HODGE THEORY OF THE TURAEV COBRACKET AND THE KASHIWARA–VERGNE PROBLEM

RICHARD HAIN

ABSTRACT. In this paper we show that, after completing in the $I$-adic topology, the Turaev cobracket on the vector space freely generated by the closed geodesics on a smooth, complex algebraic curve $X$ with a quasi-algebraic framing is a morphism of mixed Hodge structure. We combine this with results of a previous paper on the Goldman bracket to construct torsors of solutions to the Kashiwara–Vergne problem in all genera. The solutions so constructed form a torsor under a pronipotent group that depends only on the topology of the framed surface. We give a partial presentation of these groups. Along the way, we give a homological description of the Turaev cobracket.

1. Introduction

Denote the set of free homotopy classes of maps $S^1 \to X$ in a topological space $X$ by $\lambda(X)$ and the free $R$-module it generates by $R\lambda(X)$. When $X$ is an oriented surface with a nowhere vanishing vector field $\xi$, there is a map

$$\delta_\xi : R\lambda(X) \to R\lambda(X) \otimes R\lambda(X),$$

called the Turaev cobracket, that gives $R\lambda(X)$ the structure of a Lie coalgebra. The cobracket was first defined by Turaev [31] on $R\lambda(M)/R$ (with no framing) and lifted to $R\lambda(M)$ for framed surfaces in [32 §18] and [3]. The cobracket $\delta_\xi$ and the Goldman bracket $\{,\} : R\lambda(X) \otimes R\lambda(X) \to R\lambda(X)$ endow $R\lambda(X)$ with the structure of an involutive Lie bialgebra [32 §18, 25].

The value of the cobracket on a loop $a \in \lambda(X)$ is obtained by representing it by an immersed circle $\alpha : S^1 \to X$ with transverse self intersections and trivial winding number relative to $\xi$. Each double point $P$ of $\alpha$ divides it into two loops based at $P$, which we denote by $a'_P$ and $a''_P$. Let $\epsilon_P = \pm 1$ be the intersection number of the initial arcs of $a'_P$ and $a''_P$. The cobracket of $a$ is then defined by

$$\delta_\xi(a) = \sum_P \epsilon_P (a'_P \otimes a''_P - a''_P \otimes a'_P),$$

where $a'_P$ and $a''_P$ are the classes of $a'_P$ and $a''_P$, respectively.

The powers of the augmentation ideal $I$ of $R\pi_1(X,x)$ define the $I$-adic topology on it and induce a topology on $R\lambda(X)$. Kawazumi and Kuno [25] showed that $\delta_\xi$
is continuous in the $I$-adic topology and thus induces a map

$$\delta_\xi : R\lambda(X)^\wedge \to R\lambda(X)^\wedge \otimes R\lambda(X)^\wedge$$

on $I$-adic completions. This and the completed Goldman bracket give $R\lambda(X)^\wedge$ the structure of an involutive completed Lie bialgebra [25].

Now suppose that $X$ is a smooth affine curve over $\mathbb{C}$ or, equivalently, the complement of a non-empty finite set $D$ in a compact Riemann surface $\overline{X}$. In this case $Q\lambda(X)^\wedge$ has a canonical mixed Hodge structure [10]. Our first main result is that the Turaev cobracket is compatible with this structure.

**Theorem 1.** If $\xi$ is a nowhere vanishing holomorphic vector field on $X$ that is meromorphic on $\overline{X}$, then

$$\delta_\xi : Q\lambda(X)^\wedge \otimes \mathbb{Q}(-1) \to Q\lambda(X)^\wedge \otimes \mathbb{Q}(1)$$

is a morphism of pro-mixed Hodge structures, so that $Q\lambda(X)^\wedge \otimes \mathbb{Q}(1)$ is a complete Lie coalgebra in the category of pro-mixed Hodge structures.

We call such a framing $\xi$ an algebraic framing. The previous result also holds in the more general situation where the framing $\xi$ is a section of a twist of the holomorphic tangent bundle of $\overline{X}$ by a torsion line bundle. We call such framings quasi-algebraic framings of $X$. (See Definition 7.1.)

The main result of [17] asserts that

$$\{ , \} : Q\lambda(X)^\wedge \otimes Q\lambda(X)^\wedge \to Q\lambda(X)^\wedge \otimes \mathbb{Q}(1)$$

is a morphism of mixed Hodge structure (MHS), so that $Q\lambda(X)^\wedge \otimes \mathbb{Q}(1)$ is a complete Lie algebra in the category of pro-mixed Hodge structures.

**Corollary 2.** If $\xi$ is a quasi-algebraic framing of $X$, then $\{ , \}, \delta_\xi$ is a “twisted” completed Lie bialgebra in the category of pro-mixed Hodge structures.

By “twisted” we mean that one has to twist both the bracket and cobracket by $\mathbb{Q}(\pm 1)$ to make them morphisms of MHS. There is no one twist of $Q\lambda(X)$ that makes them simultaneously morphisms of MHS.

Let $\vec{v}$ be a non-zero tangent vector of $\overline{X}$ at a point of $D$. Standard results in Hodge theory (see [17, §10.2]) imply:

**Corollary 3.** Hodge theory determines torsors of compatible isomorphisms

$$(Q\lambda(X)^\wedge, \{ , \}, \delta_\xi) \cong \left( \prod_{m \geq 0} \text{Gr}^W_{-m} Q\lambda(X)^\wedge, \{ , \}, \text{Gr}^W_{-m} \delta_\xi \right)$$

of the Goldman–Turaev Lie bialgebra with the associated weight graded Lie bialgebra and of the completed Hopf algebras

$$(Q\pi_1(X, \vec{v})^\wedge, \{ , \}) \cong \left( \prod_{m \geq 0} \text{Gr}^W_{-m} Q\pi_1(X, \vec{v})^\wedge \right)$$

under which the logarithm of the boundary circle lies in $\text{Gr}^W_{-2} Q\pi_1(X, \vec{v})^\wedge$. These isomorphisms are torsors under the prounipotent radical $U^\text{MT}_{X, \vec{v}}$ of the Mumford–Tate group of the MHS on $Q\pi_1(X, \vec{v})^\wedge$.

In the terminology of [3], such isomorphisms solve the Goldman–Turaev formality problem.
Our main application is to the Kashiwara–Vergne problem \cite{3}. Solutions of the Kashiwara–Vergne problem of type \((g,n+1)\), where \(2g - 1 + n > 0\), are automorphisms \(\Phi\) of the complete Hopf algebra 
\[
\mathbb{Q}\langle\langle x_1, \ldots, x_g, y_1, \ldots, y_g, z_1, \ldots, z_n \rangle\rangle
\]
that solve the Kashiwara–Vergne equations. They correspond to automorphisms \(\Phi\) that induce isomorphisms of the Goldman–Turaev Lie bialgebra with the completion of its associated weight graded that satisfy certain natural boundary conditions. Corollary 3 combined with \cite[Thm. 5]{2}, implies that the automorphism \(\Phi\) constructed from a Hodge splitting of \(\mathbb{Q}\pi_1(X, \vec{v})^\wedge\) in \cite[§13.4]{17} solves the KV equations. The following result is a special case of Corollary 10.2.

**Corollary 4.** Suppose that \(X\) is an affine curve of type \((g,n+1)\), where \(2g - 1 + n > 0\). If \(\xi_0\) is a quasi-algebraic framing of \(X\), then the isomorphisms \(\Phi\) constructed in \cite[§13.4]{17} from the canonical MHS on \(\mathbb{Q}\pi_1(X, \vec{v})^\wedge\) are solutions of the Kashiwara–Vergne problem. The solutions constructed in this manner form a torsor under the Mumford–Tate group \(U_{MT}^{X,\vec{v}}\) of the canonical mixed Hodge structure on \(\mathbb{Q}\pi_1(X, \vec{v})^\wedge\).

Our solutions of the Kashiwara–Vergne problem have the property that the corresponding splitting of the filtrations are compatible with those of the Lie algebra of the relative completion of the mapping class group constructed in \cite{12}. (See \cite[Thm. 6]{17}.) Whether or not all solutions of the Kashiwara–Vergne problem have this property is not known.

The Kashiwara–Vergne problem concerns smooth surfaces and does not require a complex structure. Let \(S\) be a closed oriented surface of genus \(g\) and \(P = \{x_0, \ldots, x_n\}\) a finite subset. Set \(S = S - P\). Assume that \(S\) is hyperbolic; that is, \(2g - 1 + n > 0\). Suppose that \(\xi_0\) is a framing of \(S\). Denote the index (or local degree) of \(\xi_0\) at \(x_j\) by \(d_j\). Let \(d = (d_0, \ldots, d_n) \in \mathbb{Z}^{n+1}\) be the vector of local degrees of \(\xi_0\). The Poincaré–Hopf Theorem implies that \(\sum d_j = 2 - 2g\).

In \cite{3} it is shown that the Kashiwara–Vergne problem admits solutions for all framed surfaces of genus \(g \neq 1\) and for surfaces of genus 1 with certain, but not all, framings \footnote{To compare the two statements, one should note that if \(\gamma_j\) is the boundary of sufficiently small disk in \(X\), centered at \(x_j\), and, then \(d_j + \text{rot}_{\xi_0}\gamma_j = 1\). Note that the boundary orientation conventions used in \cite{1,2,3} differ from those used in this paper. Their “adapted framing” has the property that \(d_0 = 2 - 2g\) and \(d_j = 0\) for all \(j \geq 1\).} (See \cite[Thm. 6.1]{3}.) We obtain an independent proof of their result by showing (in Section 9) that the framings for which the KV-problem has a solution are precisely those that can be realized topologically by a quasi-algebraic framing. The proof combines work of Kawazumi \cite{23} with the existence of meromorphic quadratic differentials, which is established in the works of Kontsevich–Zorich \cite{27} and Bainbrige, Chen, Gendron, Grushevsky and Möller \cite{4}.

**Theorem 5.** If \(g \neq 1\), then there is a complex structure \((\overline{X}, D)\) on \((\overline{S}, P)\) such that \(\xi_0\) is homotopic to a quasi-algebraic framing of \(X\). When \(g = 1\), then there is a complex structure on \((\overline{S}, P)\) for which \(\xi_0\) is quasi-algebraic if and only if the rotation number of \(\text{rot}_{\xi_0}\gamma\) of every simple closed curve \(\gamma\) in \(\overline{X}\) is divisible by \(\gcd(d_0, \ldots, d_n)\).

Solutions of the Kashiwara–Vergne (KV) problem for \((S, \xi_0)\) form a torsor under a pronipotent group, denoted \(\mathcal{KRV}_{g,n+1}^{\text{rel}}\) in \cite{3}. It depends only on the vector of
local degrees \( \mathbf{d} \) and not on other topological invariants of \( \xi_o \). Corollary \([11]\) implies that each quasi-algebraic structure

\[
\phi : (X, D, \tilde{\nabla}, \xi) \rightarrow (S, P, \tilde{\nu}_o, \xi_o)
\]
determines an injection \( \mathcal{U}^{\mathcal{MT}}_{X, \tau} \rightarrow \mathcal{K}\mathcal{R}\mathcal{V}_{g, n+\overline{1}}^d \). Letting the stabilizer of \( \xi_o \) in the mapping class group of \( (S, P) \) act on the complex structure \( \phi \) by precomposition, we obtain a larger a larger torsor of solutions to the KV-problem. These form a torsor under a pronipotent group \( \tilde{U}_{g, n+\overline{1}}^d \) whose construction and structure is discussed below. It is a subgroup of \( \mathcal{K}\mathcal{R}\mathcal{V}_{g, n+\overline{1}}^d \). We conjecture that it is equal to \( \mathcal{K}\mathcal{R}\mathcal{V}_{g, n+\overline{1}}^d \). Equivalently, we conjecture that all solutions of the Kashiwara-Vergne problem arise from the Hodge theoretic constructions for some quasi-algebraic structure \( \phi \).

In order to state the next theorem, we need to introduce several pronipotent groups. Denote the category of mixed Tate motives unramified over \( \mathbb{Q} \) and its pronipotent radical by \( U \). Denote the image of \( \pi_1(M\mathcal{T}\mathcal{M}, \omega^B) \) (with respect to the Betti realization \( \omega^B \)) by \( K \). Its Lie algebra \( \mathfrak{k} \) is non-canonically isomorphic to the free Lie algebra

\[
\mathfrak{k} \cong \mathcal{L}(\sigma_3, \sigma_5, \sigma_7, \sigma_9, \ldots)^\wedge.
\]

Denote the relative completion of the mapping class group of \( (S, P, \tilde{\nu}_o) \) by \( \mathcal{G}_{g, n+\overline{1}} \) and its pronipotent radical by \( \mathcal{U}_{g, n+\overline{1}} \). (See \([12]\) for definitions.) These act on \( \mathbb{Q}\pi_1(S, \tilde{\nu}_o)^\wedge \). Denote the image of \( \mathcal{U}_{g, n+\overline{1}} \) in \( \text{Aut} \, \mathbb{Q}\pi_1(S, \tilde{\nu}_o)^\wedge \) by \( \overline{\mathcal{U}}_{g, n+\overline{1}}^d \). The vector field \( \xi_o \) determines a homomorphism \( \overline{\mathcal{U}}_{g, n+\overline{1}} \rightarrow H_1(S) \) that depends only on the vector \( \mathbf{d} \) of local degrees of \( \xi \). Denote its kernel by \( \overline{\mathcal{U}}_{g, n+\overline{1}}^d \). The group \( \tilde{U}_{g, n+\overline{1}}^d \) mentioned above is the subgroup of \( \mathcal{K}\mathcal{R}\mathcal{V}_{g, n+\overline{1}}^d \) generated by \( \overline{\mathcal{U}}_{g, n+\overline{1}}^d \) and \( \mathcal{U}^{\mathcal{MT}}_{X, \tau} \).

**Theorem 6.** If \( 2g + n > 1 \) (i.e., \( S \) is hyperbolic), then the group \( \tilde{U}_{g, n+\overline{1}}^d \) does not depend on the choice of an algebraic structure \( (X, D, \tilde{\nabla}, \xi) \) on \( (S, P, \tilde{\nu}_o, \xi_o) \). The group \( \overline{\mathcal{U}}_{g, n+\overline{1}}^d \) is normal in \( \tilde{U}_{g, n+\overline{1}}^d \), and there is a canonical surjective group homomorphism \( \mathcal{K} \rightarrow \tilde{U}_{g, n+\overline{1}}^d / \overline{\mathcal{U}}_{g, n+\overline{1}}^d \), where \( \mathcal{K} \) denotes the pronipotent radical of \( \pi_1(M\mathcal{T}\mathcal{M}) \).

This result follows from a more general result, Theorem \([12, 4]\) which is proved in Section \([13]\). We expect the homomorphism \( \mathcal{K} \rightarrow \tilde{U}_{g, n+\overline{1}}^d / \overline{\mathcal{U}}_{g, n+\overline{1}}^d \) to be an isomorphism. The injectivity of this homomorphism is closely related to Oda’s Conjecture \([28]\) (proved in \([20]\)) and should follow from it.

In genus 1, the associated graded Lie algebra \( \mathcal{G}_{1, n+\overline{1}}^W \) of the Lie algebra of \( \mathcal{U}_{1, n+\overline{1}} \) contains contains the derivations \( \delta_{2n} \) (denoted \( \epsilon_{2n} \) in \([20]\)). This implies \([8, \text{Thm. 1.5}]\).

---

\(^2\)Conjecturally, the homomorphism \( \mathcal{G}_{g, n+\overline{1}} \rightarrow \text{Aut} \, \mathbb{Q}\pi_1(S, \tilde{\nu}_o)^\wedge \) is injective, which would imply that \( \mathcal{U}_{g, n+\overline{1}} = \overline{\mathcal{U}}_{g, n+\overline{1}} \).

\(^3\)Explicit presentations of the Lie algebras of the \( \mathcal{U}_{g, n+\overline{1}} \) are known for all \( n \geq 0 \) when \( g \neq 2 \) \([12, 15, 28]\). Partial presentations (e.g., generating sets) are known when \( g = 2 \). \([83]\). Presentations of the \( \tilde{U}_{g, n+\overline{1}}^d \) can be deduced easily from these.
Conjecture 1.1. The inclusion $\hat{U}_{d+1}^{g,n} \to KRV_{d+1}^{g,n}$ is an isomorphism if and only if the inclusion of $\pi_1(MTM)$ into the Grothendieck–Teichmüller group is an isomorphism. In this case, $KRV_{d+1}^{g,n}$ should be a split extension

$$1 \to \hat{U}_{d+1}^{g,n} \to KRV_{d+1}^{g,n} \to K \to 1.$$

A few remarks about the approach and the structure of the paper. As when proving that the Goldman bracket is a morphism of MHS [17], the proof of Theorem 1 consists in:

(i) Finding a homological description of the cobracket $\delta_\xi$ analogous to the homological description of the Goldman bracket given by Kawazumi–Kuno [24, §3]. This description gives a factorization of the cobracket.

(ii) Giving a de Rham description of the continuous dual of each map in this factorization.

(iii) Proving that, for each quasi-complex structure on $(S, P, \vec{v}, \xi)$, each map in this factorization of the dual cobracket is a morphism of MHS.

The homological description of the cobracket is established in Sections 4 and 5. This description appears to be new. The de Rham descriptions of the factors of the dual cobracket are given in Section 6. The proof of Theorem 1 is completed in Section 7 where it is shown that each map in the factorization of the cobracket is a morphism of MHS for each choice of a complex structure. The group $\hat{U}_{d+1}^{g,n}$ is defined and analyzed in Section 12, and Theorem 6 is proved in Section 13.

This paper is a continuation of [17]. We assume familiarity with the sections of that paper on rational $K(\pi, 1)$ spaces, iterated integrals, and Hodge theory.

Acknowledgments: I would like to thank Anton Alekseev, Nariya Kawazumi, Yusuke Kuno and Florian Naef for patiently answering my numerous questions about their work. I am also grateful to Quentin Gendron for pointing out an issue with the existence of algebraic framings which necessitated the introduction of quasi-algebraic framings.

