be a probability density function on \( \mathbb{R}_+^2 \). For a real variable \( \lambda \), define

\[
G(\lambda) = \int_{\mathbb{R}_+^2} e^{\lambda x_1 + \lambda x_2} f(x_1, x_2) dx \text{ with } g(\lambda) \text{ being a bounded and continuously differential real function, and}
\]

\[
\tau_{\tilde{G}} = \sup \{ \lambda \geq 0 : \tilde{G}(\lambda) < \infty \}.
\]  
(3.58)

Then, the complex variable function \( \tilde{G}(z) \) is analytic on \( \{ z \in \mathbb{C} : \text{Re}(z) < \tau_{\tilde{G}} \} \).

Proof: We use the Vitali’s Theorem to prove it. In fact, we have

\[
\int_{\mathbb{R}_+^2} e^{\lambda x_1 + \lambda x_2} f(x_1, x_2) dx_1 dx_2 = \int_0^{\infty} e^{g(\lambda) x_1} dx_1 \left[ \int_0^{\infty} e^{\lambda x_2} f(x_1, x_2) dx_2 \right].
\]  
(3.59)

For convenience, define

\[
F(\lambda, x_1) = \int_0^{\infty} e^{\lambda x_2} f(x_1, x_2) dx_2.
\]  
(3.60)

Since \( f(x_1, x_2) \) is a density function, we can get that \( F(\lambda, x_1) \) is analytic on the region \( \{ z \in \mathbb{C} : \text{Re}(z) < \tau_{\tilde{G}} \} \) for any \( x_1 \in \mathbb{R}_+ \). Let

\[
\tilde{F}(\lambda, x_1) = e^{g(\lambda) x_1} F(\lambda, x_1).
\]  
(3.61)

Now, it is obvious that \( \tilde{F}(\lambda, x_1) \) satisfies the conditions of the Vitali’s Theorem (see, for example, Markushevich [22]) on the region \( \{ z \in \mathbb{C} : \text{Re}(z) < \tau_{\tilde{G}} \} \). Then, the lemma holds. \( \square \)

Remark 3.2 From Lemma 3.6

(i) The convergence parameter \( \tau_{\tilde{G}} \) is unique;

(ii) If \( \alpha \in \mathbb{R}_+ \) is a singularity of \( G \), then we must have \( G(x) = \infty \) for \( x \in (\alpha, \infty) \). However, \( G(\alpha) \) may be either finite or infinite.

Remark 3.3 It follows from Lemmas 3.6 and 3.6 that

(i) \( \phi_2(0, 0, z) \) is finite on some region \( \{ z : \text{Re} z < \epsilon \} \) with \( \epsilon > 0 \), which implies that the convergence parameter \( \tau_{\phi_2(0, 0, z)} \) is greater than 0.
(ii) $\phi_3(0, y, 0)$ is finite on some region $\{y : \text{Re} y < \epsilon\}$ with $\epsilon > 0$, which implies that the convergence parameter $r_{\phi_3(0, y, 0)}$ is greater than 0.

The next lemma enables us to express $\phi_2(0, 0, z)$ in terms of the other moment generating functions.

**Lemma 3.7** $\phi_2(0, 0, z)$ can be analytically continued to the region $z \in \{z : \text{Re} z < \epsilon\}$ with $\epsilon > 0$, and

$$
\phi_2(0, 0, z) = \frac{\phi_2(k_1 Y_{\max, 0}(z), 0, z)}{1 - k_1} + z \frac{\phi_3(k_1 Y_{\max, 0}(z), Y_{\max, 0}(z), 0)}{(1 - k_1)(Y_{\max, 0}(z) - z)} - z \frac{\phi_3(0, 0, Y_{\max, 0}(z))}{(Y_{\max, 0}(z) - z)}. \quad (3.62)
$$

**Proof:** From Corollary 3.1 and (2.10), we get that

$$
\phi_1(k_1 Y_{\max, 0}(z), Y_{\max, 0}(z), z) = -\phi_2(k_1 Y_{\max, 0}(z), 0, z)(Y_{\max, 0}(z) - z) + z \phi_3(k_1 Y_{\max, 0}(z), Y_{\max, 0}(z), 0) \text{ for } y. \quad (3.63)
$$

On the other hand, equation (3.52) defines an ellipse. For fixed $z$, there are two solutions to (3.52) for $y$. Define

$$
Y_0(z) = \frac{(c_2 - \lambda_2 - c_1) - \sqrt{\Delta H(0, y, z)(z)}}{\sigma_2^2}, \quad (3.64)
$$

where

$$
\Delta H(0, y, z)(z) = (c_2 - \lambda_2 - c_1)^2 + 2\sigma_2^2((c_3 - \lambda_3 - c_2)z - \frac{1}{2}z^2). \quad (3.65)
$$

Using the same method as in the proof of Lemma 3.2, we can get that $Y_0(z)$ is analytic in the cut plane $\mathbb{C} \setminus \{(\infty, \bar{z}_\text{min}) \cup (\bar{z}_\text{max}, \infty)\}$, where

$$
\Delta H(0, y, z)(\bar{z}_\text{min}) = \Delta H(0, y, z)(\bar{z}_\text{max}) = 0
$$

with

$$
\bar{z}_\text{min} < 0 < \bar{z}_\text{max}.
$$

By (3.51) and (3.64), We can find a region such that

$$
\phi_1(0, Y_0(z), z) = \frac{\phi_2(0, Y_0(z), z) - z \phi_3(0, Y_0(z), 0)}{Y_0(z)}. \quad (3.65)
$$

Next, we study the relationship between $Y_0(z)$ and $Y_{\max, 0}(z)$ for $z > 0$. We note that both the two ellipses defined by (3.9) and (3.52), respectively, pass the origin $(0, 0)$ and

$$
H(k_1 y, y, z) = H(0, y, z) - \frac{1}{2}c_1^2\sigma_1^2 y^2 + (c_1 - \lambda_1)k_1 y
$$

$$
= H(0, y, z) + G(y), \quad (3.66)
$$

where

$$
G(y) = -\frac{1}{2}c_1^2\sigma_1^2 y^2 + (c_1 - \lambda_1)k_1 y.
$$

We should note that

$$
G(y) > 0 \text{ if and only if } y \in \left[0, \frac{2(c_1 - \lambda_1)}{\sigma_1^2 k_1}\right]. \quad (3.67)
$$
From (3.64), we obtain that for \( z \in [0, \frac{2(c_1 - \lambda_3 - c_2)}{\sigma^2_3}] \)
\[
Y_0(z) \leq 0. \quad (3.68)
\]
From (3.66) and (3.68), we get that for \( z \in (0, \frac{2(c_1 - \lambda_3 - c_2)}{\sigma^2_3}) \)
\[
H(k_1 Y_0(z), Y_0(z), z) < 0. \quad (3.69)
\]
On the other hand, from (3.10) and (3.64), we have, for \( 0 < z < \frac{2(c_1 - \lambda_3 - c_2)}{\sigma^2_3} \),
\[
Y_0(z) < 0 \text{ and } Y_{\max,0}(z) < 0.
\]
Thus,
\[
Y_{\max,0}(z) > Y_0(z), \quad (3.70)
\]
for \( z \in \left(0, \frac{2(c_1 - \lambda_3 - c_2)}{\sigma^2_3}\right) \).

It follows from Lemmas 3.5, 3.63, and 3.65 that
\[
\phi_1(0, Y_{\max,0}(z), z) = \frac{\phi_2(0, 0, z)(Y_{\max,0}(z) - z) + z\phi_3(0, Y_{\max,0}(z), 0)}{Y_{\max,0}(z)}
\]
\[
= -\frac{\phi_3(k_1 Y_{\max,0}(z), 0, z)(Y_{\max,0}(z) - z) + z\phi_3(k_1 Y_{\max,0}(z), Y_{\max,0}(z), 0)}{(k_1 - 1)Y_{\max,0}(z)}, \quad (3.71)
\]
where we use the principle of analytic continuation of several complex variables functions (see, for example, Narasimhan [23]). Therefore
\[
\phi_2(0, 0, z) = \frac{\phi_2(k_1 Y_{\max,0}(z), 0, z)}{1 - k_1} + z\frac{\phi_3(k_1 Y_{\max,0}(z), 0, z)}{(1 - k_1)(Y_{\max,0}(z) - z)} - z\frac{\phi_3(0, Y_{\max,0}(z), 0)}{(Y_{\max,0}(z) - z)}, \quad (3.71)
\]
for \( \Re z < \epsilon \) with some \( \epsilon > 0 \). The proof is completed. \( \square \)

4. Tail Asymptotic and Singularity Analysis

In order to reach our goal, we need to study tail behaviors of \( \phi_2(0, 0, z) \) around the dominant singularities. From Lemma 3.6 there exists only one dominant singularity. We denote it by \( z_{\text{dom}} \).

