\textbf{\textit{C* EXPONENTIAL LENGTH OF COMMUTATORS UNITARIES IN AH ALGEBRAS}}

CHUN GUANG LI, LIANGQING LI, AND IVÁN VELÁZQUEZ RUIZ

\textbf{Abstract.} For each unital C*-algebra $A$, we denote $cel_{CU}(A) = \sup\{cel(u) : u \in CU(A)\}$, where $cel(u)$ is the exponential length of $u$ and $CU(A)$ is the closure of the commutator subgroup of $U_0(A)$. In this paper, we prove that $cel_{CU}(A) = 2\pi$ provided that $A$ is an AH algebras with slow dimension growth whose real rank is not zero. On the other hand, we prove that $cel_{CU}(A) \leq 2\pi$ when $A$ is an AH algebra with ideal property and of no dimension growth (if we further assume $A$ is not of real rank zero, we have $cel_{CU}(A) = 2\pi$).

1. Introduction

Let $A$ be a unital $C^*$-algebra and $U(A)$ be the unitary group of $A$. We denote by $U_0(A)$ the component of $U(A)$ containing the identity. A unitary element $u \in U(A)$ belongs to $U_0(A)$ if and only if $u$ has the following form

$$u = \Pi_{j=1}^n \exp(\i h_j),$$

where $n$ is a positive integer and $h_j$ is self-adjoint for every $1 \leq j \leq n$. For $u \in U_0(A)$, the exponential rank of $u$ was defined by Phillips and Ringrose [28], and the exponential length of $u$ was defined by Ringrose [29]. We introduce the definition of $C^*$ exponential length as follows.

\textbf{Definition 1.1.} For $u \in U_0(A)$, the $C^*$ exponential length of $u$, denoted by $cel(u)$, is defined as

$$cel(u) = \inf \left\{ \sum_{j=1}^k \|h_j\| : u = \Pi_{j=1}^k \exp(\i h_j), h_j = h_j^* \right\}.$$

Define $cel(A) = \sup\{cel(u) : u \in U_0(A)\}$.

From [29], $cel(u)$ is exactly the infimum of the length of rectifiable paths from $u$ to $1_A$ in $U(A)$. Equivalently $cel(u)$ is also the infimum of the length of smooth path from $u$ to $1_A$.

Exponential rank and length have been studied extensively, (see [18, 24, 25, 26, 29, 33, 34] ) and have played important roles in the classification of $C^*$-algebras (see [6, 7, 17, 19, 20]).

Phillips [24] proved that the exponential rank of a unital purely infinite simple $C^*$-algebra is $1 + \varepsilon$ and its exponential length is $\pi$. Lin [16] proved that for any unital $C^*$-algebra $A$ of real rank zero, $u \in U_0(A)$ and $\varepsilon > 0$, there exists a self-adjoint element $h \in A$ with $\|h\| = \pi$ such that

$$\|u - \exp(\i h)\| < \varepsilon.$$
This means that $cel(u) \leq \pi$. But Phillips [26] showed that when $A$ does not have real rank zero, even for some simplest example $A = M_n(C([0,1]))$, $cel(A)$ can be $\infty$.

**Definition 1.2.** We denote by $CU(A)$ the closure of the commutator subgroup of $U_0(A)$ and we define

$$cel_{CU}(A) = \sup\{cel(u) : u \in CU(A)\}.$$ 

In the study of classification of simple amenable $C^*$-algebras, one often has to calculate the exponential length for unitaries in $CU(A)$. Pan and Wang [22] constructed a simple $AI$ algebra (inductive limit of $M_n(C([0,1]))$) $A$ such that $cel_{CU}(A) \geq 2\pi$. Applying Lin’s Lemma 4.5 in [21], the $cel_{CU}(A)$ is exactly $2\pi$.

**Definition 1.3.** An $AH$ algebra $A$ is the $C^*$-algebra inductive limit of a sequence $A = \lim(A_n, \phi_{n,n+1})$ with $A_n = \oplus_{j=1}^{t_n}P_{n,j}M_{[n,j]}(C(X_{n,j}))P_{n,j}$, where $[n,j]$ and $t_n$ are positive integers, $X_{n,j}$ are compact metrizable spaces and $P_{n,j} \in M_{[n,j]}(C(X_{n,j}))$ are projections.

By [3], one can always replace the compact metrizable space $X_{n,j}$ by finite simplicial complexes, and at the same time, replace $\phi_{n,n+1}$ by injective homomorphism (see [1] also).

In this paper, for all $AH$ inductive limits, we will always assume that $X_{n,j}$ are connected finite simplicial complexes and all connecting maps $\phi_{n,n+1}$ are injective.

In [21], Lin has obtained the following two main theorems (we rephrase the theorems in the language of $AH$ algebras):

**Theorem A** ([21], Theorem 4.6) Suppose that $A$ is a $\mathcal{Z}$-stable simple $C^*$-algebra such that $A \otimes UHF$ is an $AH$ algebra of slow dimension growth (this class includes all simple $AH$ algebras of no dimension growth and the Jiang-Su algebra $\mathcal{Z}$). Then $cel_{CU}(A) \leq 2\pi$.

**Theorem B** ([21], Theorem 5.11 and Corollary 5.12) For any unital non elementary (i.e., not isomorphic to $M_n(\mathbb{C})$) simple $AH$ algebra $B$ of slow dimension growth, there exists a unital simple $AH$ algebra $A$ of no dimension growth such that $(K_0(A), K_0(A)_+, K_1(A)) \cong (K_0(B), K_0(B)_+, K_1(B))$ and $cel_{CU}(A) > \pi$.

It is proved in [32] that for non elementary simple $AH$ algebras, the classes of no dimension growth and slow dimension growth are the same (see [6, 7, 19] also).

Our main theorem in this article is that for all (not necessary simple) $AH$ algebras $A$ with slow dimension growth, if $A$ is not of real rank zero, then $cel_{CU}(A) \geq 2\pi$. This theorem greatly generalizes and strengthens Lin’s Theorem B above. If we further assume $A$ is simple, combining with Lin’s Theorem A above, then $cel_{CU}(A) = 2\pi$. This gives the complete calculation of $cel_{CU}(A)$ for simple $AH$ algebras $A$ of slow dimension growth (note that for real rank zero case, it is already known by [16] that $cel(A) = \pi$). We will extend such calculation of $cel_{CU}(A)$ of simple $AH$ algebra $A$ to $AH$ algebras of no dimension growth with ideal property. We will also prove that $cel_{CU}(M_n(\mathcal{Z})) \geq 2\pi$ for the Jiang-Su algebra $\mathcal{Z}$. Combine with Lin’s Theorem A, we have $cel_{CU}(M_n(\mathcal{Z})) = 2\pi$.

In section 2, we will introduce some notations and some known results for preparation. In section 3, we will prove our main theorem. In section 4, we will deal with $AH$ algebras with ideal property. In section 5, we will calculate $cel_{CU}(M_n(\mathcal{Z}))$. 

2
2. Notations and some known results

Proposition 2.1 ([22], Lemma 2.5). Let $u \in C([0,1])$ be defined by $u(t) = \exp(i\alpha(t))$. Then

$$\text{cel}(u) = \min_{k \in \mathbb{Z}} \max_{t \in [0,1]} |\alpha(t) - 2k\pi|.$$ 

Proposition 2.2 ([22], Cor. 3.5). Let $H_s$ be a rectifiable path in $U(M_k(C([0,1])))$. For each $\varepsilon > 0$, there exists a piecewise smooth path $F_s$ in $U(M_k(C([0,1])))$ such that

1. $\|H_s - F_s\|_\infty < \varepsilon$, for all $s \in [0,1]$;
2. $|\text{length}_s(H_s) - \text{length}_s(F_s)| \leq \varepsilon$;
3. $F_s(t)$ has no repeated eigenvalues for any $(s, t) \in [0,1] \times [0,1]$.

Moreover, if for each $t \in [0,1]$ $H_1(t)$ has no repeated eigenvalues, then $F$ can be chosen to be such that $F_1(t) = H_1(t)$ for all $t \in [0,1]$.

Remark 2.3. In above proposition, if $H_s(0)$ and $H_s(1)$ have no repeated eigenvalues respectively, then $F$ can be chosen to satisfy that $F_s(0) = H_s(0)$ and $F_s(1) = H_s(1)$ for all $s \in [0,1]$.

Let $Y$ be a compact metric space. Let $P \in M_{k_1}(C(Y))$ be a projection with $\text{rank}(P) = k \leq k_1$. For each $y$, there exists a unitary $u_y \in M_{k_1}(\mathbb{C})$(depending on $y$) such that

$$P(y) = u_y^* \begin{bmatrix} 1 & 0 & \cdots & 0 \\ \vdots & 1 & 0 & \vdots \\ & \ddots & \ddots & \vdots \\ & & \ddots & 1 \\ & & & 0 \end{bmatrix} u_y,$$

where there are $k$ 1’s on the diagonal. If the unitary $u_y$ can be chosen to be continuous in $y$, the projection $P$ is called a trivial projection. It is well known that any projection $Q \in M_{k_1}(C(Y'))$ is locally trivial. That is, for each $y_0 \in Y$, there exists an open set $U_{y_0}$ containing $y_0$ such that $u_y$ is continuous on $U_{y_0}$. If $P$ is a trivial projection in $M_{k_1}(C(Y))$, we have

$$PM_{k_1}(C(Y))P \cong M_{k}(C(Y)).$$

Following the notions in [22], we give the following definitions.

Definition 2.4. Given a metric space $(Y, d)$, we denote

$$Y^k = Y \times Y \times \cdots \times Y.$$ 

We define an equivalent relation on $Y^k$ as follows: two elements for $(x_1, x_1, \ldots, x_k), (y_1, y_2, \ldots, y_k) \in Y^k$ are equivalent if there exists a permutation $\sigma \in S_k$ such that $x_{\sigma(i)} = y_i$ for each $1 \leq i \leq k$. We let

$$P^kY = Y^k / \sim.$$ 

The metric on $P^kY$ is defined as

$$d([x_1, x_2, \cdots, x_k], [y_1, y_2, \cdots, y_k]) = \min_{\sigma \in S_k} \max_{1 \leq j \leq k} |x_j - y_{\sigma(j)}|.$$
Let us further assume that \( Y \) is compact. Let \( F^kY = \text{Hom}(C(Y), M_k(\mathbb{C}))_1 \), the space of all unital homomorphisms from \( C(Y) \) to \( M_k(\mathbb{C}) \). Then for any \( \phi \in F^kY \), there are \( k \) points \( y_1, y_2, \cdots, y_k \) (with possible repetition) and a unitary \( u \in M_k(\mathbb{C}) \) such that

\[
\phi(f) = u \begin{bmatrix}
  f(y_1) \\
  f(y_2) \\
  \vdots \\
  f(y_k)
\end{bmatrix} u^* \quad \text{for all } f \in C(Y).
\]

Define \( Sp(\phi) \) to be the set \( \{y_1, y_2, \cdots, y_k\} \) (counting multiplicity, see [7]). Considering \( Sp(\phi) \) as a \( k \)-tuple, \( (y_1, y_2, \cdots, y_k) \), it is not uniquely determined, since the order of \( k \)-tuple is up to a choice; but as an element in \( P^kY \), it is unique. Therefore we write \( Sp(\phi) \in P^kY \). Then \( F^kY \ni \phi \mapsto Sp(\phi) \in P^kY \) gives a continuous map \( \Pi : F^kY \to P^kY \).

**Proposition 2.5** ([22], Remark 3.9). Let \( F_s \) be a path in \( U(M_k(C([0, 1]))) \) such that \( F_s(t) \) has no repeated eigenvalues for all \( (s, t) \in [0, 1] \times [0, 1] \). Let \( \Lambda : [0, 1] \times [0, 1] \to P^kS^1 \) be the eigenvalue map of \( F_s(t) \), i.e., \( \Lambda(s, t) = [x_1(s, t), x_2(s, t), \ldots, x_k(s, t)] \), where \( \{x_i(s, t)\}^{k}_{i=1} \) are eigenvalues of the matrix \( F_s(t) \). There are continuous functions \( f_1, f_2, \ldots, f_k : [0, 1] \times [0, 1] \to S^1 \) such that

\[
\Lambda(s, t) = [f_1(s, t), f_2(s, t), \ldots, f_k(s, t)].
\]

For each \( (s, t) \in [0, 1] \times [0, 1] \), there exists a unitary \( U_s(t) \) such that

\[
F_s(t) = U_s(t) \text{diag}[f_1(s, t), f_2(s, t), \ldots, f_k(s, t)] U_s(t)^*.
\]

Fix \( 1 \leq i \leq n \). For each \( (s, t) \in [0, 1] \times [0, 1] \), let \( p_i(s, t) \) be the spectral projection of \( F_s(t) \in M_n(\mathbb{C}) \) with respect to the eigenvalue \( f_i(s, t) \) (of \( F_s(t) \))—this is well defined rank one projection continuously depending on \( (s, t) \), since the continuous matrix value function \( F_s(t) \) has distinct eigenvalues. Hence \( F_s(t) = \sum_{i=1}^{k} f_i(s, t) p_i(s, t) \). Since all projections in \( M_n(C([0, 1] \times [0, 1])) \) are trivial, it is straight forward to prove that the unitary \( U_s(t) \) above can be chosen to depend on \( s \) and \( t \) continuously.

**Proposition 2.6** ([22], Lemma 3.11). Let \( F_s \) be a path in \( U(M_n(C([0, 1]))) \) and \( f^1_s(t), f^2_s(t), \cdots, f^n_s(t) \) be continuous functions such that

\[
F_s(t) = U_s(t) \text{diag}[f^1_s(t), f^2_s(t), \ldots, f^n_s(t)] U_s(t)^*;
\]

where \( U_s(t) \) are unitaries. Suppose that for any \( (s, t) \in [0, 1] \times [0, 1] \), \( f^i_s(t) \neq f^j_s(t) \) if \( i \neq j \), then

\[
\text{length}_s(F_s) \geq \max_{1 \leq i \leq n} \{\text{length}_s(f^i_s)\},
\]

where \( f^i_s \) is regarded as a path in \( U(C([0, 1])) \).

**Definition 2.7** ([2], Definition 1.1). Let \( a = a^* \in PM_n(C(X))P \), where \( X \) is path connected compact metric space. For each \( x \in X \), the eigenvalues of \( a(x) \in P(x)M_n(\mathbb{C})P_n(x) \cong M_{\text{rank}(P)}(\mathbb{C}) \) form a set of (possible repeat) \( \text{rank}(P) \) real numbers, which could be regarded as an element of \( Eg(a)(x) \in P^k\mathbb{R} \), where \( k = \text{rank}(P) \). On the other hand the topology on the space \( \mathbb{R} \) is given by the linear order on \( \mathbb{R} \) which induces a natural continuous map from \( P^k\mathbb{R} \) to \( \mathbb{R}^k \), by order the \( k \)-tuple in the increasing order; in such a way, we identify \( P^k\mathbb{R} \) as a subset of \( \mathbb{R}^k \). The map \( x \mapsto Eg(a)(x) \in P^k\mathbb{R} \subset \mathbb{R}^k \) gives \( k \) continuous maps from \( X \) to \( \mathbb{R} \).
We will call these \( k \) continuous maps the eigenvalue list \( E(a) \) of \( a \). Namely, the \textbf{eigenvalue list} of \( a \) is defined as

\[
E(a)(x) = \{h_1(x), h_2(x), \ldots, h_k(x)\},
\]

where \( h_i(x) \) is the \( i \)-th lowest eigenvalue of \( a(x) \), counted with multiplicity.

The \textbf{variation of the eigenvalues} of \( a \) is denoted by \( EV(a) \) and is defined as

\[
EV(a) = \max_{1 \leq i \leq n} \{\max_{t, s \in X} |h_i(t) - h_i(s)|\}.
\]

Here, when we use \( Eg(a) : X \to P^k \mathbb{R} \) and \( E(a) : X \to \mathbb{R}^k \), we have \( E(a) = \iota \circ Eg(a) \), where \( \iota : P^k \mathbb{R} \to \mathbb{R}^k \) is the natural inclusion.

\textbf{Remark 2.8.} (1) In this paper, we will often consider \( a \in A_+ \) with \( \|a\| \leq 1 \). Then \( Sp(a) \subset [0, 1] \). This element \( a \) naturally defines a homomorphism \( \phi : C([0, 1]) \to A \) by \( \phi(h) = a \), where \( h : [0, 1] \to [0, 1] \) is identity function: \( h(t) = t \). Let \( A = PM_n(C(X))P \) as in 2.7. Then \( E(a) \) is a map from \( X \) to \( [0, 1]^k \) (where \( k = \text{rank}(P) \) and \( Eg(a) \) is a map from \( X \) to \( P^k[0, 1] \).

(2) Let \( P, Q \in M_n(C(X)) \) be projections with \( P < Q \). An element \( a \in (PM_n(C(X))P)_+ \) can also be regarded as an element in \( QM_n(C(X))Q \). The eigenvalue list \( E_{PM_n(C(X))P}(a) \) of \( a \) as an element in \( PM_n(C(X))P \) and eigenvalue list \( E_{QM_n(C(X))Q}(a) \) of \( a \) as an element in \( QM_n(C(X))Q \) is related in the following way. Suppose \( \text{rank}(P) = k \) and \( \text{rank}(Q) = l \). If

\[
E_{PM_n(C(X))P}(a) = \{h_1(x), h_2(x), \ldots, h_k(x)\},
\]

then

\[
E_{QM_n(C(X))Q}(a) = \{0, \ldots, 0, h_1(x), h_2(x), \ldots, h_k(x)\}.
\]

In particular, this positive element \( a \) has the same eigenvalue variation no matter it is regarded as the element in which of the two algebras. (This is not true for general self-adjoint elements.) So when we discuss eigenvalue list or eigenvalue variation of a positive element \( a \) in a corner sub algebra \( PM_n(C(X))P \) of \( QM_n(C(X))Q \), we don’t need to specify in which algebras the calculation are made—that is, we will omit those \( l - k \) constant 0 functions from our eigenvalue list.