2. Notation and Conventions

Suppose that $X$ is a topological space. There are two conventions for multiplying paths. We use the topologist’s convention: The product $\alpha \beta$ of two paths $\alpha, \beta: [0, 1] \to X$ is defined when $\alpha(1) = \beta(0)$. The product path traverses $\alpha$ first, then $\beta$. We will denote the set of homotopy classes of paths from $x$ to $y$ in $X$ by $\pi(X; x, y)$. In particular, $\pi_1(X, x) = \pi(X; x, x)$. The fundamental groupoid of $X$ is the category whose objects are $x \in X$ and where $\text{Hom}(x, y) = \pi(X; x, y)$.

As in [17], we have attempted to denote complex algebraic and analytic varieties by the roman letters $X, Y$, etc and arbitrary smooth manifolds (and differentiable spaces) by the letters $M, N$, etc. This is not always possible. The diagonal in $T \times T$ will be denoted $\Delta_T$.

The singular homology of a smooth manifold $M$ will be computed using the complex $C_\ast(M)$ of smooth singular chains. The complex $C^\ast(M)$ will denote its dual, the complex of smooth singular cochains. The de Rham complex of $M$ will be denoted by $E^\ast(M)$. The integration map $E^\ast(M) \to C^\ast(M; \mathbb{R})$ is thus a well-defined cochain map.
2.1. Local systems and connections. Here we regard a local system on a manifold $N$ as a locally constant sheaf. We will denote the complex of differential forms on $N$ with values in a local system $V$ of real (or rational) vector spaces by $E^\bullet(N; V)$. As in [17], we denote the flat vector bundle associated to $V$ by $V$ and the sheaf of $j$-forms on $N$ with values in $V$ by $\mathcal{E}_N^j \otimes V$. So $E^j(N, V)$ is just the space of global sections of $\mathcal{E}_N^j \otimes V$. There are therefore isomorphisms

$$H^\bullet(E^\bullet(N; V)) \cong H^\bullet(N; V)$$

The pullback of a local system $V$ over $Y \times Y$ along the interchange map $\tau : Y^2 \to Y^2$ will be denoted by $V^{\text{op}}$.

2.2. Cones. Several homological constructions will use cones. Since signs are important, we fix our conventions. The cone of a map $\phi : A_\bullet \to B_\bullet$ of chain complexes is defined by

$$C_\bullet(\phi) := \text{cone}(A_\bullet \to B_\bullet)[-1],$$

where $C_j(\phi) = B_j \oplus A_{j-1}$ with differential $\partial(b, a) = (\partial b - \phi(a), -\partial a)$. The cone of a map $\psi : B^\bullet \to A^\bullet$ of cochain complexes is defined by

$$C^\bullet(\psi) := \text{cone}(B^\bullet \to A^\bullet)[-1],$$

where $C^j(\psi) := B^j \oplus A^{j-1}$ with differential $d(\beta, \alpha) = (d\beta, -d\alpha - \psi(\beta))$. Pairings of complexes

$$\langle , \rangle_A : A^\bullet \otimes A_\bullet \to V \quad \text{and} \quad \langle , \rangle_B : B^\bullet \otimes B_\bullet \to V$$

induce the pairing

$$\langle , \rangle : C^\bullet(\psi) \otimes C_\bullet(\phi) \to V$$

defined by $\langle \beta, \alpha \rangle \otimes (b, a) \mapsto \langle \alpha, a \rangle_A + \langle \beta, b \rangle_B$. It satisfies $\langle dz, c \rangle = \langle z, \partial c \rangle$ and thus induces a pairing

$$\langle , \rangle : H^\bullet(C^\bullet(\psi)) \otimes H_\bullet(C_\bullet(\phi)) \to V.$$

3. Preliminaries

We recall and elaborate on notation from [17]. Fix a ring $k$. Typically, this will be $\mathbb{Z}$, $\mathbb{Q}$, $\mathbb{R}$ or $\mathbb{C}$. Suppose that $M$ is a smooth manifold, possibly with boundary. All paths $[0, 1] \to M$ will be piecewise smooth unless otherwise noted. Denote the space of paths $\gamma : [0, 1] \to M$ by $PM$. This is endowed with the compact open topology. For each $t \in [0, 1]$, one has the map

$$p_t : PM \to M$$

defined by $p_t(\gamma) = \gamma(t)$. It is a (Hurewicz) fibration.

3.1. Fibrations. The most fundamental path fibration is the map

$$(3.1) \quad p_0 \times p_1 : PM \to M \times M.$$

Its fiber over $(x_0, x_1)$ is the space $P_{x_0, x_1} M$ of paths in $M$ from $x_0$ to $x_1$. When $x_0 = x_1 = x$, the fiber is the space $\Lambda_x M$ of loops in $M$ based at $x$. The local system whose fiber over $(x_0, x_1)$ is $H_0(P_{x_0, x_1} M, k)$ will be denoted by $P_M$.

More generally, for $(t_1, \ldots, t_n) \in [0, 1]^n$ with $0 < t_1 \leq t_2 \leq \cdots \leq t_n < 1$, one has the fibration

$$\prod_{j=1}^n p_{t_j} : PM \to M^n.$$
whose fiber over \((x_1, \ldots, x_n)\) is
\[
P_{x_1}M \times P_{x_1, x_2}M \times \cdots \times P_{x_{n-1}, x_n}M \times P_{x_n}M.
\]
Here \(P_{x}M\) denotes the space of paths terminating at \(x \in M\) and \(P_{x}M\) denotes the space of paths emanating from \(x\). Since \(P_{x}M\) and \(P_{x}M\) are contractible, the fiber of the corresponding local system over \(M^n\) is
\[
\pi^*_{1,2}P_M \otimes \pi^*_{2,3}P_M \otimes \cdots \otimes \pi^*_{n-1,n}P_M,
\]
where \(\pi_{j,k} : M^n \to M \times M\) denotes the projection onto the product of the \(j\)th and \(k\)th factors.

The “pullback path fibration” obtained by pulling back (3.1) along a smooth map \(f : N \to M \times M\) will be denoted by \(P_f M \to N\). When \(f\) is the diagonal map \(M \to M \times M\), the pullback is the fibration \(p : \Lambda M \to M\) of the free loop space of \(M\) over \(M\). Its fiber over \(x \in M\) is the space \(\Lambda_x M\) of loops in \(M\) based at \(x\). The corresponding local system will be denoted by \(L_M\). It has fiber \(H_0(\Lambda_x M; k)\) over \(x \in M\).

3.2. Homology. The following result follows easily from the fact that a non-compact surface is a \(K(\pi, 1)\) and has cohomological dimension 1. Cf. [17, Prop. 3.5].

Proposition 3.1. If \(M\) is a surface and if \(M\) is not closed, then \(H_j(\Lambda M)\) vanishes (with all coefficients) for all \(j > 1\). \(\square\)

4. Factoring Loops

In this section \(M\) is a smooth manifold and \(k\) is any commutative ring. Recall from [17, §3.3] the construction of the Chas–Sullivan map
\[
\beta_{CS} : H_0(\Lambda M) \to H_1(M; L_M).
\]
It is induced by the map that takes a loop \(\alpha : S^1 \to M\) to the horizontal lift \(\hat{\alpha} : S^1 \to L_M\) of \(\alpha\) defined by \(\hat{\alpha}(t)(\phi) = \alpha(\phi + t)\). We now describe a generalization of the Chas–Sullivan map. It arises from the factorization of a loop into two arcs.

The evaluation map
\[
p_0 \times p_{1/2} : \Lambda M \to M \times M
\]
is a fibration. Its fiber over \((x,y)\) is \(P_{x,y}M \times P_{y,x}M\). The corresponding local system over \(M \times M\) is
\[
P_M \otimes P_M^{\text{op}}
\]
where \(V^{\text{op}}\) denotes the pullback of the local system \(V\) on \(M \times M\) along the map \((x, y) \mapsto (y, x)\). The restriction of \(P_M \otimes P_M^{\text{op}}\) to the diagonal \(\Delta_M \cong M\), is \(L_M \otimes L_M\).

Composing \(\beta_{CS}\) with the maps induced on homology by the two maps \(L_M \to L_M \otimes L_M\) defined by
\[
\alpha \mapsto \alpha \otimes 1 \text{ and } \alpha \mapsto 1 \otimes \alpha,
\]
where 1 denotes the horizontal section of \(L_M\) whose value at \(x\) is 1, gives two maps
\[
\beta_{CS} \otimes 1 \text{ and } 1 \otimes \beta_{CS} : H_0(\Lambda M) \to H_1(M; L_M \otimes L_M).
\]
Composing these with the diagonal map
\[
\Delta_* : H_1(M; L_M \otimes L_M) \to H_1(M^2; P_M \otimes P_M^{\text{op}})
\]
yields two maps
\[ \Delta_\ast(\beta_{CS} \otimes 1) \text{ and } \Delta_\ast(1 \otimes \beta_{CS}) : H_0(\Lambda M) \longrightarrow H_1(M^2; P_M \otimes P_M^{op}). \]

**Proposition 4.1.** These two maps are identical.

**Proof.** Each loop \( \alpha : S^1 \rightarrow M \) induces a map \( \alpha^2 : S^1 \times S^1 \rightarrow M \times M \). This lifts to a horizontal section \( s_\alpha \) of \( P_M \otimes P_M^{op} \) defined over \( (S^1 \times S^1) - \Delta_{S^1} \). It is defined by
\[ s_\alpha(\theta, \phi) = \alpha' \otimes \alpha'', \]
where \( \alpha' \) is the restriction of \( \alpha \) to the positively oriented arc in \( S^1 \) from \( \theta \) to \( \phi \) and \( \alpha'' \) is its restriction to the arc from \( \phi \) to \( \theta \). This lift does not extend continuously to \( S^1 \times S^1 \), except when \( \alpha \) is null homotopic.

To extend the lift, we replace \( S^1 \times S^1 \) by \( U := [0, 2\pi] \times S^1 \). The map
\[ U \rightarrow S^1 \times S^1, \quad (t, \phi) \mapsto (t + \phi, \phi) \]
is a quotient map that takes the boundary of \( U \) onto the diagonal \( \Delta_{S^1} \). It induces a homeomorphism \( (0, 2\pi) \times S^1 \approx (S^1 \times S^1) - \Delta \) and identifies \( (0, \phi) \) with \( (2\pi, \phi) \). The horizontal lift \( s_\alpha : (S^1 \times S^1) - \Delta_{S^1} \rightarrow P_M \otimes P_M^{op} \) of \( \alpha^2 \) extends uniquely to a horizontal lift
\[ U \rightarrow P_M \otimes P_M^{op} \]
which we will also denote by \( s_\alpha \). The boundary of \( U \) is \( \{2\pi\} \times S^1 - \{0\} \times S^1 \). The result follows from the fact that \( \partial s_\alpha = 1 \otimes \dot{\alpha} - \dot{\alpha} \otimes 1. \)

5. **A Homological Description of the Turaev Cobracket**

Throughout this section, \( M \) will be a smooth oriented surface, possibly with boundary, and \( k \) is arbitrary. Denote space of non-zero tangent vectors of \( M \) by \( \hat{M} \) and the projection by \( \pi : \hat{M} \rightarrow M \). Denote the composition of the projection \( \pi : \hat{M} \rightarrow M \) with the diagonal map \( \Delta : M \rightarrow M \times M \) by \( \overline{\Delta} \).

5.1. **The group** \( H_\ast(M^2, \hat{M}; L_{\hat{M}} \rightarrow P_M \otimes P_M^{op}) \). The homological description of the Turaev cobracket uses a cone construction that arises from the computations in the proof of Proposition 4.1. Define
\[ \iota : L_{\hat{M}} \rightarrow \overline{\Delta} (P_M \otimes P_M^{op}) \]
to be the map whose restriction to the fiber \( L_{\hat{M},v} \) over \( v \) is defined by
\[ \iota(\alpha) = 1_x \otimes (\pi \circ \alpha) - (\pi \circ \alpha) \otimes 1_x \in H_0(P_{x,v}M) \otimes H_0(P_{x,v}M), \]
where \( \alpha \in \Lambda_{x,v} \hat{M} \) and \( x = \pi(v) \).

The maps \( \overline{\Delta} \) and \( \iota \) induce a chain map
\[ \overline{\Delta} \otimes \iota : C_\ast(\hat{M}; L_{\hat{M}}) \rightarrow C_\ast(\hat{M}; P_M \otimes P_M^{op}) \]
of singular chain complexes. We can therefore form the cone
\[ C_\ast(\overline{\Delta} \otimes \iota) := \text{cone} \ (C_\ast(\hat{M}; L_{\hat{M}}) \rightarrow C_\ast(\hat{M}; P_M \otimes P_M^{op}))[-1] \]
Set
\[ H_\ast(M^2, \hat{M}; L_{\hat{M}} \rightarrow P_M \otimes P_M^{op}) := H_\ast(C_\ast(\overline{\Delta} \otimes \iota)) \]
For each \( \alpha \in \Lambda \hat{M} \) we have the 2-cycle \( (s_{\pi\alpha}, \dot{\alpha}) \in C_2(\hat{M}; \overline{\Delta} \otimes \iota) \), where
\[ s_{\pi\alpha} : U \rightarrow P_M \otimes P_M^{op} \]
is the section associated to the loop \( \pi \circ \alpha \in \Lambda \hat{M} \) that is defined in the proof of Proposition 4.1.

**Proposition 5.1.** The map that takes the class of a loop \( \alpha \in \Lambda \hat{M} \) to the class of the cycle \((s_{\pi \circ \alpha}, \hat{a}) \in C_*(\tilde{\Delta} \otimes \iota)\) defines a homomorphism

\[
\varphi : H_0(\Lambda \hat{M}) \to H_2(M^2, \tilde{M}; L_{\tilde{M}} \to P_M \otimes P_M^{op})
\]

whose composition with the map \( H_2(M^2, \tilde{M}; L_{\tilde{M}} \to P_M \otimes P_M^{op}) \to H_1(\tilde{M}; L_{\tilde{M}}) \) is the Chas–Sullivan map \( \beta_{CS} \) for \( \hat{M} \).

**Remark 5.2.** If \( M \) is not \( S^2 \), then \( M \) is a \( K(\pi, 1) \). In this case, after applying the Serre spectral sequence to the fibration \( (3.1) \), one sees that

\[
H_2(M \times \hat{M}; P_M \otimes P_M^{op}) \cong H_2(\Lambda M).
\]

This vanishes when \( M \) is not a closed surface by Proposition 3.1. Plugging this into the long exact sequence of the cone \( C_*(\tilde{\Delta} \otimes \iota) \), we obtain the commutative diagram

\[
\begin{array}{ccc}
0 & \to & H_2(M^2, \tilde{M}; L_{\tilde{M}} \to P_M \otimes P_M^{op}) \\
& \downarrow{\varphi} & \downarrow{\beta_{CS}} \\
& & H_1(\Lambda \hat{M}) \to H_1(\Lambda M) \to \cdots
\end{array}
\]

whose bottom row is exact for all non-closed surfaces. For future reference, we note that the existence of the lift \( \varphi \) implies that \( \psi \circ \beta_{CS} = 0 \).

\[
\square
\]

**5.2. The groups \( H^*_\Delta(M^2, N) \).** Denote the singular cochain complex of a pair \((Y, Z)\) with coefficients in \( k \) by \( C^*(Y, Z) \). For a continuous map \( h : T \to M^2 \), define

\[
C^*_\Delta(M^2, T) := \text{cone}(C^*(M^2, M^2 - \Delta_M) \xrightarrow{h^*} C^*(T))[-1]
\]

where \( j : M^2 - \Delta_M \to M^2 \) is the inclusion. Denote its cohomology groups by \( H^*_\Delta(M^2, T) \). They can also be computed by the complex

\[
\text{cone}(C^*(M^2) \xrightarrow{j^* \otimes h^*} C^*(M^2 - \Delta_M) \oplus C^*(T))[-1].
\]

**Lemma 5.3.** There is a long exact sequence

\[
\cdots \to H^{j-1}(T) \to H^j_\Delta(M^2, T) \to H^j_\Delta(M^2) \to H^j(T) \to \cdots
\]

**Proof.** The long exact sequence comes from the short exact sequence

\[
0 \to C^*(T)[-1] \to C^*_\Delta(M^2, T) \to C^*_\Delta(M^2) \to 0
\]

of complexes.

\[
\square
\]

We are interested in the 3 cases: \( T \) is empty; \( T = \Delta_M \) and \( h \) is the inclusion; \( T = \hat{M} \) and \( h \) is the composition of the projection \( \pi \) with the diagonal map. When \( T \) is empty, the Thom isomorphism gives an isomorphism \( H^j(M) \cong H^{j+2}_\Delta(M^2) \).

We’ll consider the case \( T = \hat{M} \) in the next section. Here we consider the case \( T = \Delta_M \).

We will suppose that \( \xi \) is a nowhere vanishing vector field on \( M \). The normal bundle of the diagonal \( \Delta_M \) in \( M^2 \) is isomorphic to the tangent bundle \( TM \) of \( M \).

The exponential map induces a diffeomorphism of a closed disk bundle in \( TM \) with
a regular neighbourhood $N$ of $\Delta M$ in $M^2$. By rescalling $\xi$, we may assume that $\exp \xi$ is mapped into $\partial N$. We will henceforth regard $\xi$ as the section $\exp \xi$ of $\partial N$. Denote the closed unit ball in $\mathbb{R}^2$ by $B$. We can choose a trivialization $\pi \times q : V \xrightarrow{\cong} \Delta M \times B$ such that $q \circ \xi : M \to B - \{0\}$ is null homotopic. This condition determines the homotopy class of the trivialization.

The inclusion $(N, \partial N) \hookrightarrow (M^2, M^2 - \Delta M)$ induces an isomorphism

$$H_\Delta^*(M^2, \Delta M) \xrightarrow{\cong} H^*(N, \Delta M \cup \partial N).$$

The Künneth Theorem implies that $q^* : H^2(B, \partial B) \to H^2(N, \partial N)$ is an isomorphism.

