Abstract

Consider the action of $GL(n, \mathbb{Q}_p)$ on the $p$-adic unit sphere $S_n$ arising from the linear action on $\mathbb{Q}_p^n \setminus \{0\}$. We show that for the action of a semigroup $S$ of $GL(n, \mathbb{Q}_p)$ on $S_n$, the following are equivalent: (1) $S$ acts distally on $S_n$. (2) the closure of the image of $S$ in $PGL(n, \mathbb{Q}_p)$ is a compact group. On $S_n$, we consider the ‘affine’ maps $T_a$ corresponding to $T$ in $GL(n, \mathbb{Q}_p)$ and a nonzero $a$ in $\mathbb{Q}_p^n$ satisfying $\|T^{-1}(a)\|_p < 1$. We show that there exists a compact open subgroup $V$, which depends on $T$, such that $T_a$ is distal for every nonzero $a \in V$ if and only if $T$ acts distally on $S_n$. The dynamics of ‘affine’ maps on $p$-adic unit spheres is quite different from that on the real unit spheres.

Keywords and phrases: distal actions, affine maps, $p$-adic unit spheres.

1 Introduction

Let $X$ be a (Hausdorff) topological space. Let $\mathcal{S}$ be a semigroup of homeomorphisms of $X$. The action of $\mathcal{S}$ is said to be distal if for any pair of distinct elements $x, y \in X$, the closure of $\{(T(x), T(y)) \mid T \in \mathcal{S}\}$ does not intersect the diagonal $\{(d, d) \mid d \in X\}$; equivalently we say that the $\mathcal{S}$ acts distally on $X$. Let $T : X \to X$ be a homeomorphism. The map $T$ is said to be distal if the group $\{T^n\}_{n \in \mathbb{Z}}$ acts distally on $X$. If $X$ is compact, then $T$ is distal if and only if the semigroup $\{T^n\}_{n \in \mathbb{N}}$ acts distally (cf. Berglund et al. [1]).

The notion of distality was introduced by Hilbert (cf. Moore [8]) and studied by many in different contexts (see Ellis [3], Furstenberg [4], Raja-Shah [10] [11] and Shah [12], and references cited therein). Note that a homeomorphism $T$ of a topological space is distal if and only if $T^n$ is so, for every $n \in \mathbb{Z}$.

For the $p$-adic field $\mathbb{Q}_p$, let $| \cdot |_p$ denote the $p$-adic absolute value on $\mathbb{Q}_p$ and for $x = (x_1, \ldots, x_n) \in \mathbb{Q}_p^n$, $n \in \mathbb{N}$, let $\|x\|_p = \max_{1 \leq i \leq n} |x_i|_p$. This defines a $p$-adic vector space norm on $\mathbb{Q}_p^n$. Let $S_n = \{x \in \mathbb{Q}_p^n \mid \|x\|_p = 1\}$ be the $p$-adic unit sphere (in $\mathbb{Q}_p^n$). We refer
the reader to Koblitz [7] for basic facts on $p$-adic vector spaces. We first define a canonical group action of $GL(n, \mathbb{Q}_p)$ on $S_n$ as follows: For $T \in GL(n, \mathbb{Q}_p)$, let $\mathcal{T}_n : S_n \rightarrow S_n$ be defined as $\mathcal{T}_n(x) = \|T(x)\|_p T(x)$, $x \in S_n$. This is a continuous group action. We show that a semigroup $\mathcal{G}$ of $GL(n, \mathbb{Q}_p)$ acts distally on $S_n$ if and only if the closure of the image of $\mathcal{G}$ in $PGL(n, \mathbb{Q}_p)$ is a compact group; where $D$ is the centre of $GL(n, \mathbb{Q}_p)$ (see Theorem 2.4). This is a $p$-adic analogue of Theorem 1 in Shah-Yadav [13] for the action of a semigroup in $GL(n + 1, \mathbb{R})$ on the real unit sphere $S^n$. In particular, we show for $T \in SL(n, \mathbb{Q}_p)$ that $T$ is distal if and only if $\mathcal{T}_n$ is distal (more generally see Proposition 2.3 Corollary 2.5 and the subsequent remark). For $T \in GL(n, \mathbb{Q}_p)$ and $a \in \mathbb{Q}_p^n \setminus \{0\}$, if $\|T^{-1}(a)\|_p < 1$, then the corresponding ‘affine’ map on $S_n$, $\mathcal{T}_a(x) = \|a + T(x)\|_p (a + T(x))$, $x \in S_n$ is a homeomorphism. In case $T$, or more generally, $\mathcal{T}_n$ is distal, then there exists a neighbourhood $V$ of 0 in $\mathbb{Q}_p^n$, such that for every nonzero $a$ in $V$, $\mathcal{T}_a$ is distal. If $\mathcal{T}_n$ is not distal, then every neighbourhood of 0 contains a nonzero $a$ such that $\mathcal{T}_a$ is not distal; see Theorem 3.2 and Corollary 3.3. In case of such ‘affine’ actions on the real unit sphere $S^n$, there are many examples where $T \in GL(n + 1, \mathbb{R})$ such that $T$ and/or $\mathcal{T}_n$ are distal but $\mathcal{T}_a$ is not distal, (see Theorem 7, Corollaries 10 & 12 in [13]). This illustrates that the dynamics of such ‘affine’ actions on $S_n$ is different from that on $S^n \subset \mathbb{R}^{n+1}$.

For an invertible linear map $T$ on a $p$-adic vector space $V \approx \mathbb{Q}_p^n$, let $C(T) = \{v \in V \mid T^m(v) \rightarrow 0 \text{ as } m \rightarrow \infty\}$ and $M(T) = \{v \in V \mid \{T^m(v)\}_{m \in \mathbb{Z}} \text{ is relatively compact}\}$. These are closed subspaces of $V$, $C(T)$ is known as the contraction space of $T$, and $V = C(T) \oplus M(T) \oplus C(T^{-1})$. It is easy to see that $T$ is distal (on $V$) if and only if $C(T)$ and $C(T^{-1})$ are trivial. We refer the reader to Wang [14] for more details on the structure of $p$-adic contraction spaces. We will use the notion of contraction spaces below.