(3) As in (2), for some (not necessarily positive) self-adjoint elements \( a \in PM_n(C(X))P \subset QM_n(C(X))Q \), we can also ignore in which algebra (in the corner sub algebra \( PM_n(C(X))P \) or in the algebra \( QM_n(C(X))Q \), the calculation are made, when we calculate eigenvalue list and eigenvalue variation. The case is that none of the functions in the eigenvalue list of \( a \) are crossing over point 0, that is, they are either non-positive functions or non-negative functions. More precisely, if

\[
E_{PM_n(C(X))P}(a) = \{h_1(x), \ldots, h_i(x), h_{i+1}(x), \ldots, h_k(x)\}
\]

with \( h_i(x) \leq 0 \leq h_{i+1}(x) \) for all \( x \in X \), then

\[
E_{QM_n(C(X))Q}(a) = \{h_1(x), \ldots, h_i(x), 0, \ldots, 0, h_{i+1}(x), h_k(x)\}.
\]

In this case, we will also omit those \( l - k \) constant 0 functions from our eigenvalue list for \( E_{QM_n(C(X))Q}(a) \).
Definition 2.9. If \( A = \lim(\oplus_{j=1}^{k} P_{n,j} M_{[n,j]}(C(X_{n,j})))P_{n,j}, \phi_{n,m} \) is a unital inductive limit system with simple limit, the following slow dimension growth condition was introduced by [BDR, Math Scand]

\[
\lim_{n \to \infty} \max_{j} \left\{ \frac{\dim(X_{n,j}) + 1}{\text{rank}(P_{n,j})} \right\} = 0.
\]

For general AH inductive limit system, we will use the following slow dimension growth condition: for any summand \( A_{n}^{i} = P_{n,i} M_{[n,i]}(C(X_{n,i}))P_{n,i} \) of a fixed \( A_{n} \),

\[
\lim_{m \to \infty} \max_{i,j} \left\{ \frac{\dim(X_{m,j}) + 1}{\text{rank}(\phi_{n,m}^{ij}(1_{A_{n}^{i}}))} \right\} = 0,
\]

where \( \phi_{n,m}^{ij} \) is the partial map of \( \phi_{n,m} \) from \( A_{n}^{i} \) to \( A_{m}^{j} \). This notion of slow dimension growth condition is used in most literatures (see [3]). In particular in this definition, it is automatically true that \( \lim_{m \to \infty} \text{rank}(P_{m,j}) = \infty \).

An inductive limit system \( A = \lim(\oplus_{j=1}^{k} P_{n,j} M_{[n,j]}(C(X_{n,j})))P_{n,j}, \phi_{n,m} \) is called of no dimension growth if \( \sup_{n,j} \dim(X_{n,j}) < +\infty \). For general nonsimple inductive limit system, no dimension growth does not imply slow dimension growth, as it does not automatically imply that \( \lim_{m \to +\infty} \text{rank}(P_{m,j}) = \infty \).

We avoid to use the more general concept of slow dimension growth introduced by Gong [8] which does not imply that \( \lim_{m \to \infty} \text{rank}(P_{m,j}) = \infty \), since in this case our main theorem is not true. See Proposition 3.11.

Proposition 2.10 ([3], Corollary 1.3 and 1.4). Let \( A = \lim_{n}(A_{n}, \phi_{n,m}) \) be a C*-algebra which is the inductive limit of C*-algebras \( A_{n} \) with morphisms \( \phi_{n,m} : A_{n} \to A_{m} \). Assume that each \( A_{n} \) has the form

\[
A_{n} = \oplus_{k=1}^{k_{n}} P_{n,k} M_{[n,k]}(C(X_{n,k})))P_{n,k}
\]

where \( k_{n} \) are positive integers, \( X_{n,k} \) are connected compact Hausdorff spaces, \( [n,k] \) are positive integers and \( M_{[n,k]} \) are the C*-algebras of \( [n,k] \times [n,k] \) matrices. If \( A \) has slow dimension growth (see Corollary 1.4 of [3]) or has no dimension growth (see Corollary 1.3 of [3]), the following are equivalent:

1. \( A \) has real rank zero;
2. For any \( a \in (A_{n})_{+} \) with \( \|a\| = 1 \) and \( \varepsilon > 0 \), there exists an \( m \) such that every partial homomorphism

\[
\phi_{n,m}^{ij} : P_{i} M_{[n,i]}(C(X_{n,i}))P_{i} \to P_{j} M_{[m,j]}(C(X_{m,j}))P_{j}
\]

of \( \phi_{n,m} \) (i.e., the composition of the restriction of the map \( \phi_{n,m} \) on the \( i \)-th block of \( A_{n} \) and the quotient map from \( A_{n} \) to the \( j \)-th block of \( A_{m} \)) satisfies that

\[
\text{EV}(\phi_{n,m}^{ij}(a)) < \varepsilon.
\]

In general, (1) implies (2) is always true. Predated [3], it was proved in [2] that if \( \dim(X_{n,k}) \leq 2 \) for all \( n \) and \( k \), then (2) implies (1).

The following proposition and remark are to discuss how the eigenvalue function behaves under a homomorphism from a single block to a single block.

Proposition 2.11 ([3], Section 1.4). Let \( \phi : Q M_{l_{1}}(C(X))Q \to P M_{k_{1}}(C(Y))P \) be a unital homomorphism, where \( X, Y \) are connected finite simplicial complexes, and \( P, Q \) are projections in \( M_{l_{1}}(C(X)) \) and \( M_{k_{1}}(C(Y)) \) respectively. Assume that \( \text{rank}(P) = k \), which is
a multiple of \( \text{rank}(Q) = l \). Then for each \( y \in Y \), \( \phi(f)(y) \) only depends on the value of \( f \in QM_{l_1}(C(X))Q \) at finite many points \( x_1(y), x_2(y), \ldots, x_{k/l}(y) \), where \( x_i(y) \) may repeat. In fact, if we identify \( Q(x_i(y))M_{l_1}(C)Q(x_i(y)) \) with \( M_{l}(C) \), and still denote the image of \( f(x_i(y)) \) in \( M_{l}(C) \) by \( f(x_i(y)) \), then there is a unitary \( U_y \in M_{k_1}(C(Y)) \) such that

\[
\phi(f)(y) = P(y)U_y \begin{bmatrix}
 f(x_1(y))_{l \times l} & f(x_2(y))_{l \times l} & \cdots & f(x_{k/l}(y))_{l \times l} \\
 f(x_{k/l}(y))_{l \times l} & 0 & \cdots & 0 \\
 0 & \cdots & 0 & 0
\end{bmatrix} U_y^* P(y).
\]

Obviously, \( U_y \) depends on the identification of \( Q(x_i(y))M_{l_1}(C)Q(x_i(y)) \) and \( M_{l}(C) \).

We denote the set (with possible multiplicity) \( \{x_1(y), x_2(y), \ldots, x_{k/l}(y)\} \) by \( Sp(\phi|_y) \).

**Remark 2.12.** One can regard \( Sp(\phi|_y) := [x_1(y), x_2(y), \ldots, x_{k/l}(y)] \) as an element in \( P^{l/k}/X \). Then \( Y \ni y \mapsto Sp(\phi|_y) \in P^{l/k}(X) \) defines a map \( \phi^* : Y \to P^{l/k}X \).

Let \( X, Y, Z \) be path connected compact metric spaces, and let \( \alpha : Y \to P^kX \) and \( \beta : Z \to P^lY \) be two maps. Then \( \alpha \) naturally induces a map \( \tilde{\alpha} : P^lY \to P^{kl}X \). We will call the the map \( \tilde{\alpha} \circ \beta : Z \to P^{kl}X \) the composition of \( \alpha \) and \( \beta \) and denote it by \( \alpha \circ \beta \). Namely, if \( \alpha(y) = [\alpha_1(y), \alpha_2(y), \ldots, \alpha_k(y)] \in P^kX, \) for all \( y \in Y \) and \( \beta(z) = [\beta_1(z), \beta_2(z), \ldots, \beta_l(y)] \in P^lY, \) for all \( z \in Z, \) then \( \alpha \circ \beta \) is defined as

\[
\alpha \circ \beta(z) = [\alpha_i(\beta_j(z)) : 1 \leq i \leq k, 1 \leq j \leq l] \in P^{kl}(X) \text{ for all } z \in Z.
\]

We have the following facts:

(a) Let \( \phi : QM_{l_1}(C(X))Q \to PM_{k_1}(C(Y))P \) and \( \psi : PM_{k_1}(C(Y))P \to RM_{m_1}(Z)R \) be two unital homomorphisms, then \( (\psi \circ \phi)^* = \phi^* \circ \psi^* : Z \to P^sX \), with \( \phi^* : Y \to P^sX \) and \( \psi^* : Z \to P^tY \), where \( s = \text{rank}(P)/\text{rank}(Q) \) and \( t = \text{rank}(R)/\text{rank}(P) \).

(b) Let \( \phi : QM_n(C(X))Q \to PM_m(C(Y))P(\text{rank}(Q) = k, \text{rank}(P) = kl) \) be a unital homomorphism and let \( f \in (Q M_n(C(X))Q)s.a. \). Use the above notation, we have

\[
E_g(\phi(f)) = Eg(f) \circ \phi^* : Y \to P^{kl}\mathbb{R},
\]

(see [27]). Let us write the eigenvalue list \( E(f) : X \to \mathbb{R}^k \) (of \( f \)) as

\[
E(f)(x) = \{h_1(x) \leq h_2(x) \leq \cdots \leq h_k(x)\}
\]

with \( h_i : X \to \mathbb{R} \) being continuous functions for all \( i \). It follows that

\[
E_g(\phi(f))(y) = [(h_1 \circ \phi^*)(y), (h_2 \circ \phi^*)(y), \ldots, (h_k \circ \phi^*)(y)] \in P^{kl}\mathbb{R}.
\]

For each \( 1 \leq i \leq k \), we write the element \( (h_i \circ \phi^*)(y) \in P^l\mathbb{R} \) as element \( (g_{i,1}(y), g_{i,2}(y), \ldots, g_{i,l}(y)) \in \mathbb{R}^l \) in increasing order \( g_{i,j}(y) \leq g_{i,j+1}(y) \). Then \( g_{i,j} : Y \to [0,1] \) are continuous functions with \( \text{rang}(g_{i,j}) \subseteq \text{rang}(h_i) \). Also we have \( E_g(\phi(f))(y) = [g_{i,j}(y) : 1 \leq i \leq k, 1 \leq j \leq l] \). (Note that, in this calculation, we did not get precise order of all the eigenfunctions \( g_{i,j} \), so we use \( E_g(\phi(f))(y) \) instead of \( E(\phi(f))(y) \).)
3. Main Theorem

The following lemma and its corollary are well known and we omit the proofs.

**Lemma 3.1.** If \( u \in U_0(A) \) and \( \| u - 1_A \| < \varepsilon < 1 \), then \( \text{cel}(u) \leq \frac{\pi}{2} \varepsilon \).

**Corollary 3.2.** If \( u, v \in U_0(A) \) and \( \| u - v \| < \varepsilon < 1 \), then \( |\text{cel}(u) - \text{cel}(v)| \leq \frac{\pi}{2} \varepsilon \).

**Theorem 3.3.** Suppose \( u \in U_0(M_n(C([0, 1]))) \) have distinct eigenvalues \( \alpha_1(t), \alpha_2(t), \ldots, \alpha_n(t) \), where \( \alpha_1, \alpha_2, \ldots, \alpha_n : [0, 1] \to S^1 \) are continuous. Then

\[
\text{cel}(u) \geq \max_{1 \leq j \leq n} \text{cel}(\alpha_j).
\]

**Proof.** Arbitrarily choose a path \( H_s(\cdot) \) from \( u \) to \( 1 \). Applying Proposition 2.2, for each \( \varepsilon > 0 \), there exists \( F_s(\cdot) \) such that

1. \( \| H_s - F_s \|_\infty < \varepsilon \), for all \( s \in [0, 1] \);
2. \( |\text{length}_s(H_s) - \text{length}_s(F_s)| \leq \varepsilon \);
3. \( F_s(t) \) has no repeated eigenvalues for all \( (s, t) \in [0, 1] \times [0, 1] \).
4. \( \Lambda(F_1(t)) = [\alpha_1(t), \alpha_2(t), \ldots, \alpha_n(t)] \).

By Proposition 2.5 there exist continuous functions \( \beta_1(\cdot, \cdot), \beta_2(\cdot, \cdot), \ldots, \beta_n(\cdot, \cdot) \) such that

\[
\Lambda(F_s(t)) = [\beta_1(s, t), \beta_2(s, t), \ldots, \beta_n(s, t)].
\]

Then

\[
\Lambda(F_1(t)) = [\alpha_1(t), \alpha_2(t), \ldots, \alpha_n(t)]
\]

\[
= [\beta_1(1, t), \beta_2(1, t), \ldots, \beta_n(1, t)],
\]

and

\[
\Lambda(F_0(t)) = [\beta_1(0, t), \beta_2(0, t), \ldots, \beta_n(0, t)].
\]

For each \( 1 \leq j \leq n \), we have

\[
|\beta_j(0, t) - 1| \leq \max_{1 \leq j \leq n} |\beta_j(0, t) - 1| \leq \| F_s(\cdot) - H_s(\cdot) \| \leq \varepsilon.
\]

By Lemma 3.1 we have

\[
\text{cel}(\beta_j(0, \cdot)) \leq \frac{\pi}{2} \varepsilon, \ 1 \leq j \leq n.
\]

Hence,

\[
\text{cel}(\beta_j(1, \cdot)) \leq \text{cel}(\beta_j(0, \cdot)) + \text{length}_s(\beta_j(s, \cdot)), \ 1 \leq j \leq n.
\]

By Proposition 2.6 we have

\[
\text{length}_s(F_s) \geq \max_{1 \leq j \leq n} \{\text{length}_s(\beta_j(s, \cdot))\}.
\]

It follows that

\[
\text{length}_s(F_s) \geq \max_{1 \leq j \leq n} \{\text{cel}(\beta_j(1, \cdot))\} - \frac{\pi}{2} \varepsilon = \max_{1 \leq j \leq n} \text{cel}(\alpha_j) - \frac{\pi}{2} \varepsilon.
\]

\[\square\]

Apply the above theorem, we get the following result.
Theorem 3.4. Let $u \in M_n(C([0,1]))$ with $u(t) = \exp(iH(t))$, where the eigenvalue list of $H$

$$E(H)(t) = \{h_1(t), h_2(t), \ldots, h_n(t)\}$$

satisfies that

$$-2\pi \leq \alpha \leq h_1(t) \leq h_2(t) \leq \cdots \leq h_n(t) \leq \alpha + 2\pi,$$

for some $\alpha < 0$. Then

$$cel(u) \geq \max_{1 \leq j \leq n} cel(\exp(ih_j(t))) = \max_{1 \leq j \leq n} \min_{k \in \mathbb{Z}} |h_j(t) - 2k\pi|.$$

Proof. By Corollary 1.3 in [30], without loss of generality, we assume that

$$H(t) = diag[h_1(t), h_2(t), \cdots, h_n(t)].$$

We denote $a := \min_{t \in [0,1]} h_1(t)$.

Case 1. $\alpha < a$. For any $0 < \varepsilon < \min\{a - \alpha, 1\}$, we choose $\varepsilon_i$ such that

$$-\varepsilon < \varepsilon_1 < \varepsilon_2 < \cdots < \varepsilon_n < 0.$$

Then we have

$$\alpha < a - \varepsilon < h_1(t) + \varepsilon_1 < \cdots < h_n(t) + \varepsilon_n \leq 2\pi + \alpha.$$

We let $g_j(t) = h_j(t) + \varepsilon_j$, $G(t) = diag[h_1(t), \cdots, h_n(t)]$ and $v(t) = \exp(iG(t))$. Obviously, we have

$$\|v(t) - u(t)\| = \|\exp[iG(t)] - \exp[ih_1(t)]\| = \max_{1 \leq j \leq n} \{2|\sin(\frac{\varepsilon_j}{2})|\}$$

$$\leq \max_{1 \leq j \leq n} \{2|\varepsilon_j|\} < \varepsilon < 1.$$

By Corollary 3.2, we have

$$|cel(v(\cdot)) - cel(u(\cdot))| < \frac{\pi}{2} \varepsilon.$$ 

Notice that

$$|h_j(t) + \varepsilon_j - 2\pi k| \geq |h_j(t) - 2\pi k| - |\varepsilon_j| > |h_j(t) - 2\pi k| - \varepsilon,$$

for all $1 \leq j \leq n, k \in \mathbb{Z}$.