Next, we characterize the dominant singularity \( z_{\text{dom}} \) of \( \phi_2(0, 0, z) \). For convenience, let
\[
F(y) = \frac{\phi_3(k_1 y, y, 0)}{1 - k_1} - \phi_3(0, y, 0) \text{ and } D(y, z) = \phi_2(0, y, z) - \frac{\phi_2(k_1 y, y, z)}{1 - k_1}.
\]
Moreover, let
\[
G(z) = D(Y_{\max,0}(z), z), \text{ and } \bar{G}(y) = D(y, Z_{\max,0}(y)). \quad (4.1)
\]
From Lemma 3.6 we have:

**Lemma 4.1** \( F(y) \) can be analytically continued to a region \( \{ y : \Re(y) < \epsilon \} \) with \( \epsilon > 0 \), and
\[
F(y) = \frac{Z_{\max,0}(y) - y}{Z_{\max,0}(y)} \bar{G}(y). \quad (4.2)
\]
We introduce the following notation.
\[
\hat{\phi}_2(0, 0, z) = \phi_2(k_1 Y_{\max,0}(z), 0, z).
\]

Next, we first study the relationship between the convergence parameters of \(\phi_2(0, 0, z), \hat{\phi}_2(0, 0, z)\) and \(G(z)\). In fact, we have:

**Lemma 4.2** For the convergence parameters \(\tau_{\phi_2}, \tau_{\hat{\phi}_2}\) and \(\tau_G\) of \(\phi_2(0, 0, z), \hat{\phi}_2(0, 0, z)\) and \(G(z)\), respectively, we have
\[
\tau_G = \tau_{\phi_2} = \tau_{\hat{\phi}_2}. \tag{4.3}
\]

**Proof:** We first show
\[
\tau_{\phi_2} = \tau_{\hat{\phi}_2}. \tag{4.4}
\]

By Lemma 3.5, we just need to focus on \(z > 0\). By (2.9), we get that if \(Y_{\max,0}(z) \geq 0\), then
\[
\tau_{\phi_2} \geq \tau_{\hat{\phi}_2}; \tag{4.5}
\]
if \(Y_{\max,0}(z) < 0\), then
\[
\tau_{\phi_2} \leq \tau_{\hat{\phi}_2}, \tag{4.6}
\]
since \(L_1(u) \geq 0, L_2(u) \geq 0, z > 0\) and \(k_1 > 0\).

In order to prove (4.4), we first locate the dominant singularity \(z_{\text{dom}}\). From (3.62), we have
\[
\phi_2(0, 0, z) - \frac{\phi_2(k_1 Y_{\max,0}(z), 0, z)}{1 - k_1} \tag{4.7}
\]
\[
= z \frac{\phi_3(k_1 Y_{\max,0}(z), Y_{\max,0}(z), 0)}{(1 - k_1)(Y_{\max,0}(z) - z)} - z \frac{\phi_3(0, Y_{\max,0}(z), 0)}{(Y_{\max,0}(z) - z)} \tag{4.8}
\]
We observe from (3.10) and (3.12) that
\[
Y_{\max,0} \left( \frac{2(c_3 - \lambda_3 - c_2)}{\sigma^2_3} \right) = 0. \tag{4.9}
\]
From (3.11), (3.17) and (4.9), we get
\[
\phi_2(0, 0, \frac{2(c_3 - \lambda_3 - c_2)}{\sigma^2_3}) = \phi_3(0, 0, 0) = c_3 - \sum_{i=1}^{3} \lambda_i. \tag{4.10}
\]
Hence, from Lemma 3.6 and (4.10), we get
\[
\tau_{\phi_2} > \frac{2(c_3 - \lambda_3 - c_2)}{\sigma^2_3}. \tag{4.11}
\]
For \(z \in \left( \frac{2(c_3 - \lambda_3 - c_2)}{\sigma^2_3}, z_{\max} \right)\), one can easily get that
\[
Y_{\max,0}(z) > 0. \tag{4.12}
\]
Therefore,
\[
\tau_{\phi_2} \geq \tau_{\hat{\phi}_2}. \tag{4.13}
\]
However, from (3.71), we must have (4.4).

Next, we prove (4.3). From (3.62) and (4.4), it is obvious that
\[ \tau_{\phi_2} \leq z_{\max}. \]  
(4.14)

If \( \tau_{\phi_2} = z_{\max} \), then, from (3.71), it must be the dominant singularity of \( G(z) \). Next, we assume \( \tau_{\phi_2} \in (0, z_{\max}) \). From (2.9), (4.11) and (4.12), we have for \( \frac{2(c_3 - \lambda_3 - c_2)}{\sigma_2^2} < z < z_{\max} \)
\[ \dot{\phi}_2(0, 0, z) - \phi_2(0, Y_{\max, 0}(z), z) = \phi_2(k_1 Y_{\max, 0}(z), 0, z) - \phi_2(0, 0, z) \]
\[ = \int_{\mathbb{R}_+^3} \left( e^{k_1 Y_{\max, 0}(z) x_1} - 1 \right) e^{x_2} V_2(dx) \]
\[ \geq \int_{\mathbb{R}_+^3} \left( e^{k_1 Y_{\max, 0}(z) x_1} - 1 \right) V_2(dx) > 0. \]  
(4.15)

It is worth noting that, from Lemma 3.6, (4.4), and (4.15), we have
\[ \lim_{z \to \tau_{\phi_2}} \phi_2(0, 0, z) = \lim_{z \to \tau_{\phi_2}} \dot{\phi}_2(0, 0, z) = \infty. \]  
(4.16)

If \( \tau_{\phi_2} \) is not the dominant singularity of \( G(z) \), then \( G(z) \) is analytic around \( \tau_{\phi_2} \). So, \( G(z) \) is bounded in a neighbourhood of \( \alpha \). On the other hand, from (4.11)
\[ \dot{\phi}_2(0, 0, z) = (1 - k_1) \phi_2(0, Y_{\max, 0}(z), z) - (1 - k_1) G(z). \]

Hence,
\[ \dot{\phi}_2(0, 0, z) - \phi_2(0, Y_{\max, 0}(z), z) = -k_1 \phi_2(0, Y_{\max, 0}(z), z) - (1 - k_1) G(z). \]  
(4.17)

From the maximum modulus principle, Lemma 3.6 and (4.17), we obtain that for some region \( \{ z : 0 < |z - \alpha| \leq \epsilon \} \)
\[ \dot{\phi}_2(0, 0, z) - \phi_2(0, Y_{\max, 0}(z), z) < 0, \]  
(4.18)
since \( k_1 > 0 \). It is obvious that (4.16) contradicts to (4.18). Hence the lemma holds. \( \square \)

**Remark 4.1** From the proof of Lemma 4.2 we have the following important fact
\[ \tau_{\phi_2} \leq z_{\max}. \]  
(4.19)

Next, we study the convergence parameter \( \tau_G \).

**Lemma 4.3** If \( z^G \in (0, z_{\max}] \) is the dominant singularity of \( G(z) \), then \( G(y) \) is analytic at the point \( y^0 := Z_{\max, 0}(z^G) \).

**Proof:** From (3.22), we obtain the zero \( y^* \) of \( Z_{\max, 0}(y) \) is
\[ y^* = 2 \sum_{i=1}^{2} \frac{(c_i - \lambda_i - c_{i-1})}{\sigma_i^2 k_i^2}. \]  
(4.20)

From (3.10) and Lemma 3.1 we get
\[ Y_{\max, 0}(z_{\min}) = Y_{\max, 0}(z_{\max}) = \frac{2 \sum_{i=1}^{2} (c_i - \lambda_i - c_{i-1})}{\sum_{i=1}^{2} \sigma_i^2 k_i^2} := \tilde{y}^m. \]  
(4.21)

Combing (4.20) and (4.21), we obtain that
\[ \tilde{y}^m < y^*. \]  
(4.22)
It follows from (3.20) and (3.22) that for $y \in (0, y^*)$

$$Z_{max,0}(y) < 0.$$  \hspace{1cm} (4.23)

From (3.10), one can easily get that $Y_{max,0}(z)$ is increasing on $[\frac{2(c_3-\lambda_3-c_2)}{\sigma_3^2}, z_{max}]$. Hence

$$y^0 \leq \hat{y}^m < y^*.$$  \hspace{1cm} (4.24)

From (4.23) and (4.24), we obtain that

$$Z_{max,0}(y^0) < 0.$$  \hspace{1cm} (4.25)

Therefore $\phi_2(0, 0, z)$ is analytic at the point $z^0 := Z_{max,0}(y^0)$. From (4.11), in order to prove the lemma, we only need to show that $\phi_2(k_1y, 0, Z_{max,0}(y))$ is analytic at $y^0$. From (4.25), we must have

$$Z_{max,1}(y^0) = z^G.$$  \hspace{1cm} (4.26)

It follows from Lemma 4.2 that $\phi_2(k_1Y_{max,0}(z), 0, z)$ is analytic at $z^0$. It follows from (3.10) and (4.21) that

$$Z_{max,0}(y^0) = z^0.$$  \hspace{1cm} (4.27)

From the above arguments, we can get that the lemma holds. \hfill $\square$

The zero of $Y_{max,0}(z) - z$ is critical for us to prove Lemma 4.2. Hence, we demonstrate how to evaluate it. Let $f(z) = (Y_{max,0}(z) - z)(Y_{max,1}(z) - z)$. Then we have

$$f(z) = Y_{max,0}(z)Y_{max,1}(z) - z(Y_{max,1}(z) + Y_{max,0}(z)) + z^2.$$  \hspace{1cm} (4.28)

It follows from (3.8) and (3.10) that

$$-\frac{1}{2} \sum_{i=1}^{3} \sigma_i^2 k_i^2 f(z) = \left( -\frac{1}{2} \sum_{i=1}^{3} \sigma_i^2 k_i^2 \right) z + \frac{3}{2} \sum_{i=1}^{3} (c_i - \lambda_i - c_{i-1}) k_i z.$$  \hspace{1cm} (4.29)

Hence, the non-zero root of $Y_{max,0}(z) - z = 0$ is

$$z^* = 2 \frac{\sum_{i=1}^{3} (c_i - \lambda_i - c_{i-1}) k_i}{\sum_{i=1}^{3} \sigma_i^2 k_i^2}.$$  \hspace{1cm} (4.30)

**Lemma 4.4** If $\tau_G \in \left( \frac{2(c_3-\lambda_3-c_2)}{\sigma_3^2}, z_{max} \right)$, then $\tau_G$ is the zero $z^*$ of $Y_{max,0}(z) - z$.