## 2 Distality of the semigroup actions on $S_n$

Let $\mathbb{Q}_p^n$ be an $n$-dimensional $p$-adic vector space equipped with the $p$-adic norm defined as above. For $T \in GL(n, \mathbb{Q}_p)$, let $\|T\|_p = \sup\{\|T(x)\|_p \mid x \in \mathbb{Q}_p, \|x\|_p = 1\}$. Observe that the norm of an element or a matrix, defined this way, is of the from $p^m$ for some $m \in \mathbb{Z}$. The map $GL(n, \mathbb{Q}_p) \times \mathbb{Q}_p^n \rightarrow \mathbb{Q}_p^n$ given by $(T, x) \mapsto T(x)$, $T \in GL(n, \mathbb{Q}_p)$, $x \in \mathbb{Q}_p^n$, is continuous. We call $T \in GL(n, \mathbb{Q}_p)$ an isometry if it preserves the norm, i.e. if $T$ keeps the $p$-adic unit sphere $S_n$ invariant. Note that $T$ is an isometry if and only if $\|T\|_p = 1 = \|T^{-1}\|_p$. For $x, y \in \mathbb{Q}_p^n$, $\|x + y\|_p \leq \max\{\|x\|_p, \|y\|_p\}$; the equality holds if $\|x\|_p \neq \|y\|_p$. We will use this fact extensively. We first consider the group action of $GL(n, \mathbb{Q}_p)$ on $S_n$ defined in the introduction. For semigroups of $GL(n, \mathbb{Q}_p)$, we prove a result analogous to Theorem 1 in [13] (see Theorem 2.4).

Recall that $T \in GL(n, \mathbb{Q}_p)$ is said to be distal if $\{T^m\}_{m \in \mathbb{Z}}$ acts distally on $\mathbb{Q}_p^n$.

The following useful lemma may be known. We will give a short proof for the sake of completion.

2
Lemma 2.1. Let \( T \in GL(n, \mathbb{Q}_p) \). The following are equivalent.

1. \( T \) is distal.
2. The closure of the group generated by \( T \) in \( GL(n, \mathbb{Q}_p) \) is compact.
3. \( T^m \) is an isometry for some \( m \in \mathbb{N} \).

Proof. (3) \( \Rightarrow \) (2) is obvious and (2) \( \Rightarrow \) (1) follows as compact groups act distally. Now suppose \( T \) is distal, i.e. \( \{T^m\}_{m \in \mathbb{Z}} \) acts distally on \( \mathbb{Q}_p^n \). Then the contraction spaces \( C(T) \) and \( C(T^{-1}) \) are trivial. By Lemma 3.4 of [12], we get that \( \mathbb{Q}_p^n = M(T) = \{x \in \mathbb{Q}_p^n \mid \{T^m(x)\}_{m \in \mathbb{Z}} \text{ is relatively compact}\} \), (cf. [14]). By Proposition 1.3 of [14], \( \cup_{m \in \mathbb{Z}} T^m(S_n) \) is relatively compact, i.e. \( \{\|T^m\|_p\}_{m \in \mathbb{Z}} \) is bounded and hence \( \{T^m \mid m \in \mathbb{Z}\} \) is relatively compact in \( GL(n, \mathbb{Q}_p) \). This proves (1) \( \Rightarrow \) (2). Now suppose \( T \) is contained in a compact group. Then \( T^{m_k} \to \text{Id} \), for some \( m_k \subset \mathbb{N} \). Therefore, \( \|T^{m_k}\|_p \to 1 \) and as \( \{\|T^m\|_p \mid m \in \mathbb{Z}\} \subset \{p^l \mid l \in \mathbb{Z}\} \), we get that for all large \( k \), \( \|T^{m_k}\|_p = 1 \) and \( T^{m_k} \) is an isometry. Therefore, (2) \( \Rightarrow \) (3). \( \square \)

We say that a topological group \( G \) acts continuously on a topological space \( X \) by homeomorphisms if there is a homomorphism \( \psi : G \to \text{Homeo}(X) \) such that the corresponding map \( G \times X \to X \) given by \( (g, x) \mapsto \psi(g)(x) \), \( g \in G \), \( x \in X \), is continuous. We say that a semigroup \( H \) of \( G \) (resp. \( T \in G \)) acts distally on \( X \) if \( \psi(H) \) acts distally on \( X \) (resp. \( \psi(T) \) is distal). We state a useful lemma which is well-known and can be proven easily.

Lemma 2.2. Let \( X \) be a Hausdorff topological space and let \( G \) be a Hausdorff topological group which acts continuously on \( X \) by homeomorphisms. Let \( H \) be a semigroup and \( K \) be a compact subgroup of \( G \) such that all the elements of \( H \) normalise \( K \). Then the semigroup \( HK \) acts distally on \( X \) if and only if \( H \) acts distally on \( X \). In particular, if \( T, S \in G \) are such that \( TS = ST \) and \( S \) generates a relatively compact group in \( G \), then \( T \) acts distally on \( X \) if and only if \( TS \) acts distally on \( X \).

We now recall the natural action of \( GL(n, \mathbb{Q}_p) \) on \( S_n \) defined earlier: For \( T \in GL(n, \mathbb{Q}_p) \) and \( x \in S_n \), \( T(x) = \|T(x)\|_pT(x) \). Here, \( T \) defines a homeomorphism of \( S_n \) and it is trivial if and only if \( T = p^n\text{Id} \) for some \( n \in \mathbb{Z} \). The map \( GL(n, \mathbb{Q}_p) \to \text{Homeo}(S_n) \), given by \( T \mapsto T \) as above, is a homomorphism which factors through the discrete central subgroup \( \{p^n\text{Id} \mid n \in \mathbb{Z}\} \) of \( GL(n, \mathbb{Q}_p) \). The corresponding map \( GL(n, \mathbb{Q}_p) \times S_n \to S_n \), given by \( (T, x) \mapsto T(x) \), is continuous. Therefore, \( GL(n, \mathbb{Q}_p) \) acts continuously on \( S_n \) by homeomorphisms as above. Observe that \( S_1 = Z^*_p = \{x \in \mathbb{Q}_p \mid |x|_p = 1\} \) and \( GL(1, \mathbb{Q}_p) = \mathbb{Q}_p \setminus \{0\} \) acts distally on \( S_1 \) as \( T = \|T\|_pT \in S_1 \) for every \( T \in GL(1, \mathbb{Q}_p) \).