It follows from Theorem 3.3 and Lemma 2.1 that

$$cel(v(\cdot)) \geq \max_{1 \leq j \leq n} cel(\exp(ig_j(t)))$$

$$= \max_{1 \leq j \leq n} \min_{k \in \mathbb{Z}} \max_{t \in [0,1]} |h_j(t) + \varepsilon_j - 2\pi k|$$

$$\geq \max_{1 \leq j \leq n} \min_{k \in \mathbb{Z}} \max_{t \in [0,1]} |h_j(t) - 2\pi k| - \varepsilon.$$

Hence we have

$$cel(u(\cdot)) \geq \max_{1 \leq j \leq n} \min_{k \in \mathbb{Z}} \max_{t \in [0,1]} |h_j(t) - 2\pi k| - \varepsilon - \frac{\pi}{2} \varepsilon.$$
Case 2. \( \alpha = a \). For any \( 0 < \varepsilon < 1 \), we let \( g_j(t) = \max\{ h_j(t), \alpha + \varepsilon \} \) for \( 1 \leq j \leq n \). We also define \( G(t) = \text{diag}[g_1(t), \ldots, g_n(t)] \) and \( v(t) = \exp(iG(t)) \). Then we have
\[
\alpha < \alpha + \varepsilon \leq g_1(t) \leq \cdots \leq g_n(t) \leq 2\pi + \alpha, \text{ for all } t \in [0, 1].
\]
By the proof of Case 1, we have
\[
\text{cel}(v(\cdot)) \geq \max \min_{1 \leq j \leq n} \max_{k \in \mathbb{Z}} |g_j(t) - 2\pi k|.
\]
Since \( |g_j(t) - h_j(t)| < \varepsilon < 1 \) for all \( t \in [0, 1] \), we also have \( \|v(\cdot) - u(\cdot)\| < \varepsilon < 1 \). Applying Corollary 3.2, we have
\[
|\text{cel}(\exp(ig_j(\cdot))) - \text{cel}(\exp(ih_j(\cdot)))| < \frac{\pi}{2} \varepsilon, \text{ for all } 1 \leq j \leq n,
\]
and
\[
|\text{cel}(v(\cdot)) - \text{cel}(u(\cdot))| < \frac{\pi}{2} \varepsilon.
\]
This means that
\[
\text{cel}(\exp(ig_j(\cdot))) > \text{cel}(\exp(ih_j(\cdot))) - \frac{\pi}{2} \varepsilon, \text{ for all } 1 \leq j \leq n,
\]
and
\[
\text{cel}(u(\cdot)) > \text{cel}(v(\cdot)) - \frac{\pi}{2} \varepsilon.
\]
Hence we have
\[
\text{cel}(u(\cdot)) > \max_{1 \leq j \leq n} \text{cel}(\exp(ih_j(\cdot))) - \pi \varepsilon = \max_{1 \leq j \leq n} \max_{k \in \mathbb{Z}} |h_j(t) - 2\pi k| - \pi \varepsilon.
\]
\[\square\]

**Corollary 3.5.** Let \( X \) be a path connected compact metric space. Let \( P \in M_n(C(X)) \) be a projection with \( \text{rank}(P) = n \) and \( u \in PM_n(C(X))P \) be with \( u(x) = \exp(iH(x)) \), where the eigenvalue list of \( H \)
\[
E(H)(x) = \{h_1(x), h_2(x), \cdots, h_n(x)\}
\]
satisfies that
\[
-2\pi \leq \alpha \leq h_1(x) \leq h_2(x) \leq \cdots \leq h_n(x) \leq \alpha + 2\pi,
\]
for some \( \alpha < 0 \). Then
\[
\text{cel}(u) \geq \max_{1 \leq j \leq n} \min_{k \in \mathbb{Z}} \max_{x \in X} |h_j(x) - 2\pi k|.
\]

**Proof.** For each \( 1 \leq j \leq n \), let \( x_0 \in X \) and \( x_1 \in X \) be the minimum and maximum points of \( \{h_j(x)\}_{x \in X} \) respectively. Choose an embedding \( \iota : [0, 1] \rightarrow X \) satisfying that \( \iota(0) = x_0 \) and \( \iota(1) = x_1 \). Then
\[
\min_{k \in \mathbb{Z}} \max_{x \in X} |h_j(x) - 2\pi k| = \min_{k \in \mathbb{Z}} \max_{t \in [0, 1]} |h_j(\iota(t)) - 2\pi k|.
\]
Note that \( \text{cel}(u) \geq \text{cel}(\iota^*(u)) \), where \( \iota^* : PM_n(C(X))P \rightarrow P|_{[0,1]}M_n(C([0,1]))P|_{[0,1]} \cong M_n(C([0,1])) \) is given by \( \iota^*(f)(t) = f(\iota(t)) \). (Note that any projection in \( M_n(C([0,1])) \) is trivial, so \( P|_{[0,1]}M_n(C([0,1]))P|_{[0,1]} \cong M_n(C([0,1])) \).) Applying Theorem 3.4, we get the corollary.
\[\square\]

We shall use the following lemma and its corollary.
Lemma 3.6. Let $f_1, f_2, \ldots, f_n$ be a set of continuous functions from $X$ to $[0, 1]$, where $X$ is a connected finite simplicial complex. Let $[c, d] \subset [0, 1]$ be a non degenerated sub interval. Suppose that there exists no $1 \leq j \leq n$ such that $[c, d] \subset \text{rang}(f_j)$. Let $h_k(x)$ be the $k$-th lowest value of $\{f_1(x), f_2(x), \ldots, f_n(x)\}$ for each $1 \leq k \leq n$ and $x \in X$. Then there exists no $1 \leq k \leq n$ such that $[c, d] \subset \text{rang}(h_k)$.

Proof. If there exists some $1 \leq k \leq n$ such that $[c, d] \subset \text{rang}(h_k)$, we can choose $x, y \in X$ such that $h_k(x) = c$ and $h_k(y) = d$. Let $A = \{j : f_j(x) \leq c\}, B = \{i : f_i(y) \geq d\}$. Since $h_k(x) = c$, we have $|A| \geq k$. Similarly, from $h_k(y) = d$, we have $|B| \geq n - k + 1$. But $|A \cup B| \leq n$. There exists a $p \in A \cap B$. That is, $f_p(x) \leq c$ and $f_p(y) \geq d$. Since $f_p$ is continuous, we have $[c, d] \subset \text{rang}(f_p)$, a contradiction. □

Corollary 3.7. (a) Let $\phi : PM_n(C(X))P \to QM_n(C(Y))Q$ be a unital homomorphism, and let $a \in PM_n(C(X))P$ be a self-adjoint element such that $E(a) = (h_1, h_2, \ldots, h_{\text{rank}(P)})$ and $E(\phi(a)) = (f_1, f_2, \ldots, f_{\text{rank}(Q)})$ with $h_i : X \to \mathbb{R}$, and $f_k : Y \to [0, 1]$ being continuous functions. And let $[c, d] \subset \mathbb{R}$ be an interval. Then if there is a $k$ such that $[c, d] \subset \text{rang}(f_k)$, then there is an $i$, such that $[c, d] \subset \text{rang}(h_i)$. Consequently, $\text{EV}(\phi(a)) \leq \text{EV}(a)$.

(b) Let $p_1, p_2 \in PM_n(C(X))P$ be two orthogonal projections and $a_1 \in p_1M_n(C(X))p_1$, $a_2 \in p_2M_n(C(X))p_2$ be two self-adjoint elements. Then $\text{EV}(a_1 + a_2) \leq \max\{\text{EV}(a_1), \text{EV}(a_2)\}$.

Proof. Part(a): By 2.12 (b), there are continuous functions $\{g_{i,j} : 1 \leq i \leq \text{rank}(P), 1 \leq j \leq \text{rank}(Q)/\text{rank}(P)\}$, with $g_{i,j} : Y \to \mathbb{R}$, such that for each $y \in Y$, as elements in $P^{\text{rank}(Q)}\mathbb{R}$, $[f_1, f_2, \ldots, f_{\text{rank}(Q)}] = [g_{i,j} : 1 \leq i \leq \text{rank}(P), 1 \leq j \leq \text{rank}(Q)/\text{rank}(P)]$ and such that $\text{rang}(g_{i,j}) \subset \text{rang}(h_i)$. Then part (a) follows from Lemma 3.6.

Part (b) also follows from Lemma 3.6. □

Lemma 3.8. Let $A = \lim_{n \to \infty}(A_n, \phi_{n,n+1})$ be an AH algebra. Suppose the condition (2) of Proposition 2.10 does not hold for the inductive limit system (in the case of slow dimension growth or no dimension growth, this is equivalent to the condition that $A$ is not of real rank zero). There exists an interval $[c, d] \subset [0, 1]$, a positive integer $n$ and $x \in (A_n)_+$ with $\|x\| = 1$ such that for each $m \geq n$, $\phi_{n,m}(x)$ admits the following representation
\begin{equation}
\phi_{n,m}(x) = \{y_{k}^{m}\}_{k=1}^{k_{m}} \in A_{m} = \bigoplus_{k=1}^{k_{m}} P_{m,k}M[m,k]_{m,m}(C(X_{m,k}))P_{m,k},
\end{equation}
there exist $1 \leq k(m) \leq k_{m}, 1 \leq i(m) \leq [m, k(m)]$ such that
$[c, d] \subset \text{rang}(h_{i(m)}^{k(m)})$,
where $h_{i(m)}^{k(m)}(t)$ is the $i$-th lowest eigenvalue of $y_{k(m)}^{m}(t)$ for $1 \leq i \leq [m, k(m)]$.

Proof. Applying Lemma 2.10 there exist $\varepsilon > 0$, a positive integer $n$ and $x \in (A_n)_+$ with $\|x\| = 1$ such that for each $m \geq n$, $\phi_{n,m}(x)$ admits representation (2.1), there exists $1 \leq k(m) \leq k_{m}, 1 \leq i(m) \leq [m, k(m)]$, $t_{i(m)}, s_{i(m)} \in X_{m,k}$ such that
$|h_{i(m)}^{k(m)}(t_{i(m)}) - h_{i(m)}^{k(m)}(s_{i(m)})| \geq \varepsilon$,
where $h_{i(m)}^{k(m)}(t)$ is the $i$-th lowest eigenvalue of $y_{k(m)}^{m}(t)$ for $1 \leq i \leq [m, k(m)]$. For $m \geq n$, we denote by $r_{i(m)}^{k(m)}$ the closed interval with end points $h_{i(m)}^{k(m)}(s_{i(m)})$ and $h_{i(m)}^{k(m)}(t_{i(m)})$. We also
denote by $T_{i(m)}^{k(m)}$ the closed interval with the same middle point as $I_{i(m)}^{k(m)}$ so that

$$|T_{i(m)}^{k(m)}| = \frac{1}{2} |I_{i(m)}^{k(m)}| \geq \varepsilon / 2.$$ 

Choose a positive integer $N$ such that $\frac{2}{N} < \varepsilon$. We denote $a_p = \frac{2}{N}$ for $0 \leq p \leq N$. Since $|T_{i(m)}^{k(m)}| \geq \varepsilon / 2$ and $T_{i(m)}^{k(m)} \subset [0, 1]$ for all $m \geq n$, there exist a $0 \leq p \leq N$ and a subsequence $m_j$ such that

$$a_p \in T_{i(m_j)}^{k(m_j)}, \text{ for all } j \geq 1.$$ 

Denote $I = [a_p - \frac{\varepsilon}{4}, a_p]$ and $J = [a_p, a_p + \frac{\varepsilon}{4}]$, then $I \subset I_{i(m_j)}^{k(m_j)}$ or $J \subset I_{i(m_j)}^{k(m_j)}$ for each $j \geq 1$. Without loss of generality, we assume that $I \subset I_{i(m_j)}^{k(m_j)}$ for each $j \geq 1$. Otherwise, we shall choose a subsequence of $\{m_j\}_{j=1}^{\infty}$.

We have proved that the conclusion holds for $m_j$ for each $j \geq 1$. For $m \geq n$, there exists $j \geq 1$ such that $m_{j-1} < m \leq m_j (m_0 = n)$. We consider

$$\phi_{m,m_j}^{k(m)}: P_{m,l}M_{[m,l]}(C(X_{m,l}))P_{m,l} \to P_{m_j,k(m)}M_{[m_j,k(m)]}(C(X_{m_j,k(m)}))P_{m_j,k(m)},$$

the homomorphism which is composition of the restriction of $\phi_{m,m_j}$ on the $l$-th block of $A_m$ and the quotient map from $A_{m_j}$ to the $k(m_j)$-th block of $A_{m_j}$.

We claim that there exist $1 \leq k(m) \leq k_m$ and $1 \leq i(m) \leq [m, k(m)]$ such that

$$I \subset \text{rang}(h_{i(m)}^{k(m)}),$$

where $h_{i}^{k(m)}(t)$ is the $i$-th lowest eigenvalue of $y_{k(m)}^{m}(t)$. Otherwise, for each $1 \leq k \leq k_m$ and $1 \leq i \leq [m, k]$, $\text{rang}(h^{k})$ does not contain the interval $I$. By Corollary 3.7, we conclude that there exists no $1 \leq k \leq k_m$ and $1 \leq i \leq [m, k]$ such that

$$I \subset \text{rang}(g_{i}^{k})$$

where $g_{i}^{k}(t)$ is $i$-th lowest eigenvalue of $y_{k}^{m}(t)$. A contradiction.  

Let $\pi_j : A_m \to A_j^m$ be the projection map to the $j$-th block. In the proof of the following theorem and the rest of the paper, let us denote $\pi_j \circ \phi_{n,m}$ by $\phi_{n,m}^{-j}$ which is the homomorphism from $A_n$ to $A_j^m$.

**Theorem 3.9.** Let $A$ be a unital AH algebra of slow dimension growth condition which is not of real rank zero. Then

$$\text{cel}_{CU}(A) \geq 2\pi.$$ 

**Proof.** Since $A$ is not real rank zero, and each $A_k$ is unital, there exists $k_0$ such that for all $k \geq k_0$, $\phi_{k,\infty}(1_{A_k})A\phi_{k,\infty}(1_{A_k})$ is not real rank zero. For any $\varepsilon > 0$, choose an integer $L$ such that $2\varepsilon / L < \varepsilon$, since $A$ has slow dimension growth condition, there exist $n$ and a full projection $p \in A_n$ such that

$$L[p] < 1_{A_n} < m[p],$$

for some $m$. Also, we can assume that $\phi_{n,\infty}(1_{A_n})A\phi_{n,\infty}(1_{A_n})$ is not real rank zero. Then $\phi_{n,\infty}(p)A\phi_{n,\infty}(p)$ is stably isomorphic to $A$ and hence $\phi_{n,\infty}(p)A\phi_{n,\infty}(p) = \limn(p_m, m\phi_{n,m}(p), \phi_{n,m'})$ (by abusing the notation, we still use the $\phi_{m,m'}$ to denote the restriction of the map to the corner subalgebra $\phi_{n,m}(p)A_m\phi_{n,m}(p)$ is not of real rank zero. By Lemma 3.8, there exist an interval $[c, d] \subset [0, 1], an integer n_1 \geq n$
and a positive element $x \in (\phi_{n,n_1}(p)A_{n_1} \phi_{n,n_1}(p))_+$ with $\|x\| = 1$ such that for every $m \geq n_1$, $\phi_{n_1,m}(x)$ has the following representation

$$
\phi_{n_1,m}(x) = (y_1^m, y_2^m, \ldots, y_{k_m}^m) \in \bigoplus_{i=1}^{k_m} \phi_{n,m}^i(p)A_m^i \phi_{n,m}^i(p),
$$

where $\phi_{n_1,m} = \phi_{n_1,m} |_{\phi_{n,n_1}(p)A_{n_1} \phi_{n,n_1}(p)}$. There exist $1 \leq k(m) \leq k_m$, $1 \leq i(m) \leq [m, k(m)]$ such that

$$[c, d] \subset \text{rang}(h_{i(m)}^{k(m)}),$$

where $h_{i(m)}^{k(m)}(t)$ is the $i$-th lowest eigenvalue of $y_{k(m)}^m(t)$ for $1 \leq i \leq [m, k(m)]$.

Since $p$ is a full projection in $A_n$ and $L[p] < 1_{A_n}$, there exists a set of mutually orthogonal rank one projections $p_1, p_2, \ldots, p_L \in A_n$ such that $p_i \sim p_j \sim p$ and $\sum_{i=1}^L p_i < 1_{A_n}$. We let $q = \sum_{i=1}^L p_i$. It is easy to see that $qA_nq$ and $M_L(pA_np)$ are isomorphic. This means that $M_L(pA_np) \subset A_n$ and hence $M_L(\phi_{n,n_1}(p)A_{n_1} \phi_{n,n_1}(p)) \subset A_n$.

We define a continuous function on $[0, 1]$ as follows:

$$
\chi(t) = \begin{cases} 
0, & t \in [0, c] \\
\frac{1}{(d-c)}(x-c), & t \in [c, d] \\
1, & t \in [d, 1]
\end{cases}.
$$

(2.2)

Further, we define two continuous functions $\chi_1 : [0, 1] \rightarrow [0, \frac{1}{L}]$ and $\chi_2 : [0, 1] \rightarrow [-1 + \frac{1}{L}, 0]$ as follows

$$
\chi_1(t) = \frac{1}{L}t,
$$

and

$$
\chi_2(t) = (-1 + \frac{1}{L})t.
$$

We let

$$
h = \begin{bmatrix}
\varepsilon^{2\pi i \chi_2 \phi(x)} & 0 & \cdots & 0 \\
0 & \varepsilon^{2\pi i \chi_1 \phi(x)} & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & 0 & \varepsilon^{2\pi i \chi_1 \phi(x)}
\end{bmatrix}_{L \times L} \in \phi_{n,n_1}(q)A_{n_1} \phi_{n,n_1}(q),
$$

where $\chi(x) \in \phi_{n,n_1}(p)A_{n_1} \phi_{n,n_1}(p)$ and $\chi \circ \chi(x) \in \phi_{n,n_1}(p)A_{n_1} \phi_{n,n_1}(p)$ are functional calculus of self-adjoint element $x$, also we identify $\phi_{n,n_1}(q)A_{n_1} \phi_{n,n_1}(q) \cong M_L(\phi_{n,n_1}(p)A_{n_1} \phi_{n,n_1}(p))$.