**Proposition 5.4.** There is a short exact sequence

$$0 \to H^1(\Delta M) \to H^2(N, \Delta M \cup \partial N) \to H^2(N, \partial N) \to 0.$$ 

**Proof.** This is part of the long exact sequence of the triple $(N, \Delta M \cup \partial N)$. Exactness on the left follows from the Künneth Theorem (or the Thom Isomorphism Theorem); exactness on the right follows as $\Delta_M \hookrightarrow N \xrightarrow{q} B$ is the constant map 0. \qed

The projection $q : N \to B$ induces an isomorphism

$$q^* : H^2(B, \partial B) \cong H^2(B, \{0\} \cup \partial B) \to H^2(N, \Delta M \cup \partial N).$$

This map depends on the homotopy class of the trivialization $\xi$. Denote the positive integral generator of $H^2(B, \partial B)$ by $\tau_B$. Define

$$\tau_\xi := q^* \tau_B \in H^2(N, \Delta M \cup \partial N).$$

The image of $\tau_\xi$ in $H^2(N, \partial N)$ is the Thom class $\tau_M$ of the tangent bundle of $M$.

To better understand $\tau_\xi$, suppose that $\gamma : S^1 \to \partial N \cong \Delta_M \times \partial B$. Define the rotation number $\text{rot}_\xi(\gamma)$ of $\gamma$ with respect to $\xi$ to be the rotation number of $q \circ \gamma$ about $0 \in B$. Let $\Gamma_\gamma$ to be the relative 2-cycle

$$\Gamma_\gamma : (I \times S^1, \partial I \times S^2) \to (N, \Delta M \cup \partial N)$$

that corresponds to the map

$$(I \times S^1, \partial I \times S^1) \to (B, \partial B), \quad (t, \theta) \mapsto t \gamma(\theta).$$

Give $I \times S^1$ has the product orientation.

**Lemma 5.5.** We have $\langle q^* \tau_B, \Gamma_\gamma \rangle = \text{rot}_\xi(\gamma)$.

**Proof.** Write $\tau_B = d\eta_B$ in $C^2(B)$. Observe that $\text{rot}_\xi(\gamma) = \langle \eta_B, \gamma \rangle$. Since $\partial \Gamma_\gamma = \gamma - c_0$, where $c_0$ denotes the constant map $S^1 \to B$ with value 0,

$$\langle q^* \tau_B, \Gamma_\gamma \rangle = \langle \tau_B, q_* \Gamma_\gamma \rangle = \langle d\eta_B, q_* \Gamma_\gamma \rangle = \langle \eta_B, q_* \partial \Gamma_\gamma \rangle = \langle \eta_B, \gamma \rangle = \text{rot}_\xi(\gamma).$$ \qed
5.3. The class $c_\xi$. In this section, we show that each non-vanishing vector field $\xi$ determines a class $c_\xi \in H^2_{\Delta}(M^2, \tilde{M})$. Pairing with this class corresponds to intersecting with the diagonal and is a key component of the homological description of $\delta_\xi$.

**Lemma 5.6.** Each section $\xi$ of $\tilde{M} \to M$ determines a class $f_\xi \in H^1(\tilde{M}; \mathbb{Z})$ whose pullback $\xi^* f_\xi$ to $M$ vanishes and whose restriction to each fiber $\tilde{M}_x$ is the positive integral generator of $H^1(\tilde{M}_x; \mathbb{Z})$. It is characterized by these properties.

**Proof.** This follows from the K"unneth Theorem and the fact that the section $\xi$ determines a trivialization $r: \tilde{M} \simeq M \times (\mathbb{R}^2 - \{0\})$ with $r \circ \xi$ constant. It is unique up to homotopy. Take $f_\xi$ to be the pullback of the positive generator of $H^1(S^2; \mathbb{Z})$ under the projection $\tilde{M} \simeq M \times (\mathbb{R}^2 - \{0\}) \to \mathbb{R}^2 - \{0\} \to S^1$. \hfill $\square$

**Lemma 5.7.** When $\tilde{M} \to M$ is a trivial bundle, there is a short exact sequence

$$0 \to H^1(\tilde{M}) \to H^2_{\Delta}(M^2, \tilde{M}) \to H^2_{\Delta}(M^2) \to 0.$$ 

Each framing $\xi$ of $M$ induces a natural splitting $s_\xi: H^2_{\Delta}(M^2) \to H^2_{\Delta}(M^2, \tilde{M})$ which depends only on the homotopy class of $\xi$.

**Proof.** This is part of the long exact sequence in Lemma 5.3. Exactness of the sequence follows from the Thom isomorphism $H^1(\Delta_M) \cong H^2_{\Delta}(M^2)$, which implies that $H^1_{\Delta}(M^2) = 0$. The triviality of the normal bundle of the diagonal in $M^2$ is trivial, which gives the exactness on the right.

Since $H^2_{\Delta}(M^2)$ is freely generated by the Thom class $\tau_M$ of $M$, to construct the lift, it suffices to lift $\tau_M$ to $H^2_{\Delta}(M^2, \tilde{M})$. To do this, note that $\pi: \tilde{M} \to \Delta_M$ induces a map $\pi^*: H^2_{\Delta}(M^2, \Delta_M) \to H^2_{\Delta}(M^2, \tilde{M})$ and recall that $H^2_{\Delta}(M^2, \Delta_M) \cong H^2(N, \Delta_M \cup \partial N)$. Define $s_\xi(\tau_M) = \pi^* \tau_M$. \hfill $\square$

**Definition 5.8.** Define $c_\xi := \pi^* \tau_M + f_\xi \in H^2_{\Delta}(M^2, \tilde{M})$, where $f_\xi \in H^2(\tilde{M})$ is identified with its image in $H^2_{\Delta}(M^2, \tilde{M})$.

5.4. The pairing. Here we define a pairing and compute the pairing of $c_\xi$ and $s_\alpha$ whose value is close to being the value $\delta_\xi(\alpha)$ of the cobracket.

**Proposition 5.9.** There is a well-defined pairing $\langle \; , \; \rangle: H_2(M^2, \tilde{M}; L_M) \to P_M \otimes P^0_M \otimes H^2_{\Delta}(M^2, \tilde{M}) \to H_0(M; L_M \otimes L_M)$.

**Proof.** We continue with the notation above. Let $U = N - \partial N$. Let $r: U \to \Delta_M$ be a retraction. Let $\mathcal{U} = \{M^2 - \Delta_M, U\}$. It is an open cover of $M^2$. We can compute the product using $U$-small chains $C^*_U$ and cochains $C^*_{\mathcal{U}}$ via the pairing $\operatorname{cone}(C^*_{\mathcal{U}}) \otimes (C^*_U) = C^*_U(M^2; P_M \otimes P^0_M)[-1] \otimes \operatorname{cone}(C^*_{\mathcal{U}}) \otimes C^*_U(U; P_M \otimes P^0_M)$. It takes values in $H_0(U, (P_M \otimes P^0_M)|_U)$. This group is naturally isomorphic to $H_0(M; L_M \otimes L_M)$ as the homotopy equivalence $r: U \to M$ induces a natural isomorphism $r^*(L_M \otimes L_M) \cong \langle P_M \otimes P^0_M \rangle|_U$. \hfill $\square$

Recall from the introduction (or the next proof) the notation for $\epsilon_\alpha, \alpha'_\beta$, and $\alpha''_\beta$. 
Lemma 5.10. If \( \alpha : S^1 \to M \) is an immersed circle with transverse self intersections, then

\[
\langle \tau_\xi, s_\alpha \rangle = \text{rot}_\xi(\alpha)(\alpha \otimes 1 - 1 \otimes \alpha) - \sum P \epsilon_P(\alpha'_P \otimes \alpha''_P - \alpha''_P \otimes \alpha'_P)
\]

where \( P \) ranges over the double points of \( \alpha \).

**Proof.** We use the notation of Section 5.2. Since the map \( \alpha^2 : S^1 \times S^1 \to M^2 \) maps the diagonal \( \Delta_{S^1} \) in \( S^1 \times S^1 \) to the diagonal in \( M^2 \), \( \alpha^2 \) cannot be transverse to \( \Delta_M \). However, by shrinking \( N \) if necessary, we may assume that \( \alpha \) is transverse to \( \partial N \) for all \( 0 < r \leq 1 \), where \( N_r \) denotes disk sub-bundle of \( N \) of radius \( r \), where \( N = N_1 \). In this case, the inverse image of \( N \) under \( \alpha^2 \) is a disjoint union

\[
\Gamma \cup \bigcup_{(\theta, \phi)} U_{\theta, \phi}
\]

where \( \Gamma \) is a neighbourhood of \( \Delta_{S^1} \) diffeomorphic to \([-1, 1] \times S^1 \), and where \( U_{\theta, \phi} \) is a disk about the point \((\theta, \phi) \in (S^1 \times S^1) - \Delta_{S^1} \) that corresponds to a double point of \( \alpha \).

Each double point \( P \) of \( \alpha \) determines a pair of points \((\theta, \phi) \) and \((\phi, \theta) \in S^1 \times S^1 - \Delta_{S^1} \), where \( \alpha(\theta) = \alpha(\phi) = P \). As in the introduction, \( \alpha'_P \) denotes the restriction of \( \alpha \) to the positively oriented arc in \( S^1 \) from \( \theta \) to \( \phi \), and \( \alpha''_P \) denotes its restriction to the arc from \( \phi \) to \( \theta \). Denote the initial tangent vectors of \( \alpha'_P \) and \( \alpha''_P \) by \( \vec{v}' \) and \( \vec{v}'' \). The intersection number \( \epsilon_P \) is defined by

\[
\vec{v}' \wedge \vec{v}'' \in \epsilon_P \times (\text{a positive number}) \times (\text{the orientation of } M \text{ at } P).
\]

An elementary computation shows that the intersection number of \( \alpha^2 : S^1 \times S^1 \to M^2 \) with \( \Delta_M \) at \((\theta, \phi) \) is \(-\epsilon_P \), and is \( \epsilon_P \) at \((\phi, \theta) \). Consequently,

\[
\langle \tau_\xi, Z' \rangle = -\epsilon_P \text{ and } \langle \tau_\xi, Z'' \rangle = \epsilon_P
\]

where \( U' \) (resp. \( U'' \)) denotes \( U_{\theta, \phi} \) (resp. \( U_{\phi, \theta} \)) and \( Z' \) (resp. \( Z'' \)) is the positive generator of \( H_2(U', \partial U'; Z) \) (resp. \( H_2(U'', \partial U''; Z) \)).

The contribution of the double point \( P \) to \( \langle \tau_\xi, s_\alpha \rangle \) is thus

\[
(5.3) \quad \langle \tau_\xi, Z' \rangle \alpha'_P \otimes \alpha''_P + \langle \tau_\xi, Z'' \rangle \alpha''_P \otimes \alpha'_P = -\epsilon_P(\alpha'_P \otimes \alpha''_P - \alpha''_P \otimes \alpha'_P).
\]

It remains to compute the contribution of the strip \( \Gamma \) to \( \langle \tau_\xi, s_\alpha \rangle \). The derivative \( \dot{\alpha} : M \to TM \) of \( \alpha \) corresponds to a section of the circle bundle \( \partial N \to \Delta_M \), unique up to homotopy. By the construction preceding Lemma 5.5 this determines a relative chain \( \Gamma_\alpha \) in \((N, \Delta_M \cup \partial N)\).

The inverse image of \( \Gamma \) in \([0, 1] \times S^1 \) under the map \( \iota_{1,2} \) is the disjoint union of two strips, \( \Gamma_0 \), a regular neighbourhood of \( 0 \times S^1 \), and \( \Gamma_{2\pi} \), a regular neighbourhood of \( 2\pi \times S^1 \).

Give \( \Gamma_0 \) and \( \Gamma_{2\pi} \) the orientation induced from \( S^1 \times S^1 \). Then, as classes in \( H_2(N, \Delta_M \cup \partial N) \), we have

\[
[G_0] = [\Gamma_\alpha] \text{ and } [G_{2\pi}] = -[\Gamma_\alpha].
\]

As observed in the proof of Proposition 4.1 the restriction of \( s_\alpha \) to \( \Gamma_{2\pi} \) is homotopic to \( 1 \otimes \alpha \), and to \( \Gamma_0 \) is homotopic to \( \alpha \otimes 1 \).
Lemma 5.5 now implies that the contribution to $\langle \tau_\xi, \alpha \rangle$ from $\Gamma$ is

\begin{equation}
(5.4) \quad \langle \tau_\xi, \Gamma \rangle = \langle \tau_\xi, \Gamma_{2\pi} \rangle 1 \otimes \alpha + \langle \tau_\xi, \Gamma_0 \rangle \alpha \otimes 1 = -\langle \tau_\xi, \Gamma_0 \rangle \cdot \alpha \otimes 1 + \langle \tau_\xi, \Gamma_{\alpha} \rangle \alpha \otimes 1
= \text{rot}_\xi(\alpha) (\alpha \otimes 1 - \alpha \otimes 1).
\end{equation}

The result follows by adding the contribution of the strip (5.4) to the sum of the contributions of the double points $P$. □

Remark 5.11. By an elementary case of a theorem of Hirsch [21] (that goes back to Whitney [34]), regular homotopy classes of immersed loops in $M$ correspond to Whitney classes (5.4) of $\hat{M}$. As shown in [25], the expression for $\langle \tau_\xi, \alpha \rangle$ in Lemma 5.10 is constant on regular homotopy classes of immersed circles in $M$ and thus defines a map

$$H_0(\Lambda \hat{M}) \to H_0(\Lambda M) \otimes H_0(\Lambda M).$$

5.5. A homological description of $\delta_\xi$. We can now give a homological description of the Turaev cobracket. Recall that, when $V$ is a local system over $M$, then $H_0(M; V)$ is the maximal trivial quotient of $V$. Applying this when $V = L_M \otimes L_M$, we see that there is a canonical map

$$H_0(M; L_M \otimes L_M) \to H_0(M; L_M) \otimes H_0(M; L_M) \cong H_0(\Lambda M) \otimes H_0(\Lambda M).$$

For a section $\xi$ of $\hat{M} \to M$, define$\\psi$ 

$$p_\xi : H_2(M^2, \hat{M}; L_M) \to P_M \otimes P_M^{\text{op}} \to H_0(M; L_M) \otimes H_0(M; L_M) \cong H_0(\Lambda M) \otimes H_0(\Lambda M).$$

to be the composite

$$H_2(M^2, \hat{M}; L_M) \to P_M \otimes P_M^{\text{op}} \xrightarrow{\delta_\xi} H_0(\Lambda M) \otimes H_0(\Lambda M).$$

Each section $\xi : M \to \hat{M}$ of $\pi$ induces a map $\Lambda \xi : \Lambda M \to \Lambda \hat{M}$ and thus a homomorphism

$$(\Lambda \xi)_* : H_0(\Lambda M) \to H_0(\Lambda \hat{M}).$$

It is injective as its composition with $(\Lambda \pi)_*$ is the identity. The image of a free homotopy class of $f : S^1 \to M$ corresponds to the regular homotopy class of an immersed circle $\alpha$ with rot $\xi(\alpha) = 0$ that is freely homotopic to $f$.

The following factorization of $\delta_\xi$ follows directly from Lemma 5.10.

Theorem 5.12. If $\xi$ is a section of $\pi : \hat{M} \to M$, then the diagram

$$H_0(\Lambda M) \xrightarrow{(\Lambda \xi)_*} H_0(\Lambda \hat{M}) \xrightarrow{\psi} H_2(M^2, \hat{M}; L_M) \xrightarrow{\delta_\xi} H_0(\Lambda M) \otimes H_0(\Lambda M)$$

commutes.

6. De Rham Aspects

In this section, in preparation for applying the machinery of Hodge theory in Section 7, we construct de Rham versions of the continuous duals of the maps used in the homological description of the Turaev cobracket given in Section 5.
6.1. Preliminaries. Suppose that \( N \) is a smooth manifold with finite first Betti number and that \( \mathbb{k} \) is a field of characteristic zero. We are especially interested in the case where \( N \) is a rational \( K(\pi,1) \) space.

Recall from [17, §7] that \( H_0(P_{x_0,x_1},N;\mathbb{k}) \) and \( H_0(\Lambda M;\mathbb{k}) \) have natural topologies and that their continuous duals are denoted

\[
\tilde{H}^0(P_{x_0,x_1},N;\mathbb{k}) := \text{Hom}_{\text{cts}}(H_0(P_{x_0,x_1},N),\mathbb{k})
\]

and

\[
\tilde{H}^0(\Lambda N;\mathbb{k}) := \text{Hom}_{\text{cts}}(H_0(\Lambda N),\mathbb{k}).
\]

Recall from [17, §8] that \( \tilde{L}_N \) denotes the continuous dual of the local system \( L_N \).

There is a natural isomorphism [17 Thm. 6.9].

\[
\tilde{H}^0(\Lambda N;\mathbb{k}) \cong H^0(N;\tilde{L}_N).
\]

Denote the local system over \( N \times N \) whose fiber over \((x_0,x_1)\) is \( \tilde{H}^0(P_{x_0,x_1},N;\mathbb{k}) \) by \( P_N \) and its pullback along the interchange map \( N^2 \to N^2 \) by \( P_N^{\text{op}} \).

**Lemma 6.1.** Let \( p : N \times N \to N \) be projection onto the first factor. If \( N \) is a rational \( K(\pi,1) \), then there is a natural isomorphism of locally constant sheaves

\[
R^k p_*(P_N \otimes P_N^{\text{op}}) \cong \begin{cases} \tilde{L}_N & k = 0, \\ 0 & k \neq 0 \end{cases}
\]

over \( N \).

**Proof.** This follows directly from [17 Cor. 9.2]. \( \square \)

**Corollary 6.2.** If \( N \) is a rational \( K(\pi,1) \), then there is a natural isomorphism

\[
H^1(N^2;P_N \otimes P_N^{\text{op}}) \cong H^1(N;\tilde{L}_N).
\]

**Proof.** Apply the Leray spectral sequence of the projection \( p : N \times N \to N \). The previous result and the fact that \( N \) is a rational \( K(\pi,1) \) imply that

\[
E_2^{k} \cong \begin{cases} H^1(N;\tilde{L}_N) & k = 0, \\ 0 & k > 0 \end{cases}
\]

so that the spectral sequence collapses at \( E_2 \). \( \square \)

6.1.1. Differential forms. Now \( \mathbb{k} \) will be \( \mathbb{R} \) or \( \mathbb{C} \). We regard a local system on \( N \) as a locally constant sheaf. We will denote the complex of differential forms on \( N \) with values in a local system \( V \) of real (or rational) vector spaces by \( E^*(N;V) \).