The following will be useful in proving the main result of this section.

Proposition 2.3. Let \( T \in GL(n, \mathbb{Q}_p) \). If \( bT \) is distal for some \( b \in \mathbb{Q}_p \), then \( T \) is distal. Conversely, if \( T \) is distal, then for some \( m \in \mathbb{N} \) and \( l \in \mathbb{Z} \), \( p^lT^m \) is distal. If \( \det T|_p = 1 \) and \( T \) is distal, then \( T \) is distal.
Proof. Observe that \( bT \) is distal if and only if \( |b|^{-1}T \) is so. As \( T = p^{m} \bar{T} \) for any \( m \in \mathbb{Z} \), we may replace \( T \) by \( |b|^{-1}T \) and assume that \( T \) is distal. By Lemma \[2.7\] \( T \) generates a relatively compact group, and hence \( \bar{T} \) is distal. Conversely, suppose \( \bar{T} \) is distal. By 3.3 of [3], there exists \( m \in \mathbb{N} \) such that \( T^m = AU \), where \( C \) is a diagonal matrix, \( U \) is unipotent, \( A \) is semisimple, \( A, U \) and \( C \) commute with each other, and \( A \) as well as \( U \) generate a relatively compact group. Now by Lemma \[2.2\], we have that \( C \) is distal. Here, \( C = DD' = D'D \) for some diagonal matrices \( D \) and \( D' \) such that the diagonal entries of \( D \) (resp. \( D' \)) are of the form \( p^k \), \( l_k \in \mathbb{Z} \), \( k = 1, \ldots, n \) (resp. in \( \mathbb{Z}_p^* \)). Since \( D' \) also generates a relatively compact group and it commutes with \( D \), by Lemma \[2.2\] \( D \) is distal. It is enough to show that \( D = p^l \text{Id}, \) as in this case, \( D \) would be central in \( GL(n, \mathbb{Q}_p) \) and this would imply that \( A \) and \( D' \) commute, and hence, \( p^{-l}T^m = A UD' \) would generate a relatively compact group which in turn would imply that it is distal. If possible, suppose \( p^l \) and \( p^j \) are two entries in \( D \) such that \( l < l_1 \). As \( \overline{D} = p^{−l}D \), we get for \( D_1 = p^{-l}D \) that \( \overline{D}_1 = \overline{D} \) is distal, \( 1 \) is an eigenvalue of \( D_1 \) and \( D_1 \) has another eigenvalue \( p^{j−l} \) which has \text{p-adic absolute} value less than \( 1 \). Then the contraction space of \( D_1, C(D_1) \neq \{0\} \) as we can take a nonzero \( y \in \mathbb{Q}_p^n \) satisfying \( D_1(y) = p^k y \) for \( k = l_1-l \in \mathbb{N} \); and it follows that \( y \in C(D_1) \). Let \( x \in S_n \) be such that \( D_1(x) = x \) and let \( y \) be as above such that \( 0 < ||y||_p < 1 \). Then \( \overline{D}_1(x) = x \) and \( x + y \in S_n \). Now \( D_1(x + y) = (x + p^k y) \rightarrow x \in S_n \) as \( i \rightarrow \infty \). Therefore, \( \overline{D}_1(x + y) \rightarrow x \) and it leads to a contradiction as \( \overline{D}_1 \) is distal. Therefore, \( D = p^l \text{Id} \) and \( p^{-l}T^m \) is distal.

Suppose \( |\det T|_p = 1 \). Then \( |\det(T^m)|_p = |\det T|^m = 1 \). As \( \bar{T} \) is distal, \( T^m = p^lS \) for some \( l \in \mathbb{Z} \), where \( S \) generates a relatively compact group. Therefore, \( |\det S|_p = 1 \), and hence \( l = 0 \) and \( T^m = S \). This implies that \( T \) also generates a relatively compact group, and by Lemma \[2.7\] it is distal.

From now on, \( \mathcal{D} = \{b \text{Id} \mid b \in \mathbb{Q}_p\} \), the centre of \( GL(n, \mathbb{Q}_p) \). The following characterises distal actions of semigroups on \( S_n \). Recall that \( PGL(n, \mathbb{Q}_p) = GL(n, \mathbb{Q}_p)/\mathcal{D} \).

**Theorem 2.4.** Let \( \mathcal{S} \subset GL(n, \mathbb{Q}_p) \) be a semigroup. Then the following are equivalent:

(i) \( \mathcal{S} \) acts distally on \( S_n \).

(ii) The group generated by \( \mathcal{S} \) acts distally on \( S_n \).

(iii) The closure of \( (\mathcal{S}\mathcal{D})/\mathcal{D} \) in \( PGL(n, \mathbb{Q}_p) \) is a compact group.

**Proof.** Suppose (i) holds. First suppose \( \mathcal{S} \subset SL(n, \mathbb{Q}_p) \). As the closure \( \overline{\mathcal{S}} \) of \( \mathcal{S} \) is a semigroup in \( SL(n, \mathbb{Q}_p) \) and it also acts distally on \( S_n \), we may assume that \( \mathcal{S} \) is closed. By Proposition \[2.3\] and Lemma \[2.7\], each element in \( \mathcal{S} \) generates a relatively compact group (in \( \mathcal{S} \)). In particular, each element of \( \mathcal{S} \) has an inverse in \( \mathcal{S} \) and \( \mathcal{S} \) is a group. Now by Lemma 3.3 of [3], \( \mathcal{S} \) is contained in a compact extension of a unipotent subgroup in \( GL(n, \mathbb{Q}_p) \) which is normalised by \( \mathcal{S} \). Now suppose \( \mathcal{S} \not\subset SL(n, \mathbb{Q}_p) \). We will first show that \( \mathcal{S} \) is contained in a compact extension of a nilpotent group in \( GL(n, \mathbb{Q}_p) \) and the latter
is isomorphic to a direct product of $D$ and a unipotent subgroup normalised by elements of $S$.