Let $u = h \oplus (1_{A_n} - \phi_{n,n_1}(q))$. It is easy to check that $det(u(z)) = 1$ for all $z \in Sp(A_{n_1})$, furthermore we have $u \in U_0(A_{n_1})$. It follows from [27] that $u \in CU(A_{n_1})$.

We shall show that $cel(\phi_{n_1,m}(u)) \geq 2\pi(1 - \varepsilon)$, for all $m \geq n_1$. For a fixed $m \geq n_1$, we have $\phi_{n_1,m}(h) = exp(2\pi i H)$, where

$$
H = \begin{bmatrix}
\chi_2 \circ \chi(\phi_{n_1,m}(x)) & 0 & \cdots & 0 \\
0 & \chi_1 \circ \chi(\phi_{n_1,m}(x)) & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & 0 & \chi_1 \circ \chi(\phi_{n_1,m}(x))
\end{bmatrix}_{L \times L},
$$
and \( \tilde{\phi}_{n,m} = \phi|_{\phi_{n,m}(p)A_{m}\phi_{n,m}(p)} \). It follows that \( \tilde{\phi}_{n,m}(x) \in \phi_{n,m}(p)A_{m}\phi_{n,m}(p) \) and hence \( H \in M_{L}(\phi_{n,m}(p)A_{m}\phi_{n,m}(p)) = \phi_{n,m}(q)A_{m}\phi_{n,m}(q) \subset A_{m} \).

Note that \( \tilde{\phi}_{n,m}(x) = (y_{1}^{m}, y_{2}^{m}, \ldots, y_{k}^{m}) \) with each \( y_{j}^{m} \in \phi_{n,m}^{-1}(p)A_{m}\phi_{n,m}^{-1}(p) \). There exists \( 1 \leq k(m) \leq k_{m}, 1 \leq i(m) \leq [m, k(m)] \) such that

\[ [c, d] \subset \text{rang}(h_{i(m)}^{k(m)}), \]

where \( h_{i}^{k(m)}(t) \) is the \( i \)-th lowest eigenvalue of \( y_{k(m)}^{m}(t) \) for \( 1 \leq i \leq [m, k(m)] \), we have

\[ \chi_{2} \circ \chi(\tilde{\phi}_{n,m}(x)) = (\chi_{2} \circ \chi(y_{1}^{m}), \chi_{2} \circ \chi(y_{2}^{m}), \ldots, \chi_{2} \circ \chi(y_{k}^{m})) \in \bigoplus_{i=1}^{k_{m}} \phi_{n,m}^{-i}(p)A_{m}^{i}\phi_{n,m}^{-i}(p) \]

and

\[ \chi_{1} \circ \chi(\tilde{\phi}_{n,m}(x)) = (\chi_{1} \circ \chi(y_{1}^{m}), \chi_{1} \circ \chi(y_{2}^{m}), \ldots, \chi_{1} \circ \chi(y_{k}^{m})) \in \bigoplus_{i=1}^{k_{m}} \phi_{n,m}^{-i}(p)A_{m}^{i}\phi_{n,m}^{-i}(p). \]

Write \( H = (H_{1}, H_{2}, \ldots, H_{k_{m}}) \in \bigoplus_{i=1}^{k_{m}} \phi_{n,m}^{-i}(q)A_{m}^{i}\phi_{n,m}(q) \). It follows that

\[ H_{i} = \begin{bmatrix}
\chi_{2} \circ \chi(y_{i}^{m}) & 0 & \cdots & 0 \\
0 & \chi_{2} \circ \chi(y_{i}^{m}) & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & 0 & \chi_{1} \circ \chi(y_{i}^{m})
\end{bmatrix}_{L \times L}. \]

This means that

\[ \phi_{n,m}(h) = \exp(2\pi i H) = \exp(2\pi i H_{1}), \exp(2\pi i H_{2}), \ldots, \exp(2\pi i H_{k_{m}}), \]

and hence

\[ \text{cel}(\phi_{n,m}(h)) \geq \text{cel}(\exp(2\pi i H_{k}(x))), \text{ for all } 1 \leq k \leq k_{m}. \]

In particular, we have \( \text{cel}(\phi_{n,m}(h)) \geq \text{cel}(\exp(2\pi i H_{k(m)})), \) and

\[ \text{cel}(\phi_{n,m}(u)) \geq \text{cel}(\exp(2\pi i H_{k(m)}) \oplus (1_{A_{m}^{k(m)}} - \phi_{n,m}^{-k(m)}(q))). \]

Furthermore, the eigenvalue list of \( H_{k(m)} \) satisfies that

\[ -1 + \frac{1}{L} \leq \chi_{2} \circ \chi \circ h_{[m,k]}^{k(m)} \leq \chi_{2} \circ \chi \circ h_{[m,k]-1}^{k(m)} \leq \cdots \leq \chi_{2} \circ \chi \circ h_{1}^{k(m)} \]

\[ \leq \chi_{1} \circ \chi \circ h_{1}^{k(m)} \leq \chi_{1} \circ \chi \circ h_{1}^{k(m)} \leq \cdots \leq \chi_{1} \circ \chi \circ h_{1}^{k(m)} \]

\[ \leq \chi_{1} \circ \chi \circ h_{2}^{k(m)} \leq \chi_{1} \circ \chi \circ h_{2}^{k(m)} \leq \cdots \leq \chi_{1} \circ \chi \circ h_{2}^{k(m)} \]

\[ \leq \cdots \]

\[ \leq \chi_{1} \circ \chi \circ h_{[m,k]}^{k(m)} \leq \chi_{1} \circ \chi \circ h_{[m,k]}^{k(m)} \leq \cdots \leq \chi_{1} \circ \chi \circ h_{[m,k]}^{k(m)} \leq \frac{1}{L}. \]
Remark 2.8, we know that $\phi_{n,m}^{-k}(h) = \exp(2\pi i H_{k(m)})$ satisfies the condition of Corollary 3.5. Applying (3) of Remark 2.8 we know that $\phi_{n,m}^{-k}(u) = \exp(2\pi i H_{k(m)}) \oplus (1_{A_{k(m)}} - \phi_{n,m}^{-k}(q)))$ also satisfies the condition of Corollary 3.5. By the corollary, we have

$$\phi_{n,m}^{-k}(u) \geq \min_{p \in \mathbb{Z}} \max_{y \in X_{n,k(m)}} 2\pi |\chi_2 \circ h_{k(m)}^{i}(y) - p|.$$ 

Noting that $[c, d] \subset \text{rang}(h_{k(m)}^{i}) \subset [0, 1]$, by the definitions of $\chi$ and $\chi_2$, we have

$$\text{rang}(\chi_2 \circ h_{k(m)}^{i}) = [-1 + \frac{1}{L}, 0]$$

and hence

$$\min_{p \in \mathbb{Z}} \max_{y \in X_{n,k(m)}} 2\pi |\chi_2 \circ h_{k(m)}^{i}(y) - p| = (1 - \frac{1}{L})2\pi \geq 2\pi - \varepsilon.$$

\[\Box\]

Remark 3.10. Evidently, our proof also works for the case of no dimension growth provided that $\lim_{n \to \infty} \min_i \{\text{rank}(1_{A_k})\} = \infty.$

For all $k \geq 1$ and $u \in CU(M_k(C([0, 1])))$, Lin [21] prove that $\text{cel}(u) \leq 2\pi$, in fact, we have the following proposition. This proposition also tells us, we can not replace the slow dimension growth condition by Gong’s slow dimension growth condition, which does not imply that $\lim_{n \to \infty} \min_i \{\text{rank}(1_{A_k})\} = \infty.$

Proposition 3.11. $\text{cel}_{CU}(M_k(C([0, 1]))) = \frac{k-1}{k}2\pi$.

Proof. From the construction in [22], we know that $\text{cel}_{CU}(M_k(C([0, 1]))) \geq \frac{k-1}{k}2\pi$. The following proof of $\text{cel}_{CU}(M_k(C([0, 1]))) \leq \frac{k-1}{k}2\pi$ is inspired by Section 3 of [12] (see also the proof of Lemma 4.2 in [21]). Let $u \in CU(M_k(C([0, 1])))$ and $\varepsilon > 0$, using the proof of Lemma 4.2 in [21], we can find $v \in CU(M_k(C([0, 1])))$ which satisfies the following conditions.

1. $v(t) = \sum_{j=1}^{k} \exp(2\pi i h_j(t))p_j(t)$, where $h_j(t) \in C([0, 1])_{s,a}$ and $\{p_1, p_2, \ldots, p_k\}$ is a set of mutually orthogonal rank one projections,

2. $\sum_{j=1}^{k} h_j(t) = 0$ for all $t \in [0, 1]$, this ensures that $\text{det}(v(t)) = 0$ for all $t \in [0, 1]$ and hence $v \in CU(M_k(C([0, 1])))$,

3. $h_j(t) - h_l(t) \notin \mathbb{Z}$ for any $t \in [0, 1]$ when $j \neq l$, this ensures that $v(t)$ has distinct eigenvalues, further, $0 < \max_{1 \leq j \leq k} h_j(t) - \min_{1 \leq j \leq k} h_j(t) < 1$ for all $t \in [0, 1]$.

4. $|h_j(t)| < 1$ for all $t \in [0, 1]$ and $1 \leq j \leq k$.

5. $\|u - v\| < \varepsilon$.

We shall show that

$$\|h_j\| < \frac{k-1}{k}, \text{ for all } 1 \leq j \leq k.$$ 

Since $\{h_j\}_{j=1}^{k}$ satisfy condition (3), without loss of generality, we can assume that

$$h_1(t) > h_2(t) > \cdots > h_k(t), h_1(t) - h_k(t) < 1, \text{ for all } t \in [0, 1].$$
For fixed $1 \leq k_0 \leq k$ and $t \in [0, 1]$, we have
\[
0 = h_1(t) + h_2(t) + \cdots + h_{k_0}(t) + \cdots + h_k(t) > k_0 h_{k_0}(t) + (k - k_0) h_k(t) \\
> k_0 h_{k_0}(t) + (k - k_0) (h_1(t) - 1) \\
> k_0 h_{k_0}(t) + (k - k_0) (h_{k_0}(t) - 1) \\
= kh_{k_0}(t) - k + k_0,
\]
hence
\[
h_{k_0}(t) < \frac{k - k_0}{k}.
\]
On the other hand, we have
\[
0 = h_1(t) + h_2(t) + \cdots + h_{k_0}(t) + \cdots + h_k(t) < (k_0 - 1) h_1(t) + (k - k_0 + 1) h_{k_0}(t) \\
< (k_0 - 1) (1 + h_k(t)) + (k - k_0 + 1) h_{k_0}(t) \\
< (k_0 - 1) (1 + h_{k_0}(t)) + (k - k_0 + 1) h_{k_0}(t) \\
< kh_{k_0}(t) + k_0 - 1,
\]
hence
\[
h_{k_0}(t) > -\frac{k_0 - 1}{k}.
\]
It follows that
\[
\|h_{k_0}\| < \frac{k - 1}{k}.
\]
We let
\[
v_s(t) = \sum_{j=1}^{k} \exp(2\pi is_j(t)) p_j(t), \text{ for all } s \in [0, 1], t \in [0, 1].
\]
Then $v_s$ is a path with $v_0(t) = v(t)$ and $v_1(t) = 1$. Further, we have
\[
\text{length}_s(v_s) = \int_0^1 \| \frac{dv_s}{ds} \| ds \\
= \int_0^1 \| \sum_{j=1}^{k} 2\pi i h_j(t) \exp(2\pi is_j(t)) p_j(t) \| ds \\
= 2\pi \int_0^1 \max_{1 \leq j \leq k} \| h_j \| ds \\
< 2\pi \frac{k - 1}{k}.
\]
By (4) and Corollary 3.2, it follows that
\[
\text{cel}(u) \leq \text{cel}(v) + \frac{\pi}{2} \varepsilon \leq \text{length}_s(v_s) + \frac{\pi}{2} \varepsilon < 2\pi \frac{k - 1}{k} + \frac{\pi}{2} \varepsilon.
\]
As $\varepsilon$ goes to zero, we have $\text{cel}(u) \leq 2\pi \frac{k - 1}{k}$. \qed
4. Exponential Length in AH Algebras with Ideal Property

Definition 4.1. We say a C*-algebra $A$ has the ideal property, if each closed two sided ideal of $A$ is generated by the projections inside the ideal.

Evidently, all simple AH algebras and all real rank zero C*-algebras have ideal property. In this part, we shall show that $cel_{CU}(A) \leq 2\pi$ for each AH algebras with ideal property which is of no dimension growth.

As in [1], we denote by $T_{II,k}$ the 2-dimensional connected simplicial complex with $H^1(T_{II,k}) = 0$ and $H^2(T_{II,k}) = \mathbb{Z}/k\mathbb{Z}$, and we denote by $I_k$ the subalgebra of $M_k(\mathbb{C})$ consisting of functions $f$ with property $f(0) \in \mathbb{C}1_k$ and $f(1) \in \mathbb{C}1_k$. $I_k$ is called Elliott dimension drop interval algebra. As in [2], we denote by $\mathcal{HD}$ the class of algebras of direct sums of building blocks of forms $M_l(I_k)$ and $PM_n(C(X))P$, with $X$ being one of the spaces $\{pt\}$, $[0,1]$, $S^1$ and $T_{II,k}$, and with $P \in M_n(C(X))$ being a projection. We will call a C*-algebra an $\mathcal{AHD}$ algebra, if it is an inductive limit of algebras in $\mathcal{HD}$. In [10, 11], it is proved that all AH algebras with ideal property of no dimension growth are $\mathcal{AHD}$ algebras.

Lemma 4.2 ([22, Corollary 3.2]). Let $Z = \{u \in U(M_n(\mathbb{C})) : u$ has repeated eigenvalues\}. Then $Z$ is the union of finitely many submanifolds of $U(M_n(\mathbb{C}))$, all of codimension at least three.

Noting that $\dim(T_{II,k}) = 2$, by Lemma 4.2 and a standard transversal argument, we can get the following result.

Lemma 4.3. Let $u \in U(PM_n(C(T_{II,k})))P$, where $P$ is a projection in $M_n(C(T_{II,k}))$. For any $\varepsilon > 0$, there exists $v \in U(PM_n(C(T_{II,k})))P$ such that

1. $\|u - v\| \leq \varepsilon$;
2. and $Sp(v(y)) = \{\beta_1(y), \beta_2(y), \ldots \beta_k(y)\}$, where $k = rank(P)$ and $\beta_i(y) \neq \beta_j(y)$ for all $i \neq j$ and $y \in T_{II,k}$.

Recall that $F^kS^1 = Hom(C(S^1), M_k(\mathbb{C}))$ and $\Pi : F^kS^1 \rightarrow P^kS^1$ be as Defined in [24]. Let $\tilde{F}^kS^1$ be the set of homomorphism with distinct spectrum and $\tilde{\Pi}^kS^1 = \Pi(F^kS^1)$.

Lemma 4.4. $\pi_1(\tilde{F}^kS^1) = \mathbb{Z}$ is torsion free.

Proof. Note that $F^kS^1$ is homeomorphic to $U_k(\mathbb{C}) = U(k)$, and $\tilde{F}^kS^1$ corresponds to the set of all unitaries $u \in U(k)$ with distinct spectrum, which is a union of finitely many sub-manifolds of $U(k)$ of codimensions at least three. Hence $\pi_1(\tilde{F}^kS^1) = \pi_1(U(k)) = \mathbb{Z}$.

Consider the fibration map $\Pi|_{\tilde{F}^kS^1} : \tilde{F}^kS^1 \rightarrow \tilde{\Pi}^kS^1$, whose fibre is the simply connected flag manifold $U(k)/U(1) \times U(1) \times \cdots U(1)$, we get the desired result. \hfill \Box

Lemma 4.5. Let $F : T_{II,k} \rightarrow P^kS^1$ be a continuous function. Suppose

$$F(t) = [x_1(t), x_2(t), \ldots, x_k(t)],$$

and for all $t \in T_{II,k}$, $x_i(t) \neq x_j(t)$ for $i \neq j$. Then there are continuous functions $f_1, f_2, \ldots, f_k : T_{II,k} \rightarrow S^1$ such that

$$F(t) = [f_1(t), f_2(t), \ldots, f_k(t)].$$
Lemma 1.33 in [13]. □

Theorem 4.6. Let \( u \in CU(\mathcal{P}_n(\mathcal{C}(T_{II,k}))P) \), then for any \( \varepsilon > 0 \), there exists a self-adjoint element \( h \in \mathcal{P}_n(\mathcal{C}(T_{II,k}))P \) with \( \|h\| \leq 1 \) such that \( \|u - \exp(2\pi ih)\| < \varepsilon \). In particular, \( cel(u) \leq 2\pi \).