In [17], we denoted the flat vector bundle associated to \( V \) by \( \mathcal{V} \) and the sheaf of \( j \)-forms on \( N \) with values in \( V \) by \( \mathcal{E}^j_N \otimes \mathcal{V} \). So \( E^j(N,V) \) is just the space of global sections of \( \mathcal{E}^j_N \otimes \mathcal{V} \). There are therefore isomorphisms

\[
H^*(E^*(N;V)) \cong H^*(N;V)
\]

To connect with [17], we point out that the flat vector bundle associated to \( \tilde{L}_N \) is denoted by \( \mathcal{L}_N \), and the flat vector bundle associated to \( P_N \) by \( \mathcal{P}_N \).

6.2. Continuous DR duals. In this section, \( M \) is an oriented surface of non-positive Euler characteristic and \( \pi : \tilde{M} \to M \) is the bundle of non-zero tangent vectors of \( M \). Both \( M \) and \( \tilde{M} \) are rational \( K(\pi,1) \) spaces.\(^4\)

\[^4\text{For } M \text{ this is proved in [17 §5.1]. That } \tilde{M} \text{ is also a rational } K(\pi,1) \text{ follows from this using the fact that an oriented circle bundle over a rational } K(\pi,1) \text{ is a rational } K(\pi,1).\]
6.2.1. The continuous dual of $H_\bullet(M^2, \hat{M}; L_{\hat{M}} \to P_M \otimes P_M^{op})$. As in Section 5 we denote the composition of the projection $\pi$ with the diagonal map $M \to M^2$ by $\Delta$. There is a natural restriction mapping

$$\iota^* : \hat{\Sigma}^* (\hat{P}_M \otimes \hat{P}_M^{op}) \to \hat{L}_{\hat{M}}$$

dual to the map (6.1). Its restriction

$$\hat{H}^0(\Lambda_\pi M) \otimes \hat{H}^0(\Lambda_\pi M) \to \hat{H}^0(\Lambda_\pi \hat{M})$$
to the fiber over $v \in \hat{M}$, where $x = \pi(v)$, is

$$f \otimes g \mapsto (\pi^* f) \otimes g(1_x) - f(1_x) \otimes (\pi^* g).$$

Since $\hat{P}_M$ and $L_{\hat{M}}$ are local systems of algebras, $\Sigma$ and $\iota$ induce a DGA homomorphism

$$\Sigma \otimes \iota^* : E^\bullet(M^2; \hat{P}_M \otimes \hat{P}_M^{op}) \to E^\bullet(\hat{M}, \hat{L}_{\hat{M}}).$$

Define

$$E^\bullet(M^2, \hat{M}; P_M \otimes P_M^{op} \to L_{\hat{M}}) := \mathrm{cone} \left( E^\bullet(M^2; P_M \otimes P_M^{op}) \Sigma \otimes \iota^* E^\bullet(\hat{M}, \hat{L}_{\hat{M}}) \right)[-1].$$

Denote its cohomology groups by

$$H^\bullet(M^2, \hat{M}; P_M \otimes P_M^{op} \to \hat{L}_{\hat{M}}).$$

Proposition 6.3. If $M$ is not a closed surface, then there is an exact sequence

$$\cdots \to H^1(M, L_M) \xrightarrow{\hat{\psi}} H^1(\hat{M}, \hat{L}_{\hat{M}}) \to H^2(M^2, \hat{M}; P_M \otimes P_M^{op} \to \hat{L}_{\hat{M}}) \to 0.$$  

where $\hat{\psi}$ is dual to the connecting homomorphism $\psi$ in Remark 5.2.

Proof. The cohomology long exact sequence of the cone is

$$\cdots \to H^1(M^2; \hat{P}_M \otimes \hat{P}_M^{op}) \to H^1(\hat{M}, \hat{L}_{\hat{M}})$$

$$\to H^2(M^2, \hat{M}; P_M \otimes P_M^{op} \to \hat{L}_{\hat{M}}) \to H^2(M^2; P_M \otimes P_M^{op}) \to \cdots$$

Since $M$ is not closed, it is homotopy equivalent to a wedge of circles and therefore a rational $K(\pi, 1)$ of cohomological dimension 1. In particular, $H^2(M^2; P_M \otimes P_M^{op})$ vanishes. Finally, Corollary 6.2 gives an isomorphism $H^1(M^2; P_M \otimes P_M^{op}) \cong H^1(M; L_M)$. □

The cohomology of this cone is dual to the homology of the cone defined in Section 5.

Proposition 6.4. The pairing

$$\langle \ , \rangle : E^\bullet(M^2, \hat{M}; P_M \otimes P_M^{op}) \otimes C_\bullet(\Sigma) \otimes \iota \to \mathbb{k}$$

$$\langle (\omega, \xi), (s, u) \rangle = \int_s \omega + \int_u \xi$$

defined using integration and the pairings

$$P_M \otimes P_M \to \mathbb{k} \text{ and } \hat{L}_{\hat{M}} \otimes L_{\hat{M}} \to \mathbb{k}$$

respect the differentials and thus induces a pairing

$$\langle \ , \rangle : H^\bullet(M^2, \hat{M}; P_M \otimes P_M^{op} \to \hat{L}_{\hat{M}}) \otimes H_\bullet(M^2, \hat{M}; L_{\hat{M}} \to P_M \otimes P_M^{op}) \to \mathbb{k}.$$

□
6.2. There is a well-defined product

\[
\beta_{\text{CS}} : H^1(\tilde{M}; \tilde{L}_M) \to \tilde{H}^0(\tilde{M}).
\]

dual to the dual Chas–Sullivan map

\[
\beta_{\text{CS}} : H_0(\hat{\Lambda} M) \to H_1(\hat{M}, L_{\tilde{M}}).
\]

Proposition 6.6. There is a (necessarily unique) map

\[
\hat{\varphi} : H^2(M^2, \hat{M}; P_M \otimes P_M^{\text{op}} \to \tilde{L}_{\tilde{M}}) \to \hat{H}^0(\hat{\Lambda} M)
\]

that makes the diagram

\[
\begin{array}{c}
\hat{H}^0(\hat{\Lambda} M) \\
\downarrow \hat{\varphi} \\
H^2(M^2, \hat{M}; P_M \otimes P_M^{\text{op}} \to \tilde{L}_{\tilde{M}}) \\
\end{array}
\]

commute. It is defined over \( k = \mathbb{Q} \) and is dual to the map \( \varphi \) in the sense that

\[
\langle \Omega, \varphi(z) \rangle = \langle \hat{\varphi}(|\Omega|, z) \rangle
\]

whenever \( z \in H_0(\hat{\Lambda} M) \) and \( \Omega \in H^2(M^2, \hat{M}; P_M \otimes P_M^{\text{op}} \to \tilde{L}_{\tilde{M}}) \).

Proof. Since \( \beta_{\text{CS}} \) is exact, it suffices to show that

\[
H^1(M, \tilde{L}_M) \xrightarrow{\hat{\psi}} H^1(\hat{M}; \hat{L}_{\tilde{M}}) \xrightarrow{\beta_{\text{CS}}} \hat{H}(\hat{\Lambda} M)
\]

is zero, where \( \hat{\psi} \) is the connecting homomorphism in the long exact sequence \( \text{(6.1)} \).

Since the diagram

\[
\begin{array}{c}
H^1(M, \tilde{L}_M) \\
\downarrow \hat{\psi} \\
H_1(M; L_M)^* \\
\end{array}
\]

\[
\begin{array}{c}
H^1(\tilde{M}; \tilde{L}_{\tilde{M}}) \\
\downarrow \beta_{\text{CS}} \\
H_0(\hat{\Lambda} M)^*
\end{array}
\]

commutes, where \( (\cdot)^* \) denotes \( \text{Hom}_k(\_, k) \), and since the right-hand vertical map is injective, it suffices to show that \( \hat{\psi} \circ \beta_{\text{CS}} = 0 \). But this follows from the commutative diagram in Remark \( \text{(6.2)} \) as noted there.

6.2.3. The cup product. The de Rham incarnation of the complex \( C^*_\Delta(M^2, \hat{M}) \) defined in Section \( \text{(5.3)} \) is

\[
E^*_\Delta(M^2, \hat{M}) := \text{cone}(E^*(M^2) \to E^*(M^2 - \Delta) \oplus E^*(\hat{M}))[1].
\]

De Rham’s Theorem and the 5-lemma imply that it computes \( H^*_\Delta(M^2, \hat{M}; k) \).

Lemma 6.6. There is a well-defined product

\[
\sim : H^0(M; \tilde{L}_M \otimes \tilde{L}_{\tilde{M}}) \otimes H^2_\Delta(M^2, \hat{M}) \to H^2(M^2, \hat{M}; P_M \otimes P_M^{\text{op}} \to \tilde{L}_{\tilde{M}}).
\]

It is dual to the pairing

\[
\langle \cdot, \cdot \rangle : H_2(M^2, \hat{M}; L_{\tilde{M}} \to P_M \otimes P_M^{\text{op}}) \otimes H^2_\Delta(\hat{M}) \to \hat{H}_0(M; L_M \otimes L_M).
\]

of Proposition \( \text{(5.9)} \) in the sense that

\[
\langle f \sim c, z \rangle = \langle f, \langle z, c \rangle \rangle
\]
for all  
\[ f \in H^0(M; \tilde{L}_M \otimes \tilde{L}_M), \quad c \in H^2(M, \tilde{M}; L_{\tilde{M}} \to P_M \otimes P_M^{op}).\]

**Proof.** This result can be proved using differential forms or singular cochains. We will use differential forms. The proof using singular cochains is similar.

Choose regular neighbourhoods \( U \) and \( V \) of the diagonal \( \Delta \) in \( M^2 \), where \( V \subset U \), \( V \) is closed and \( U \) is open. Since \( \Delta \to U \) is a homotopy equivalence, every flat section of \( L_M \otimes L_M \) over the diagonal extends uniquely to a flat section of \( P_M \otimes P_M^{op} \) over \( U \). It follows that restriction to the diagonal induces a quasi-isomorphism

\[ E^\bullet(U; P_M \otimes P_M^{op}) \to E^\bullet(M, \tilde{L}_M \otimes \tilde{L}_M). \]

Since the inclusion \( \Delta \to V \) is a homotopy equivalence, the map

\[ E^\bullet(M^2) \to E^\bullet(M^2) := \text{cone} \left( E^\bullet(M^2) \to E^\bullet(M^2 - V) \right)[-1] \]

is a quasi-isomorphism. Denote the complex of forms of \( M^2 \) that vanish on \( M^2 - V \) by \( E^\bullet(M^2, M^2 - V) \). The 5-lemma implies that the cochain map

\[ E^\bullet(M^2, M^2 - V) \to E^\bullet(M^2) \]

that takes \( \omega \) to \([\omega, 0] \) is a quasi-isomorphism. Together these imply that \( E^\bullet(M^2, \tilde{M}) \) is quasi-isomorphic to the complex

\[ \text{cone} \left( E^\bullet(M^2, M^2 - V) \to E^\bullet(\tilde{M}) \right)[-1]. \]

The cup product pairing (6.2) is induced by the map of complexes

\[ E^\bullet(U, P_M \otimes P_M^{op}) \otimes \text{cone} \left( E^\bullet(M^2, M^2 - V) \to E^\bullet(\tilde{M}) \right)[-1] \]

\[ \to E^\bullet(M^2, \tilde{M}; P_M \otimes P_M^{op} \to L_{\tilde{M}}) \]

defined by \( F \otimes [\omega, \eta] \mapsto [F \wedge \omega, (-1)^{|F|}(\pi^*F) \wedge \eta] \). This is a chain map according to the conventions in Section 2.2.

To prove the remaining assertion, suppose that \( z \) is represented by \([s, u]\) in \( C_2(M^2, \tilde{M}; L_{\tilde{M}} \to P_M \otimes P_M^{op}) \), \( f \) is represented by \( F \in E^0(U, \tilde{P}_M \otimes \tilde{B}_M^{op}) \), and \( c \) is represented by \([\omega, \eta]\) in \( \text{cone} \left( E^\bullet(M^2, M^2 - V) \to E^\bullet(\tilde{M}) \right)[-1] \). Then, \( f \sim c \) is represented by \([F \omega, \pi^*F \cdot \eta]\), and

\[ \langle f \sim c, z \rangle = \langle [F \omega, \pi^*F \cdot \eta], [s, u] \rangle = \int_s F\omega + \int_u F\eta. \]

On the other hand, since \( F \) is locally constant,

\[ \langle f, \langle z, c \rangle \rangle = \langle f\langle [\omega, \eta], [s, u]\rangle \rangle \]

\[ = \langle F, \int_s \omega + \int_u \eta \rangle \]

\[ = \int_s F\omega + \int_u F\eta. \]

\( \square \)

6.3. **Factorization of the continuous dual of the Turaev cobracket.** Define

\[ \tilde{\delta}_c : \tilde{H}^0(\Lambda M) \otimes \tilde{H}^0(\Lambda M) \to \tilde{H}^0(\Lambda M) \]

so that the diagram

\[ \begin{array}{ccc}
H^0(\Lambda M \otimes \Lambda M) & \xrightarrow{\tilde{\delta}_c} & H^0(M, \tilde{L}_M) \otimes H^0(M, \tilde{L}_M) \\
\uparrow & & \downarrow \text{mult} \\
\tilde{H}^0(\Lambda M) & \xrightarrow{(\Lambda \xi)^*} & \tilde{H}^0(\tilde{M}, L_{\tilde{M}}) \end{array} \]

\[ \xrightarrow{\varphi} H^2(M^2, \tilde{M}; \tilde{P}_M \otimes P_M^{op} \to L_{\tilde{M}}) \]
commutes. The next result follows directly from Theorem 5.12 and the results in Section 6.2.

**Proposition 6.7.** The map \( \tilde{\delta}_\xi \) is the continuous dual of \( \delta_\xi \) in the sense that
\[
\langle \tilde{\delta}_\xi(f \otimes g), \alpha \rangle = \langle f \otimes g, \delta_\xi(\alpha) \rangle
\]
for all \( f, g \in \hat{H}^0(\Lambda M) \) and \( \alpha \in \Lambda M \).

7. **Proof of Theorem 1**

In this section, \( k \) will be \( \mathbb{Q}, \mathbb{R} \) or \( \mathbb{C} \), as appropriate, and \( X \) will be a smooth affine curve over \( \mathbb{C} \). Equivalently, \( X \) is the complement \( X - D \) of a finite subset \( D \) of a compact Riemann surface \( X \). Denote the holomorphic tangent bundle of \( X \) by \( T\overline{X} \).

**Definition 7.1.** Suppose that \( m \) is a positive integer. An algebraic \( m \)-framing of \( X \) is a meromorphic section of \( L \otimes T\overline{X} \) whose divisor is supported on \( D \), where \( L \) is a holomorphic line bundle over \( X \) whose \( m \)-th power \( L^m \) is trivial. Equivalently, \( \xi \) is the \( m \)-th root of a meromorphic section of the \( m \)-th power of the holomorphic tangent bundle of \( X \) whose divisor is supported on \( D \). A quasi-algebraic framing of \( X \) is an algebraic \( m \)-framing for some \( m > 0 \). An algebraic framing of \( X \) is, by definition, a 1-framing.

Since torsion line bundles on \( \overline{X} \), such as \( L \), are topologically trivial, each quasi-algebraic framing of \( X \) determines a homotopy class of smooth framings of \( \overline{X} \) and a cobracket \( \delta_\xi \). In this section, we prove the following stronger version of Theorem 1.

**Theorem 7.2.** If \( \xi \) is a quasi-algebraic framing of \( X \), then
\[
\delta_\xi : \mathbb{Q}\lambda(X)^\wedge \otimes \mathbb{Q}(-1) \to \mathbb{Q}\lambda(X)^\wedge \otimes \mathbb{Q}\lambda(X)^\wedge
\]
is a morphism of pro-mixed Hodge structures.

Throughout this section, \( m \) is a fixed positive integer, and \( \xi \) is an algebraic \( m \)-framing of \( X \). Its \( m \)-th power \( \xi^m \) is a meromorphic section of \( (T\overline{X})^\otimes m \). The theorem is proved by showing that each group in the factorization of
\[
\tilde{\delta}_\xi : \hat{H}^0(\Lambda X) \otimes \hat{H}^0(\Lambda X) \to \hat{H}^0(\Lambda X) \otimes \mathbb{Q}(-1)
\]
given in Section 6.3 has a mixed Hodge structure (MHS) and that each morphism in the factorization is a morphism of MHS. The twist by \( \mathbb{Q}(-1) \) occurs in the map \( \sim \circ \xi \). Note that the topological factorization of \( \delta_\xi \) in Section 3 implies that all of the maps in the factorization of \( \tilde{\delta}_\xi \) in Section 6.3 are also defined over \( \mathbb{Q} \). So we need only show that each preserves the Hodge and weight filtrations after extending scalars to \( \mathbb{C} \).

For a positive integer \( d \), denote the set of non-zero elements of \( (TX)^\otimes d \) by \( \tilde{X}_d \). This is a smooth quasi-projective variety. The map \( TX \to (TX)^\otimes d \) that takes a tangent vector \( v \) to \( v^d \) induces a covering map \( p_d : \tilde{X} \to \tilde{X}_d \). Since \( X, \tilde{X}_d \) are smooth algebraic varieties, \( \hat{H}^0(\Lambda \tilde{X}_d) \) and \( \hat{H}^0(\Lambda X) \) have natural MHS by [17, Cor. 10.7].

**Lemma 7.3.** For all \( d \geq 1 \), the map \( (\Lambda p_d)^* : \hat{H}^0(\Lambda \tilde{X}_d; \mathbb{Q}) \to \hat{H}^0(\Lambda \tilde{X}; \mathbb{Q}) \) is an isomorphism of MHS.
Proof. Since \( p_d : \hat{X} \to \hat{X}_d \) is a morphism of varieties, \((\Lambda p_m)^* \) is a morphism of MHS. So, to prove the result, it suffices to prove that it is an isomorphism of vector spaces.