Let $C = \{ p^n \text{Id} \mid n \in \mathbb{Z} \}$ and let $Z = \{ z \text{Id} \mid z \in \mathbb{Z}_p^* \}$. Then $C$ and $Z$ are closed subgroups of $D$, $C$ is discrete, $Z$ is compact and $D = C \times Z$. As the actions of both $S$ and $SC$ on $S_n$ are same and the latter is also a semigroup, without loss of any generality, we may replace $S$ by $SC$ and assume that $C \subset S$. As noted earlier, we may also assume that $S$ is closed. Moreover, as $Z$ is compact and central, $SZ$ is a closed semigroup and by Lemma 2.4, $SZ$ acts distally on $S_n$. Therefore, we may replace $S$ by $SZ$ and assume that $Z \subset S$.

Now we have $D \subset S$ and $S \subset D = S$. Let $T \in S$. By Proposition 2.3, $T^m = p^l S$ for some $l \in \mathbb{Z}$ and $S \in GL(n, \mathbb{Q}_p)$ such that $S$ generates a relatively compact group. Moreover, as $D \subset S$, we have that $S \subset S$. Therefore, the closure of the semigroup generated by $S$ in $S$ is compact and hence a group. In particular, $S$ is invertible in $S$ and we have that $T^m$ is invertible in $S$, and hence $T^{-1} (T^m)^{-1}$ is the inverse of $T$ in $S$. Therefore, we may assume that $S$ is a closed group. Let $T$ be a maximal torus in $GL(n, \mathbb{Q}_p)$. Let $T_a$ (resp. $T_d$) be the anisotropic (resp. split) torus in $T$. Then $T_a$ is compact and $T_a T_d$ is an almost direct product. Moreover, since all maximal tori are conjugate to each other, there exists $m \in \mathbb{N}$, such that for any element $T \in S \subset GL(n, \mathbb{Q}_p)$, we have $T^m = \tau_a \tau_d \tau_u$, where $\tau_u$ is unipotent, $\tau_s = \tau_a \tau_d \in T$ is semisimple, $\tau_a \in T_a$ which is a compact group, $\tau_d \in T_d$ and $\tau_a, \tau_d$ and $\tau_u$ commute with each other. Note that $T$ depends on $T$, but $m$ is independent of the choice of $T$. We know that $\tau_u$, being unipotent, generates a relatively compact group. As $T$ is distal, arguing as above in the proof of Proposition 2.3, we get that $\tau_d = (t_{ij})_{n \times n}$ is such that $t_{ij} = 0$ if $i \neq j$ and $|t_{ii}|_p$ is the same for all $i$. We have $T^m = CS$, where $C \in D$ and $S$ generates a relatively compact group. Let $\pi : GL(n, \mathbb{Q}_p) \to GL(n, \mathbb{Q}_p)/D$ be the natural projection. Note that $GL(n, \mathbb{Q}_p)/D$ is an algebraic group and it is linear, i.e. it can be realised as a subgroup of $GL(V)$ for some $p$-adic vector space $V$. Now $\pi(S)$ is a (closed) subgroup of $GL(n, \mathbb{Q}_p)/D$ and every element of $\pi(S)$ generates a relatively compact group, by Lemma 3.3 of [2], $\pi(S)$ is contained in a compact extension of a unipotent group, i.e. $\pi(S) \subset K \times U$, a semi-direct product, where $K, U \subset GL(V), K$ is a compact group and $U$ is unipotent. We can choose $K$ such that $\pi(S) \cap U$ is isomorphic to $K$. Let $H = K \times U = \pi(S) \cap U$. Let $G$ be the smallest algebraic subgroup of $GL(n, \mathbb{Q}_p)/D$ containing $\pi(S)$. Here, since $U$ is unipotent and it is normalised by $\pi(S)$, it is also normalised by $G$. Then $GU$ is an algebraic group, and hence it is closed. As $H \subset GU$ and $H = (G \cap H) \cap U$, it follows that $K = H/\cap U$ is isomorphic to $(G \cap H)/(G \cap U)$. Let $H_0 = G \cap H$ and let $U_0 = G \cap U$. Then $\pi(S) \subset H_0$ and $\pi(S)$ normalises $U_0$. Here, $\pi^{-1}(U_0) = D \times U'$ where $U'$ is the unipotent radical of $\pi^{-1}(U_0), U'$ is isomorphic to $\pi(U') = U_0$ and it is normalised by $S$. Therefore $S \subset H' = \pi^{-1}(H_0)$. Also, $D \times U'$ is a co-compact nilpotent normal subgroup in $H'$ and it is also algebraic, (see [2] and [4] for details on algebraic groups).

By Kolchin's Theorem, there exists a flag $\{0\} = V_0 \subset \cdots \subset V_k = \mathbb{Q}_p^*$ of maximal $U'$-invariant subspaces such that $U'$ acts trivially on $V_j/V_{j-1}$, $j = 1, \ldots, k$. Note that each $V_j$
is maximal in the sense that for any subspace $W$ containing $V_j$ such that $W \neq V_j$, $U'$ does not act trivially on $W/V_{j-1}$. It is easy to see that each $V_j$ is $S$-invariant as $S$ normalises $U'$. Now suppose $S/D$ is not compact. Then there exists a sequence $\{T_i\} \subset S$ such that $\{\pi(T_i)\}$ is unbounded. Now we have $T_i = K_iD_iU_i$, $i \in \mathbb{N}$, where $D_i \in D$, $U_i \in U'$ and $K_i \in \pi^{-1}(K)$ such that $\{K_i\}$ is relatively compact and $\{U_i\}$ is unbounded. Note that for each $j$, as $S$, $U'$ and $D$ keep $V_j$ invariant, $K_j(V_j) = V_j$ for all $i$. Passing to a subsequence if necessary, we get that there exists $\pi \in S_n$ such that $\|U_i(w)\| \to \infty$, $\overline{T}_i(w) \to w' \in S_n$ and $K_i \to K_0$. For every $v \in V_1$, $T_i(v) = D_iK_i(v) \in V_1$, and hence $\{\|D_i^{-1}T_i(v)\|\}$ is bounded. Let $v \in V_1 \setminus \{0\}$ be such that $\|v\| \to 1$. Then $v + w \in S_n$. As $\{\|K_iU_i(v + w)\|\}$ is unbounded and $K_iU_i(v) = K_i(v) \to K_0v$, we get that $\overline{T}_i(v + w) = \overline{K_iU_i(v + w)} \to w'$. This contradicts (i). Therefore, $S/D$ is compact, i.e. (i) $\Rightarrow$ (iii).