**Proof:** From (3.12), we obtain that

$$G(z) = \frac{z}{Y_{max,0}(z) - z} F(Y_{max,0}(z)).$$  \hspace{1cm} (4.31)

Hence, in order to prove our result, we only need to show $F(Y_{max,0}(z))$ is analytic on $\{z : Re(z) < z^* + \epsilon\}$ with small enough $\epsilon > 0$. From (3.22), we have

$$Y_{max,0}(z^*) = z^*.$$  \hspace{1cm} (4.32)

Next, we show that

$$Y_{max,0}(z^*) \neq y^*.$$  \hspace{1cm} (4.33)

Since $Y_{max,0}(z)$ is increasing on $[\frac{2(c_3-\lambda_3-c_2)}{\sigma_3^2}, z_{max}]$, by (4.22),

$$Y_{max,0}(z^*) < y^*.$$  \hspace{1cm} (4.34)

Finally, it follows from Lemma 4.3 that $G(y)$ is analytic at the point $Y_{max,0}(z^*)$. From the above arguments and (4.2), we have the lemma. \hfill $\square$

From Lemma 4.2 and (4.11), we have:
Lemma 4.5 If the convergence parameter $\tau_{f_2}$ is less than $z_{\text{max}}$, then

$$
\tau_{f_2} = \frac{2\sum_{i=1}^{3}(c_i - \lambda_i - c_{i-1})k_i}{\sum_{i=1}^{3}\sigma_i^2k_i^2}.
$$

From Lemmas 4.2 and 4.3, we can get that $z_{\text{dom}}$ is either $z^*$ or $z_{\text{max}}$. In order to obtain tail asymptotics for the marginal $L_3$, we need to study asymptotic properties of the moment generating function $\phi_2(\cdot)$ at the point $z_{\text{dom}}$. We first present asymptotic properties of $G(\cdot)$ at the point $z_{\text{dom}}$.

Lemma 4.6 For the function $G(z)$, we have

(i) If $z_{\text{dom}} < z_{\text{max}}$, then $z_{\text{dom}}$ is a simple pole of $G(z)$, and

$$
\lim_{z \to z_{\text{dom}}} (z_{\text{dom}} - z)G(z) = \frac{2(Y_{\text{max},1}(z_{\text{dom}}) - z_{\text{dom}})F(Y_{\text{max},0}(z_{\text{dom}}))}{\sum_{i=1}^{3}\sigma_i^2k_i^2}.
$$

(ii) If $z_{\text{dom}} = z_{\text{max}} < z^*$, then $z_{\text{dom}}$ is a branch point of $G(z)$. Moreover

$$
\lim_{z \to z_{\text{dom}}} \frac{G(z_{\text{max}}) - G(z)}{\sqrt{z_{\text{dom}} - z}} = z_{\text{max}} \frac{2}{-Z''_{\text{max},1}(\tilde{y}^m)} F(\tilde{y}^m) + F'(\tilde{y}^m) z_{\text{max}} - \tilde{y}^m
$$

(iii) If $z_{\text{dom}} = z_{\text{max}} = z^*$, then $z_{\text{dom}}$ is a pole of $G(z)$, and

$$
\lim_{z \to z_{\text{dom}}} \sqrt{z_{\text{dom}} - z}G(z) = \frac{(\sum_{i=1}^{2}\sigma_i^2k_i^2)(Y_{\text{max},0}(z_{\text{max}}))^{z_{\text{max}}}}{(\sum_{i=1}^{2}\sigma_i^2k_i^2)^2(z_{\text{max}} - \tilde{y}^{\text{min}})}.
$$

Proof: We first prove case (i). From Lemma 4.4 in such a situation, $z_{\text{dom}}$ is the zero of $H_2(Y_{\text{max},0}(z), z) = Y_{\text{max},0}(z) - z$. From 4.10, we get that $Y_{\text{max},1}(z^*) - z^* \neq 0$.

From 4.27, 

$$
f(z) = \frac{2(z^* - z)z}{\sum_{i=1}^{3}\sigma_i^2k_i^2}.
$$

From 4.29 and 4.31, we obtain that

$$
G(z) = \frac{2z(Y_{\text{max},1}(z) - z)}{f(z) \sum_{i=1}^{3}\sigma_i^2k_i^2} F(Y_{\text{max},0}(z)) = \frac{2(Y_{\text{max},1}(z) - z)}{\sum_{i=1}^{3}\sigma_i^2k_i^2(z^* - z)} F(Y_{\text{max},0}(z)).
$$

(4.38) follows from (4.38), since $z_{\text{dom}} = z^*$.

Next, we prove case (ii). From Lemma 4.3 4.21 and 4.22, we get that $F(z)$ is analytic at the point $\tilde{y}^m$. Hence,

$$
F(Y_{\text{max},0}(z)) = F(\tilde{y}^m) + F'(\tilde{y}^m)(Y_{\text{max},0}(z) - \tilde{y}^m) + o(|Y_{\text{max},0}(z) - \tilde{y}^m|).
$$

(4.39) It follows from 4.29 that

$$
G(z) = \frac{z}{(Y_{\text{max},0}(z) - \tilde{y}^m + \tilde{y}^m - z)} F(Y_{\text{max},0}(z)) = \frac{z(Y_{\text{max},0}(z) - \tilde{y}^m) - (\tilde{y}^m - z)}{(Y_{\text{max},0}(z) - \tilde{y}^m + \tilde{y}^m - z)^2} F(Y_{\text{max},0}(z)).
$$

(4.40) From (4.39) and (4.40),

$$
G(z) = \frac{F(\tilde{y}^m)z(Y_{\text{max},0}(z) - \tilde{y}^m)}{(Y_{\text{max},0}(z) - \tilde{y}^m)^2 - (\tilde{y}^m - z)^2}
\frac{-(\tilde{y}^m - z)}{(Y_{\text{max},0}(z) - \tilde{y}^m + \tilde{y}^m - z)^2} F(\tilde{y}^m) + F'(\tilde{y}^m)(Y_{\text{max},0}(z) - \tilde{y}^m)
+ o(|Y_{\text{max},0}(z) - \tilde{y}^m|).
$$