To this end, fix a smooth section \( \xi_0 \) of \( \hat{X} \to X \). Then for all \( k \geq 1 \), \( \xi^k \) is a smooth section of \( \hat{X}_k \to X \). Since \( \hat{X}_k \to X \) is a principal \( \mathbb{C}^* \)-bundle with section \( \xi^k \), it is trivialized by the map

\[
(7.1) \quad \phi_k : X \times \mathbb{C}^* \to \hat{X}_k, \quad (x, t) \mapsto \xi_0(x)^k.
\]

This trivialization induces an isomorphism

\[
(\Lambda \phi_k)^* : \hat{H}^0(\Lambda \hat{X}_k; \mathbb{Q}) \to \hat{H}^0(\Lambda (X \times \mathbb{C}^*)) \cong \hat{H}^0(\Lambda X; \mathbb{Q}) \otimes \hat{H}^0(\Lambda \mathbb{C}^*; \mathbb{Q})
\]

as there is a canonical isomorphism \( \Lambda (A \times B) \cong \Lambda A \times \Lambda B \).

The \( d \)-fold covering map \( \chi_d : \mathbb{C}^* \to \mathbb{C}^* \) induces an isomorphism \( \hat{H}^0(\Lambda \mathbb{C}^*; \mathbb{Q}) \to \hat{H}^0(\Lambda \mathbb{C}^*; \mathbb{Q}) \). Since the diagram

\[
\begin{array}{ccc}
X \times \mathbb{C}^* & \xrightarrow{\phi} & \hat{X} \\
\downarrow \text{id} \times \chi_d & & \downarrow p_d \\
X \times \mathbb{C}^* & \xrightarrow{\phi_d} & \hat{X}_d
\end{array}
\]

commutes, so does

\[
\begin{array}{ccc}
\hat{H}^0(\Lambda \hat{X}_d; \mathbb{Q}) & \xrightarrow{(\Lambda \phi_d)^*} & \hat{H}^0(\Lambda X; \mathbb{Q}) \otimes \hat{H}^0(\Lambda \mathbb{C}^*; \mathbb{Q}) \\
\downarrow (\Lambda p_d)^* & & \downarrow \text{id} \otimes \chi_d \\
\hat{H}^0(\Lambda \hat{X}; \mathbb{Q}) & \xrightarrow{(\Lambda \phi_1)^*} & \hat{H}^0(\Lambda X; \mathbb{Q}) \otimes \hat{H}^0(\Lambda \mathbb{C}^*; \mathbb{Q})
\end{array}
\]

The result follows as the two horizontal maps and the right-hand vertical map are isomorphisms. \( \square \)

When \( m > 1 \), it is not immediately obvious that \((\Lambda \xi)^* \) is a morphism of MHS. However, this is the case.

**Corollary 7.4.** The map \((\Lambda \xi)^* : \hat{H}^0(\Lambda \hat{X}) \to \hat{H}^0(\Lambda X)\) is a morphism of MHS.

**Proof.** Regard \( \xi \) as a smooth section of \( \hat{X} \to X \). Since \( \xi^m \) is homotopic to \( p_m \circ \xi \), the diagram

\[
\begin{array}{ccc}
\hat{H}^0(\Lambda \hat{X}) & \xrightarrow{(\Lambda \xi)^*} & \hat{H}^0(\Lambda X; \mathbb{Q}) \\
\downarrow (\Lambda p_m)^* & & \downarrow \cong \\
\hat{H}^0(\Lambda \hat{X}_m) & \xrightarrow{(\Lambda \xi^m)^*} & \hat{H}^0(\Lambda X; \mathbb{Q})
\end{array}
\]

commutes. Since \( \xi^m \) is algebraic, the map \((\Lambda \xi^m)^* \) is a morphism of MHS. The result follows as \((\Lambda p_m)^* \) is an isomorphism of MHS by the previous result. \( \square \)

Since the map \( L_X \to \tilde{L}_X \otimes \tilde{L}_X \) is a direct limit of morphisms of admissible variations of MHS over \( X \), the Theorem of the Fixed Part (alternatively, by a direct argument that uses the construction of these MHS) implies that

\[
\text{mult} : H^0(X, \tilde{L}_X) \otimes^2 \to H^0(X, \tilde{L}_X^2)
\]

is a morphism of MHS.
To prove that the remaining groups have natural MHS and that the maps between them are morphisms, we need to recall the following standard fact about cones of mixed Hodge complexes, which is implicit in [7].

**Lemma 7.5.** The cone $C^\bullet(\phi)$ of a morphism $\phi: B^\bullet \to A^\bullet$ of mixed Hodge complexes is a mixed Hodge complex, and the corresponding long exact sequence

$$\cdots \to H^{j-1}(A^\bullet) \to H^{j}(C^\bullet(\phi)) \to H^{j}(B^\bullet) \to H^{j}(A^\bullet) \to \cdots$$

is a long exact of MHS.

**Proposition 7.6.** Each group in the diagram

\[ \begin{array}{ccc}
\hat{H}^0(\Delta \hat{X}) & \xrightarrow{\hat{\beta}_{CS}} & H^1(\hat{X}; L_{\hat{X}}) \\
& \downarrow{\hat{\varphi}} & \downarrow{\hat{\varphi}} \\
H^1(\tilde{X}; L_{\tilde{X}}) & \xrightarrow{H^2(X^2, \tilde{X}; P_X \otimes P_{\tilde{X}} \to \tilde{L}_{\tilde{X}})} & 0
\end{array} \]

has a natural MHS, and each map is a morphism of MHS.

**Proof.** The work of Saito [29] implies that if $V$ is an admissible variation of MHS over the complement of a divisor $W$ with normal crossings in a smooth variety $Z$, then the complex $E^\bullet(Z \log W; V)$ of smooth forms on $Z$ with values in the canonical extension of $V$ to $Z$ and log poles along $W$ is part of a mixed Hodge complex and is naturally quasi-isomorphic to $E^\bullet(Z - W; V)$. In particular, it computes $H^\bullet(Z - W; V) \otimes \mathbb{C}$, together with its Hodge and weight filtrations.

The compactification $P = \mathbb{P}(T \tilde{X} \otimes \mathcal{O}_{\tilde{X}})$ of the tangent bundle $T \tilde{X}$ of $\tilde{X}$ is a compactification of $\tilde{X}$ whose complement $W$ is a divisor with normal crossings. The cone

$$\text{cone}(E^\bullet(\tilde{X}^2, \log((\tilde{X} \times D) \cup (D \times \tilde{X})); \hat{P}_X \otimes \hat{P}_{\tilde{X}} \to \hat{L}_{\tilde{X}}), E^\bullet(\mathcal{P} \log W; L_{\tilde{X}}))[-1]$$

is quasi-isomorphic to $E^\bullet(X^2, \hat{X}; \hat{P}_X \otimes \hat{P}_{\tilde{X}} \to \hat{L}_{\tilde{X}})$. Lemma 7.5 implies that it is the complex part of a mixed Hodge complex and that the bottom row of the diagram is an exact sequence of MHS.

The map $\hat{\beta}_{CS}$ is morphism of MHS by Lemma [17] Lem. 11.1. The fact that the category of MHS is abelian implies that $\hat{\varphi}$ is a morphism of MHS.

**Proposition 7.7.** The group $H^\bullet_{\Delta}(X^2, \hat{X})$ has a natural mixed Hodge structure and $c_\xi$ is a Hodge class of type $(1, 1)$.

**Proof.** Let $Y$ be the blow up $\tilde{X} \times \tilde{X}$ at $\Delta_D$. Then $X^2 - \Delta$ is the complement of a normal crossing divisor $E$ in $Y$. Write $E = E' + \Delta_{\tilde{X}}$. The restriction of $E'$ to the diagonal $\Delta_{\tilde{X}}$ is $\Delta_D$.

Let $Z$ be the normal crossings compactification of $\hat{X}$ constructed in the proof of Proposition 7.6. The commutative diagram of morphisms of complex algebraic maps

\[ \begin{array}{cccccc}
\hat{X} & \xrightarrow{\pi} & X & \xrightarrow{\Delta} & X^2 & \xleftarrow{X^2 - \Delta_X} \\
\downarrow Z - W & & \downarrow X - D & & \downarrow Y - E' & \downarrow Y - E
\end{array} \]
induces a commutative diagram

\[
\begin{array}{ccc}
E^*(Y \log E) & \to & E^* \left( Y \log E' \right) \\
\downarrow & & \downarrow \\
E^* \left( X^2 - \Delta_X \right) & \to & E^* \left( X^2 \right) \\
\downarrow & & \downarrow \\
E^* \left( X \log D \right) & \to & E^* \left( X \right) \\
\downarrow & & \downarrow \\
E^* \left( Z \log W \right) & \to & E^* \left( \hat{X} \right) \\
\end{array}
\]

of DGAs in which each vertical map is a quasi-morphism. Each DGA in this diagram is the complex part of the natural mixed Hodge complex associated to the corresponding variety. The Five Lemma implies that the complex \( E^*_\Delta(X^2, \hat{X}) \) is naturally quasi-isomorphic to

\[
(7.2) \quad \text{cone}(E^*(Y \log E') \to E^*(Y \log E) \oplus E^*(Z \log W))[−1]
\]

Lemma 7.5 implies that it is the complex part of a mixed Hodge complex. It follows that \( H^*_\Delta(X, \hat{X}) \) has a natural MHS and that the exact sequence of Lemma 5.7

\[
0 \to H^1(\hat{X}) \to H^2_\Delta(X^2, \hat{X}) \to H^2_\Delta(X^2) \to 0
\]
is an exact sequence of mixed Hodge structures.

It remains to show that \( c_{\xi} \) is a Hodge class that spans a copy of \( \mathbb{Q}(-1) \). Recall the notation and the construction of \( c_{\xi} \) from Section 5.5. In particular, \( c_{\xi} = \pi^* \tau_{\xi} + f_{\xi} \). The topological constructions in that section imply that \( \pi^* \tau_{\xi} \) and \( f_{\xi} \) are both defined over \( \mathbb{Q} \). We first show that \( f_{\xi} \) is a Hodge class.

Let \( r_m : \hat{X}_m \to \mathbb{C}^* \) be the composite

\[
\hat{X} \xrightarrow{p_m} \hat{X}_m \xrightarrow{\pi} \mathbb{C}^*
\]

where the second map is the composition of the inverse of the isomorphism \( \phi_m \) with the projection \( X \times \mathbb{C}^* \to \mathbb{C}^* \) given by \( \xi^m \). Since \( \xi^m \) is algebraic, this is a morphism of varieties and thus induces a morphism of MHS on cohomology. The map \( r \) used in Lemma 5.6 in the construction of \( f_{\xi} \) is the topological nth root of \( r_m \). Since \( r_m dt/t = mr^* dt/t \), we have

\[
2\pi i f_{\xi} = r^* \frac{dt}{t} = \frac{1}{m} r_m^* \frac{dt}{t} \in H^1(\hat{X}; \mathbb{Q}) \subset H^2_\Delta(X^2, \hat{X})
\]

which spans a copy of \( \mathbb{Q}(-1) \) as \( H^1(\mathbb{C}^*; \mathbb{Q}) \cong \mathbb{Q}(-1) \). Thus \( f_{\xi} \) is a Hodge class.

Since \( c_{\xi} \) is defined over \( \mathbb{Q} \), to prove that it is a Hodge class, it suffices to show that it is a real Hodge class. To do this, we use the fact that the MHS on \( H^*_\Delta(X^2, \Delta_X) \) depends only on \( X \) and the normal bundle of \( \Delta_X \) in \( X^2 \), which is just the (holomorphic) tangent bundle \( TX \) of \( X \). This follows from the construction of a (real) mixed Hodge complex for the punctured neighbourhood of one variety in another that was constructed in [5]. That construction implies that the natural isomorphism

\[
H^*_\Delta(TX, X) \cong H^*_\Delta(X^2, \Delta_X)
\]

that is constructed using topology, is an isomorphism of real MHS. There is also a natural isomorphism

\[
p_d : H^*_\Delta((TX)^{\otimes d}, X) \xrightarrow{\cong} H^*_\Delta(TX, X)
\]
of MHS for all \( d \geq 1 \), where \( H^*_\Delta((TX)^{\otimes d}, X) \) is defined to be the homology of the complex

\[
\text{cone} \left( C^\bullet(TX, X) \to C^\bullet(X) \right)[−1]
\]
where the map is restriction to the zero section.
The trivialization $\phi_m : \mathcal{X}_m \to X \times \mathbb{C}^*$ given by $\xi^m \mathcal{Z}_1$ induces a MHS morphism $\phi^\ast : H^2(\mathbb{C}, \mathbb{C}^*) \to H^2_X(TX, \mathcal{X}_m)$. The class $c_{\xi}$ is the image of the positive generator $\tau_B$ of $H^2(\mathbb{C}, \mathbb{C}^*) \cong \mathbb{Z}(1)$ under the sequence

$$
H^2(\mathbb{C}, \mathbb{C}^*) = H^2_{[0]}(\mathbb{C}) \xrightarrow{r_{2\ast}} H^2_X(TX, \mathcal{X}) \xrightarrow{p_{m\ast}} H^2_{\mathcal{X}}(TX, \mathcal{X}) \xleftarrow{\sim} H^2_A(X^2, \Delta_X).
$$

It follows that $c_{\xi}$ is a real (and therefore rational) Hodge class. The final observation is that $\pi^* : H^2_A(X^2, \Delta_X) \to H^2_A(X^2, \mathcal{X})$ is a morphism of MHS, from which it follows that $\pi^*c_{\xi}$ is a Hodge class.

\[ \square \]

**Corollary 7.8.** The cup product \( \mathcal{Z}_1, \mathcal{Z}_2 \) is a morphism of MHS. Consequently, cupping with $c_{\xi}$

$$
\sim c_{\xi} : \tilde{H}^0(X; \mathcal{L}_X \otimes \mathcal{L}_X) \to H^2(X^2; \tilde{\mathcal{L}}, \mathcal{P}_X \otimes \mathcal{P}_X^{op} \to \mathcal{L}_X) \otimes \mathbb{Q}(-1)
$$

is a morphism of MHS

---

### 8. Mapping Class Group Orbits of Framings

In this section, we recall Kawazumi’s classification \[23\] of mapping class group orbits of framings of a surface. As we shall see subsequently, this classification is closely related to the classification of the strata of meromorphic 1-forms studied by Kontsevich and Zorich \[27\] in the holomorphic case, and by Chen, Gendron, Grushevsky and Möller \[4\] in the meromorphic case.

We first recall the definition of mapping class groups and our notation for them. Suppose that $Q$ is a finite subset of $\mathcal{S}$ with $\#Q = m$, and $V$ is a set of $r$ non-zero tangent vectors that are anchored at $r$ distinct points, none of which are in $Q$. The mapping class group $\Gamma_{g,m+r}$ is defined to be the group $\pi_0 \text{Diff}^+(\mathcal{S}, Q; V)$ of isotopy classes of $\mathcal{S}$ that fix the points $Q$ and the tangent vectors $V$. The indices $m$ and $r$ are omitted when they vanish.

Suppose that $Q$ is non-empty. Set $S = \mathcal{S} - Q$. The mapping class group $\Gamma_{g,m}$ acts on framings of $S$ by pushforward. Kawazumi \[23\] determined the set of mapping class group orbits. They depend on the vector $d(\xi) = (d_q)_{q \in Q} \in \mathbb{Z}^Q$ of local degrees of $\xi$ at the points of $Q$. We say that $d(\xi)$ is even if each $d_q$ is even. When $g > 0$ and $d(\xi)$ is even, we can associate the $\mathbb{F}_2$ quadratic form

$$
f_\alpha : H_1(\mathcal{S}; \mathbb{F}_2) \to \mathbb{F}_2, \quad a \mapsto 1 + \text{rot}_\alpha(a) \mod 2
$$

to $\xi$, where $\alpha$ is an imbedded circle that represents $a$. Denote the Arf invariant of this form by $\text{Arf}(\xi)$.

**Theorem 8.1** (Kawazumi). Suppose that $\xi_0$ and $\xi_1$ are framings of $S$.

(i) If $g = 0$, then $\xi_0$ and $\xi_1$ are in the same $\Gamma_{0,m}$ orbit if and only if $d(\xi_0) = d(\xi_1)$.

(ii) If $g > 1$ and $d(\xi_0)$ is not even, then $\xi_0$ and $\xi_1$ are in the same $\Gamma_{g,m}$-orbit if and only if $d(\xi_0) = d(\xi_1)$.

(iii) If $g > 1$ and $d(\xi_0)$ is not even, then $\xi_0$ and $\xi_1$ are in the same $\Gamma_{g,m}$-orbit if and only if $d(\xi_0) = d(\xi_1)$.

(iv) If $g > 1$ and $d(\xi_0)$ is even, then $\xi_0$ and $\xi_1$ are in the same $\Gamma_{g,m}$-orbit if and only if $d(\xi_0) = d(\xi_1)$ and $\text{Arf}(\xi_0) = \text{Arf}(\xi_1)$. 

(v) If \( g = 1 \), then \( \xi_0 \) and \( \xi_1 \) are in the same \( \Gamma_{1,m} \)-orbit if and only if \( d(\xi_0) = d(\xi_1) \) and \( A(\xi_0) = A(\xi_1) \), where

\[
A(\xi) := \gcd\{\text{rot}_\xi(\alpha) : \alpha \text{ is a non-separating simple closed curve in } S\}.
\]

**Remark 8.2.** The role of the quadratic form \( f_\xi \) is not mysterious. When \( d(\xi) \) is even, there is a unique “square root” \( \sqrt{\xi} \) of \( \xi \). It is a section of a rank 2 vector bundle that is a square root of \( T\overline{S} \) whose local degree at \( q \in Q \) is \( d(\xi)/2 \). This bundle corresponds to a spin structure on \( \overline{S} \). As is well known, spin structures correspond to \( \mathbb{F}_2 \) quadratic forms on \( H_1(\overline{S}; \mathbb{F}_2) \). There are only two \( \text{Sp}_g(\mathbb{F}_2) \) orbits of these, and they are distinguished by the Arf invariant.

We can regard the topological tangent bundle \( T\overline{S} \) of the oriented surface \( \overline{S} \) as complex line bundle \( T \). This allows us to define the section \( \xi_0^m \) of the complex line bundle \( T^{\otimes m} \) over \( S \) for all \( m > 0 \). These are well defined up to homotopy. The obstruction to two “even” framings being in the same mapping class group orbit vanishes when we take squares.

**Corollary 8.3.** When \( g > 1 \), \( \xi_0^2 \) and \( \xi_1^2 \) are in the same \( \Gamma_{g,m} \) orbit if and only if \( d(\xi_0) = d(\xi_1) \).