Proof. The proof is inspired by the proof of Lemma 3 of \([21]\) (see also Remark 3.11 of \([12]\)). By Lemma 4.3 and Lemma 4.5, for each \( \varepsilon > 0 \), there exists \( v \in CU(\mathcal{P}_n(\mathcal{C}(T_{II,k}))P) \) with \( \|u - v\| \leq \varepsilon \) and \( Sp(v(y)) = \{\beta_1(y), \beta_2(y), \ldots, \beta_q(y)\} \), where \( q = rank(P) \) and \( \beta_i(y) \neq \beta_j(y) \) for all \( i \neq j \) and \( y \in T_{II,k} \). Further, \( \beta_j : T_{II,k} \to S^1 \) is continuous for each \( 1 \leq j \leq q \). Also, \( v \) can be chosen in \( CU(\mathcal{P}_n(\mathcal{C}(T_{II,k}))P) \).

Arbitrarily choose a point \( y_0 \in T_{II,k} \). We can choose some real \( b_j \in \mathcal{C}(T_{II,k}) \) such that \( \beta_j(y) = \exp(2\pi i b_j(y)) \), where \( b_j(y_0) \in (-\frac{1}{2}, \frac{1}{2}] \), \( j = 1, 2, \ldots, q \). Since \( v \in CU(\mathcal{P}_n(\mathcal{C}(T_{II,k}))P) \), we have \( det(v(y)) = 1 \) for each \( y \in T_{II,k} \). Then \( \sum_{j=1}^q b_j(y_0) = m \) for some integer \( m \). Since \( b_j(y_0) \in (0, 1] \), we have \( -q < m < q \).

If \( m \geq 1 \), without loss of generality, we can assume that \( b_1(y_0) > b_2(y_0) > \cdots > b_q(y_0) \). It follows that \( b_m(y_0) > 0 \). Define \( a_j(y) = b_j(y) - 1 \), \( j = 1, 2, \ldots, m \), \( y \in T_{II,k} \) and \( a_j(y) = b_j(y) \) for \( j > m \), \( y \in T_{II,k} \).

Then

\[
\sum_{j=1}^q a_j(y_0) = 0, \quad \text{and} \quad |a_j(y_0)| < 1. \tag{4.1}
\]

Also, since \( b_j(y_0) > -\frac{1}{2} \), we have \( \min_j a_j(y_0) = b_m(y_0) - 1 \). Note that \( \max_j a_j(y_0) < b_m(y_0) \), we have

\[
\max_j a_j(y_0) - \min_j a_j(y_0) < 1. \tag{4.2}
\]

If \( m \leq -1 \), we directly assume that \( b_1(y_0) < b_2(y_0) < \cdots < b_q(y_0) \). It follows that \( b_m(y_0) < 0 \). Define \( a_j(y) = b_j(y) + 1 \) for \( j = 1, 2, \ldots, m \), \( y \in T_{II,k} \) and \( a_j(y) = b_j(y) \) for \( j > m \), \( y \in T_{II,k} \). Then (4.1) and (4.2) also hold.

Hence \( \beta_j(t) = \exp(2\pi i b_j(y)) = \exp(2\pi i a_j(y)) \) for each \( 1 \leq j \leq q \). Since \( det(v(y)) = 1 \) for all \( y \in T_{II,k} \), we have

\[
\sum_{j=1}^q a_j(y_0) \in \mathbb{Z} \quad \text{for all} \quad y \in T_{II,k}.
\]

Since \( \sum_{j=1}^q a_j \in \mathcal{C}(T_{II,k}) \) and \( T_{II,k} \) is connected, it follows that it is a constant. By (4.1), we have

\[
\sum_{j=1}^q a_j(y) = 0 \quad \text{for all} \quad y \in T_{II,k}. \tag{4.3}
\]

Since \( \beta_l(y) \neq \beta_j(y) \) for any \( l \neq j \) and \( y \in T_{II,k} \), we have

\[
a_l(y) - a_j(y) \notin \mathbb{Z} \quad \text{for all} \quad y \in T_{II,k}, l \neq j.
\]

Note that \( \max_{1 \leq j \leq q} a_j(y) - \min_{1 \leq j \leq q} a_j(y) \) is a continuous function on \( T_{II,k} \) and \( T_{II,k} \) is connected, by (4.2), we have

\[
0 < \max_j a_j(y) - \min_j a_j(y) < 1 \quad \text{for all} \quad y \in T_{II,k}. \tag{4.4}
\]
By (4.3), either \( a_j(y) = 0 \) for all \( 1 \leq j \leq q \), which is impossible, since \( a_j(y) \neq a_i(y) \) when \( j \neq l \), or, \( h_j(y) < 0 \) for some \( j \) and \( h_l(y) > 0 \) for other \( l \). By (4.4), we have

\[ |a_j(y)| < 1 \text{ for all } y \in T_{I,k}. \]

Fixed \( 1 \leq j \leq q \). For any \( y \in T_{I,k} \), let \( p_j(y) \) be the spectrum projection of \( v(y) \) with respect to the spectrum \( \exp(2\pi i a_j(y)) \), which is rank one projection continuously depending on \( y \). Then \( v(y) = \sum_{j=1}^q \exp(2\pi i a_j(y))p_j(y) \).

We let \( h \in PM_n(C(T_{I,k}))(PM_n(C(T_{I,k}))) \) be defined by \( h(y) = \sum_{j=1}^q a_j(y)p_j(y) \). Then \( \|h\| \leq 1 \) and \( v = \exp(2\pi ih) \). Consequently, \( \|u - \exp(2\pi i h)\| < \varepsilon. \)

□

Using a similar method, we can get the following result.

**Theorem 4.7.** Let \( u \in CU(PM_n(C(X))P) \), where \( X \) is one of the space \{pt\}, \([0,1]\) and \( S^1 \) and \( P \) is a projection in \( M_n(C(X)) \). Then for any \( \varepsilon > 0 \), there exists a self-adjoint element \( h \in PM_n(C(X))P \) with \( \|h\| \leq 1 \) such that \( \|u - \exp(2\pi ih)\| < \varepsilon. \) In particular, \( cel(u) \leq 2\pi. \)

Now we are going to prove the following result. Its proof is similar to Lemma 3.12 in [12].

**Theorem 4.8.** Let \( u \in CU(M_l(I_k)) \). Then for any \( \varepsilon > 0 \), there exists a self-adjoint element \( h \in M_l(I_k) \) with \( \|h\| \leq 1 \) such that \( \|u - \exp(2\pi ih)\| < \varepsilon. \) In particular, \( cel(u) \leq 2\pi. \)

**Proof.** For any \( u \in CU(M_l(I_k)) \) and \( \varepsilon > 0 \), there exists a unitary \( v \in M_l(I_k) \) such that

\[ \|u - v\| < \varepsilon, \]

where \( v \) can be written as \( v(t) = U(t)^* \exp(2\pi i H(t)) U(t), \) \( H(t) \) is a self-adjoint element in \( M_l(I_k) \) with \( \|H(t)\| \leq 2\pi. \) Then \( cel(v) \leq 2\pi. \)

□

Now we get the following result.

**Theorem 4.9.** Let \( A \) be an AH algebra with ideal property of no dimension growth. Then for any \( \varepsilon > 0 \) and any \( u \in CU(A) \), there exists a self-adjoint element \( h \) in \( A \) with \( \|h\| \leq 1 \) such that \( \|u - \exp(2\pi ih)\| < \varepsilon. \) In particular, \( cel_{CU}(A) \leq 2\pi. \)

**Proof.** We assume that \( A = \lim(A_n, \phi_{n, n+1}) \), where \( A_n \in \mathcal{HD} \) for each \( n \geq 1 \). Using Theorem 4.7 and 4.8 for each \( u \in CU(A_n) \) we have \( cel(\phi_{n,m}(u)) \leq 2\pi \) for each \( m \geq n \). Noting that \( cel(\phi_{n,\infty}(u)) = \inf_{m \geq n} cel(\phi_{n,m}(u)) \leq 2\pi, \) hence \( cel(\phi_{n,\infty}(u)) \leq 2\pi. \)

The above theorem generalize Theorem 4.6 of [21] (see Theorem A in the introduction) for the case of simple AH algebra.

The following Theorem is the main theorem of this section. This theorem is not quite a consequence of Theorem 4.9 and Theorem 4.10, since it is not assume that \( \lim_{n \to \infty} rank(P_{n,i}) = \infty \). But we assume \( A \) has ideal property.

**Theorem 4.10.** Let \( A \) be an AH algebra with ideal property of no dimension growth. If we further assume that \( A \) is not of real rank zero, then \( cel_{CU}(A) = 2\pi. \)

To prove the above result, we need the following Pasinici’s dichotomy lemma.
Proposition 4.11 ([23], Lemma 2.11). Let $A = \lim_n (A_n = \oplus_{i=1}^n P_{n,i}) M_{[n,i]}(C(X_{n,i})) P_{n,i}, \phi_{n,m}$ be an AH algebra with the ideal property and with no dimension growth condition. Then for any $n$, any finite subset $F_n \subset P_{n,i} M_{[n,i]}(C(X_{n,i})) P_{n,i} \subset A_n$, any $\varepsilon > 0$ and any positive integer $N$, there exists $m_0 > n$ such that each partial map $\phi_{n,m}^j$ with $m \geq m_0$ satisfies either:

1. $\text{rank}(\phi_{n,m}^j (P_{n,i})) \geq N(\dim X_{m,j} + 1)$,
2. there is a homomorphism

$$\psi_{n,m}^j : A_n^j \rightarrow \phi_{n,m}^j (P_{n,i}) A_m^j \phi_{n,m}^j (P_{n,i})$$

with finite dimensional image such that $\|\phi_{n,m}^j (f) - \psi_{n,m}^j (f)\| < \varepsilon$ for all $f \in F_n^i$.

Remark 4.12. Let $X, Y$ be connected finite simplicial complexes. Let $f \in PM_n(C(X)) P$ be a self-adjoint element and $\psi : PM_n(C(X)) P \rightarrow QM_m(C(Y)) Q$ be two unital homomorphisms with $\psi$ factoring through a finite dimensional algebra such that $\|\phi(f) - \psi(f)\| < \varepsilon$. Then all functions in the eigenvalue list of $\psi(f)$ are constant functions and consequently $EV(\psi(f)) = 0$. Also by Weyl inequality [31], $EV(\psi(f)) < \varepsilon$.

Proof of Theorem 4.10. Since $A$ is not real rank zero, by Proposition 2.10 (for the case of no dimension growth), there exist $\delta_0 > 0$, $N$, $x \in (A_N)_+$ with $\|x\| = 1$ and a subsequence $(A_{n_k})_{k=2}$ with $n_2 > N$ such that for each $k \geq 2$, there is a block $A_{n_k}^j$ with

$$EV(\phi_{N,n_k}^j (x)) \geq \delta_0. \quad (4.5)$$

To save notations, we can directly assume that $N = 1$ and $n_k = k$ for every $k \geq 2$.

For any $\varepsilon > 0$ and $N > \frac{4}{\varepsilon}$, by Proposition 4.11 and Remark 4.12 there exists $m_0 > 1$ such that for each block $A_{m}^j = P_{m,j} M_{[m,j]}(C(X_{m,j})) P_{m,j}$, either:

$$\text{rank}(P_{m,j}) \geq N(\dim X_{m,j} + 1),$$

or

$$EV(\phi_{1,m}^j (x)) < \delta_0.$$

We denote

$$\Lambda = \{1 \leq j \leq t_{m_0} : \text{rank}(P_{m,j}) \geq N(\dim X_{m,j} + 1)\}.$$

Let $P = \oplus_{j \in \Lambda} P_{m_0,j}^j$ and $R = \oplus_{j \in \Lambda} P_{m_0,j}^j$ and $x^j = \phi_{1,m_0}^j (x)$. Set $x_1 = \oplus_{j \in \Lambda} x^j = P \phi_{1,m_0} (P) x$ and $x_2 = \oplus_{j \notin \Lambda} x^j = R \phi_{1,m_0} (R) x$. From above, we know that $EV(x^j) < \delta_0$ for $j \notin \Lambda$. By Corollary 3.7 for any $m > m_0$ and any $j \in \{1, 2, \ldots, t_m\}$, $\phi_{m_0,m}^j (x_2) < \delta_0$. By (4.5), for each $m > m_0$, there is a $j \in \{1, 2, \ldots, t_m\}$ such that $\phi_{m_0,m}^j (x) \geq \delta_0$. Note that $\phi_{1,m_0}^j (x) = \phi_{m_0,m}^j (x_1) + \phi_{m_0,m}^j (x_2)$. By 3.7 (b), $EV(\phi_{m_0,m}^j (x_1)) \geq \delta_0$.

Hence by Proposition 2.10, $\phi_{m_0,\infty}(P) A \phi_{m_0,\infty}(P) = \lim(\phi_{m_0,m}(P) A_m \phi_{m_0,m}(P), \phi_{m,m'})$ is not real rank zero.

By Theorem 1.2 in Page 112 of [14], for each $j \in \Lambda$, there exists a set of mutually orthogonal rank one projections $p_1^{(j)}, p_2^{(j)}, \ldots, p_L^{(j)}$ with $p_l^{(j)} < P_{m_0,j}$ and $p_l^{(j)} \sim p_1^{(j)}$ for each $1 \leq l \leq L$. We let $q = \oplus_{j \in \Lambda} p_1^{(j)}$. There exists some $W \in \mathbb{N}$ such that

$$P < W[q].$$

It follows that $\phi_{m_0,\infty}(q) A \phi_{m_0,\infty}(q)$ is stably isomorphic to $\phi_{m_0,\infty}(P) A \phi_{m_0,\infty}(P)$, and hence $\phi_{m_0,\infty}(q) A \phi_{m_0,\infty}(q) = \lim(\phi_{m_0,m}(q) A_m \phi_{m_0,m}(q), \phi_{m,m'})$ is not of real rank zero. By Lemma
there exist an interval \([c, d] \subset [0, 1]\), an integer \(m_1 \geq m_0\), and \(y \in (\phi_{m_0, m_1}(q) A_{m_1} \phi_{m_0, m_1}(q))^+\) with \(\|y\| = 1\) such that for each \(m \geq m_1\), \(\tilde{\phi}_{m_1, m}(y)\) has the following representation

\[
\tilde{\phi}_{m_1, m}(y) = (z_1^m, z_2^m, \ldots, z_{k_m}^m) \in \bigoplus_{j=1}^{k_m} \phi_{m_0, m}^{-j}(q) A_{m_1}^j \phi_{m_0, m}^{-j}(q) = \phi_{m_0, m}(q) A_m \phi_{m_0, m}(q),
\]

where \(\tilde{\phi}_{m_1, m} = \phi_{m_1, m} |_{\phi_{m_0, m_1}(q) A_{m_1} \phi_{m_0, m_1}(q)}\), there exists \(1 \leq k(m) \leq k_m\), \(1 \leq i(m) \leq [m, k(m)]\) such that

\[
[c, d] \subset \text{rang}(h_{i(m)}^{k(m)}),
\]

where \(h_{i(m)}^{k(m)}\) is the \(i\)-th lowest eigenvalue of \(y_{k(m)}^m\) for \(1 \leq i \leq [m, k(m)]\).

We let \(Q = \sum_{l=1}^L \oplus_{\lambda \in A_L^{(j)}}\), then \(QA_{m_0}Q\) and \(M_L(q A_{m_0}q)\) are isomorphic. This means that \(M_L(q A_{m_0}q) \subset A_{m_0}\) and hence \(M_L(\phi_{m_0, m_1}(q) A_{m_3} \phi_{m_0, m_1}(q)) \subset A_{m_1}\).

Applying a similar proof as in Theorem 3.9, we can prove that

\[
\text{cel}_{CU}(A) \geq 2\pi.
\]

\[
\square
\]

5. Exponential length in the Jiang-Su algebra

We shall show that there exists \(u \in CU(\mathcal{Z})\) such that \(\text{cel}(u) \geq 2\pi\). First, we review the construction of the Jiang-Su algebra \(\mathcal{Z}\). We refer the readers to [13] for details. We denote by \(I[m_0, m, m_1]\) the following dimension drop algebra:

\[
\{ f \in C([0, 1], M_m) : f(0) \in M_{m_0} \otimes 1_{m/m_0}, f(1) \in 1_{m/m_1} \otimes M_{m_1}\},
\]

where \(m_0, m_1\) and \(m\) are positive integers with \(m\) divisible by both \(m_0\) and \(m_1\). If \(m_0\) and \(m_1\) are relatively prime, and \(m = m_0 m_1\), then \(I[m_0, m, m_1]\) is called a prime dimension drop algebra.

The Jiang-Su algebra is constructed as below. We let \(A_1 = I[2, 6, 3]\). Suppose that a prime dimension drop algebra \(A_m = I[p_m, d_m, q_m]\) is chosen for some \(m \geq 1\). We construct \(A_{m+1}\) and \(\phi_{m_0, m_1} : A_m \to A_{m+1}\) as follows.