Suppose $S/D$ is a compact group. Then it contains $GD/D$, where $G$ is the group generated by $S$. Therefore, $GD/D$ is relatively compact. Using this fact, we want to show that $G$ acts distally on $S_n$. Let $C$ and $Z$ be closed subgroups of $D$ as above. Since the actions of both $G$ and $GC$ on $S_n$ are same, without loss of any generality we may replace $G$ by $GC$ and assume that $C \subset G$. We may also assume that $G$ is closed. Now, using the facts that $D = C \times Z$ and $Z$ is compact, we get that $GD = GZ$ is closed. Now $GD/D$ is compact and it is isomorphic to $G/([G \cap Z] \times C)$. Therefore, $G/C$ is compact, as $G \cap Z$ is compact. Since the action of $G$ on $S_n$ factors through $C$, the preceding assertion implies that $G$ acts distally on $S_n$. Hence (iii) $\Rightarrow$ (ii). It is obvious that (ii) $\Rightarrow$ (i).

The following is a consequence of the above theorem.

**Corollary 2.5.** A semigroup $S$ of $SL(n, \mathbb{Q}_p)$ acts distally on $S_n$ if and only if the closure of $S$ is a compact group.

**Proof.** Let $\pi : GL(n, \mathbb{Q}_p) \to GL(n, \mathbb{Q}_p)/D$ be as above. By Theorem 2.4, $S$ acts distally on $S_n$ if and only if $\pi(S)$ is a compact group. Note that $\pi(S) \subset \pi(S)$. As $SL(n, \mathbb{Q}_p)D$ is closed and $SL(n, \mathbb{Q}_p) \cap D$ is finite, we get that $\pi(S)$ is compact if and only if $S$ is compact; the latter statement is equivalent to the following: $S$ is a compact group. Now the assertion follows from above.

**Remark.** Note that the above corollary is valid for a semigroup $S \subset GL(n, \mathbb{Q}_p)$ satisfying the condition that $|\det(T)|_p = 1$ for all $T \in S$, as the elements of $GL(n, \mathbb{Q}_p)$ satisfying the condition form a closed subgroup (say) $G$ such that $GD$ is closed and $G \cap D$ is a compact group (isomorphic to $\mathbb{Z}_p^*$).

In the real case, Corollary 5 in [13] showed that a semigroup $S \subset GL(n + 1, \mathbb{R})$ acts distally on the (real) unit sphere $S^n$ if (and only if) every cyclic subsemigroup of $S$ acts distally on $S^n$. The corresponding statement does not hold in the $p$-adic case, as there exists a class of closed non-compact subgroups of $SL(n, \mathbb{Q}_p)$, every cyclic subgroup of which is relatively compact but which do not act distally on $S_n$ as they are not compact; e.g. the group of strictly upper triangular matrices in $SL(n, \mathbb{Q}_p)$, $n \geq 2$. 

6
3 Distality of ‘affine’ actions on $S_n$

In this section, we discuss the ‘affine’ maps on the $p$-adic unit sphere $S_n$. Consider the affine action on $\mathbb{Q}_p^n$: $T_a(x) = a + T(x)$, $x \in \mathbb{Q}_p^n$, where $T \in GL(n, \mathbb{Q}_p)$, and $a \in \mathbb{Q}_p^n$. We first consider the corresponding ‘affine’ map $\overline{T}_a$ on $S_n$ which is defined for any nonzero $a$ satisfying $\|T^{-1}(a)\|_p \neq 1$ as follows: $\overline{T}_a(x) = \|T_a(x)\|_p T_a(x)$, $x \in S_n$. (For $a = 0$, $\overline{T}_a = \overline{T}$, which is studied in Section 2). Observe that $T_a(x) = 0$ for some $x \in S_n$ if and only if $T^{-1}(a)$ has norm 1. Therefore, $\overline{T}_a(S_n) \subset S_n$ if $\|T^{-1}(a)\|_p \neq 1$. The map $\overline{T}_a$ is a homeomorphism for any nonzero $a$ satisfying $\|T^{-1}(a)\|_p < 1$ (see Lemma 3.1 below). In this section, we study the distality of such homeomorphisms $\overline{T}_a$.

**Lemma 3.1.** Let $T \in GL(n, \mathbb{Q}_p)$ and let $a \in \mathbb{Q}_p^n \setminus \{0\}$ be such that $\|T^{-1}(a)\|_p \neq 1$. Then the map $\overline{T}_a$ on $S_n$ is continuous and injective. $\overline{T}_a$ is a homeomorphism if and only if $\|T^{-1}(a)\|_p < 1$.

**Proof.** Suppose $\|T^{-1}(a)\|_p \neq 1$. From the definition of $\overline{T}_a$, it is obvious that it is continuous. Suppose $x, y \in S_n$ such that $\overline{T}_a(x) = \overline{T}_a(y)$. Then

$$\|a + T(x)\|_p(a + T(y)) = \|a + T(y)\|_p(a + T(y))$$

or $(\beta - 1)T^{-1}(a) = y - \beta x$, where $\beta = \|a + T(x)\|_p/\|a + T(y)\|_p = p^m$ for some $m \in \mathbb{Z}$. If possible, suppose $\beta \neq 1$. Interchanging $y$ and $x$ if necessary, we may assume that $\beta > 1$ or equivalently, that $m \in \mathbb{N}$. This implies that $\|\beta x\|_p = |\beta|_p = p^{-m} < 1$, and we get

$$\|T^{-1}(a)\|_p = |\beta - 1|_p\|T^{-1}(a)\|_p = \|y - \beta x\|_p = 1,$$

a contradiction. Hence, $\beta = 1$ and $x = y$. Therefore, $\overline{T}_a$ is injective.

Now suppose $\|T^{-1}(a)\|_p < 1$. It is enough to show that $\overline{T}_a$ is surjective, as any continuous bijection on a compact Hausdorff space is a homeomorphism.

Let $y \in S_n$. Let $z = T^{-1}(y)$ and let $z = \|z\|_p z - T^{-1}(a)$. Since the norm of $\|z\|_p z$ is 1 and $\|T^{-1}(a)\|_p < 1$, we have that $\|z\|_p = 1$. Moreover, as $\|y\|_p = 1$, we have that $\|z\|_p^{-1} = \|a + T(x)\|_p$. Therefore, $\overline{T}_a(x) = y$. Hence $\overline{T}_a$ is surjective.