**Proof.** If any \( d_j \) is odd or if all \( d_j \) are even and \( \text{Arf}(\xi_0) = \text{Arf}(\xi_1) \), then Kawazumi’s result implies that \( \xi_0 \) and \( \xi_1 \) are in the same mapping class group orbit, so \( \xi_0^2 \) and \( \xi_1^2 \) are as well. Now suppose that all \( d_j \) are even and that \( \text{Arf}(\xi_0) \neq \text{Arf}(\xi_1) \). In this case, \( \text{Arf}(\xi_1) - \text{Arf}(\xi_0) = \delta \), a non-zero element of \( H^1(\overline{S}; \mathbb{F}_2) \). This class corresponds to a homomorphism \( H_1(\overline{S}) \to \mathbb{F}_2 \), and thus to a flat complex line bundle \( L \) over \( \overline{S} \) whose square \( L^{\otimes 2} \) is the trivial flat bundle. \( \square \)

### 9. The Existence of Quasi-algebraic Framings

In this section we prove Theorem 5. We first fix the notation to be used in this and subsequent sections.

Suppose that \( 2g + n > 1 \), where \( g \) and \( n \) are non-negative integers. Suppose that \( S \) is an \((n + 1)\)-punctured surface of genus \( g \). Write \( S = \overline{S} - P \), where \( P = \{x_0, \ldots, x_n\} \) is a subset of \( \overline{S} \). Fix a vector \( d = (d_0, \ldots, d_n) \in \mathbb{Z}^{n+1} \) with \( \sum d_j = 2 - 2g \). Suppose that \( \nu_o \) is a non-zero tangent vector of \( \overline{S} \) anchored at the point \( x_0 \) and that \( \xi_o \) is a nowhere vanishing vector field on \( S \) with local degree \( d_j \) at \( x_j \).

A complex structure on \((\overline{S}, P)\) is an orientation preserving diffeomorphism

\[
\phi : (\overline{S}, P) \to (\overline{X}, D),
\]

where \( \overline{X} \) is a compact Riemann surface and \( D \) a finite subset. It induces the complex structure \((\overline{S}, P, \nu_o) \to (\overline{X}, D, \phi_*\nu_o)\) on \((\overline{S}, P, \nu_o)\). A complex structure \( \phi : (\overline{S}, P) \to (\overline{X}, D) \) determines a base point of \( \mathcal{M}_{g,n+1} \) and a natural isomorphism \( \phi_* : \Gamma_{g,n+1} \to \pi_1(\mathcal{M}_{g,n+1}, \phi) \).

**Definition 9.1.** Suppose that \( m \) is a positive integer. A **complex structure on** \((\overline{S}, P, \xi_o^m)\) (or on \( \xi_o^m \) for short) is a complex structure \( \phi : (\overline{S}, P) \to (\overline{X}, D) \) on \((\overline{S}, P)\) and a meromorphic section \( \eta \) on \( \overline{X} \) of \((T\overline{X})^{\otimes m}\) (an algebraic \( m \)-framing) whose divisor is supported on \( D \) and whose pullback \( \phi_*\eta \) to \( S \) is homotopic to \( \xi_o^m \). A **quasi-complex structure on** \((\overline{S}, P, \xi_o)\) is a complex structure on \((\overline{S}, P, \xi_o^m)\) for some \( m > 0 \). These correspond to quasi-algebraic framings on \((\overline{X}, D)\).
Remark 9.2. The residue theorem implies that \((\overline{S}, P, \xi_o)\) does not have a complex structure when, say, \(d_0 = 1\) and all other \(d_j < 0\) are negative. However, \(\xi_o^2\) can have a complex structure in this case. For example, suppose that \(g \geq 1\) and that \(\overline{X}\) is the smooth projective model of the curve
\[
y^2 = \prod_{j=0}^{2g} (x-a_j),
\]
where the \(a_j\) are distinct elements of \(\mathbb{C}^*\). Let \(x_j\) be the point of \(\overline{X}\) lying over \(a_j\) and \(x_{2g+1}\) the point lying over \(\infty\). Then the meromorphic section \(\eta\) of \((TX)^{\otimes 2}\) dual to the quadratic differential
\[
\omega := \prod_{j=0}^{2g} (x-a_j)^{-d_j} \left(\frac{dx}{y}\right)^2
\]
is a 2-framing. It has divisor \(2 \sum_{j=0}^{2g+1} d_j x_j\). Each square root of \(\omega\) is a topological framing of \(X\). In particular, we can take \(d_0 = 1\) and all other \(d_j \leq 0\).

Remark 9.3. When \(g = 1\) and \(d = 0\), \(X\) is a punctured elliptic curve. So \(\overline{X} = \mathbb{C}/\Lambda\) for some lattice \(\Lambda\). Since \(T \overline{X}\) is a trivial holomorphic line bundle, the only holomorphic sections of \((T \overline{X})^{\otimes m}\) are multiplies of the translation invariant section \((\partial/\partial z)^m\). All other smooth sections \(\xi\) of \(TX\) with \(d = 0\) differ from it by an element \(e(\xi)\) of \(H^1(\overline{X}; \mathbb{Z})\). If \(e(\xi) \neq 0\), then \((\overline{S}, \xi)\) does not admit a quasi-complex structure.

**Proposition 9.4.** For each \(g\) below, \(d \in \mathbb{Z}^{n+1}\) satisfies \(\sum_0^n d_j = 2 - 2g\).

(i) If \(g = 0\), then for all \(d\), there is exactly one mapping class group orbit of homotopy classes of complex structure on \((\overline{S}, P, \xi_o)\).

(ii) If \(g > 1\) and \(d\) satisfying \(d_j \leq 0\) for \(j = 1, \ldots, n\), there is exactly one mapping class group orbit of complex structures on \((\overline{S}, P, \xi_o)\).

(iii) If \(g > 1\), then there is exactly one mapping class group of homotopy class of complex structure on \((\overline{S}, P, \xi_o)\) for all \(d\).

(iv) If \(g = 1\) and \(d = 0\), there is exactly one complex structure on \((\overline{S}, P, \xi_o)\) up to homotopy.

(v) If \(g = 1\) and \(d \neq 0\), then there is a quasi-complex structure on \((\overline{S}, P, \xi_o)\) if and only if \(A(\xi_o) = \text{gcd}\{d_0, \ldots, d_n\}\).

(vi) If \(g = 1\), \#\(\{j : d_j \neq 0\}\) \(> 2\) and \(A(\xi_o) = \text{gcd}\{d_0, \ldots, d_n\}\), then there \((\overline{S}, P, \xi_o)\) has a complex structure for all complex structures \((\overline{X}, D)\) on \((\overline{S}, P)\).

**Proof.** The proof of the genus 0 case is elementary and is left to the reader. We now assume that \(g > 0\).

Suppose now that \(g > 1\). Denote the locus of \((n+1)\)-pointed curves \((C; x_0, \ldots, x_n)\) in \(M_{g,n}\) for which \(m \sum_j d_j x_j\) an \((-m)\)-canonical divisor by \(\mathcal{J}_d^m\). This locus may be empty and may be disconnected. Each connected component of \(\mathcal{J}_d^m\) determines a \(\Gamma_{g,n+1}\)-orbit of \(m\)-framings \(\xi\) of the punctured reference surface \(S\). The classification of strata of abelian differentials in \([27]\) implies that if all \(d_j < 0\), then \(\mathcal{J}_d^1\) has one component when at least one \(d_j\) is odd and that \(\mathcal{J}_d^1\) has 2 components, distinguished by the Arf invariant, when all \(d_j\) are even. This and Theorem 8.3.

---

5The condition that \(A(\xi_o) = \text{gcd}\{d_0, \ldots, d_n\}\) is equivalent to the condition that \(\text{rot}_{\xi_o}(\alpha)\) is divisible by \(\text{gcd}(d_j)\) for all simple closed curves \(\alpha\) in \(S\).
imply \((\ref{Hodge})\). The classification of meromorphic differentials in \((\ref{meromorphic})\) implies that \(S_d^2\) is non-empty all \(d\). Combined with Corollary \((\ref{classification})\) it proves \((\ref{Hodge})\).

Suppose now that \(g = 1\) and that \(X = \mathbb{C}/\Lambda\). Every algebraic \(m\)-framing of \((X, D)\) is of the form

\[\eta = f(\partial/\partial z)^m\]

where \(f\) is a non-zero meromorphic function whose divisor is \(\sum_j d_j x_j\), where \(D = \{x_0, \ldots, x_n\}\). If \(\xi\) is an \(m\)th root of \(\eta\), then as \(A(\partial/\partial z) = 0\), it follows that the rotation number \(\text{rot}_\xi(\gamma)\) of every closed curve in \(X\) lies in the ideal generated by \(d_j\). It follows that \(A(\xi) = \gcd(d_j)\) for all quasi-algebraic framings of \(X\). This proves \((\ref{Hodge})\) and the “only if” part of \((\ref{Hodge})\). If \(d = \pm(-m, m)\), where \(m > 0\), then we can take \(x_1 - x_0\) to be a non-zero \(m\)-torsion point of the jacobian of \(X\) and \(f\) to be a function whose divisor is \(m(x_1 - x_0)\). We prove the remainder of the converse by proving \((\ref{Hodge})\).

Suppose that \(g = 1\) and \(d \neq 0\). By decreasing \(n\) if necessary, we may assume that all \(d_j\) are non-zero. Suppose that \(n > 1\). Define

\[F_d : X^{n+1} \to \text{Jac} X\]

by \(F_d(x_0, \ldots, x_n) = \sum_j d_j x_j\). We have to show that the fiber \(Y\) of \(F_d\) over 0 is not contained in any of the diagonals \(\Delta_{j,k} := \{x_j = x_k\}\). To see that \(Y\) cannot be contained in \(\Delta_{j,k}\), choose \(\ell\) such that \(j, k, \ell\) are distinct. This is possible as \(n > 1\).

If \((x_0, \ldots, x_n) \in Y\) then for all but finitely many \(u \in \text{Jac} X\), \((y_0, \ldots, y_n)\) is not in \(\Delta_{j,k}\), where

\[y_a := \begin{cases} x_a & a \neq k, \ell, \\ x_k + du & a = k, \\ x_\ell - du & a = \ell. \end{cases}\]

This completes the proof of \((\ref{Hodge})\) and \((\ref{Hodge})\).

Remark 9.5. This result implies that the framings that occur in \((\ref{classification})\) Thm. 6.1] are precisely those that admit a quasi-complex structure. See footnote \([\ref{conventions}]\) on page \([3]\) for conventions.

10. TORSORS OF SPLITTINGS OF THE GOLDMAN–TURAEV LIE BIALGEBRA

In this section, we explain how Hodge theory gives torsors of simultaneous splittings of \((\ref{split1})\) and \((\ref{split2})\) and explain how these give solutions to the Kashiwara–Vergne problem. In particular, we prove Corollary \([\ref{corollary}]\) and take the first steps towards proving Theorem \([\ref{theorem}]\).

Proposition 10.1. Each homotopy class of quasi-complex structures on \((\overline{S}, P, \overline{v}_0, \xi_0)\) gives a torsor of simultaneous splittings of \((\ref{split1})\) and \((\ref{split2})\). The splittings constructed from a fixed complex structure on \((\overline{S}, P, \overline{v}_0) \to (X, D, \overline{v}_0)\) are torsors under the pro-unipotent radical \(U_{\text{MT}}^{X, v}\) of the Mumford–Tate group of \(\mathbb{Q}\pi_1(X, \overline{v})^\wedge\).

Proof. By \([\ref{mhs}]\) Thm. 6], the MHS on \(\mathbb{Q}\pi_1(X, \overline{v})^\wedge\) determines a torsor of isomorphisms

\[\mathbb{Q}\pi_1(X, \overline{v})^\wedge \to \prod_{m \leq 0} \text{Gr}_m^{W} \mathbb{Q}\pi_1(X, \overline{v})^\wedge\]
each of which solves the KV-problem $\text{KV}^{(g,n+1)}$, as defined in $[1]$. These are a torsor under $U^\text{MT}_{\tilde{X},\tilde{v}}$. Corollary 2 implies (via the discussion in $[17, \S 10.2]$) that the induced isomorphism
\[
\mathbb{Q}\lambda(X)^\wedge \cong \prod_{m \leq 0} \text{Gr}^W_m \mathbb{Q}\lambda(X)^\wedge
\]
is an isomorphism of Lie bialgebras. □

These Hodge theoretic splittings give solutions to the KV-problem $\text{KV}^{(g,n+1)}$. This result implies Corollary 4.

**Corollary 10.2.** Each homotopy class of quasi-complex structures on $(\tilde{S}, P, \tilde{v}_o, \xi_o)$ gives a torsor of solutions to the Kashiwara–Vergne problem $\text{KV}^{(g,n+1)}$. These solutions form a torsor under the prounipotent radical $U^\text{MT}_{\tilde{X},\tilde{v}}$ of the Mumford–Tate group of $\mathbb{Q}\pi_1(\tilde{X},\tilde{v})^\wedge$.

**Proof.** This follows from Proposition 10.1 and $[1$, Thm. 5], which implies that the automorphism $\Phi$ of $\mathbb{Q}\langle\langle x_1, \ldots, x_g, y_1, \ldots, y_g, z_1, \ldots, z_n \rangle\rangle$ constructed from the choice of a lifting $\tilde{\chi}$ of the canonical central cocharacter $\chi : \mathbb{G}_m \to \pi_1(\text{MHS}^\text{ss})$ in $[17, \S 13.4]$ is a solution of $\text{KV}^{(g,n+1)}$. □

**Remark 10.3.** In view of Remark 9.5, this gives a new and independent proof of the main result, Theorem 6.1, of $[3]$.

Solutions of $\text{KV}^{(g,n+1)}$ that arise from Hodge theory will be called **motivic solutions** as they arise from a complex (and thus algebraic) structure on $(S, P, \tilde{v}_o, \xi_o)$ for some $m>0$. All solutions of $\text{KV}^{(g,n+1)}$ comprise a torsor under a prounipotent group subgroup $K\text{RV}^{d}_{g,n+\tilde{v}}$ of $\text{Aut} \mathbb{Q}\pi_1(S,\tilde{v})^\wedge$. For each complex structure $\phi$ on $(S, P, \tilde{v}_o, \xi_o)$, there is an inclusion $\phi^*: K\text{RV}^{d}_{g,n+\tilde{v}} \hookrightarrow K\text{RV}^{d}_{g,n+\tilde{v}}$. These homomorphisms depend non-trivially on $\phi$ and are, in general, not surjective.

**11. The Stabilizer of a Framing**

A second way to generate solutions of the KV-problem $\text{KV}^{(g,n+\tilde{v})}$ from a given solution is to conjugate it by an element of the Torelli group $T_{g,n+\tilde{v}}$ (defined below) that fixes the framing $\xi_o$. In this section, we compute the stabilizer of a framing.

Suppose that $\tilde{S}$ is a compact oriented surface of genus $g$ and that $2g-2+n>0$. For each commutative ring $A$ set $H_A = H_1(\tilde{S}; A)$. The intersection pairing $H_A \otimes H_A \to A$ is a unimodular symplectic form. Denote the corresponding symplectic group by $\text{Sp}(H_A)$. We will regard both $H$ and $\text{Sp}(H)$ as affine groups over $\mathbb{Z}$ whose $A$-rational points are $H_A$ and $\text{Sp}(H_A)$, respectively. The Torelli group $T_{g,m+r}$ is defined to be the kernel of the homomorphism
\[
\rho : \Gamma_{g,m+r} \to \text{Sp}(H_\mathbb{Z})
\]
that is induced by the action of $\Gamma_{g,m+r}$ on $H_\mathbb{Z}$. This homomorphism is well-known to be surjective.

For the remainder of this section $(\tilde{S}, P)$ will be an $(n+1)$ pointed surface of genus $g$, where $2g-2+n>0$, and $\xi_o$ will be a framing of $\tilde{S}$ with vector of local degrees $\tilde{v}$. Denote the pushforward of $\xi_o$ by $\psi \in \text{Diff}^+(\tilde{S}, P)$ by $\psi_*\xi_o$. The homotopy class of this pushforward depends only on the class of $\psi$ in the mapping class group $\Gamma_{g,n+1}$.
of \((\mathcal{S}, P)\). Since \(\psi\) fixes the punctures \(P, \psi_* \xi_o\) and \(\xi_o\) have the same local degrees. The homotopy class of their ratio

\[
(\psi_* \xi_o)/\xi_o : \mathcal{S} \to \mathbb{C}^*
\]

is an element of \(H^1(\mathcal{S}; \mathbb{Z})\) that we denote by \(f_{\xi_o}(\psi)\). It vanishes if and only if \(\psi\) fixes \(\xi_o\).

**Lemma 11.1.** The function \(f_{\xi_o} : \Gamma_{g,n+1} \to H_2\) is a 1-cocycle. Its restriction to the Torelli group \(T_{g,n+1}\) is an \(\text{Sp}(H_2)\)-equivariant homomorphism whose kernel is the stabilizer of \(\xi_o\) in \(T_{g,n+1}\).

**Proof.** It is clear from the definition that \(\psi \in \Gamma_{g,n+1}\) stabilizes the homotopy class of \(\xi_o\) if and only if \(f_{\xi_o}(\psi) = 0\). Suppose that \(\psi', \psi'' \in \Gamma_{g,n+1}\). Since

\[
\frac{(\psi' \psi'')(\psi' \psi'' \xi_o)}{\xi_o} = \frac{\psi' \psi' \xi_o}{\xi_o} \frac{(\psi' \psi'') \xi_o}{\xi_o} = \frac{\psi' \xi_o}{\xi_o} \frac{(\psi' \psi'' \xi_o)}{\xi_o}
\]

as homotopy classes of functions \(\mathcal{S} \to \mathbb{C}^*\), it follows that \(f_{\xi_o}\) satisfies the 1-cocycle condition

\[
f_{\xi_o}(\psi' \psi'') = f_{\xi_o}(\psi') + \psi'_* f_{\xi_o}(\psi'').
\]

The restriction of \(f_{\xi_o}\) to \(T_{g,n+1}\) is a homomorphism as the Torelli group acts trivially on \(H_2\).

In the next section, we will need to know that the class of \(f_{\xi_o}\) is a Hodge class. In preparation for proving this, we give an algebro-geometric interpretation of \(f_{\xi_o}\).