Choose \(k_0^{(m)}\) and \(k_1^{(m)}\) to be the first two prime numbers that are greater than \(2d_m\). This means that

\[
k_0^{(m)} > 2p_m, \quad k_1^{(m)} > 2q_m, \quad (k_0^{(m)} p_m, k_1^{(m)} q_m) = 1.
\]

Let \(p_{m+1} = k_0^{(m)} p_m, q_{m+1} = k_1^{(m)} q_m, d_{m+1} = p_{m+1} q_{m+1}\) and \(A_{m+1} = I[p_{m+1}, d_{m+1}, q_{m+1}]\). Obviously, \(A_{m+1}\) is a prime dimension drop algebra. Denote \(k^{(m)} = k_0^{(m)} k_1^{(m)}\). Choose \(r_0^{(m)}\) such that

\[
0 < r_0^{(m)} \leq q_{m+1}, \quad q_{m+1}(k^{(m)} - r_0^{(m)}).
\]

Choose \(r_1^{(m)}\) such that

\[
0 < r_1^{(m)} \leq p_{m+1}, \quad p_{m+1}(k^{(m)} - r_1^{(m)}).
\]

Define

\[
\zeta_j^{(m)}(x) = \begin{cases} 
    x/2, & 1 \leq j \leq r_0^{(m)} \\
    1/2, & r_0^{(m)} < j \leq k^{(m)} - r_1^{(m)} \\
    (x+1)/2, & k^{(m)} - r_1^{(m)} < j \leq k^{(m)}
  \end{cases}
\]
It follows that
\[
\xi_j^{(m)}(0) = \begin{cases} 
0, & 1 \leq j \leq r_0^{(m)} \\
1/2, & r_0^{(m)} < j \leq k^{(m)} 
\end{cases}, \text{ and }
\]
\[
\xi_j^{(m)}(1) = \begin{cases} 
1/2, & 1 \leq j \leq k^{(m)} - r_1^{(m)} \\
1, & k^{(m)} - r_1^{(m)} < j \leq k^{(m)} 
\end{cases}.
\]
Obviously, we have
\[
r_0^{(m)} q_m \equiv k^{(m)} q_m = k_0^{(m)} q_{m+1} \equiv 0, \ (\text{mod} \ q_{m+1}).
\]
It follows that \(q_{m+1} | r_0^{(m)} q_m\). Notice that \(q_{m+1} | (k^{(m)} - r_0^{(m)})\), there exists a unitary \(u_0 \in M_{d_{m+1}}\) such that
\[
\rho_0(f) = u_0^* \begin{bmatrix} f(\xi_1^{(m)}(0)) & 0 & \cdots & 0 \\
0 & f(\xi_2^{(m)}(0)) & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & f(\xi_{k^{(m)}}(0)) \end{bmatrix} u_0, \text{ for all } f \in A_m,
\]
defines a morphism \(\rho_0 : A_m \rightarrow M_{p_{m+1}} \otimes 1_{q_{m+1}} \subset M_{p_{m+1}} \otimes M_{q_{m+1}}\).

On the other hand, we have
\[
p_{m+1} | r_1^{(m)} p_m, \ p_{m+1} | (k^{(m)} - r_1^{(m)}).
\]
There exists a unitary \(u_1 \in M_{d_{m+1}}\) such that
\[
\rho_1(f) = u_1^* \begin{bmatrix} f(\xi_1^{(1)}(1)) & 0 & \cdots & 0 \\
0 & f(\xi_2^{(1)}(1)) & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & f(\xi_{k^{(m)}}(1)) \end{bmatrix} u_1, \text{ for all } f \in A_m,
\]
defines a morphism \(\rho_1 : A_m \rightarrow 1_{p_{m+1}} \otimes M_{q_{m+1}} \subset M_{p_{m+1}} \otimes M_{q_{m+1}}\).

Let \(u\) be any continuous path of unitaries in \(M_{d_{m+1}}\) connecting \(u_0\) and \(u_1\) and let \(\phi_{m,m+1}\) be given as follows
\[
\phi_{m,m+1}(f) = u^* \begin{bmatrix} f \circ \xi_1^{(m)} & 0 & \cdots & 0 \\
0 & f \circ \xi_2^{(m)} & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & f \circ \xi_{k^{(m)}} \end{bmatrix} u, \text{ for all } f \in A_m.
\]

**Theorem 5.1** ([15], Proposition 2.5). Jiang-Su algebra \(\mathcal{Z}\) can be written as the limit \(\mathcal{Z} = \lim_n (A_n, \phi_{n,n+1})\), such that each connecting map \(\phi_{m,n} = \phi_n \circ \phi_{n-1} \circ \cdots \circ \phi_{m+1} \circ \phi_m\) has the following form:
\[
\phi_{m,n}(f) = U^* \begin{bmatrix} f \circ \xi_1 & 0 & \cdots & 0 \\
0 & f \circ \xi_2 & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & f \circ \xi_k \end{bmatrix} U,
\]
where \(U\) is a continuous path in \(U(M_{d_{n}})\), \(k = k_1^{(n)} k_1^{(n+1)} \cdots k_1^{(n-2)}\) and
\[
\xi_1 \leq \xi_2 \leq \cdots \leq \xi_k \leq \xi_k.
\]
Proof. For any $0 < \varepsilon < 1$, we can find $\delta > 0$ such that $\|u_s(t_1) - u_s(t_2)\| < \frac{\varepsilon}{2}$ and $\frac{du_s}{ds}(t_1) - \frac{du_s}{ds}(t_2)\| < \frac{\varepsilon}{4}$ for any $s \in [0, 1]$ and $t_1, t_2 \in [0, 1]$ with $|s_1 - s_2| < \delta$.

Since $u_s \in A_n$, then we can write $u_s(0) = u_s(0) = \gamma^{(0)}(0) \otimes 1_{q_0}$, where $\gamma^{(0)}$ is a unitary in $C([0, 1], M_{q_0})$. By Lemma 4.1 in [21], we can find a set of mutually orthogonal rank one projections $\{a_j\}_{j=1}^{p_n}$ in $C([0, 1], M_{q_0})$ and $h_j \in C([0, 1])$ s.a., with $\exp(2\pi i h_j(s)) \neq \exp(2\pi i h_k(s))$ for each $j \neq k$ and $s \in [0, 1]$ such that

$$\|\gamma^{(0)}(s) - \gamma^{(0)}(s)\| < \frac{\varepsilon}{6(1 + \max_{s \in [0, 1]} \|\frac{du_s}{ds}\|)} \left|\frac{d\gamma^{(0)}(s)}{ds} - \frac{d\gamma^{(0)}(s)}{ds}\right| < \frac{\varepsilon}{3}, \text{ for all } s \in [0, 1],$$

where $\gamma^{(0)}(s) = \exp(2\pi i \sum_{j=1}^{p_n} h_j a_j)$.

On the other hand, we can write $u_s(1) = u_s(1) = \gamma^{(1)}(1) \otimes 1_{p_n}$, where $\gamma^{(1)}$ is a unitary in $C([0, 1], M_{p_n})$. By Lemma 4.1 in [21], we can find a set of mutually orthogonal rank one projections $\{b_j\}_{j=1}^{q_n}$ in $C([0, 1], M_{q_0})$ and $g_j \in C([0, 1])$ s.a., with $\exp(2\pi i g_j(s)) \neq \exp(2\pi i g_k(s))$ for each $j \neq k$ and $s \in [0, 1]$ such that

$$\|\gamma^{(1)}(s) - \gamma^{(1)}(s)\| < \frac{\varepsilon}{6(1 + \max_{s \in [0, 1]} \|\frac{du_s}{ds}\|)} \left|\frac{d\gamma^{(1)}(s)}{ds} - \frac{d\gamma^{(1)}(s)}{ds}\right| < \frac{\varepsilon}{3}, \text{ for all } s \in [0, 1],$$

In fact, each $\xi_j$ can be chosen from the following list:

$$\xi(t) = \frac{l}{2^{n-m}}, \text{ where } l \in \mathbb{Z}, \; 0 < l < 2^{n-m},$$

or

$$\xi(t) = \frac{t + l}{2^{n-m}}, \text{ where } l \in \mathbb{Z}, \; 0 < l < 2^{n-m}.$$
where \( \gamma^{(1)}(s) = \exp(2\pi i \sum_{j=1}^{q_n} g_j b_j) \).

We denote \( v^{(0)}(s) = \gamma^{(0)}(s) \otimes 1_{q_n} \) and \( v^{(1)}(s) = \gamma^{(1)}(s) \otimes 1_{p_n} \). Then
\[
\|v^{(0)}(s) - u_s(0)\| = \|(\gamma^{(0)}(s) - \gamma^{(0)}(s)) \otimes 1_{q_n}\| < \frac{\varepsilon}{6(1 + \max_{s \in [0, 1]} \|\frac{du_s(0)}{ds}\|)}
\]
and
\[
\|v^{(1)}(s) - u_s(1)\| = \|(\gamma^{(1)}(s) - \gamma^{(1)}(s)) \otimes 1_{p_n}\| < \frac{\varepsilon}{6(1 + \max_{s \in [0, 1]} \|\frac{du_s(1)}{ds}\|)}
\]
for all \( s \in [0, 1] \). Also, we have
\[
\left\| \frac{dv^{(0)}(s)}{ds} - \frac{du_s(0)}{ds} \right\| < \frac{\varepsilon}{3}
\]
and
\[
\left\| \frac{dv^{(1)}(s)}{ds} - \frac{du_s(1)}{ds} \right\| < \frac{\varepsilon}{3}
\]

Since \( \|u^{(0)}(0)v^{(0)}(s) - 1_{A_n}\| = \|v^{(0)}(s) - u_s(0)\| < \frac{\varepsilon}{6} < \frac{1}{6} \), there exists \( H \in M_{dn}(C([0, 1])) \),\( s.a. \) with \( \|H\| < 1 \) such that \( u^{(0)}(0)v^{(0)}(s) = \exp(2\pi i H(s)) \). Also, there exists \( G \in M_{dn}(C([0, 1])) \),\( s.a. \) with \( \|G\| < 1 \) such that \( u^{(1)}(1)v^{(1)}(s) = \exp(2\pi i G(s)) \). In fact, \( H(s) = \frac{1}{2\pi i} \log(u^{(0)}(0)v^{(0)}(s)) \) and \( G(s) = \frac{1}{2\pi i} \log(u^{(1)}(1)v^{(1)}(s)) \).

We denote
\[
w(s, t) = \begin{cases} u_s(0)\exp(2\pi i \frac{\delta}{\delta} H(s)), & -\delta \leq t < 0 \\ u_s(t), & 0 \leq t \leq 1 \\ u_s(1)\exp(2\pi i \frac{t-1}{\delta} G(s)), & 1 < t \leq 1 + \delta \end{cases}
\]

Let \( v_s(t) = w(s, (1 + 2\delta)t - \delta) \) for \( (s, t) \in [0, 1] \times [0, 1] \). Then \( v_s \) is a path in \( A_n \) and it satisfies conditions (3) and (4).

For \( t \in [0, \frac{\delta}{1 + 2\delta}] \), by the choice of \( \delta \), we have
\[
\|v_s(t) - u_s(t)\| = \|u_s(0)\exp(2\pi i \frac{\delta - (1 + 2\delta)t}{\delta} H(s)) - u_s(t)\|
\]
\[
\leq \|u_s(0)\exp(2\pi i \frac{\delta - (1 + 2\delta)t}{\delta} H(s)) - u_s(0)\| + \|u_s(0) - u_s(t)\|
\]
\[
= \|\exp(2\pi i \frac{\delta - (1 + 2\delta)t}{\delta} H(s)) - 1_{A_n}\| + \|u_s(0) - u_s(t)\|
\]
\[
\leq \|\exp(2\pi i H(s)) - 1_{A_n}\| + \|u_s(0) - u_s(t)\|
\]
\[
< \frac{\varepsilon}{6} + \frac{\varepsilon}{2}
\]
\[
< \varepsilon.
\]

For \( t \in \left[\frac{\delta}{1 + 2\delta}, \frac{1 + \delta}{1 + 2\delta}\right] \), we have \(|(1 + 2\delta)t - \delta - t| < \delta \) and hence
\[
\|v_s(t) - u_s(t)\| = \|u_s((1 + 2\delta)t - \delta) - u_s(t)\| < \frac{\varepsilon}{2}.
\]
For \( t \in (\frac{1+\delta}{1+2\delta}, 1] \), by the choice of \( \delta \), we have

\[
\|v_s(t) - u_s(t)\| = \|u_s(1) \exp(2\pi i (1 + 2\delta)t - \delta - 1) G(s) - u_s(t)\|
\leq \|u_s(1) \exp(2\pi i (1 + 2\delta)t - \delta - 1) G(s) - u_s(1)\| + \|u_s(1) - u_s(t)\|
= \|\exp(2\pi i (1 + 2\delta)t - \delta - 1) G(s) - 1_{A_n}\| - \|u_s(1) - u_s(t)\|
\leq \frac{\varepsilon}{6} + \frac{\varepsilon}{2}
< \varepsilon.
\]

It follows that \( \|v_s - u_s\| \leq \varepsilon \).

For \( t \in [0, \frac{\delta}{1+2\delta}) \), a direct calculation shows that

\[
\left|\frac{dv_s}{ds} - \frac{du_s}{ds}\right| = \left|\sup_{t \in [0,1]} u_s(0) \exp(2\pi i \frac{\delta - (1 + 2\delta)t}{\delta} H(s)) 2\pi i \frac{\delta - (1 + 2\delta)t}{\delta} dH(s)\right|
+ \left|\frac{du_s(0)}{ds} \exp(2\pi i \frac{\delta - (1 + 2\delta)t}{\delta} H(s)) - \frac{dv_s(0)}{ds}\right|
\leq 2\pi \left|\frac{dH(s)}{ds}\right| + \left|\sup_{s \in [0,1]} \frac{du_s(0)}{ds} - \frac{dv_s(0)}{ds}\right| + \left|\sup_{t \in [0,1]} \|1 - \exp(2\pi i \frac{\delta - (1 + 2\delta)t}{\delta} H(s))\|\right|
\leq \left|\varepsilon - u_s^*(0) \frac{du_s(0)}{ds} u_s^*(0)v^{(0)}(s)\right| + \left|\frac{dv_s(0)}{ds}\right| + \left|\sup_{t \in [0,1]} \|1 - \exp(2\pi i H(s))\|\right|
\leq \left|\frac{du_s(0)}{ds} - \frac{dv_s(0)}{ds}\right| + 2\left|\frac{dv_s(0)}{ds}\right| \left|u_s^*(0)v^{(0)}(s) - 1_{A_n}\right| + \frac{\varepsilon}{3}
\leq \frac{\varepsilon}{3} + \frac{\varepsilon}{3} + \frac{\varepsilon}{3}
= \varepsilon.
\]

With a similar calculation, one have

\[
\left|\frac{dv_s}{ds} - \frac{du_s}{ds}\right| < \varepsilon, \text{ for all } t \in \left[\frac{1+\delta}{1+2\delta}, 1\right].
\]

For \( t \in \left[\frac{\delta}{1+2\delta}, \frac{1+\delta}{1+2\delta}\right) \), we have \(|(1 + 2\delta)t - \delta - t| < \delta\) and hence

\[
\left|\frac{dv_s(t)}{ds} - \frac{du_s(t)}{ds}\right| \leq \left|\frac{du_s((1 + 2\delta)t - \delta)}{ds} - \frac{du_s(t)}{ds}\right| < \frac{\varepsilon}{3}.
\]
It follows that \(|\|\frac{dv_s}{ds}\| - \|\frac{du_s}{ds}\|| < \varepsilon\) for all \(s \in [0, 1]\). We have
\[
|\text{length}_s(v_s) - \text{length}_s(u_s)| = |\int_0^1 \|\frac{dv_s}{ds}\| ds - \int_0^1 \|\frac{du_s}{ds}\| ds| < \varepsilon.
\]

\[\square\]

**Remark 5.4.** In above Lemma, we can assume that \(h_1(0), h_2(0), \cdots, h_{p_n}(0) \in [0, 1], g_1(0), g_2(0), \cdots, g_{q_n}(0) \in [0, 1]\) and
\[
h_1(s) < h_2(s) < \cdots < h_{p_n}(s),
g_1(s) < g_2(s) < \cdots < g_{q_n}(s)
\]
for all \(s \in [0, 1]\). Notice that \(\exp(2\pi ih_j(s)) \neq \exp(2\pi h_k(s)), \exp(2\pi ig_j(s)) \neq \exp(2\pi ig_k(s))\) for any \(j \neq k\) and \(s \in [0, 1]\), we have
\[
h_{p_n}(s) - h_1(s) < 1, g_{q_n}(s) - g_1(s) < 1
\]
for all \(s \in [0, 1]\).