Conversely, suppose $\overline{T}_a$ is surjective. Then there exists $x \in S_n$ such that $\overline{T}_a(x) = \|a\|_p a$. We get that $x = (p^m - 1)T^{-1}(a)$, where $p^m = \|a + T(x)\|_p^{-1} \|a\|_p$ for some $m \in \mathbb{Z}$; here $m \neq 0$ since $x \neq 0$. Now $1 = \|x\|_p = |p^m - 1|_p \|T^{-1}(a)\|_p \geq \|T^{-1}(a)\|_p$ since $|p^m - 1|_p \geq 1$ for every $m \in \mathbb{Z} \setminus \{0\}$. As $\|T^{-1}(a)\|_p \neq 1$, we have that $\|T^{-1}(a)\|_p < 1$. \(\square\)

In [13], we have studied ‘affine’ maps $\overline{T}_a$ on the real unit sphere $\mathbb{S}^n$. The following result shows that in the $p$-adic case, $\overline{T}_a$ is distal for every nonzero $a$ in a certain neighbourhood of 0 in $\mathbb{Q}_p^n$ if and only if $\overline{T}$ is distal. This illustrates that the behaviour of such maps in the $p$-adic case is very different from that in the real case.

**Theorem 3.2.** Suppose $T \in GL(n, \mathbb{Q}_p)$. For $a \in \mathbb{Q}_p^n \setminus \{0\}$ with $\|T^{-1}(a)\|_p \neq 1$, let $\overline{T}_a : S_n \to S_n$ be defined as $\overline{T}_a(x) = \|a + T(x)\|_p(a + T(x))$, $x \in S_n$. There exists a
compact open subgroup $V \subset \mathbb{Q}_p^n$ such that for all $a \in V \setminus \{0\}$ we have $\|T^{-1}(a)\|_p < 1$, $T_a$ is a homeomorphism and the following hold:

(I) If $\overline{T}$ is distal, then $T_a$ is distal for all nonzero $a \in V$.

(II) If $\overline{T}$ is not distal, then for every neighbourhood $U$ of $0$ contained in $V$, there exists a nonzero $a \in U$ such that $T_a$ is not distal.

Proof. By 3.3 of [14], we get that there exist $D$ and $S$ which commute with $T$ and $m \in \mathbb{N}$ such that $T^m = SD = DS$, where $D$ is a diagonal matrix with the diagonal entries in $\{p^j \mid i \in \mathbb{Z}\}$ and $S$ generates a relatively compact group. Therefore, $S^k$ is an isometry for some $k \in \mathbb{N}$. Replacing $m$ by $km$, we may assume that $S$ itself is an isometry. Let $c_0 = \min\{1/\|T^{-j}\|_p \mid 1 \leq j \leq m - 1\}$ and $c_1 = \max\{\|T^j\|_p \mid 1 \leq j \leq m - 1\}$. As $S_n$ is compact, $0 < c_0 \leq c_1 < \infty$. Also, $c_0 \leq \|T^j(x)\|_p \leq c_1$ for all $x \in S_n$ and $1 \leq j \leq m - 1$. Since $\|T^j\|_p \in \{p^j \mid i \in \mathbb{Z}\}$, we get that $\{\|T^j\|_p \mid x \in S_n, 1 \leq j \leq m - 1\}$ is finite.

Let $V$ be a compact open $S$-invariant subgroup in $\mathbb{Q}_p^n$ such that $V \cup_0 V \cup c_0^2 V \cup c_1^{-2} V \subset W = \{w \in \mathbb{Q}_p^n \mid \|w\|_p < 1\}$. Then, $\|v\|_p < \min\{1, c_0, c_0^2, c_1^{-2}\} \leq 1$ for all $v \in V$ and $c_0 c_1^{-2} V \subset c_0^2 c_1^{-2} V \subset W$. Moreover, $\|T^{-1}(v)\|_p < c_0^{-1} c_0 = 1$ for every $v \in V$.

Let $p^j$ be the smallest nonzero entry in the diagonal matrix $D$ and let $H = \{x \in \mathbb{Q}_p^n \mid D(x) = p^j x\}$. This is a nontrivial closed subspace of $\mathbb{Q}_p^n$. As $S$ and $T$ commute with $D$, they keep $H$ invariant and, as $S$ is an isometry, $\|T^m(x)\|_p = p^{-l} \|x\|_p$ for all $x \in H$.

Let $a \in V \setminus \{0\}$. As noted above, $\|T^{-1}(a)\|_p < 1$, and hence by Lemma [3.7], $T_a$ is a homeomorphism. Take any $x \in S_n$. Since $\|a\|_p < c_0$ and $\|T(x)\|_p \geq c_0$, we have $\|T_a(x)\|_p = \|a + T(x)\|_p = \|T(x)\|_p$ and

$$T_a(x) = \|T_a(x)\|_p T_a(x) = \|T(x)\|_p (a + T(x)).$$

Let $\alpha_1(x) = \|T_a(x)\|_p = \|T(x)\|_p = \beta_{1,x}$. Let $\alpha_j(x) = \|T_a(T_a^{j-1}(x))\|_p = \|a + T(T_a^{j-1}(x))\|_p$ and let $\beta_{j,x} = \alpha_1(x) \cdots \alpha_j(x)$ for all $j \in \mathbb{N}$ ($j \geq 2$). Take $\beta_{0,x} = 1$ and $\phi^0 = \text{Id}$ for any map $\phi$. From above, we have that $\alpha_j(x) = \|T(T_a^{j-1}(x))\|_p$ for all $j \in \mathbb{N}$. It is easy to show by induction that for every $j \in \mathbb{N}$,

$$T_a^j(x) = \beta_{j,x} T_a^j(x) + \beta_{j,x} \sum_{i=1}^j \beta_{j-i,x}^{-1} T_a^i(a). \quad (1)$$