The vector of local degrees \(d\) of \(\xi_o\) determines a section \(F_d\) of the universal jacobian \(\mathcal{J}_{g,n+1}\) over \(\mathcal{M}_{g,n+1}\). It is defined by

\[
(11.1) \quad F_d(C; x_0, \ldots, x_n) = K_C + \sum_{j=0}^{n} d_j x_j \in \text{Jac} C
\]

where \(C\) is a compact Riemann surface of genus \(g\); \(x_0, \ldots, x_n\) are distinct labelled points of \(C\); and where \(K^C\) denotes the canonical class of \(C\).

Fix a base point \(o\) of \(\mathcal{M}_{g,n+1}\). Denote the identity of \(\text{Jac} C_o\) by \(z_o\). The fundamental group of \(\mathcal{J}_{g,n+1}\) with base point \(z_o\) is an extension of \(\Gamma_{g,n+1}\) by \(H_2\). The identity section induces a splitting of this extension and thus a canonical isomorphism

\[
\pi_1(\mathcal{J}_{g,n+1}, z_o) \cong \Gamma_{g,n+1} \ltimes H_2
\]

where we are identifying \(\pi_1(\mathcal{M}_{g,n+1}, o)\) with \(\Gamma_{g,n+1}\) and \(H_2\) with \(H_1(C_o; \mathbb{Z})\). The standard representation \(\Gamma_{g,n+1} \to \text{Sp}(H_2)\) induces a homomorphism

\[
\pi_1(\mathcal{J}_{g,n+1}, z_o) \to \text{Sp}(H_2) \ltimes H_2.
\]

The section \(F_d\) of \(\mathcal{J}_{g,n+1}\) over \(\mathcal{M}_{g,n+1}\) induces a homomorphism

\[
\tau_d : \Gamma_{g,n+1} \to \pi_1(\mathcal{J}_{g,n+1}, z_o) \to \text{Sp}(H_2) \ltimes H_2.
\]

Such as homomorphism corresponds to a cohomology class \([\tau_d] \in H^1(\Gamma_{g,n+1}, H_2)\).

\(\text{The image of } (C; x_0, \ldots, x_n) \text{ under } F_d \text{ corresponds to a } C^\infty \text{ isomorphism of the line bundle } O_C(\sum d_j x_j) \text{ with } TC \text{ under which the section of } O_C(\sum d_j x_j) \text{ with divisor } \sum d_j x_j \text{ corresponds to a framing with local degree vector } d. \text{ This gives an } m\text{-framing of } C - \{x_0, \ldots, x_n\} \text{ if and only if } F_d(C; x_0, \ldots, x_n) \text{ is a } m\text{-torsion point of Jac} C. \text{ If } g \neq 1, \text{ or if } g = 1 \text{ and } \gcd(d_j) = A(\xi_o), \text{ this gives a complex structure on } \xi^m.\)
Proposition 11.2. The cohomology classes of \( f_\omega \) and \( \tau_d \) in \( H^1(\Gamma_{g,n+1}; H_\mathbb{Z}) \) are equal. In particular, the class of \( f_\omega \) depends only on the vector \( d \) of local degrees.

**Sketch of Proof.** These classes clearly vanish when \( g = 0 \). So suppose that \( g > 0 \). First observe that \( H^1(\Gamma_{g,n+1}; H_\mathbb{Z}) \) is torsion free. This can be proved using the cohomology long the exact sequence of

\[
0 \longrightarrow H_\mathbb{Z} \xrightarrow{x} H_\mathbb{Z} \longrightarrow H_\mathbb{Z}/N \longrightarrow 0
\]

the vanishing of \( H^0(\Gamma_{g,n+1}; H_\mathbb{Z}/N) \) for all \( N > 0 \), and the finite generation of \( H^1(\Gamma_{g,n+1}; H_\mathbb{Z}) \). It therefore suffices to show that the classes of \( f_\xi_o \) and \( \tau_d \) agree in \( H^1(\Gamma_{g,n+1}; H_\mathbb{Q}) \).

By the “center kills” argument \( H^* (\text{Sp}_g(\mathbb{Z}); H_\mathbb{Q}) \) vanishes. This implies (via the Hochschild–Serre spectral sequence) that the restriction mapping

\[
H^1(\Gamma_{g,n+1}; H_\mathbb{Q}) \to \text{Hom}_{\text{Sp}(H_\mathbb{Q})}(H_1(T_{g,n+1}), H_\mathbb{Q})
\]

is an isomorphism.

Denote the pure braid group on \( n + 1 \) strings of \( \overline{S} \) by \( \pi_{g,n+1} \). The inclusion of the configuration space of \( \overline{S} \) into \( \overline{S}^{n+1} \) induces an isomorphism \( H_1(\pi_{g,n+1}) \cong H^n_\mathbb{Z}^{n+1} \). (See [12] Prop. 2.1.) When \( g > 1 \), the inclusion \( \pi_{g,n+1} \to T_{g,n+1} \) induces an isomorphism

\[
(11.2) \quad \text{Hom}_{\text{Sp}(H_\mathbb{Q})}(H_1(T_{g,n+1}), H_\mathbb{Q}) \to \text{Hom}_{\text{Sp}_g(\mathbb{Z})}(H_1(\pi_{g,n+1}), H_\mathbb{Q}) \cong \mathbb{Q}^{n+1}.
\]

When \( g > 2 \), this follows from Johnson’s work [26] as in [12] Prop. 4.6]. When \( g = 2 \), this follows similarly from results in [33]. When \( g = 1 \), there is an exact sequence

\[
0 \to H_\mathbb{Z} \to H_1(\pi_{g,n+1}) \to H_1(T_{1,n+1}) \to 0
\]

where the left-hand map is the diagonal embedding, which is induced by the diagonal action of an elliptic curve \( E \) on \( E^{n+1} \). This implies that (11.2) is injective with image the hyperplane consisting of those \((u_0, \ldots, u_n)\) with \( \sum_j u_j = 0 \).

These observations imply that to prove the equality of the classes of \( f_\xi_o \) and \( \tau_d \), we just have to see that they agree on the “point pushing” subgroup of \( T_{g,n+1} \) — that is, on the image of \( \pi_{g,n+1} \) in the Torelli group. An elementary argument implies that \( f_\xi_o \) and \( \tau_d \) both have image \( d \in \mathbb{Q}^{n+1} \). The computations for \( \tau_d \) can be found in [16] Prop. 11.2] for \( g > 1 \) and [16] §12 for \( g = 1 \).

12. Relative Completion of Mapping Class Groups and Torsors of Splittings

In this section, we consider the torsor of splittings of the Goldman–Turaev Lie bialgebra obtained by combining those constructed in Section 11 using Hodge theory with those coming from the stabilizer of \( \xi_o \) in the Torelli group. We will use the notation of the previous section. We replace mapping class groups by their relative completions, which allows us to prove stronger results.

Recall from [12] that the completion of \( \Gamma_{g,m+r} \) relative to \( \rho : \Gamma_{g,m+r} \to \text{Sp}(H_\mathbb{Q}) \) is an affine \( \mathbb{Q} \)-group \( \tilde{\mathcal{G}}_{g,m+r} \) that is an extension

\[
1 \to U_{g,m+r} \to \tilde{\mathcal{G}}_{g,m+r} \to \text{Sp}(H) \to 1
\]

of affine \( \mathbb{Q} \)-groups, where \( U_{g,m+r} \) is prounipotent. There is a Zariski dense homomorphism \( \tilde{\rho} : \Gamma_{g,m+r} \to \tilde{\mathcal{G}}_{g,m+r}(\mathbb{Q}) \) whose composition with the homomorphism
Proof. When $\delta = 0$, $\text{Sp}(H)$ is trivial and $G_{0,m+r}$ is the unipotent completion $\Gamma_{0,m+r}^u$.

Remark 12.1. The homomorphism $T_{g,m+r} \to \mathcal{U}_{g,m+r}(\mathbb{Q})$ induced by $\tilde{\rho}$ has Zariski dense image when $g > 1$. This follows from the right exactness of relative completion [13, Thm. 3.11] and the vanishing of $H^1(\text{Sp}(\mathbb{Z}), V)$ for all rational representations $V$ of $\text{Sp}(H)$ when $g \neq 1$. (See [13, Thm. 4.3].) However, when $g = 1$, $\Gamma_{g,n+1} \to \Gamma_{1,n+1}(\mathbb{Q})$ is not Zariski dense. For example, $T_{1,1}$ is trivial, while the Lie algebra of $\text{U}_{1,1}$ is freely topologically generated by an infinite dimensional vector space as explained in [12, Remarks 3.9.7.2] and in [20, §10].

The action of the mapping class group $\Gamma_{g,n+\tilde{I}}$ on $\mathbb{Q}\pi_1(S,\tilde{v}_o)$ induces an action on $\mathbb{Q}\lambda(S)$ which preserves the Goldman bracket. The stabilizer of $\xi_o$ preserves the Turaev cobracket. The universal mapping property of relative completion implies that $\mathcal{G}_{g,n+\tilde{I}}$ acts on $\mathbb{Q}\pi_1(S,\tilde{v}_o)^\wedge$ and $\mathbb{Q}\lambda(S)^\wedge$. Since the image of the mapping class group in $\mathcal{G}_{g,n+\tilde{I}}$ is Zariski dense, this action preserves the Goldman bracket. However, since $\mathcal{G}_{g,n+\tilde{I}}$ does not act on framings, it is not clear which subgroup of $\mathcal{U}_{g,n+\tilde{I}}$ preserves the cobracket. Our next task is to determine this subgroup.

The universal property of relative completion implies that the homomorphism $\tau_d : \Gamma_{g,n+\tilde{I}} \to \text{Sp}(H_\mathbb{Z}) \ltimes H_\mathbb{Z}$ constructed Section 11 induces a homomorphism

$$\tilde{\tau}_d : \mathcal{G}_{g,n+\tilde{I}} \to \text{Sp}(H) \ltimes H.$$

It is surjective as the image of $\tau_d$ is Zariski dense in $\text{Sp}(H) \ltimes H$.

Proposition 12.2. For all quasi-algebraic framings $\xi_o$ of $S$, the action of $\ker \tilde{\tau}_d$ on $\mathbb{Q}\lambda(S)^\wedge$ preserves the completed Turaev cobracket

$$(\delta_{\xi_o} : \mathbb{Q}\lambda(S)^\wedge \to \mathbb{Q}\lambda(S)^\wedge \otimes \mathbb{Q}\lambda(S)^\wedge).$$

Proof. When $\delta = 0$, $\tilde{\tau}_d$ is trivial. Since $\Gamma_{0,n+\tilde{I}}$ preserves the homotopy class of $\xi_o$, the result is trivially true. Now assume that $\delta > 0$. For the rest of the proof, we assume the reader is familiar with the general theory of relative completion as explained in [13, §3].

When $\delta \geq 2$, every framing is quasi-algebraic by Proposition 9.4 and the algebraic nature of the framing will not play any explicit role in the proof. The computation [13, Ex. 3.12] and the right exactness of relative completion [13, Prop. 3.7] imply that the completion of $\text{Sp}(H_\mathbb{Z}) \ltimes H_\mathbb{Z}$ relative to the obvious homomorphism to $\text{Sp}(H_\mathbb{Q})$ is $\text{Sp}(H) \ltimes H$; the canonical homomorphism $\text{Sp}(H_\mathbb{Z}) \ltimes H_\mathbb{Z} \to \text{Sp}(H_\mathbb{Q}) \ltimes H_\mathbb{Q}$ is the inclusion. Right exactness of relative completion implies that the sequence

$$(\ker \tau_d)^u \longrightarrow G_{g,n+\tilde{I}} \longrightarrow \tilde{\tau}_d G_{g,n+\tilde{I}} \longrightarrow \text{Sp}(H) \ltimes H \longrightarrow 1$$

is exact, where $(\ )^u$ denotes unipotent completion. Since every group is Zariski dense in its unipotent completion, the exactness of this sequence implies that $\ker \tau_d$ is Zariski dense in $\ker \tilde{\tau}_d$. Since $\ker \tilde{\tau}_d$ fixes $\xi_o$, it preserves the completed cobracket. It follows that $\ker \tilde{\tau}_d$ does as well.

In view of Remark 12.1, the proof is more intricate when $\delta = 1$. We first consider the case when $\delta = 0$. We take $\mathbb{T}$ to be the group $S^1 \times S^1$ and $P$ to be its identity. In this case, $\xi_o$ is a translation invariant vector field. Since any two translation invariant vector fields are homotopic, it follows that their homotopy classes lie in one $\text{SL}_2(\mathbb{Z})$-orbit of framings. Since the cobracket depends only on the homotopy class of the framing, $\text{SL}_2(\mathbb{Z})$ preserves the completed cobracket 12.1. Since $\text{SL}_2(\mathbb{Z})$
is Zariski dense in $G_{1,\Gamma}$, it follows that it also preserves the cobracket. Since the image of $\tau_d : G_{1,\Gamma} \to \text{Sp}(H) \times H$ is $\text{Sp}(H)$, it follows that $\ker d = U_{1,\Gamma}$ preserves the completed cobracket.

Suppose now that $g = 1$ and $n > 0$. Since $\xi_o$ is quasi-algebraic, $A(\xi_o) = \gcd(d_j)$.

So there exist two transversely intersecting simple closed curves $\alpha$ and $\beta$ in $S$ with $\text{rot}_{\xi_o}(\alpha) = \text{rot}_{\xi_o}(\beta) = 0$. A regular neighbourhood of the union of $\alpha \cup \beta$ is a genus 1 surface with one boundary component. Its complement is a subsurface of type $(0, n + 1 + \hat{1})$. Since $\text{rot}_{\xi_o}(\alpha) = \text{rot}_{\xi_o}(\beta) = 0$, the restriction of the framing to the genus 1 subsurface is homotopic to a translation invariant framing.

The inclusion of the genus 1 subsurface induces an inclusion $\Gamma_{1,\Gamma} \to \Gamma_{1,n+\Gamma}$. By the $n = 0$ case, the image of $\Gamma_{1,\Gamma}$ in $\Gamma_{1,n+\Gamma}$ preserves the homotopy class of $\xi_o$. The kernel of the restriction of $\tau_d : T_{1,n+\Gamma} \to H^2$ also preserves the class of $\xi_o$. So the subgroup

$$G_{\xi_o} := \ker \tau_d \cap T_{1,n+\Gamma}, \Gamma_{1,\Gamma}$$

of $\Gamma_{1,n+\Gamma}$ generated by these two groups stabilizes the class of $\xi_o$ and thus preserves the cobracket. The pronipotent radical $U_{\xi_o}$ of the Zariski closure of $G_{\xi_o}$ in $G_{1,n+\Gamma}$ is generated by the image of $U_{1,\Gamma}$ and the kernel of $\tau_d : T_{1,n+\Gamma} \to H$. It is precisely the kernel of $\tau_d : U_{1,n+\Gamma} \to H$. Since $G_{\xi_o}$ preserves the cobracket, so does $U_{\xi_o}$. \qed

Denote $\ker \hat{\tau}_d$ by $U^d_{g,n+\Gamma}$. There is a natural homomorphism

$$U^d_{g,n+\Gamma} \to K^R V_{g,n+\Gamma}^d.$$ Denote the image of $U^d_{g,n+\Gamma}$ in $\text{Aut} \ Q\pi_1(S,\vec{\nu}_0)^\wedge$ by $\overline{U^d_{g,n+\Gamma}}$ and the image of $U^d_{g,n+\Gamma}$ by $\overline{U^d_{g,n+\Gamma}}$. A complex structure $\phi : (S, P, \vec{\nu}_0) \to (\hat{X}, D, \vec{\nu})$ determines a Mumford–Tate group $\text{MT}_{X,\vec{\nu}}$. Identify $\pi_1(X, \vec{\nu})$ with $\pi_1(S, \vec{\nu}_0)$ via $\phi$. This gives $Q\pi_1(S,\vec{\nu}_0)^\wedge$ a MHS and allows us to regard $\text{MT}_{X,\vec{\nu}}$ as as acting on $Q\pi_1(S,\vec{\nu})^\wedge$. Denote the subgroup of $\text{Aut} \ Q\pi_1(S,\vec{\nu}_0)^\wedge$ generated by $U^\text{MT}_{X,\vec{\nu}}$ and $U^d_{g,n+\Gamma}$ by $\hat{U}^d_{g,n+\Gamma}(\phi)$.

Recall that a MHS on an affine $\mathbb{Q}$-group $G$ is, by definition, a MHS on its coordinate ring $\mathcal{O}(G)$. Equivalently, a MHS on $G$ is an algebraic action of $\pi_1(\mathbb{MHS})$ on $G$. A homomorphism $G_1 \to G_2$ of affine $\mathbb{Q}$-groups with MHS is a morphism of MHS if it is $\pi_1(\mathbb{MHS})$ equivariant. A MHS on $G$ induces one on its Lie algebra.

**Lemma 12.3.** A quasi-complex structure $\phi$ on $(S, P, \vec{\nu}_0, \xi_o)$ determines pro-MHS on the Lie algebras (and coordinate rings) of $U^d_{g,n+\Gamma}$ and $\hat{U}^d_{g,n+\Gamma}(\phi)$. The homomorphism $\hat{U}^d_{g,n+\Gamma}(\phi) \to \text{Aut} \ Q\pi_1(X, \vec{\nu})^\wedge$ is a morphism of MHS.

**Proof.** The quasi-complex structure $\phi$ determines a MHS on $U^d_{g,n+\Gamma}$. Observe that $U^d_{g,n+\Gamma}$ is the kernel of the the homomorphism

$$G_{g,n+\Gamma} \longrightarrow G_{g,n+1} \longrightarrow \tau_d \longrightarrow \text{Sp}(H) \times H$$

induced on completed fundamental groups by the morphism of pointed varieties

$$(\mathcal{M}_{g,n+\Gamma}(X, D, \vec{\nu})) \longrightarrow (\mathcal{M}_{g,n+1}(X, D)) \longrightarrow (\mathcal{X}(\text{Jac} \ X, 0),$$

were $\mathcal{X} \to \mathcal{A}_g$ is the universal abelian variety over $\mathcal{A}_g$, the moduli space of principally polarized abelian varieties. Since morphisms of pointed varieties induce
morphisms of MHS on completed fundamental groups, it follows that \( \mathcal{U}^d_{g,n+\Gamma} \) has a natural MHS.