**Lemma 5.5.** Let \(\mathcal{Z} = \lim(A_n, \phi_{n,n+1})\) be the Jiang-Su algebra, which is defined as above. If \(v \in A_n\) is a unitary and \(u_s\) is a path of unitaries connecting \(v\) and \(1_{A_n}\), then for any \(\varepsilon > 0\), there exists another path \(v_s \in A_n\) of unitaries such that
\[
\begin{align*}
(1) & \quad \|v_s - u_s\| < \varepsilon, \\
(2) & \quad |\text{length}(v_s) - \text{length}(u_s)| < \varepsilon, \\
(3) & \quad v_s(t) = \exp(2\pi iH_s(t)), H_s(t) = \sum_{j=1}^{d_n} \lambda_j^s(t)p_j(s,t), \{p_j\}_{j=1}^{d_n} \text{ is a set of mutually orthogonal rank one projections in } C([0, 1] \times [0, 1], M_{d_n}) \text{ and } h_j \in C([0, 1] \times [0, 1])_{s.a.}, \\
& \quad \exp(2\pi i\lambda_j^s(t)) \neq \exp(2\pi i\lambda_k^s(t)) \text{ for each } j \neq k \text{ and } (s,t) \in (0, 1) \times [0, 1].
\end{align*}
\]

**Proof.** For any \(0 < \eta < 1\), since \(u_s(t)\) is uniformly continuous on \([0, 1] \times [0, 1]\), there exists \(\delta_1 > 0\) such that
\[
\|u_s(t_1) - u_s(t_2)\| < \frac{\eta}{4}
\]
for all \(s \in [0, 1]\) and \(t_1, t_2 \in [0, 1]\) with \(|t_1 - t_2| < 4\delta_1\). Since \(u_s(0), u_s(1) \in C([0, 1]) \otimes M_{d_n}\), there are continuous functions \(f_i, g_i : [0, 1] \to \mathbb{C}, i = 1, 2, \cdots, d_n\) such that \(f_1(s), f_2(s), \cdots, f(s)\) are the eigenvalues for \(v_s(0)\) and \(\{g_1(s), g_2(s), \cdots, g_{d_n}(s)\}\) are the eigenvalues for \(v_s(1)\), respectively. By Lemma 5.3, without loss of generality, we may assume that \(u_s(0)\) and \(u_s(1)\) can be written as the following forms:
\[
u_s(0) = U^{(0)}(s) \begin{bmatrix} \exp(2\pi if_1(s)) & \exp(2\pi if_2(s)) & \cdots & \exp(2\pi if_{d_n}(s)) \end{bmatrix} (U^{(0)}(s))^* \text{ for all } s \in [0, 1],
\]
and
\[
u_s(1) = U^{(1)}(s) \begin{bmatrix} \exp(2\pi ig_1(s)) & \exp(2\pi ig_2(s)) & \cdots & \exp(2\pi ig_{d_n}(s)) \end{bmatrix} (U^{(1)}(s))^* \text{ for all } s \in [0, 1],
\]
26
where $U^{(0)}$, $U^{(1)}$ are unitaries in $C([0, 1]) \otimes M_{d_n}$. By Remark 5.4, we can assume that $f_1(0), f_2(0), \ldots, f_{d_n}(0) \in [0, 1]$, $g_1(0), g_2(0), \ldots, g_{d_n}(0) \in [0, 1]$ and

$$f_1(s) \leq f_2(s) \leq \cdots \leq f_{d_n}(s),$$

$$g_1(s) \leq g_2(s) \leq \cdots \leq g_{d_n}(s),$$

for all $s \in [0, 1]$. Further, we can assume that $f_{d_n}(s) - f_1(s) < 1$ and $g_{d_n}(s) - g_1(s) < 1$ for all $s \in [0, 1]$.

Let $0 < \delta < \delta_1$ be such that $\frac{2\delta}{1 - 4\delta} < \delta_1$. We choose $h_1, h_2, \ldots, h_{d_n} \in C([0, 1])_{s.a.}$ with $h_1(s) < h_2(s) < \cdots < h_{d_n}(s)$ with $h_{d_n}(s) - h_1(s) < 1$ for $s \in [0, 1]$ such that $\|\exp(2\pi ih_j(s)) - \exp(2\pi if_j(s))\| < \frac{\delta}{4}$ for $1 \leq j \leq d_n$ and $s \in [0, 1]$.

Also we can choose $k_1, k_2, \ldots, k_{d_n} \in C([0, 1])_{s.a.}$ with $k_1(s) < k_2(s) < \cdots < k_{d_n}(s)$ for $s \in [0, 1]$ such that $\|\exp(2\pi ik_j(s)) - \exp(2\pi ig_j(s))\| < \frac{\delta}{4}$ for $1 \leq j \leq d_n$ and $s \in [0, 1]$.

We define a new path $\tilde{u}_s$ as follows:

$$\tilde{u}_s(t) = \begin{cases} 
U^{(0)}(s) \text{diag}[\exp(2\pi i(\frac{t}{\delta} f_j(s) + \frac{h_j(s)}{\delta}))]_{j=1}^{d_n} \left( U^{(0)}(s) \right)^*, & t \in [0, \delta] \\
U^{(0)}(s) \text{diag}[\exp(2\pi i(\frac{t}{\delta} f_j(s) + \frac{2\delta - t}{\delta} h_j(s)))]_{j=1}^{d_n} \left( U^{(0)}(s) \right)^*, & t \in (\delta, 2\delta] \\
U^{(1)}(s) \text{diag}[\exp(2\pi i(\frac{t}{\delta} f_j(s) + \frac{1 - \delta - t}{\delta} g_j(s)))]_{j=1}^{d_n} \left( U^{(1)}(s) \right)^*, & t \in (1 - 2\delta, 1 - \delta] \\
U^{(1)}(s) \text{diag}[\exp(2\pi i(\frac{1}{\delta} (1 + 2\delta) k_j(s) + \frac{1 - \delta - t}{\delta} g_j(s)))]_{j=1}^{d_n} \left( U^{(1)}(s) \right)^*, & t \in (1 - \delta, 1] 
\end{cases}$$

As in the construction, it is easy to see that $\tilde{u}_s$ is a path of unitaries in $A_n$. We have $\tilde{u}_s(t)$ has no repeat eigenvalues for $(s, t) \in [0, 1] \times (0, \delta]$ or $(s, t) \in [0, 1] \times [1 - \delta, 1)$. Moreover, when $t \in [0, \delta]$, we have

$$|\tilde{u}_s(t) - u_s(t)| \leq |\tilde{u}_s(t) - \tilde{u}_s(0)| + |\tilde{u}_s(0) - u_s(t)|$$

$$\leq \max_{1 \leq j \leq d_n} |\exp(2\pi i \frac{t}{\delta} (h_j(s) - f_j(s))) - 1| + |u_s(0) - u_s(t)|$$

$$\leq \max_{1 \leq j \leq d_n} |\exp(2\pi i (h_j(s) - f_j(s))) - 1| + \frac{\eta}{4}$$

$$= \max_{1 \leq j \leq d_n} |\exp(2\pi i f_j(s)) - \exp(2\pi i h_j(s))| + \frac{\eta}{4}$$

$$\leq \frac{\eta}{2}.$$
In the same way, we have

\[ |\tilde{u}_s(t) - u_s(t)| \leq \frac{3\eta}{4} \text{ for all } t \in (1 - 2\delta, 1]. \]

Further, for \( t \in [2\delta, 1 - 2\delta] \), it is easy to see that

\[ \frac{t - \delta}{1 - 4\delta} - t < \frac{2\delta}{1 - 4\delta} < \delta_1. \]

Hence

\[ |\tilde{u}_s(t) - u_s(t)| = |u_s(t - \frac{2\delta}{1 - 4\delta}) - u_s(t)| < \frac{\eta}{4}. \]

It follows that

\[ ||\tilde{u}_s - u_s|| < \frac{3\eta}{4}, \forall s \in [0, 1]. \]

In the construction of \( \tilde{u}_s \), it is easy to see that the lengths of \( \tilde{u}_s \) and \( u_s \) are close enough if \( \eta \) is small enough.

Notice that \( \tilde{u}_0|_{[\delta, 1-\delta]} \), \( \tilde{u}_1|_{[\delta, 1-\delta]} \) are unitaries in \( M_{d_n}(C([\delta, 1-\delta])) \) with distinct eigenvalues and \( \tilde{u}_s|_{[\delta, 1-\delta]} \) is a path connecting these two elements. By Proposition 2.2 and Remark 2.3 there exists another path \( \tilde{u}_s \) in \( U(M_{d_n}(C[\delta, 1-\delta])) \) such that

\[ ||\tilde{u}_s - \tilde{u}_s|_{[\delta, 1-\delta]}|| < \frac{\eta}{2}. \]

\[ |\text{length}(\tilde{u}_s) - \text{length}(\tilde{u}_s|_{[\delta, 1-\delta]})| < \eta, \]

\( \tilde{u}_s \) has no repeat eigenvalues for all \((s, t) \in [0, 1] \times [\delta, 1-\delta]\), and

\[ \tilde{u}_0(\delta) = \tilde{u}_s(\delta), \tilde{u}_0(1-\delta) = \tilde{u}_s(1-\delta). \]  

(5.1)

By Proposition 2.3 there exists a unitary \( U_s(t) \in C([0, 1] \times [\delta, 1-\delta], M_{d_n}(C)) \) such that

\[
\tilde{u}_s(t) = U_s(t) \begin{bmatrix}
\xi_1(t) \\
\xi_2(t) \\
\vdots \\
\xi_{d_n}(t)
\end{bmatrix} U_s(t)^*, \text{ for all } (s, t) \in [0, 1] \times [\delta, 1-\delta],
\]

where \( \xi_j(t) : [0, 1] \times [\delta, 1-\delta] \to S^1 \) is continuous for each \( 1 \leq j \leq d_n \). Since \( \mathbb{R} \) is a covering space of \( S^1 \), there exists \( \psi_j : [0, 1] \times [\delta, 1-\delta] \to \mathbb{R} \) such that

\[ \exp(2\pi i\psi_j(s, t)) = \xi_j(t), \text{ for all } (s, t) \in [0, 1] \times [\delta, 1-\delta]. \]

By 5.1, without loss of generality, we can assume that

\[ \exp(2\pi i\psi_j(s)) = \exp(2\pi i\psi_j(s, \delta)), \text{ for all } 1 \leq j \leq d_n, \]

and

\[ \exp(2\pi ik_j(s)) = \exp(2\pi i\psi_j(s, \delta)), \text{ for all } 1 \leq j \leq d_n. \]

We can choose integers \( m_j, l_j \) such that

\[ h_j(s) = \psi_j(s, \delta) + m_j, \]

and

\[ \psi_j(s, 1-\delta) + m_j = k_j(s) + l_j \]

for each \( 1 \leq j \leq d_n \) and \( s \in [0, 1] \).
We denote

$$\lambda^j_i(t) = \begin{cases} \frac{\delta-t}{\delta} f_j(s) + \frac{t}{\delta} h_j(s), & t \in [0, \delta] \\ \psi_j(s, t) + m_j, & t \in [\delta, 1 - \delta] \\ \frac{t-1+\delta}{\delta} g_j(s) + \frac{1-t}{\delta} k_j(s) + l_j, & t \in (1 - \delta, 1] \end{cases}.$$ 

Then $\lambda^j_i(t)$ is continuous on $[0, 1] \times [0, 1]$ and $exp(2\pi i \lambda^j_i(t)) \neq exp(2\pi i \lambda^j_k(t))$ if $j \neq k$ and $(s, t) \in [0, 1] \times (0, 1)$.

**Theorem 5.6.** Let $\mathcal{Z}$ be the Jiang-Su algebra. Then $cel_{CU}(\mathcal{Z}) \geq 2\pi$.

**Proof.** Let $\mathcal{Z} = \lim_m A_m$ be the Jiang-Su algebra. For each $m \geq 1$, we define a unitary $u \in A_m$ as follows:

$$u(t) = \begin{bmatrix} exp(2\pi i h_1(t)) \\ \vdots \\ exp(2\pi i h_{d_m}(t)) \end{bmatrix},$$

where $h_i(t) = \frac{2n-1}{d} t$ for each $1 \leq i \leq p_m$, $h_i(t) = -\frac{1}{d} t$ for each $p_m + 1 \leq i \leq d_m$. (Here we identify $1_{p_m} \otimes M_{q_m} \cong 1 \otimes (a_{ij})_{q_m \times q_m}$ with $(a_{ij}1_{p_m}) \in M_{p_m q_m}$.) It follows Lemma 3.7 in [12] that $u \in CU(A_m)$. For any fixed $n \geq 1$, denote $v = \phi_{m,n}(u)$. Let $u_s(t)$ be a unitary path in $A_n$ with $u_0(t) = v(t)$ and $u_1(t) = 1_{A_n}$.

For any $0 < \varepsilon < \frac{1}{2n}$, by Lemma 5.5, there exists another piecewise smooth unitary path $v_s(t)$ such that

1. $\|v_s - u_s\| < \frac{\varepsilon}{2}$,
2. $\text{length}_s(v_s) - \text{length}_s(u_s) < \frac{\varepsilon}{2}$,
3. $\text{length}_s(v_s) < \frac{\varepsilon}{2}$.

$$v_s(t) = U_s(t) \begin{bmatrix} exp(2\pi i f_1(s, t)) \\ exp(2\pi i f_2(s, t)) \\ \vdots \\ exp(2\pi i f_{d_n}(s, t)) \end{bmatrix} U_s(t)^*, \text{ for all } (s, t) \in [0, 1] \times [0, 1],$$

where $f_j(s, t) : [0, 1] \times [0, 1] \to \mathbb{R}$ is continuous and $exp(2\pi i f_j(s, t)) \neq exp(2\pi i f_k(s, t))$ if $j \neq k$ and $(s, t) \in [0, 1] \times (0, 1)$.

In the above construction, we can choose $f_j$ such that

$$\max_{1 \leq j \leq d_n} f_j(s, t) - \min_{1 \leq j \leq d_n} f_j(s, t) < 1, \text{ for all } (s, t) \in [0, 1] \times (0, 1).$$

In fact, arbitrarily fix a $t_0 \in (0, 1)$. Without loss of generality, we can assume that $f_j(0, t_0) \in [0, 1)$ for all $1 \leq j \leq d_n$. This means that

$$\max_{1 \leq j \leq d_n} f_j(0, t_0) - \min_{1 \leq j \leq d_n} f_j(0, t_0) < 1.$$ 

Since $exp(2\pi i f_j(s, t)) \neq exp(2\pi i f_k(s, t))$ for $j \neq k$, we have $f_j(s, t) - f_k(s, t) \notin \mathbb{Z}$. Notice that $f_j(\cdot, \cdot)$ is continuous, we have

$$\max_{1 \leq j \leq d_n} f_j(s, t) - \min_{1 \leq j \leq d_n} f_j(s, t) < 1 \text{ for all } (s, t) \in [0, 1] \times (0, 1). \quad (5.2)$$
Also, we can assume that
\[ f_1(s, t) \leq f_2(s, t) \leq \cdots \leq f_{d_n}(s, t), \text{ for all } (s, t) \in [0, 1] \times [0, 1]. \] 
(5.3)

By the construction of the Jiang-Su algebra, we have
\[ v(t) = b^* \begin{bmatrix} \exp(2\pi i \mu_1(t)) & 0 & \cdots & 0 \\ 0 & \exp(2\pi i \mu_2(t)) & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \exp(2\pi i \mu_{d_n}(t)) \end{bmatrix} b, \]
where \( \mu_1(t) \leq \mu_2(t) \leq \cdots \leq \mu_{d_n}(t) \) for all \( t \in [0, 1] \), \( b \) is a unitary element in \( M_{d_n}(C([0, 1])) \).

There is a permutation \( \sigma \) such that \( \exp(2\pi if_j(s, \cdot)) \) is a path connecting an element near \( e^{2\pi i \mu_{\sigma(j)}(t)} \) with some function near 1 for each \( 1 \leq j \leq d_n \). Without loss of generality, we assume that \( \sigma(j) = j \) for each \( j \).

We have
\[ \frac{-1}{q_m} \leq \mu_j(t) \leq \frac{1}{q_m}, \text{ for all } 1 \leq j \leq (d_m - p_m)k^{(m)}k^{(m+1)} \cdots k^{(n-1)} + p_mr_1^{(m)}r_1^{(m+1)} \cdots r_1^{(n-1)} \],
and
\[ \mu_j(t) = \frac{(q_m - 1)(t + 2^{n-m} - 1)}{q_m 2^{n-m}}, \text{ for all } d_n - p_mr_0^{(m)}r_0^{(m+1)} \cdots r_0^{(n-1)} < j \leq d_n. \]

Obviously, we have \( \text{length}_s(v_s(\cdot)) \geq \text{length}_s(\exp(2\pi if_j(s, \cdot))) \) for each \( j \). It is easy to see that \( f_j(s, \cdot) \) is a path connecting an element near \( \mu_j(t) \) with an element near \( l_j \), where \( l_j \in \mathbb{Z} \), it follows that \( \text{length}_s(f_j(s, \cdot)) \geq 2\pi \max_{t \in [0, 1]} |\mu_j(t) - l_j| - \varepsilon. \) We consider the following cases:

**Case 1:** \( l_{j_0} \geq 2 \) for some \( 1 \leq j_0 \leq d_n \). Then
\[ \text{length}_s(e^{2\pi if_{j_0}(s, \cdot)}) \geq 2\pi \max_{t \in [0, 1]} |\mu_{j_0}(t) - l_{j_0}| - \varepsilon \geq 2\pi - \varepsilon. \]

**Case 2:** \( l_{j_1} \leq -1 \) for some \( 1 \leq j_1 \leq d_n \). Then
\[ \text{length}_s(e^{2\pi if_{j_1}(s, \cdot)}) \geq 2\pi \max_{t \in [0, 1]} |\mu_{j_1}(t) - l_{j_1}| - \varepsilon \geq 2\pi - \varepsilon. \]

**Case 3:** \( l_j = 0 \) for all \( 1 \leq j \leq d_n \). Then
\[ \text{length}_s(e^{2\pi if_{d_n}(s, \cdot)}) \geq 2\pi \max_{t \in [0, 1]} |\mu_{d_n}(t) - 0| - \varepsilon = 2\pi \frac{q_m - 1}{q_m} - \varepsilon. \]

**Case 4:** \( l_j = 1 \) for all \( 1 \leq j \leq d_n \).
\[ \text{length}_s(e^{2\pi if_1(s, \cdot)}) \geq 2\pi \max_{t \in [0, 1]} |\mu_1(t) - 1| - \varepsilon = 2\pi \frac{q_m + 1}{q_m} - \varepsilon. \]

**Case 5:** All \( l_j \) are either 0 or 1, it follows that \( \{ j : l_j = 0 \} \neq \emptyset \) and \( \{ j : l_j = 1 \} \neq \emptyset \). By (5.3), we can assume that there exists \( 1 \leq K < d_n \) such that \( l_j = 0 \) for all \( 1 \leq j \leq K \) and \( l_j = 1 \) for all \( K + 1 \leq j \leq d_n \).