Observe that as $a \in V$, $\|T^k(a)\|_p \leq c_1 ||a||_p < c_1 (c_0 c_1^{-1}) = c_0$ and for any $x \in S_n$, $\|T^k(x)\|_p \geq c_0$, $1 \leq k \leq m - 1$. Therefore, for $j \in \mathbb{N}$ and $1 \leq k \leq m - 2$,

$$\|T^k(T_a^{j}(x))\|_p = \|a_j(x)\|^{-1} \|T^k(a) + T^{k+1}(T_a^{j-1}(x))\|_p = \|T_a^{j-1}(T_a^{j}(x))\|_p.$$
c_1 for all x ∈ S_n and 1 ≤ j ≤ m − 1. Moreover, applying the same equation again successively, we get for j ≥ m that
\[
\alpha_j(x) = [\alpha_{j-1}(x) \cdot \alpha_{j-m+1}(x)]^{-1} T^{m-1}(a) + T^m(T_{\alpha}^{j-m}(x))_p.
\] (2)

Now we take a ∈ V \cap H \setminus \{0\}. Then T_{\alpha}(S_n \cap H) = S_n \cap H. Let x ∈ S_n \cap H. Then \|T^{-1}(a)\|_p < c_0^{-1}c_0 = 1 and hence, \|T^{-1}(a) + T^{j-m}(x)\|_p = 1. This implies that
\[
\|T^{m-1}(a) + T^m(T^{j-m}(x))\|_p = \|T^m(T^{-1}(a) + T^{j-m}(x))\|_p = p^{-1}.
\] (3)

Using Eqs. (2) and (3), we get \[\alpha_j(x) = [\alpha_{j-1}(x) \cdot \alpha_{j-m+1}(x)]^{-1} p^{-l},\ and\ hence\ \beta_{j,x} = p^{-l} \beta_{j-m,x}\] for all j ≥ m. In particular, \[\beta_{m,x} = p^{-l} = \|T^m(x)\|_p.\] This implies that \[\beta_{km+j,x} = p^{-kl} \beta_{j,x} = p^{-kl} \|T^j(x)\|_p, k, j ∈ N.\] Therefore, \[\beta_{j,x} = \|T^j(x)\|_p, j ∈ N.\] Moreover, for all k, j ∈ Z and x ∈ H, \[T^{km+j}(x) = p^{kl} S^k T^j(x) = p^{kl} T^j S^k(x)\] and, \[\|T^{km+j}(x)\|_p = p^{-kl} \|T^j(x)\|_p\] as S is an isometry. In particular, \[\beta_{km+j,x} = p^{-kl} \|T^j(x)\|_p\] for all k, j ∈ Z such that km + j ≥ 0. Using the above facts together with Eq. (1), we get for k ∈ N,
\[
T_{\alpha}^{km}(x) = \beta_{km,x} T^{km}(x) + \beta_{km,x} \sum_{j=1}^{km} \beta_{km-j,x}^{-1} T^{j-1}(a)
= S^k(x) + \sum_{j=1}^{km} \|T^{-j}(x)\|_p^{-1} T^{j-1}(a)
= S^k(x) + \sum_{i=1}^{k} \sum_{j=1}^{m} \|T^{-j}(x)\|_p^{-1} T^{j-1}(S^{i-1}(a))
= S^k(x) + \sum_{j=1}^{m} \gamma_{j,x}^{-1} T^{j-1}(a_k),
\]
where \[a_k = \sum_{i=1}^{k} S^{i-1}(a) ∈ V \cap H, k ∈ N, \gamma_{j,x} = \|T^{-j}(x)\|_p = p^j \beta_{m-j,x}\ and\ c_1^{-1} ≤ \gamma_{j,x} ≤ c_0^{-1}, 1 ≤ j ≤ m - 1,\ and\ \gamma_{m,x} = p^l.\ From\ above,\ we\ get\ that\ for\ any\ k ∈ N\ and\ x, y ∈ S_n \cap H,
\[
T_{\alpha}^{km}(x) - T_{\alpha}^{km}(y) = S^k(x - y) + \sum_{j=1}^{m-1} [(\gamma_{j,x}^{-1} - \gamma_{j,y}^{-1}) T^{j-1}(a_k)].
\] (4)

Let x, y ∈ S_n \cap H such that \[\|x - y\|_p < c_0c_1^{-1}.\ As\ T\ is\ linear, T^j(x) = T^j(y) + T^j(x - y),\ j ∈ N.\ For\ 1 ≤ j ≤ m - 1,\ as\ \|T^j(x - y)\|_p ≤ c_1 \|x - y\|_p < c_0,\ and\ \|T^j(y)\|_p ≥ c_0,\ we\ get\ that\ \beta_{j,x} = \|T^j(x)\|_p = \|T^j(y)\|_p = \beta_{j,y},\ and\ hence\ \gamma_{j,x} = \gamma_{j,y}.\ Therefore,
\[
\|T_{\alpha}^{km}(x) - T_{\alpha}^{km}(y)\|_p = \|S^k(x) - S^k(y)\|_p = \|x - y\|_p, k ∈ N.
\]

Now suppose \[\|x - y\|_p ≥ c_0c_1^{-1}.\ Observe that \[\gamma_{j,x}^{-1} - \gamma_{j,y}^{-1} ≤ c_1^{-1},\ \|T^j(a_k)\|_p ≤ c_1 \|a_k\|_p,\ 1 ≤ j ≤ m - 1\ and\ a_k ∈ V, \|a_k\|_p < c_0^2c_1^{-2}.\ Now\ Eq. (4)\ implies\ that T_{\alpha}^{km}(x) - T_{\alpha}^{km}(y) \in
$S^k(x - y) + c_0^{-1}c_1W$. Since $\|S^k(x - y)\|_p = \|x - y\|_p \geq c_0c_1^{-1}$, we get that $\|T_a^{km}(x) - T_a^{km}(y)\|_p = \|x - y\|_p$. This shows that $T_a^{km}|_{S_n \cap H}$ preserves the distance and is distal and hence, $T_a^{km}|_{S_n \cap H}$ is distal, where $a \in V \cap H$.

If $T$ is distal, then so is $T^m$, and hence its image in $GL(n, \mathbb{Q}_p)/D$ generates a relatively compact group. This implies that $D = p^t \text{Id}$, $H = \mathbb{Q}_p^n$, $S_n \cap H = S_n$ and $V \cap H = V$.

Therefore, $(I)$ holds.