(4.41)
Next, we consider the term $Y_{max,0}(z) - \tilde{y}^m$. From Lemma 3.2 and (4.22), we obtain that $Z_{max,1}(y)$ is analytic at the point $\tilde{y}^m$. Hence
\[
Z_{max,1}(y) = Z_{max,1}(\tilde{y}^m) + Z'_{max,1}(\tilde{y}^m)(y - \tilde{y}^m) + \frac{1}{2}Z''_{max,1}(\tilde{y}^m)(y - \tilde{y}^m)^2 + o(|y - \tilde{y}^m|^2). \tag{4.42}
\]
Since $Z_{max,1}(y)$ takes the maximum at the point $\tilde{y}^m$ on $[y^{min}, y^{max}]$,
\[
Z'_{max,1}(\tilde{y}^m) = 0. \tag{4.43}
\]
On the other hand, from (3.22) and (4.22),
\[
Z_{max,1}(y) - Z_{max,1}(\tilde{y}^m) < 0. \tag{4.44}
\]
From (4.42), (4.43) and (4.44),
\[
\tilde{y}^m - y = \sqrt{\frac{2(Z_{max,1}(y^m) - Z_{max,1}(y))}{-Z''_{max,1}(\tilde{y}^m)}} + o(|y - \tilde{y}^m|). \tag{4.45}
\]
Similar to (4.26), we have that for $z$ close to $z^{max}$
\[
Y_{max,0}(z) = y \text{ and } Z_{max,1}(y) = z. \tag{4.46}
\]
Combining (4.45) and (4.46), we obtain that
\[
\tilde{y}^m - Y_{max,0}(z) = (z^{max} - z)^\frac{1}{2} \sqrt{\frac{2}{-Z''_{max,1}(\tilde{y}^m)}} + o(|z - z^{max}|^{\frac{1}{2}}). \tag{4.47}
\]
From (4.41) and (4.37), we obtain that
\[
G(z) = (z^{max} - z)^\frac{1}{2} \frac{F(\tilde{y}^m)z^{max} - 2}{-\tilde{y}^m - z^{max}} \sqrt{\frac{2}{-Z''_{max,1}(\tilde{y}^m)}} + z^{max} \frac{F(\tilde{y}^m)}{\tilde{y}^m - z^{max}} \tag{4.48}
\]
Combining (4.41) and (4.47), we obtain that
\[
\lim_{z \to z^{max}} \frac{G(z) - G(z^{max})}{\sqrt{y^{max} - z}} = z^{max} \sqrt{\frac{2}{-Z''_{max,1}(\tilde{y}^m)}} \frac{F(\tilde{y}^m) + F'(\tilde{y}^m)}{z^{max} - \tilde{y}^m}. \tag{4.49}
\]
Finally, we prove case (iii). Due to Lemma 3.1, we obtain that
\[
H_2(Y_{max,0}(z^{max}), z^{max}) = 0. \tag{4.50}
\]
Hence,
\[
\sqrt{z^{max} - z} \frac{z}{Y_{max,0}(z) - z} F(Y_{max,0}(z)) = \frac{z}{H_2(Y_{max,0}(z), z) - H_2(Y_{max,0}(z^{max}), z^{max})} F(Y_{max,0}(z)). \tag{4.51}
\]
From (4.21), (4.22) and (4.50), $F(z)$ is analytic at $\hat{y}^m = Y_{max,0}(y^{max})$. Therefore,

$$
\lim_{z \to z^{max}} \sqrt{z^{max} - z} \frac{z}{Y_{max,0}(z) - z} F(Y_{max,0}(z)) = \frac{(\sum_{i=1}^{2} \sigma_i^2 k_i^2) F(Y_{max,0}(z^{max})) z^{max}}{\sqrt{(\sum_{i=1}^{2} \sigma_i^2 k_i^2) \sigma_3^2 (z^{max} - y^{min})}}. \tag{4.52}
$$

We are now in the position to obtain asymptotic properties of $\phi_2(0,0,z)$ and $\hat{\phi}_2(0,0,z)$ at the dominant singularity $z_{dom}$.

**Lemma 4.7** For the asymptotic behaviors of $\phi_2(0,0,z)$ and $\hat{\phi}_2(0,0,z)$ around the dominant singularity $z_{dom}$, we have

(i) If $z_{dom} = z^* < z^{max}$, then

$$
\lim_{z \to z^*} (z^* - z) \phi_2(0,0,z) = C_1(z^*), \tag{4.53}
$$

$$
\lim_{z \to z^*} (z^* - z) \hat{\phi}_2(0,0,z) = C_2(z^*). \tag{4.54}
$$

(ii) If $z_{dom} = z^* = z^{max}$, then

$$
\lim_{z \to z^*} \frac{\phi_2(0,0,z^*) - \phi_2(0,0,z)}{\sqrt{z^* - z}} = C_3(z^*), \tag{4.55}
$$

$$
\lim_{z \to z^*} \frac{\hat{\phi}_2(0,0,z^*) - \hat{\phi}_2(0,0,z)}{\sqrt{z^* - z}} = C_4(z^*). \tag{4.56}
$$

(iii) If $z_{dom} = z^{max} < z^*$, then

$$
\lim_{z \to z^*} \sqrt{z^* - z} \phi_2(0,0,z) = C_5(z^*), \tag{4.57}
$$

$$
\lim_{z \to z^*} \sqrt{z^* - z} \hat{\phi}_2(0,0,z) = C_6(z^*). \tag{4.58}
$$

Here $C_i(z^*), i = 1, \cdots, 6$, are non-zero constants.

**Proof:** Here, we only prove case (i), other cases can be proved in the same fashion. It follows from (4.41) that we only need focus on $z \in (2 \frac{(c_3 - \lambda_3 - c_2)}{\sigma_3}, z^{max})$. From (3.10), we get that

$$
Y_{max}(z) \geq 0 \text{ for all } z \in (2 \frac{(c_3 - \lambda_3 - c_2)}{\sigma_3}, z^{max}). \tag{4.59}
$$

Combining (2.10) and (4.50), we get

$$
\hat{\phi}_2(0,0, z) \geq \phi_2(0,0, z) \tag{4.60}
$$

for any $z \in (2 \frac{(c_3 - \lambda_3 - c_2)}{\sigma_3}, z^{max})$. If case (i) would not hold, then, from Lemmas 3.6, 4.2 and 4.6 we should have

$$
C_1(z^*) = C_2(z^*) = \infty. \tag{4.61}
$$

If $k_1 > 1$, then from (4.60) we have

$$
G(z) = \phi_2(0,0,z) + \frac{1}{k_1 - 1} \phi_2(0,0, z) \geq \frac{k_1}{k_1 - 1} \phi_2(0,0,z). \tag{4.62}
$$

From (4.61) and (4.62), we get that

$$
\lim_{z \to z^*} (z^* - z) G(z) = \infty, \tag{4.63}
$$

21
which contradicts to Lemma 4.6. On the other hand, if $0 < k_1 < 1$, then from (4.60), we have
\[ G(z) = \hat{\phi}_2(0, 0, z) + \frac{1}{k_1 - 1} \hat{\phi}_2(0, 0, z) \leq \frac{k_1}{k_1 - 1} \hat{\phi}_2(0, 0, z). \] (4.64)

Under this, it is easily to check that
\[ G(z) < 0 \text{ for } z \in \left(2 \frac{(c_3 - \lambda_3 - c_2)}{\sigma_3}, \max \right). \] (4.65)

Hence, from Lemma 4.6, we get that
\[ -\infty < \lim_{z \to z^*} (z^* - z)G(z) < 0. \] (4.66)

However, from (4.60) and (4.64), we have
\[ \lim_{z \to z^*} (z^* - z)G(z) = -\infty, \] (4.67)

which contradicts to (4.66). From above arguments, case (i) is proved.

Now we show that $C_i(z^*)$, $i = 1, 2$ are non-zero. It follows from (4.33), (4.60) and (4.62) that $C_2(z^*) \neq 0$. Now we assume that $C_1(z^*) = 0$. Then from (2.9), we have
\[ \hat{\phi}_2(0, 0, z) = \int_{\mathbb{R}_+^3} \exp \left\{ k_1 Y_{max, 0}(z) x_1 + z x_3 \right\} V_2(dx) \]
\[ < \frac{1}{2} \left( \int_{\mathbb{R}_+^3} \exp \left\{ 2k_1 Y_{max, 0}(z) x_1 \right\} V_2(dx) + \int_{\mathbb{R}_+^3} \exp \left\{ 2z x_3 \right\} V_2(dx) \right). \] (4.68)

Hence, as $z \to z^*$, from (4.68) we have
\[ C_2(z^*) < \hat{C}_2(z^*) + C_1(z^*), \] (4.69)

where
\[ \hat{C}_2(z^*) = \frac{1}{2} (z^* - z) \int_{\mathbb{R}_+^3} \exp \left\{ 2k_1 Y_{max, 0}(z) x_1 \right\} V_2(dx). \]

On the other hand, it is obvious that
\[ \frac{1}{2} \int_{\mathbb{R}_+^3} \exp \left\{ 2k_1 Y_{max, 0}(z) x_1 \right\} V_2(dx) < \frac{1}{2} \int_{\mathbb{R}_+^3} \exp \left\{ 2k_1 Y_{max, 0}(z) x_1 + 2z x_3 \right\} V_2(dx). \] (4.70)

Finally, we note that
\[ Y_{max, 0}(z) \to z, \text{ as } z \to z^*. \] (4.71)

Letting $z \to z^*$ yields
\[ \hat{C}_2(z^*) < C_2(z^*). \] (4.72)

Hence, (4.69) and (4.72) contradict to $C_1(z^*) = 0$. From above arguments, we get that $C_1(z^*) > 0$, $i = 1, 2$.

By Lemma 2.3 in order to get tail asymptotics for the marginal $L_3$, we need to focus on $\phi_2(0, 0, z)$. From asymptotic properties of $\phi_2(0, 0, z)$ obtained above, we can apply the Tauberian-like Theorem given below to transform asymptotic properties of $\phi_2(0, 0, z)$ to that of the marginal distribution $P(L_3 \leq x)$. To use the Tauberian-like theorem, we need study some properties of $\phi_2(0, 0, z)$ around the point $z_{dom}$. By Lemma 4.6, there is exactly one dominant singularity for $\phi_2(0, 0, z)$. By Lemma 4.3 there are two candidates for the dominant singularity $z_{dom}$ of $\phi_2(0, 0, z)$:
A pole, i.e., a zero of $Y_{\max,0}(z) - z$; or

branch point $z^{\max}$.

For each of these two cases, we show that the analytic condition of the unknown function satisfies the Tauberian-like theorem.