**Claim 1.** If \( q_n \nmid K \), then \( \text{length}_s(v_s) \geq 2\pi \left( \frac{(q_m - 1)(2^{n-m} - 1)}{q_m 2^{n-m}} - \varepsilon \right). \)

We divide the proof of Claim 1 into several steps.

Step 1. We denote
\[ s_0 = \sup \{ s \in [0, 1] : f_K(s', 0) = f_{K+1}(s', 0) \text{ for all } s' \in [0, s] \}. \]
First, we shall show that $s_0 > 0$. Otherwise, we have $s_0 = 0$.

Since $\mu_{d_n}(0) - \mu_1(0) = \frac{2n-m-1}{2n} < 1$, $\|f_{d_n}(0, \cdot) - \mu_{d_n}(\cdot)\| < \frac{\varepsilon}{2}$ and $\|f_1(0, \cdot) - \mu_1(0, \cdot)\| < \frac{\varepsilon}{2}$, we have $f_{d_n}(0, 0) - f_1(0, 0) < 1$. Notice that $f_j$ is continuous, there exists $\delta_1 > 0$ such that

$$f_{d_n}(s, 0) - f_1(s, 0) < 1, \text{ for all } 0 \leq s < \delta_1.$$  

By the definition of $s_0$, there exists $s' \in (0, \delta_1)$ such that $f_K(s', 0) < f_{K+1}(s', 0)$. It follows that

$$\{f_j(s', 0) : 1 \leq j \leq K\} \cap \{f_j(s', 0) : K + 1 \leq j \leq d_n\} = \emptyset.$$  

By (5.4), we have

$$\{\exp(2\pi i f_j(s', 0)) : 1 \leq j \leq K\} \cap \{\exp(2\pi i f_j(s', 0)) : K + 1 \leq j \leq d_n\} = \emptyset.$$  

Since $q_n \nmid K$, we have $v_{s_0} \notin A_n$. This leads a contradiction. Hence $s_0 > 0$.

Step 2. Before we prove Claim 1, we shall show the following Claim:

**Claim 2.** \(f_1(s_0, 0) = f_K(s_0, 0)\) or \(f_{d_n}(s_0, 0) = f_{K+1}(s_0, 0)\). (5.5)

If (5.5) does not hold, we have \(f_1(s_0, 0) < f_K(s_0, 0) < f_{d_n}(s_0, 0)\). We denote

$$\{f_j(s_0, 0) : 1 \leq j \leq d_n\} = \{c_k\}_{k=1}^L,$$

where \(c_1 < c_2 < \cdots < c_L\). Then \(L \geq 3\). We let \(H_k = \{1 \leq j \leq d_n : f_j(s_0, 0) = c_k\}\) for \(1 \leq k \leq L\). In fact, \(H_1 = \{j : f_j(s_0, 0) = f_1(s_0, 0)\}\). Then \(H_{k_1} \cap H_{k_2} = \emptyset\) for \(k_1 \neq k_2\).

Also, there exists \(1 < k_0 < L\), such that \(K \in H_{k_0}\). We let \(H_{k_0}^1 = \{j \in H_{k_0} : j \leq K\}\) and \(H_{k_0}^2 = \{j \in H_{k_0} : j > K\}\).

Notice that \(c_L - c_1 \leq 1\), we have \(|c_{k_0} - c_k| < 1\) for each \(1 \leq k \leq L\) and hence

$$\{\exp(2\pi i f_j(s_0, 0)) : j \in H_{k_0}^1\} \cap \{\exp(2\pi i f_j(s_0, 0)) : j \in H_{k_0}^2\} = \emptyset,$$  

and

$$\{\exp(2\pi i f_j(s_0, 0)) : j \in H_{k_0}^1\} \cap \{\exp(2\pi i f_j(s_0, 0)) : j \in H_{k_0}^2\} = \emptyset, \text{ for all } k \neq k_0.$$  

Since \(v_{s_0} \in A_n\), by (5.6) and (5.7), we have

$$q_n(|H_{k_0}^1|).$$  

Use a similar argument, we can prove that

$$q_n(|H_k|), \text{ for all } 2 \leq k \leq k_0 - 1.$$  

Notice that \(\{j : 1 \leq j \leq K\} = (\cup_{k=1}^{k_0-1} H_k) \cup H_{k_0}^1\) and \(q_n \nmid K\), we have \(q_n \nmid (|H_1|)\). That is \(q_n \nmid (|\{j : f_j(s, 0) = f_1(s, 0)\}|)\).

We define

$$s_1 = \inf\{s \in [0, s_0] : q_n \nmid (|\{j : f_j(s, 0) = f_1(s, 0)\}|)\}.$$  

Notice that \(q_n(|\{j : f_j(0, 0) = f_1(0, 0)\}|)\) and \(f_{d_n}(0, 0) - f_1(0, 0) < 1\), by a similar argument as the proof of (5.8), we can prove that \(s_1 > 0\).

We denote

$$\{f_j(s_1, 0) : 1 \leq j \leq d_n\} = \{a_k\}_{k=1}^T,$$

where \(a_1 < a_1 < \cdots < a_T\). We denote \(G_k = \{1 \leq j \leq d_n : f_j(s_1, 0) = a_k\}\) for each \(1 \leq k \leq T\). In fact, \(G_1 = \{j : f_j(s_1, 0) = f_1(s_1, 0)\}.$$
For any $0 < \varepsilon_1 < \min\{|a_{k_1} - a_{k_2}| : k_1 \neq k_2\}$, there exists $\delta_1 > 0$ such that
\[
|f_j(s, 0) - f_j(s_1, 0)| < \frac{\varepsilon_1}{4},
\] for each $s$ with $0 < |s - s_1| < \delta_1$
It follows that $\{f_j(s, 0) : j \in G_{k_1}\} \cap \{f_j(s, 0) : j \in G_{k_2}\} = \emptyset$ for all $k_1 \neq k_2$ and $0 < |s - s_1| < \delta_3$.
To finish the proof of Claim 2, we need to consider the following two cases.

Case 1. $q_n \uparrow (\{j : f_j(s_1, 0) = f_1(s_1, 0)\})$. By the definition of $s_1$, for any $s \in (s_1 - \delta_1, s_1)$, we have $q_n(\{|\{j : f_j(s, 0) = f_1(s, 0)\}|\})$. We denote
\[
\{f_j(s, 0) : j \in G_1\} = \{r_k\}_{k=1}^W, \text{ where } r_1 < r_2 \cdots < r_W.
\]
Further, we let $G^{(k)}_1 = \{j : f_j(s, 0) = r_k\}, k = 1, 2, \cdots, W$. By (5.10), it is easy to see that $G^{(k)}_1 \subset G_1$ for each $1 \leq k \leq W$. In particular, we have $G^{(1)}_1 = \{j : f_j(s, 0) = f_1(s, 0)\}$. Notice that $q_n \uparrow (\{|\{j : f_j(s_1, 0) = f_1(s_1, 0)\}|\})$ and $q_n(\{|\{j : f_j(s, 0) = f_1(s, 0)\}|\})$, we have $W \geq 2$ and there exists some $2 \leq k_1 \leq W$ such that $q_n \uparrow (|G^{(k_1)}_1|)$.
It follows that
\[
\{f_j(s, 0) : j \in G^{(k_1)}_1\} \cap \{f_j(s, 0) : j \in G_k\} = \emptyset, \text{ for all } 2 \leq k \leq T, \tag{5.11}
\]
and
\[
\{f_j(s, 0) : j \in G^{(k_1)}_1\} \cap \{f_j(s, 0) : j \in G^{(k)}_1\} = \emptyset, \text{ for all } 1 \leq k \leq W \text{ and } k \neq k_1. \tag{5.12}
\]
Since $k_1 \geq 2$, we have $f_j(s, 0) > f_1(s, 0)$ for all $j \in G^{(k_1)}_1$. It is easy to check that
\[
|f_{j_1}(s, 0) - f_{j_2}(s, 0)| < 1, j_1 \in G^{(k_1)}_1, j_2 \notin G^{(k_1)}_1.
\]
Combining with (5.11) and (5.12), we have
\[
\{\exp(2\pi i f_j(s, 0)) : j \in G^{(k_1)}_1\} \cap \{\exp(2\pi i f_j(s, 0)) : j \in G_k\} = \emptyset, \text{ for all } 2 \leq k \leq T,
\]
and
\[
\{\exp(2\pi i f_j(s, 0)) : j \in G^{(k_1)}_1\} \cap \{\exp(2\pi i f_j(s, 0)) : j \in G^{(k)}_1\} = \emptyset, \text{ for all } 1 \leq k \leq W \text{ and } k \neq k_1.
\]
Combining with $q_n \uparrow (|G^{(k_1)}_1|)$, it leads $v_s \notin A_n$ for any $s \in (s_1 - \delta_1, s_1)$, which is a contradiction.

Case 2. $q_n(\{|\{j : f_j(s_1, 0) = f_1(s_1, 0)\}|\})$. Then $s_1 < s_0$. By the definition of $s_1$, there exists $s \in (s_1, s_1 + \delta_1)$ such that $q_n \uparrow (|\{j : f_j(s, 0) = f_1(s, 0)\}|)$. We denote
\[
\{f_j(s, 0) : j \in G_1\} = \{z_k\}_{k=1}^M, \text{ where } z_1 < z_2 \cdots < z_M.
\]
Further, we let $V^{(k)} = \{j : f_j(s, 0) = z_k\}, k = 1, 2, \cdots, M$. Also, by (5.10), we have $V^{(k)} \subset G_1$ for each $1 \leq k \leq M$. In particular, we have $V^{(1)} = \{j : f_j(s, 0) = f_1(s, 0)\}$. Notice that $q_n(\{|\{j : f_j(s_1, 0) = f_1(s_1, 0)\}|\})$ and $q_n \uparrow (|\{j : f_j(s, 0) = f_1(s, 0)\}|)$, we have $M \geq 2$ and there exists some $2 \leq k_2 \leq M$ such that $q_n \uparrow (|V^{(k_2)}|)$.
It follows that
\[
\{f_j(s, 0) : j \in V^{(k_2)}\} \cap \{f_j(s, 0) : j \in G_k\} = \emptyset, \text{ for all } 2 \leq k \leq T, \tag{5.13}
\]
Combining with (5.13) and (5.14), we have

\[ \{ f_j(s, 0) : j \in V(k_2) \} \cap \{ f_j(s, 0) : j \in V(k) \} = \emptyset, \text{ for all } 1 \leq k \leq W \text{ and } k \neq k_2. \tag{5.14} \]

Since \( k_2 \geq 2 \), we have \( f_j(s, 0) > f_1(s, 0) \) for all \( j \in V(k_2) \). It is easy to check that

\[ |f_{j_1}(s, 0) - f_{j_2}(s, 0)| < 1, \text{ for all } j_1 \in V(k_1), j_2 \notin V(k_2). \]

Combining with (5.13) and (5.14), we have

\[ \{ \exp(2\pi i f_j(s, 0)) : j \in V(k_2) \} \cap \{ \exp(2\pi i f_j(s, 0)) : j \in G_k \} = \emptyset, \text{ for all } 2 \leq k \leq T, \]

and

\[ \{ \exp(2\pi i f_j(s, 0)) : j \in V(k_2) \} \cap \{ \exp(2\pi i f_j(s, 0)) : j \in V(k) \} = \emptyset, \text{ for all } 1 \leq k \leq W \text{ and } k \neq k_2. \]

Combining with \( q_n \nmid (|V(k_2)|) \), it leads to \( v_s \notin A_n \) for some \( s \in (s_1, s_1 + \delta_1) \), which is a contradiction.

Hence (5.5) holds and Claim 2 is proved.

Step 3. We denote \( v_s^{(1)}(t) = v_s(t) \) for \( s \in [0, s_0] \) and \( v_s^{(2)}(t) = v_s(t) \) for \( s \in [s_0, 1] \). Then we have

\[ \text{length}_s(v_s) = \text{length}_s(v_s^{(1)}) + \text{length}_s(v_s^{(2)}). \tag{5.15} \]

If \( f_1(s_0, 0) = f_K(s_0, 0) \), by Theorem 3.4, we have

\[ \text{length}_s(v_s^{(1)}) \geq 2\pi|f_1(0, 0) - f_1(s_0, 0)| = 2\pi|f_1(0, 0) - f_K(s_0, 0)|, \tag{5.16} \]

and

\[ \text{length}_s(v_s^{(2)}) \geq 2\pi|f_{K+1}(s_0, 0) - 1| = 2\pi|f_K(s_0, 0) - 1|. \tag{5.17} \]

Combining (5.15), (5.16) and (5.17), we have

\[ \text{length}_s(v_s) \geq 2\pi|f_1(0, 0) - 1| \geq 2\pi(1 + \frac{2^{n-m} - 1}{q_m 2^{n-m}} - \varepsilon). \tag{5.18} \]

If \( f_{d_n}(s_0, 0) = f_{K+1}(s_0, 0) \), also by Theorem 3.4, we have

\[ \text{length}_s(v_s^{(1)}) \geq 2\pi|f_{d_n}(0, 0) - f_{d_n}(s_0, 0)| = 2\pi|f_{d_n}(0, 0) - f_{K+1}(s_0, 0)|, \tag{5.19} \]

and

\[ \text{length}_s(v_s^{(2)}) \geq 2\pi|f_K(s_0, 0) - 0| = 2\pi|f_{K+1}(s_0, 0) - 0|. \tag{5.20} \]

Combining (5.15), (5.19) and (5.20), we have

\[ \text{length}_s(v_s) \geq 2\pi|f_{d_n}(0, 0) - 0| \geq 2\pi(\frac{(q_m - 1)(2^{n-m} - 1)}{q_m 2^{n-m}} - \varepsilon). \tag{5.21} \]

Claim 1 follows from (5.18) and (5.21).

By a similar argument, we can prove that, if \( p_n \nmid (d_n - K) \), then

\[ \text{length}_s(v_s) \geq \min\{2\pi|f_{d_n}(0, 1) - 0|, 2\pi|f_1(0, 1) - 1|\} \]

\[ = \min\{2\pi(\frac{q_m - 1}{q_m} - \varepsilon), 2\pi(\frac{q_m + 1}{q_m} - \varepsilon)\} \]

\[ = 2\pi(\frac{q_m - 1}{q_m} - \varepsilon). \]

33
Now we shall show that \( q_n | K \) and \( p_n | (d_n - K) \) can not hold together. Otherwise, there are positive integers \( l \) and \( s \) such that

\[
p_n l + q_n s = d_n.
\]

Noting that

\[(p_n, q_n) = 1,
\]

and

\[p_n | d_n,
\]

we have \( p_n | s \). We denote \( s' = \frac{s}{p_n} \). It follows that

\[l + q_n s' = \frac{d_n}{p_n} = q_n.
\]

Hence \( q_n | l \). We denote \( l' = \frac{l}{q_n} \). Then

\[l' + s' = 1.
\]

This contradicts to the fact that \( l' \) and \( s' \) are positive integers.

Hence either \( q_n \nmid K \) or \( p_n \nmid (d_n - K) \).

As \( m \) goes to infinity and \( \varepsilon \) goes to zero, applying Claim 1 (for the case \( q_n \nmid K \)) and (\( \ast \)) (for the case \( p_n \nmid (d_n - K) \)), we get an element \( v := \phi_{m, \infty}(u) \in CU(Z) \) such that \( \text{cel}(v) \geq 2\pi - \eta \), for any preassigned positive number \( \eta \). Hence we have

\[
\text{cel}_{CU}(Z) \geq 2\pi.
\]

\( \square \)

Further, we get a more general result.

**Theorem 5.7.** Let \( Z \) be the Jiang-Su algebra and \( k \) be a positive integer. Then

\[
\text{cel}_{CU}(M_k(Z)) \geq 2\pi.
\]

**Proof.** Let \( Z = \lim_m A_m \) be the Jiang-Su algebra. For each \( m \geq 1 \), we define a unitary \( u_1 \in A_m \) as follows:

\[
u_1(t) = \begin{bmatrix}
    e^{2\pi i h_1(t)} & & \\
    & \ddots & \\
    & & e^{2\pi i h_d(t)}
\end{bmatrix}_{d \times d},
\]

where \( h_i(t) = \frac{q_{m-1}}{q_m} t \) for each \( 1 \leq i \leq p_m \) and \( h_i(t) = -\frac{1}{q_m} t \) for each \( p_m + 1 \leq i \leq d_m \). We denote

\[
u = \text{diag}[u_1, u_2, \ldots, u_k] \in M_k(A_m),
\]

where \( u_i(t) = 1_{A_m} \) for each \( 2 \leq i \leq k \). It follows that \( u \in CU(M_k(A_m)) \).

For any \( \varepsilon > 0 \), use a similar proof of Theorem 5.6, we can prove that

\[
\text{cel}(u) \geq 2\pi - \varepsilon.
\]

\( \square \)