This MHS corresponds to an action of \( \pi_1(\text{MHS}) \) on it, so that one has the group \( \pi_1(\text{MHS}) \times \mathcal{U}^d_{g,n+\Gamma} \). The pro-MHS on \( \mathbb{Q} \pi_1(X,\bar{\nu})^\wedge \) corresponds to a homomorphism \( \pi_1(\text{MHS}) \rightarrow \text{Aut} \mathbb{Q} \pi_1(X,\bar{\nu})^\wedge \). By [12, Lem. 4.5], the homomorphism \( \mathcal{U}^d_{g,n+\Gamma} \rightarrow \text{Aut} \mathbb{Q} \pi_1(X,\bar{\nu})^\wedge \) is a morphism of MHS. It thus extends to a homomorphism

\[
\pi_1(\text{MHS}) \times \mathcal{U}^d_{g,n+\Gamma} \rightarrow \text{Aut} \mathbb{Q} \pi_1(X,\bar{\nu})^\wedge.
\]

Its image is \( \hat{\mathcal{U}}^d_{g,n+\Gamma}(\phi) \). The inner action of \( \pi_1(\text{MHS}) \) on \( \hat{\mathcal{U}}^d_{g,n+\Gamma} \) gives it a MHS. The inclusion \( \hat{\mathcal{U}}^d_{g,n+\Gamma} \hookrightarrow \text{Aut} \mathbb{Q} \pi_1(X,\bar{\nu})^\wedge \) is \( \pi_1(\text{MHS}) \)-invariant, which implies that it is a morphism of MHS. \( \square \)

The following theorem is proved in Section 13. It and the previous lemma imply Theorem 6.

**Theorem 12.4.** For each quasi-complex structure \( \phi : (\vec{S},P,\vec{\nu},\xi_o) \rightarrow (X,D,\bar{\nu},\bar{\xi}) \), there is an injective homomorphism \( \hat{\mathcal{U}}^d_{g,n+\Gamma}(\phi) \rightarrow \mathcal{K}_\mathcal{R}^d_{g,n+\Gamma} \) of prounipotent \( \mathbb{Q} \)-groups. Its image does not depend on the quasi-complex structure \( \phi \). The group \( \mathcal{K}^d_{g,n+\Gamma} \) is a normal subgroup of \( \hat{\mathcal{U}}^d_{g,n+\Gamma} \). There is a canonical surjection \( \mathcal{K} \rightarrow \hat{\mathcal{U}}^d_{g,n+\Gamma}/\mathcal{K}^d_{g,n+\Gamma} \), where \( \mathcal{K} \) is the prounipotent radical of \( \pi_1(\text{MTM}) \).

Since \( \hat{\mathcal{U}}^d_{g,n+\Gamma}(\phi) \) is independent of the choice of \( \phi \), we denote it by \( \hat{\mathcal{U}}^d_{g,n+\Gamma} \).

**Remark 12.5.** The complex structure on \( (\vec{S},P,\vec{\nu},\xi_o) \) defines a \( \mathbb{C} \)-point, and thus a geometric point, \( p \) of the moduli stack \( \mathcal{M}_{g,n+\Gamma}/\mathbb{Q} \). Its étale fundamental group \( \pi_1(\mathcal{M}_{g,n+\Gamma},p) \) is an extension

\[
1 \rightarrow \Gamma^\wedge_{g,n+\Gamma} \rightarrow \pi_1^\wedge(\mathcal{M}_{g,n+\Gamma},p) \rightarrow \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \rightarrow 1,
\]

where \( \Gamma^\wedge_{g,n+\Gamma} \) denotes the profinite completion of the mapping class group. For each prime number \( \ell \), there is an homomorphism \( \pi_1^\wedge(\mathcal{M}_{g,n+\Gamma},p) \rightarrow \text{Sp}(H_{2\ell}) \times H_{2\ell} \). Denote its kernel by \( \pi_1^\wedge(\mathcal{M}_{g,n+\Gamma},p)^d \). There is a homomorphism

\[
\phi_\ell : \pi_1^\wedge(\mathcal{M}_{g,n+\Gamma},p)^d \rightarrow \mathcal{K}_\mathcal{R}^d_{g,n+\Gamma}(\mathbb{Q}_\ell).
\]

Using weighted completion [14] §8, one can show that the Zariski closure of the image of \( \phi_\ell \) is \( \hat{\mathcal{U}}^d_{g,n+\Gamma}(\mathbb{Q}_\ell) \).

Recall from [17] §10.2] that natural splittings of the weight filtration of a MHS correspond to lifts of the central cocharacter \( \chi : \mathbb{G}_m \rightarrow \pi_1(\text{MHS}^\text{ss}) \) to \( \pi_1(\text{MHS}) \). Each MHS on the completed Goldman–Turaev Lie bialgebra and each lift of \( \chi \) gives rise to a splitting of the Goldman–Turaev Lie bialgebra \( \hat{\mathcal{U}}^d_{g,n+\Gamma} \). It also gives a grading of \( \hat{\mathcal{U}}^d_{g,n+\Gamma} \). Thus

**Corollary 12.6.** Each choice of a quasi-complex structure \( \phi : (\vec{S},P,\vec{\nu},\xi_o) \rightarrow (X,D,\bar{\nu},\bar{\xi}) \) and each choice of a lift of the central cocharacter \( \chi : \mathbb{G}_m \rightarrow \pi_1(\text{MHS}^\text{ss}) \)

This is called Goldman–Turaev formality in [3].
Proposition 13.1. For each complex structure \( \phi : (S, P, \nu, \xi) \to (X, D, \varphi) \) on \((S, P, \nu, \xi)\). This determines an isomorphism \( \Gamma_{g,n+\bar{1}}^! \cong \pi_1(\mathcal{M}_{g,n+\bar{1}}, \phi_o) \). The corresponding MHS on the relative completion \( \mathcal{G}_{g,n+\bar{1}} \) corresponds to an action of \( \pi_1(\text{MHS}) \) on \( \mathcal{G}_{g,n+\bar{1}} \). The quasi-complex structure \( \phi \) determines a semi-direct product

\[
\pi_1(\text{MHS}) \ltimes \mathcal{G}_{g,n+\bar{1}}.
\]

Since the natural homomorphism \( \mathcal{G}_{g,n+\bar{1}} \to \text{Aut} \, \pi_1(X, \varphi_o)^\wedge \) is a morphism of MHS, \([12\, \text{Lem. } 4.5]\), the monodromy homomorphism extends to a homomorphism

\[
\pi_1(\text{MHS}) \ltimes \mathcal{G}_{g,n+\bar{1}} \to \text{Aut} \, \pi_1(X, \varphi_o)^\wedge.
\]

Denote its image by \( \widehat{\mathcal{G}}_{g,n+\bar{1}} \) and the image of \( \mathcal{G}_{g,n+\bar{1}} \) by \( \overline{\mathcal{G}}_{g,n+\bar{1}} \). It is normal in \( \widehat{\mathcal{G}}_{g,n+\bar{1}} \). The group \( \widehat{\mathcal{G}}_{g,n+\bar{1}} \) is an extension

\[
1 \to \widehat{U}_{g,n+\bar{1}} \to \widehat{\mathcal{G}}_{g,n+\bar{1}} \to \text{GSp}(H) \to 1,
\]

where GSp denotes the general symplectic group and \( \widehat{U}_{g,n+\bar{1}} \) is pronipotent\(^8\).

**Proposition 13.1.** For each complex structure \( \phi : (S, P, \nu, \xi) \to (X, D, \varphi) \), the coordinate ring \( \mathcal{O}(\widehat{\mathcal{G}}_{g,n+\bar{1}}/\overline{\mathcal{G}}_{g,n+\bar{1}}) \) has a canonical MHS. These form an admissible variation of MHS over \( \mathcal{M}_{g,n+\bar{1}} \) with trivial monodromy. Consequently, the MHS on \( \mathcal{O}(\widehat{U}_{g,n+\bar{1}}/\overline{U}_{g,n+\bar{1}}) \) does not depend on the complex structure \( \phi \).

**Proof.** The first task is to show that the \( \widehat{G}_{g,n+\bar{1}} \) form a local system over \( \mathcal{M}_{g,n+\bar{1}} \). This is not immediately clear, as the size of the Mumford–Tate group depends non-trivially on complex structure on \( (S, P, \nu) \). To this end, let \( x = (X, D, \varphi) \) be a point of \( \mathcal{M}_{g,n+\bar{1}} \). Denote the relative completion of \( \pi_1(\mathcal{M}_{g,n+\bar{1}}; x) \) by \( \mathcal{G}_x \).

\(^8\)One can argue as in \([13\, \text{Lem. } 4.3]\) that, if \( g \geq 3 \), then \( \mathcal{U}^{\mathcal{MT}}_{g,n+\bar{1}} \to \widehat{U}_{g,n+\bar{1}} \) is an isomorphism if and only if \( \pi_1(\text{MHS}) \to \text{GSp}(H) \) is surjective: the Griffiths invariant \( \nu(X) \in \text{Ext}^1_{\text{MHS}}(\mathcal{O}(\text{Pic}^0(X))) \) of the Ceresa cycle in \( \text{Jac } X \) is non-zero; and if the points \( \kappa_j := (2g - 2)x_j - R_{X} \in (\text{Jac } X) \otimes \mathbb{Q} \), \( 0 \leq j \leq n \), are linearly independent over \( \mathbb{Q} \). This holds for general \( (X, D, \varphi) \).
y = (Y, E, \mathcal{V}) be another point of \mathcal{M}_{g,n+1} and let \mathcal{G}_y be the relative completion of \pi_1(\mathcal{M}_{g,n+1}, y). Denote the relative completion of the torsor of paths in \mathcal{M}_{g,n+1} from x to y by \mathcal{G}_{x,y}. Its coordinate ring has a natural Hodge structure and the multiplication map
\[ \mathcal{G}_x \times \mathcal{G}_{x,y} \to \mathcal{G}_y \]
is a morphism of Hodge structures. This is equivalent to the statement that the map
\[ (\pi_1(\text{Hodge}) \times \mathcal{G}_x) \times \mathcal{G}_{x,y} \to \pi_1(\text{Hodge}) \times \mathcal{G}_y \]
defined by \((\sigma, \lambda, \gamma) \mapsto (\sigma, \gamma^{-1} \lambda \gamma)\) is a \(\pi_1(\text{Hodge})\)-equivariant surjection, where \(\alpha \in \pi_1(\text{Hodge})\) acts by
\[ \alpha : (\sigma, \lambda, \gamma) \mapsto (\alpha \sigma^{-1}, \alpha \cdot \lambda, \alpha \cdot \gamma) \text{ and } \alpha : (\sigma, \mu) \mapsto (\alpha \sigma \mu^{-1}, \alpha \cdot \mu). \]
The diagram
\[ \begin{array}{ccc}
(\pi_1(\text{Hodge}) \times \mathcal{G}_x) \times \mathcal{G}_{x,y} & \longrightarrow & \pi_1(\text{Hodge}) \times \mathcal{G}_y \\
\text{Aut } \mathbb{Q} \pi_1(X, \mathcal{V})^\wedge \times \mathcal{G}_{x,y} & \longrightarrow & \text{Aut } \mathbb{Q} \pi_1(Y, \xi')^\wedge \\
\end{array} \]
commutes, where \(Y = Y - E\) and where the bottom arrow is induced by parallel transport in the local system whose fiber over \(x\) is \(\text{Aut } \mathbb{Q} \pi_1(X, \mathcal{V})^\wedge\). This implies that there is a morphism \(\hat{\mathcal{G}}_x \times \mathcal{G}_{x,y} \to \hat{\mathcal{G}}_y\) that is compatible with path multiplication. It follows that \(\mathcal{G}_x\) form a local system over \(\mathcal{M}_{g,n+1}\).

We now prove the remaining assertions. The monodromy action of \(\Gamma_{g,n+1}\) on \(\hat{\mathcal{G}}_{g,n+1}/\overline{\mathcal{G}}_{g,n+1}\) is the composite
\[ \Gamma_{g,n+1} \to \hat{\mathcal{G}}_{g,n+1}(\mathbb{Q}) \to \text{Aut } (\hat{\mathcal{G}}_{g,n+1}/\overline{\mathcal{G}}_{g,n+1})(\mathbb{Q}), \]
where the first homomorphism is the canonical map, and the second is induced by conjugation. It is easily seen to be trivial as \(\overline{\mathcal{G}}_{g,n+1}\) is normal in \(\hat{\mathcal{G}}_{g,n+1}\).

The coordinate ring of \(\hat{\mathcal{G}}_{g,n+1}/\overline{\mathcal{G}}_{g,n+1}\) has a Hodge structure as the inclusion \(\overline{\mathcal{G}}_{g,n+1} \to \hat{\mathcal{G}}_{g,n+1}\) is \(\pi_1(\text{Hodge})\)-equivariant. This variation has no geometric monodromy, and so is constant by the theorem of the fixed part. Since \(\overline{\mathcal{G}}_{g,n+1} = \hat{\mathcal{G}}_{g,n+1} \cap \overline{\mathcal{G}}_{g,n+1}\), the map
\[ \hat{\mathcal{U}}_{g,n+1}/\overline{\mathcal{G}}_{g,n+1} \to \hat{\mathcal{G}}_{g,n+1}/\overline{\mathcal{G}}_{g,n+1} \]
is a \(\pi_1(\text{Hodge})\)-equivariant inclusion. It follows that \(\hat{\mathcal{U}}_{g,n+1}/\overline{\mathcal{G}}_{g,n+1}\) is also a constant variation of Hodge structures over \(\mathcal{M}_{g,n+1}\).

The homomorphism \(\tilde{\tau}_d : \hat{\mathcal{G}}_{g,n+1} \to \text{Sp}(H) \ltimes H\) lifts to a homomorphism
\[ \tilde{\tau}_d : \hat{\mathcal{G}}_{g,n+1} \to \text{GSp}(H) \ltimes H \]
Its kernel is the group \(\hat{\mathcal{U}}_{g,n+1}\) defined in the previous section. Since \(\overline{\mathcal{U}}_{g,n+1} = \hat{\mathcal{U}}_{g,n+1} \cap \overline{\mathcal{G}}_{g,n+1}\), we have:

**Corollary 13.2.** \(\mathbb{O}(\hat{\mathcal{U}}_{g,n+1}/\overline{\mathcal{G}}_{g,n+1})\) is a constant VMHS over \(\mathcal{M}_{g,n+1}\).

**Proposition 13.3.** There is a canonical surjection \(\pi_1(\text{MTM}) \to \hat{\mathcal{G}}_{g,n+1}/\overline{\mathcal{G}}_{g,n+1}\).
The prounipotent analogue of the proof of Oda’s Conjecture [30] should imply that this is an isomorphism.

**Sketch of Proof.** Since the variation $\mathcal{O}(\hat{U}_{g,n+1}/\hat{M}_{g,n+1})$ is constant, it extends over the boundary of $\mathcal{M}_{g,n+1}$. Since the variation of MHS over $\mathcal{M}_{g,n+1}$ with fiber $u_{g,n+1}$ is admissible, it has a limit MHS at each tangent vector of the boundary divisor $\Delta$ of $\mathcal{M}_{g,n+1}$. These tangent vectors correspond to first order smoothings of an $(n+1)$-pointed stable nodal curve of genus $g$ together with a tangent vector at the initial point $x_0$. For each such maximally degenerate stable curve $\hat{\mathcal{X}}_0$ (with fiber $\hat{\mathcal{X}}_0$), Ihara and Nakamura [22] construct a proper flat curve

$\mathcal{X} \to \text{Spec } \mathbb{Z}[[q_1, \ldots, q_N]], \quad N = \dim \mathcal{M}_{g,n+1} = 3g + n - 2$

with sections $x_j$, $0 \leq j \leq n$ and a non-zero tangent vector field $\hat{v}$ along $x_0$ that specialize to the points of $P$ and the tangent vector $\xi_q$ at $q = 0$. The projection is smooth away from the divisor $q_1 q_2 \ldots q_N = 0$. These are higher genus generalizations of the Tate curve in genus 1.

There is a limit MHS on each of

$\mathbb{Q} \pi_1(\mathcal{X}_q, \hat{v})^\wedge$, \quad $\mathcal{O}(\hat{U}_{g,n+1}), \quad \mathcal{O}(\hat{M}_{g,n+1})$

corresponding to the tangent vector $\hat{q} := \sum_{j=1}^N \partial / \partial q_j$ of $\mathcal{M}_{g,n+1}$ at the point corresponding to $(\mathcal{X}_0, P, \hat{v}_0)$. These can be thought of as MHSs on the invariants of $(\mathcal{X}_q, \hat{v})$, where $\mathcal{X}_q$ denotes the fiber of $\mathcal{X}$ over $\hat{q}$ and $\mathcal{X}_q$ the corresponding affine curve.

The main result of [18] is that these MHS are Hodge realizations of objects of $\text{MTM}$. This implies that each has an action of $\pi_1(\text{MTM})$ and that the action of $\pi_1(\text{MHS})$ on each factors through the canonical surjection $\pi_1(\text{MHS}) \to \pi_1(\text{MTM})$.

Brown’s result [5] asserts that $\pi_1(\text{MTM})$ acts faithfully on

$\mathbb{Q} \pi_1(\mathbb{P}^1 - \{0, 1, \infty\}, \hat{v}_0)^\wedge$.

This implies that it also acts faithfully on $\mathbb{Q} \pi_1(\mathcal{X}_q, \hat{v})^\wedge$ as (by the construction in [18]), the unipotent path torsor of $\mathcal{X}_q$ is built up from the path torsors of copies of $\mathbb{P}^1 - \{0, 1, \infty\}$ (and is 6 canonical tangent vectors) in $\mathcal{X}_q$. In other words, $\text{MT}_{\mathcal{X}_q, \hat{v}}$ is naturally isomorphic to $\pi_1(\text{MTM})$. This implies that there is a surjective homomorphism $h : \pi_1(\text{MTM}) \to \hat{U}_{g,n+1} / \hat{M}_{g,n+1}$.

**Corollary 13.4.** There is a canonical surjection $\mathcal{K} \to \hat{U}_{g,n+1} / \hat{M}_{g,n+1}$.