**Lemma 4.8** If $z_{\text{dom}} < z^{\max}$, then there exists an $\epsilon > 0$ such that $\phi_2(0,0,z)$ is analytic for $\text{Re}(z) < z_{\text{dom}} + \epsilon$ except for $z = z_{\text{dom}}$ and for each $a > 0$

$$\sup_{z \notin B_a(z_{\text{dom}})} \frac{1}{Y_{\max,0}(z) - z} < \infty,$$

where $B_a(z_{\text{dom}}) = \{z \in \mathbb{C} : |z - z_{\text{dom}}| < a\}$.

**Proof:** From Lemma 4.4, we see that if $z_{\text{dom}} < z^{\max}$, then $z_{\text{dom}}$ is a pole of the function $\phi_2(0,0,z)$. Hence, $\phi_2(0,0,z)$ is analytic for $\text{Re}(z) < z_{\text{dom}} + \epsilon$ except for $z = z_{\text{dom}}$. It remains to show (4.73) for each $a > 0$. In such a case, $z_{\text{dom}}$ is a pole of $\phi_2(0,0,z)$. It follows from Lemma 4.4 that $z_{\text{dom}}$ is a zero of $Y_{\max,0}(z) - z$. So

$$\sup_{z \notin B_a(z_{\text{dom}})} \frac{1}{Y_{\max,0}(z) - z} < \infty.$$  

(4.74)

From (4.32) and (4.38), we have for $\text{Re}(z) < z_{\text{dom}} + \epsilon$

$$F(Y_{\max,0}(z)) < \infty.$$  

(4.75)

Finally, we can easily get that

$$k_1 - 1 < \infty.$$  

(4.76)

Equations (4.74) to (4.76) yield (4.73). The proof is completed. □

**Lemma 4.9** If $z_{\text{dom}} = z^{\max}$, then $\phi(0,0,z)$ is analytic in $G_{\delta_0}(z^{\max})$. Moreover, for each $a > 0$,

$$\sup_{z \in G_{\delta_0}(z^{\max})} |\phi_2(0,0,z)| < \infty.$$  

Proof: We first show that $\phi_2(0,0,z)$ is analytic on $z \in G_0(z^{\max})$. It follows from Lemma 3.6 that $\phi_2(0,0,z)$ is analytic for $\text{Re}(z) < z_{\text{dom}}$. Furthermore, by (4.10), we have $z_{\text{dom}} > 0$. Hence, in order to prove the lemma, it suffices to show that $\phi_2(0,0,z)$ is analytic on $z \in G_{\delta_0}(z^{\max}) \cap \{z \in \mathbb{C} : \text{Re}(z) > 0\}$.

Since $z_{\text{dom}} = z^{\max}$, from Lemma 4.4 we must have $z^* \geq z^{\max}$. We first assume that

$$z^{\max} < z^*.$$  

(4.77)

Combing (4.22) and Lemma 4.3 we have that $F(Y_{\max,0}(z))$ is analytic at $G_{\delta_0}(z^{\max})$. Hence, from (4.29) and Corollary 3.1 we can get the lemma.

Next, we assume that $z^{\max} = z^*$. The proof of this case is the combination of the proof of Lemma 4.8 and that of the case (4.77). So, we omit the details of the proof here. □
5. Exact Tail Asymptotics for Marginal Distributions

From the arguments in the previous section, the asymptotic behavior and properties of \(\phi_2(0, 0, z)\) around the point \(z_{dom}\) have been obtained. In this section, we apply these results to get exact tail asymptotics for the marginal \(L_3\). Here, we also note that asymptotic behaviour of the marginal \(L_3\) is closely related to the two points \(z^*\) and \(z^{max}\), which are the candidates for \(z_{dom}\). In practice, we need to determine which one should be chosen as the dominant singularity \(z_{dom}\). In fact, we have the following lemma.

**Lemma 5.1** \(z^*\) exists between \((0, z^{max})\) if and only if \(Y_{max,0}(z^{max}) \geq z^{max}\).

**Proof:** If \(z^{max} = z^*\), one can easily see that the lemma holds. Next, we assume \(z^{max} \neq z^*\). From (5.10), we obtain that \(Y_{max,0}(z)\) is increasing on \((\frac{2(c_3-\lambda_3-c_2)}{\sigma_3^2}, z^{max})\]. We first assume that \(z^*\) exists in \((0, z^{max})\). Since

\[
0 < z^* = Y_{max,0}(z^*),
\]

we have

\[
z^* > \frac{2(c_3-\lambda_3-c_2)}{\sigma_3^2}.
\]

Therefore

\[
y^{max} := Y_{max,0}(z^{max}) > Y_{max,0}(z^*). \tag{5.2}
\]

On the other hand, we note that the line \(H_2(y, z) = z - y = 0\) intersects the ellipse \(H(ky, y, z) = 0\) at one point except for the point \((0, 0)^t\). From (4.28), we know that the point \((Y_{max,0}(z^*), z^*)^t\) is the other intersection point of \(H_2(y, z) = 0\) and \(H(ky, y, z) = 0\). Hence, we must have

\[
y^{max} > z^{max}. \tag{5.3}
\]

Next, we assume

\[
y^{max} > z^{max}. \tag{5.4}
\]

We prove that \(z^*\) belongs to \((0, z^{max})\). From (5.3), we obtain that the point \((y^{max}, z^{max})^t\) is above the line \(H_2(y, z) = 0\). From (3.10), we get that the point \((Y_{max,0}(\frac{2(c_3-\lambda_3-c_2)}{\sigma_3^2}, \frac{2(c_3-\lambda_3-c_2)}{\sigma_3^2})^t, z^{max})^t\) is below the line \(H_2(y, z) = 0\). On the other hand, \(Y_{max,0}(z)\) is continuous on \((\frac{2(c_3-\lambda_3-c_2)}{\sigma_3^2}, z^{max})\). By the above arguments, one can get that the lemma holds. \(\square\)

**Remark 5.1** From the proof of Lemma 5.1, we can get that if \(z^*\) exists, it is unique.

Once the dominant singularity is determined, we need to evaluate it. In fact, from Lemma 4.5, we can get \(z^*\). On the other hand, from Lemma 5.1, we can obtain the value of \(z^{max}\). Actually, we have

\[
z^{max} = \frac{c_3 - \lambda_3 - c_2}{\sigma_3^2} + \sqrt{(\sigma_1^2 + \sigma_2^2)^2(c_3 - \lambda_3 - c_2)^2 + \sigma_3^4(c_1k^2 + \sigma_2^2)((c_1 - \lambda_1)k_1 + c_2 - \lambda_2 - c_1)^2}{\sigma_3^2(\sigma_1^2k^2 + \sigma_2^2)}. \tag{5.5}
\]

After finding the values of \(z^*\) and \(z^{max}\), we can discuss the tail asymptotics of the marginal distribution. From Lemma 2.3, we can see that the asymptotic behavior of \(\phi(0, 0, z)\) is closely related to that of \(\phi_2(0, 0, z)\). So, we first state the asymptotic behaviors of \(\phi_2(0, 0, z)\). The following lemma follows from Lemmas 4.6 and 4.7.
Lemma 5.2 For the function $\phi_2(0,0,z)$, a total of three types asymptotics exist as $x$ approaches $z_{\text{dom}}$, based on the detailed properties of $z_{\text{dom}}$.

Case 1: If $z_{\text{dom}} = z^* < z_{\text{max}}$, then
\[
\lim_{z \to z_{\text{dom}}} (z_{\text{dom}} - z) \phi_2(0,0,x) = K_1(z_{\text{dom}}); \quad (5.6)
\]

Case 2: If $z_{\text{dom}} = z^* = z_{\text{max}}$, then
\[
\lim_{z \to z_{\text{dom}}} \sqrt{z_{\text{dom}} - z} \phi_2(0,0,x) = K_2(z_{\text{dom}}); \quad (5.7)
\]

Case 3: If $z_{\text{dom}} = z_{\text{max}} < z^*$, then
\[
\lim_{z \to z_{\text{dom}}} \frac{\phi_2(0,0,x) - \phi_2(0,0,z_{\text{dom}})}{\sqrt{z_{\text{dom}} - z}} = K_3(z_{\text{dom}}); \quad (5.8)
\]

where $K_i(z_{\text{dom}})$, $i = 1, 2, 3$, are non-zero constants depending on the point $z_{\text{dom}}$.

From Lemmas 2.3 and 5.2, we can easily obtain asymptotic behavior of $\phi(0,0,x)$. In fact, we have:

Lemma 5.3 For the moment generating function $\phi(0,0,x)$, a total of three types asymptotics exist as $z$ approaches to $z_{\text{dom}}$, based on the detailed property of $z_{\text{dom}}$.

Case 1: If $z_{\text{dom}} = z^* < z_{\text{max}}$, then
\[
\lim_{z \to z_{\text{dom}}} (z_{\text{dom}} - z) \phi(0,0,z) = \bar{K}_1(z_{\text{dom}}) \quad (5.9)
\]

Case 2: If $z_{\text{dom}} = z^* = z_{\text{max}}$, then
\[
\lim_{z \to z_{\text{dom}}} \sqrt{z_{\text{dom}} - z} \phi(0,0,z) = \bar{K}_2(z_{\text{dom}}) \quad (5.10)
\]

Case 3: If $z_{\text{dom}} = z_{\text{max}} < z^*$, then
\[
\lim_{z \to z_{\text{dom}}} \frac{\phi(0,0,z) - \phi(0,0,z_{\text{dom}})}{\sqrt{z_{\text{dom}} - z}} = \bar{K}_3(z_{\text{dom}}) \quad (5.11)
\]

where $\bar{K}_i(z_{\text{dom}})$, $i = 1, 2, 3$, are non-zero constants depending on $z_{\text{dom}}$.

Before we present the main result of this section, we need the following technical tool. Let $g(s)$ be the Laplace-transformation of $f(s)$, i.e.,
\[
g(s) = \int_0^\infty e^{st} f(t) dt.
\]

Then, $g(s)$ is analytic on the left half-plane. The singularities of $g(s)$ are all in the right half-plane. We have the following Tauberian-like theorem, which is due to Dai, Dawson and Zhao [3].

Theorem 5.1 Assume that $g(z)$ satisfies the following conditions:

1. The left-most singularity of $g(z)$ is $\alpha_0$ with $\alpha_0 > 0$. Furthermore, we assume that as $z \to \alpha_0$,
\[
g(z) \sim (\alpha_0 - z)^{-\lambda}
\]

for some $\lambda \in \mathbb{C} \setminus \mathbb{Z}_{\leq 0}$;

2. $g(z)$ is analytic on $\mathbb{G}_{\epsilon_0}(\alpha_0)$ for some $\epsilon_0 \in (0, \frac{\lambda}{2}]$;

3. $g(z)$ is bounded on $\mathbb{G}_{\epsilon_1}(\alpha_0)$ for some $\epsilon_1 > 0$.
Then, as \( t \to \infty \),

\[
f(t) \sim e^{-\alpha t^\lambda - 1} \frac{t^{\lambda - 1}}{\Gamma(\lambda)},
\]

where \( \Gamma(\cdot) \) is the Gamma function.

Now, we state the main result of this paper.

**Theorem 5.2** For the tail of the marginal distribution \( P(L_3 > z) = V_3(z, \infty) \), we have the following tail asymptotic properties for large \( z \):

**Case 1:** If \( z_{dom} = z^* < z_{max} \), then

\[
V_3(z, \infty) \sim C_1 e^{-z_{dom} z};
\]

**Case 2:** If \( z_{dom} = z^* = z_{max} \), then

\[
V_3(z, \infty) \sim C_2 e^{-z_{dom} z - \frac{1}{2}};
\]

**Case 3:** If \( z_{dom} = z_{max} < z^* \), then

\[
V_3(z, \infty) \sim C_3 e^{-z_{dom} z - \frac{3}{2}};
\]

where \( C_i \), \( i = 1, 2, 3 \), are non-zero constants.

**Proof:** Cases (1) and (2) are direct consequences of Lemmas 2.3, 4.8, 5.3 and Theorem 5.1.

Next, we prove case (3). From (5.11), we have

\[
\lim_{z \to z_{dom}} \sqrt{z_{dom} - z} \frac{\phi(0, 0, z) - \phi(0, 0, z_{dom})}{z_{dom} - z} = \bar{K}_3(z_{dom}).
\]  

(5.13)

From Dai and Miyazawa [5], we get that

\[
\frac{\phi(0, 0, z_{dom}) - \phi(0, 0, z)}{z_{dom} - z}
\]

is the moment generating function of the density function

\[
\tilde{f}(x) = e^{-x_{dom} x} \int_x^\infty e^{z_{dom} u} f(u) du,
\]

(5.14)

where \( f(z) \) is the density function of the marginal distribution \( P(L_3 < x) \). Therefore, from Theorem 5.1 and (5.13), we have

\[
\tilde{f}(z) \sim \bar{K}(z_{dom}) z^{-\frac{1}{2}} e^{-z_{dom} z},
\]

(5.15)

where \( \bar{K} \) is a constant depending on \( z_{dom} \).

From (5.14) and (5.15), we obtain that

\[
\int_x^\infty e^{z_{dom} u} f(u) du \sim \bar{K}(z_{dom}) x^{-\frac{1}{2}}.
\]

(5.16)

Taking derivatives at the both sides of (5.16), we obtain that

\[
f(x) \sim K_1 (z_{dom}) e^{-z_{dom} x} x^{-\frac{3}{2}};
\]

(5.17)

where \( K_1 \) is a constant. From (5.17), we conclude that case (3) holds. \( \square \)
6. Tail Behaviours of Joint Stationary Distributions

In this section, we study tail behaviours of the joint stationary distribution $\pi$ by using extreme value theory. Before we state our main result of this section, we first introduce the domain of attraction of some extreme value distribution function $G(\cdot)$.

**Definition 6.1 (Domain of Attraction)** Assume that $\{X_n = (X_n^{(1)}, \ldots, X_n^{(d)})\}$ are i.i.d. multivariate random vectors with common distribution $\tilde{F}(\cdot)$ and the marginal distributions $\tilde{F}_i(\cdot)$, $i = 1, \ldots, d$. If there exist normalizing constants $a_n(i) > 0$ and $b_n(i) \in \mathbb{R}$, $1 \leq i \leq d$, $n \geq 1$ such that as $n \to \infty$

$$\mathbb{P}\left(\frac{M_n^{(i)} - b_n^{(i)}}{a_n^{(i)}} \leq x^{(i)}, 1 \leq i \leq d\right) = \tilde{F}^n(a_n^{(1)}x^{(1)} + b_n^{(1)}, \ldots, a_n^{(d)}x^{(d)} + b_n^{(d)}) \to G(x^{(1)}, \ldots, x^{(d)}),$$

where the maximum $M_n^{(i)} = \bigvee_{k=1}^n X_k^{(i)}$ is the componentwise maxima, then we call the distribution function $G(\cdot)$ a multivariate extreme value distribution function, and $\tilde{F}$ is in the domain of attraction of $G(\cdot)$. We denote this by $\tilde{F} \in D(G)$.

For convenience, we let $F(x, y, z)$ denote the joint stationary distribution of $\{L(t)\}$ and $F_i, i = 1, 2, 3$, denote the stationary distribution of the $i$-th buffer content process. Miyazawa and Rolski \[27\] obtained exact tail asymptotics for marginal distributions $F_i, i = 1, 2$. From Dai and Miyazawa \[5\], Dai, Dawson and Zhao \[3\] and Theorem 6.2, we can easily get the following lemma.

**Lemma 6.1** For any $i \in \{1, 2, 3\}$, we have

$$1 - F_i(x) \sim C_i \exp\{-\alpha_i x\}x^{\mu_i}, \tag{6.1}$$

where $\alpha_i$ is the dominant singularity of the moment generating function of the marginal distribution $F_i$, and $\mu_i \in \{0, -\frac{1}{2}, -\frac{3}{2}\}$ is the corresponding decay rate.

From Lemma 6.1 we can get that

**Lemma 6.2** For any $i \in \{1, 2, 3\}$, we have

$$F_i(x) \in D(G_1(x)),$$

where

$$G_1(x) = \exp\{-e^{-x}\}.$$

**Proof:** It follows from (6.1) that as $x \to \infty$

$$F_i'(x) \sim \alpha_i \exp\{-\alpha_i x\}x^{\mu_i} \quad \text{and} \quad F_i''(x) \sim -\alpha_i^2 \exp\{-\alpha_i x\}x^{\mu_i}. \tag{6.2}$$

It follows from the asymptotic equivalence (6.2) that

$$\lim_{x \to \infty} \frac{F_i''(x)(1 - F_i(x))}{F_i'(x)^2} = -1. \tag{6.3}$$

Then, it follows from Proposition 1.1 in Resnick \[27\] P.40] that $F_i \in D(G_1)$. \\[27\]

In the previous section, we obtained exact tail asymptotic properties of the marginal distributions. Now, based on these results, we can study the tail dependencies of joint stationary distributions. Before we state tail dependent result for the stationary distributions $F(\cdot)$, we introduce a technical lemma.
Lemma 6.3 Suppose that \( \{X_n = (X_n^{(1)}, X_n^{(2)}, X_n^{(3)})' \}_{n \in \mathbb{N}} \) are i.i.d. random vectors in \( \mathbb{R}^3 \) with a common joint continuous distribution \( \bar{F}(\cdot) \), and the marginal distributions \( \bar{F}_i(\cdot), i = 1, 2, 3 \). Moreover, we assume that \( \bar{F}_i(\cdot), i = 1, 2, 3 \), are all in the domain of attraction of some univariate extreme value distribution \( \bar{G}_1(\cdot) \), i.e., there exist \( a_n^{(i)} \) and \( b_n^{(i)} \) such that as \( n \to \infty \)

\[
\bar{F}_i^n \left( a_n^{(i)} x + b_n^{(i)} \right) \to \bar{G}_1(x),
\]

then, the following are equivalent.

1. \( \bar{F} \) is in the domain of attraction of a product measure, that is,

\[
\bar{F}^n \left( a_n^{(i)} x^{(i)} + b_n^{(i)}, i = 1, 2, 3 \right) \to \prod_{i=1}^3 \bar{G}_1(x^{(i)}).
\]

2. For any \( 1 \leq i < j \leq 3 \),

\[
\lim_{t \to \infty} \mathbb{P} \left( X^{(i)} > t, X^{(j)} > t \right) / (1 - \bar{F}_q(t)) \to 0, \tag{6.4}
\]

where \( q \in \{i, j\} \).

By a slight modification of the proof of Proposition 5.27 in Rensick [25, P.296], we can prove the above lemma. Hence, we omit the detail here.

For the joint stationary distribution \( F \), we have the following tail dependence.

Lemma 6.4 The joint stationary distribution function \( F(\cdot) \) is asymptotically independent, that is, there exist \( a_n(\mu_i, \alpha_i) \) and \( b_n(\mu_i, \alpha_i), i = 1, 2, 3 \), such that

\[
F^n(a_n(\mu_i, \alpha_i) x^{(i)} + b_n(\mu_i, \alpha_i), i = 1, 2, 3) \to \prod_{i=1}^3 \bar{G}_1(x^{(i)}) \text{ as } n \to \infty.
\]

Proof: Without loss of generality, we assume that \( L(0) = 0 \). We prove (6.4), an equivalent statement. Here, we let \( i = 1 \) and \( j = 2 \) for simplicity. Other cases can be proved in the same fashion. We construct a new process such that the stationary tail probability is an upper bound of the stationary tail probability \( \mathbb{P}\{L \geq z\} \). Let \( \bar{X}(t) = B(t) + \Lambda t \), which is a three-dimensional Brownian motion, and

\[
\bar{Y}(t) = -[R^{-1} \bar{X}(t) \wedge R^{-1} \Lambda t].
\]

Then, from Konstantopoulos, Last and Lin [14, Proposition 1], we get that for any \( z = (z_1, z_2, z_3)' \in \mathbb{R}^3_+ \)

\[
\mathbb{P}\{L(t) \geq z\} \leq \mathbb{P}\{\bar{L}(t) \geq z\}, \tag{6.5}
\]

where the operations are performed component-wise, and

\[
\bar{L}(t) = \bar{X}(t) + R\bar{Y}(t).
\]

On the other hand, for any \( z \in \mathbb{R}^3_+ \)

\[
\mathbb{P}\{L \geq z\} = \lim_{t \to \infty} \mathbb{P}\{L(t) \geq z\} = \lim_{t \to \infty} \inf_{t \to \infty} \mathbb{P}\{L(t) \geq z\} \leq \mathbb{P}\{L(1) \geq z\} \tag{6.6}
\]

For any \( \bar{z} = (\bar{z}_1, \bar{z}_2)' \in \mathbb{R}^2_+ \), let

\[
\bar{F}_{12}(\bar{z}) = \mathbb{P}\{L_1 \geq \bar{z}_1, L_2 \geq \bar{z}_2\}.
\]

Then, from (6.6),

\[
\bar{F}_{12}(\bar{z}) \leq \mathbb{P}\{\bar{L}(1) \geq \bar{z}\}, \tag{6.7}
\]

28
where $\tilde{L}(t) = AL(t)$ with

$$A = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}.$$  

From (6.5) and (6.7), we get that

$$\bar{F}_{12}(\tilde{z}) \leq \mathbb{P}\{\hat{L}(1) \geq \tilde{z}\}.$$  

Hence, for any $\tilde{z} = (\tilde{z}_1, \tilde{z}_2)' \in \mathbb{R}_+^2$,

$$\mathbb{P}\{\hat{L}(1) \geq \tilde{z}\} \leq \mathbb{P}\{A(\hat{X}(1) - \Lambda) \geq \tilde{z}\}. \quad (6.9)$$

It is obvious that $A(\hat{X}(1) - \Lambda)$ is bivariate Gaussian vector with the correlation coefficient being less than one. On the other hand, from (6.9), we have that for large enough $z \in \mathbb{R}_+$

$$\limsup_{z \to \infty} \frac{\bar{F}_{12}(z, z)}{\bar{F}_1(z)} = 0.$$  

Finally, we get that

$$\limsup_{z \to \infty} \frac{\mathbb{P}\{\hat{L}_1(1) \geq z, \hat{L}_2(1) \geq z\}}{\mathbb{P}\{L_1 \geq z\}} \leq \limsup_{z \to \infty} \frac{\mathbb{P}\{\hat{L}(1) \geq (z, z)'\}}{\bar{F}_1(z)} = 0.$$  

where the inequality is obtained by using

$$\mathbb{P}\{\hat{L}_1(1) \geq z\}/\mathbb{P}\{L_1 \geq z\} \to 0, \text{ as } z \to \infty.$$  

From above arguments, we get that

$$\limsup_{z \to \infty} \frac{\bar{F}_{12}(z, z)}{\bar{F}_1(z)} = 0.$$  

From (6.10) and Lemma 6.3 we get the lemma. \hfill \square

Remark 6.1 For $a_i(\mu_i, \alpha_i)$ and $b_i(\mu_i, \alpha_i), \ i = 1, 2, 3$ in Lemma 6.4, we can use tail equivalence to get their explicit expressions. Since they are not the focus of this paper, we will not elaborate it here.

Now, we present the main result of this section.

Theorem 6.1 As $(x, y, z)' \to (\infty, \infty, \infty)'$,

$$\mathbb{P}\{L_1 \geq x, L_2 \geq y, L_3 \geq z\}/\left(Kx^{\mu_1}y^{\mu_2}z^{\mu_3} \exp \left\{ - (\alpha_1 x + \alpha_2 y + \alpha_3 z) \right\} \right) \to 1,$$  

where $\alpha_i$ is the dominant singularity of $L_i$, and $\mu_i \in \{0, -\frac{1}{2}, -\frac{3}{2}\}$ is the exponent corresponding to $\alpha_i$ in Lemma 6.7.

Proof: To prove this theorem, we first need a transformation. Let $\tilde{X} = (\tilde{X}_1, \tilde{X}_2, \tilde{X}_3)'$ be a random vector with the joint distribution $\tilde{F}(x, y, z)$ and marginal distributions $F_i(x), \ i = 1, 2, 3$. Then we make the following transformation:

$$X_i^* = \frac{-1}{\log (F_i(X_i))}, \text{ for } i = 1, 2, 3.$$  

(6.14)
By the transformation in (6.14), we transform each marginal $X_i$ of a random vector $X$ to a unit Fréchet variable $X_i^*$, that is,

$$\mathbb{P}\{X_i^* < x\} = \exp\{-\frac{1}{x}\} \text{ for } x \in \mathbb{R}_+.$$ 

Hence, for the trivariate extreme value distribution $G(x, y, z)$

$$G^*(x, y, z) = G\left(\left(\frac{-1}{\log G_1}\right)^{-1}(x), \left(\frac{-1}{\log G_1}\right)^{-1}(y), \left(\frac{-1}{\log G_1}\right)^{-1}(z)\right),$$

(6.15)

where $G^*(\cdot, \cdot, \cdot)$ is the joint distribution function with the common marginal Fréchet distribution $\Phi(x) = \exp\{-x^{-1}\}$. Furthermore, for the stationary random vector $L$, define

$$Y_i = \frac{1}{1 - F_i(L_i)},$$

(6.16)

where $F_i$ is the marginal distribution of $L_i$. Let $F^*(y_1, y_2, y_3)$ be the joint distribution function of $Y = (Y_1, Y_2, Y_3)'$. Then, it follows from Proposition 5.10 in Resnick [25] and Lemma 6.4 that

$$F^*(y_1, y_2, y_3) \in D(G^*(y_1, y_2, y_3)).$$

(6.17)

By (6.17), we have that for any $y = (y_1, y_2, y_3)' \in \mathbb{R}^3_+$, as $n \to \infty$

$$(F^*(ny))^n \to G^*(y).$$

(6.18)

It follows from (6.18) that

$$F^*(ny) \sim \left(G^*(y)\right)^{\frac{1}{n}}.$$ 

(6.19)

By a simple monotonicity argument, we can replace $n$ in the above equation by $t$. Then we have that as $t \to \infty$,

$$F^*(ty) \sim \left(G^*(y)\right)^{\frac{1}{t}}.$$ 

(6.20)

On the other hand, by Lemma 6.2 for any $y \in \mathbb{R}_+$

$$F_i^*(ty) \sim \left(G_i^*(y)\right)^{\frac{1}{t}}, \text{ for any } i = 1, 2, 3.$$ 

(6.21)

Combing (6.19) and (6.20), we get that as $t \to \infty$

$$F^*(ty) \sim F_1^*(ty_1) \cdot F_2^*(ty_2) \cdot F_3^*(ty_3).$$

(6.22)

Let $C(u_1, u_2, u_3)$ be the copula of the random vector $(Y_1, Y_2, Y_3)'$, i.e.,

$$C\left(F_1^*(x), F_2^*(y), F_3^*(z)\right) = F^*(x, y, z).$$

(6.23)

Furthermore, let $\hat{C}(u_1, u_2, u_3)$ be the corresponding survival copula of $C$. Then, we have (see, for example, equation (2.46) in Schmitz [26]):

$$\hat{C}(u_1, u_2, u_3) = \sum_{i=1}^3 u_i + \sum_{1 \leq i < j \leq 3} C_{i,j}(1 - u_i, 1 - u_j)$$

$$(1 - u_1, 1 - u_2, 1 - u_3) - 2.$$
For convenience, for any \((x, x_2, x_3)' \in \mathbb{R}_+^3\), let \(u_i(t) = \hat{F}^*_i(tx_i)\). Hence for any \(t \in \mathbb{R}_+\),
\[
\hat{C}(u_1(t), u_2(t), u_3(t)) = \hat{F}^*(tx_1, tx_2, tx_3),
\]
\[
C(1 - u_1(t), 1 - u_2(t), 1 - u_3(t)) = F^*(tx_1, tx_2, tx_3).
\]
Moreover, from (6.21), we get that as \(t \to \infty\)
\[
C(1 - u_1(t), 1 - u_2(t), 1 - u_3(t)) \sim (1 - u_1(t)) \cdot (1 - u_2(t)) \cdot (1 - u_3(t)),
\]
and for any \(1 \leq i < j \leq 3\)
\[
C_{i,j}(1 - u_i(t), 1 - u_j(t)) \sim (1 - u_i(t)) \cdot (1 - u_j(t)).
\]
From (6.22), (6.25) and (6.26), we get that as \(t \to \infty\)
\[
\hat{C}(u_1(t), u_2(t), u_3(t)) \sim u_1(t) \cdot u_2(t) \cdot u_3(t),
\]
which is equivalent to for any \((x, y, z)' \in \mathbb{R}_+^3\)
\[
\lim_{t \to \infty} \frac{\hat{F}^*(tx, ty, tz)}{F^*_1(tx) \cdot F^*_2(ty) \cdot F^*_3(tz)} = 1.\]
To prove our theorem, we need to show
\[
\lim_{(x, y, z)' \to (\infty, \infty, \infty)} \frac{\hat{F}^*(x, y, z)}{F^*_1(x) \cdot F^*_2(y) \cdot F^*_3(z)} = 1.\]
From (6.22), to prove (6.29), we only need to show
\[
\lim_{(u, v, w)' \to (0, 0, 0)} \frac{\hat{C}(u_1, u_2, u_3)}{u_1 u_2 u_3} = 1,
\]
where \(I = [0, 1]\). Note that
\[
\lim_{x \to 0} \frac{1 - \exp\{-x\}}{x} = 1.
\]
Hence from (6.28), we get that
\[
\lim_{t \to 0} \frac{\hat{C}(tu_1, tu_2, tu_3)}{t^3 u_1 u_2 u_3} = 1.
\]
Here we should point out that the limit (6.30) has the form of \(\frac{0}{0}\). Hence, we apply the multivariate L’hôpital’s rule (see Theorem 2.1 in Lawlor [16]) to prove it. Without much effort, we can construct a multivariate differential function \(\tilde{C}(u, v, w)\) such that
\[
\hat{C}(u_1, u_2, u_3) = \tilde{C}(u_1, u_2, u_3)\) for all \((u_1, u_2, u_3)' \in I^3\),
and
\[
\hat{C}(tu_1, tu_2, tu_3) \sim t^3 u_1 u_2 u_3, \text{ as } t \to 0.
\]
Hence we only have to
\[
\lim_{(u_1, u_2, u_3)' \to (0, 0, 0)} \frac{\hat{C}(u_1, u_2, u_3)}{u_1 u_2 u_3} = \lim_{(u_1, u_2, u_3)' \to (0, 0, 0)} \frac{\hat{C}(u_1, u_2, u_3)}{u_1 u_2 u_3} = 1.\]
Near the origin $(0, 0, 0)'$, the zero sets of both $\hat{C}(u_1, u_2, u_3)$ and $u_1u_2u_3$ consist of the hypersurfaces $u_1 = 0$, $u_2 = 0$ and $u_3 = 0$. By the multivariate Lhôpital’s rule (see Theorem 2.1 in Lawlor [16]), to prove (6.33), we need to show that for each component $E_i$ of $\mathbb{R}^3 \setminus \mathcal{C}$, where $\mathcal{C} = \{u_1 = 0\} \cup \{u_2 = 0\} \cup \{u_3 = 0\}$, we can find a vector $\vec{z}$, not tangent to $(0, 0, 0)'$ such that $D\vec{z}(u_1u_2u_3) \neq 0$ on $E_i$ and

$\lim_{(u_1, u_2, u_3) \to (0, 0, 0)'} \frac{D\vec{z}\hat{C}(u_1, u_2, u_3)}{D\vec{z}(u_1u_2u_3)} = 1$ (6.34)

For the component $E_1$ bounded by the hypersurfaces of $\mathcal{H}_i = \{(u_1, u_2, u_3)' : (u_1, u_2, u_3)' \in \mathbb{R}^3_+ \text{ and } u_i = 0\}$, $i = 1, 2, 3$, choose, say $\vec{z} = (1, 1, 1)'$, then $z$ is not tangent to any hypersurfaces $u_i = 0$, $i = 1, 2, 3$ at the point $(0, 0, 0)'$. Next, we take the limits along the direction $\vec{z} = (1, 1, 1)'$.

$\lim_{(u_1, u_2, u_3) \to (0, 0, 0)'} \frac{D\vec{z}\hat{C}(u_1, u_2, u_3)}{D\vec{z}(u_1u_2u_3)} = 1$ (6.35)

From (6.33) to (6.35) and Lawlor [16] that

$\lim_{(u, v, w) \to (0, 0, 0)'} \frac{\hat{C}(u_1, u_2, u_3)}{u_1u_2u_3} = 1$. (6.36)

Finally, it follows from (6.16) that for any $(x, y, z)' \in \mathbb{R}^3_+$,

$\mathbb{P}\{L_1 \geq x, L_2 \geq y, L_3 \geq z\} = \mathbb{P}\{F_1(L_1) \geq F_1(x), F_2(L_2) \geq F_2(y), F_3(L_3) \geq F_3(z)\}

= \mathbb{P}\{Y_1 \geq \frac{1}{1 - F_1(x)}, Y_2 \geq \frac{1}{1 - F_2(y)}, Y_3 \geq \frac{1}{1 - F_3(z)}\}

= F^*(\frac{1}{F_1(x)} \cdot \frac{1}{F_2(y)} \cdot \frac{1}{F_3(z)}).$ (6.37)

Combining (6.36) and (6.37), we get that as $(x, y, z)' \to (\infty, \infty, \infty)'$

$\mathbb{P}\{L_1 \geq x, L_2 \geq y, L_3 \geq z\}/\left(\hat{F}_1^*(\frac{1}{F_1(x)}) \cdot \hat{F}_2^*(\frac{1}{F_2(y)}) \cdot \hat{F}_3^*(\frac{1}{F_3(z)})\right) \to 1.$ (6.38)

By (6.36) and (6.37), we get that as $(x, y, z)' \to (\infty, \infty, \infty)'$

$\mathbb{P}\{L_1 \geq x, L_2 \geq y, L_3 \geq Z\}/\left(\hat{F}_1(x) \cdot \hat{F}_2(y) \cdot \hat{F}_3(z)\right) \to 1.$ (6.39)

Finally, it follows from Lemma 6.34 and (6.39) that

$\hat{F}_i(x) \sim Kx^{\alpha_i} \exp\{-\alpha_i x\}, \ i = 1, 2, 3.$ (6.40)

From (6.39) and (6.40), we get the theorem. □
7. Concluding Remarks

In the previous sections, we obtained tail asymptotic properties for $L_3$, see Theorem 5.2, and asymptotic independence for $L$, see Theorem 6.1. An immediate question is: Can we generalize our study to the model with a dimension higher than three? To answer this question, we first recall the key components in our analysis for the 3-dimensional model:

1. The fundamental form, or the functional equation satisfied by the (unknown) moment generating functions of the joint stationary distribution and boundary measures (the counterpart to the equation in (2.10)). By using Itō’s formula, such a relationship can be obtained for the $n$-dimensional model.

2. The kernel method, including analytic continuation of the unknown moment generating functions and asymptotic analysis.

This seems to be the main challenge. It is our conjecture that the counterpart analytic continuation property (to Lemma 3.7) is still there for the $n$-dimensional case. If this is true, the asymptotic analysis on the dominant singularity should prevail.

3. Based on the asymptotic analysis of the unknown moment generating functions, the same Tauberian-like Theorem will lead to the tail asymptotic properties for the boundary measures and marginal distributions, the counterpart to Theorem 5.2.

4. Furthermore, by extreme value theory and copula, similar to Theorem 6.1 asymptotic independence for joint stationary distributions can be obtained.