Now suppose $T$ is not distal. Then $T^m$ is not distal and hence $D \neq p^t \text{Id}$. Let $l_1 > l$ and $H_1 = \{x \in \mathbb{Q}_p^n \mid D(x) = p^l \text{x}\}$. Then $H_1$ is a vector subspace and it is invariant under $D$, $S$ and $T$. Let $a \in V \cap H \setminus \{0\}$ as above. It is easy to see that $T_a(S_n \cap (H \oplus H_1)) = S_n \cap (H \oplus H_1)$. We show that the restriction of $T_a$ to $S_n \cap (H \oplus H_1)$ is not distal. This would imply that $(II)$ holds.

Take $y = x + z \in S_n$, where $x \in S_n \cap H$ and $z \in H_1$ such that $\|T^j(z)\|_p < \|T^j(x)\|_p$, $j \in \mathbb{N}$. It is possible to choose such a $z$; we can take $z \in H_1$ with the property that $\|T^j(z)\|_p < \|T^j(x)\|_p$ for all $0 \leq j \leq m - 1$, then as $S$ is an isometry, $\|T^{km+j}(z)\|_p = p^{-kl_1}\|T^j(z)\|_p < p^{-kl}\|T^j(x)\|_p = \|T^{km+j}(x)\|_p$, $k \in \mathbb{N}$.

Now $\|T^j(y)\|_p = \|T^j(x)\|_p$, for all $j \in \mathbb{N}$. Here,

$$T^{km}(y) - T^{km}(x) = p^{-kl}[S^k(p^l x + p^l z)] - S^k(x) = p^{k(l_1 - l)}S^k(z) \rightarrow 0$$

as $k \rightarrow \infty$, since $S$ is an isometry and since $l_1 > l$. We now show for all $k \in \mathbb{N}$ that $T_a^{km}(y) - T_a^{km}(x) = T^{km}(y) - T^{km}(x)$. (From above, the latter is equal to $\beta_{km,x}T^{km}(z)$.) This in turn would imply that $T_a$ is not distal.

From Eq. (1), it is enough to show for all $j \in \mathbb{N} \cup \{0\}$ that $\beta_{j,y} = \beta_{j,x}$, or equivalently, $\beta_{j,y} = \|T^j(y)\|_p$ as the latter is equal to $\|T^j(x)\|_p$ which is the same as $\beta_{j,x}$. This is trivially true for $j = 0$. As shown earlier, for $1 \leq j < m - 1$, $\beta_{j,u} = \|T^j(u)\|_p$ for all $u \in S_n$, and hence $\beta_{j,y} = \beta_{j,x}$; i.e. the above statement holds for $1 \leq j < m$, and we get that

$$T_a^j(y) = \beta_{j,y}T^j(y) + \beta_{j,y} \sum_{i=1}^{j} \beta_{j-i,y}^{-1}T^{i-1}(a) = T_a^j(x) + \beta_{j,x}T^j(z). \quad (5)$$

We prove by induction on $k$ that $\beta_{j,y} = \beta_{j,x} = \|T^j(x)\|_p$ and Eq. (5) is satisfied for all $1 \leq j < km$, $k \in \mathbb{N}$. We have already proven these for $k = 1$. Suppose for some $k \in \mathbb{N}$, these hold for all $j$ such that $(k-1)m \leq j < km$. Let $km \leq j < (k+1)m$. Recall that for all $j \in \mathbb{N}$, $\alpha_j(u) = \|T(T_a^{j-1}(u))\|_p$, $u \in S_n$, and Eq. (2) holds for any $x \in S_n$ and $j \geq m$. As $\beta_{j,y}^{-1}\beta_{j,m,y}^{-1} = \alpha_j(y) \ldots \alpha_{j-m+1}(y)$, from Eq. (2) and, also Eq. (5) which is assumed to hold for $(k-1)m \leq j < km$ by the induction hypothesis, we get for $x, y, z$ as above and $km \leq j < (k+1)m$ that

$$\beta_{j,y}^{-1}\beta_{j-m,y}^{-1} = \|T^{m-1}(a) + T^m(T_a^{j-m}(y))\|_p$$

$$= \|T^m(T^{-1}(a) + T_a^{j-m}(x) + \beta_{j-m,x}T^{j-m}(z))\|_p$$

10
Now using this, we get that

\[ \beta_{j,y}^{-1} \beta_{j-m,y} = ||S[p^l(T^{-1}(a) + T_a^{j-m}(x)) + p^{l_1} \beta_{j-m,x}T_a^{j-m}(z)]||_p = p^{-l}, \]

as \( S \) is an isometry, \( l_1 > l \) and \( ||\beta_{j-m,x}T_a^{j-m}(z)||_p < 1 \) (see also Eq. (3)). Since \( (k-1)m \leq j - m < km \), \( \beta_{j,y} = p^{-l} \beta_{j-m,y} = ||p^lT_a^{j-m}(x)||_p = ||T_a^{j}(x)||_p. \) Hence Eq. (5) holds for \( km \leq j < (k+1)m \). Now by induction for all \( j \in \mathbb{N} \), \( \beta_{j,x} = \beta_{j,y} \) and Eq. (5) holds. Therefore, \( T_a \) is not distal. (Note that Eq. (5) also directly shows that \( T_a^{km}(y) - T_a^{km}(x) = p^{k(l-1)}S^k(z) \to 0 \) as \( k \to \infty \)). Now if \( U \subset V \) is a neighbourhood of 0, then \( U \cap H \neq \{0\} \) and hence (II) holds.

Observe that if \( T \) is not distal, then from Theorem 3.2 (II), we get that every neighbourhood of 0 in \( \mathbb{Q}_p \) contains a nonzero \( a \) such that \( ||T^{-1}(a)||_p < 1 \) and \( T_a \) is not distal. Now the following corollary is an easy consequence of Theorem 3.2.

**Corollary 3.3.** For \( T \in GL(n, \mathbb{Q}_p) \), \( T \) is distal if and only if there exists a neighbourhood \( V \) of 0 in \( \mathbb{Q}_p^n \) such that for every \( a \in V \setminus \{0\} \), \( ||T^{-1}(a)||_p < 1 \) and \( T_a \) on \( S_n \) is distal.

If \( T \) is distal, then \( T \) is also distal and Theorem 3.2 (I) and Corollary 3.3 holds for \( T \). If \( \overline{T} \) is distal, then for some \( m \in \mathbb{N} \) and \( l \in \mathbb{Z}, p^lT^m \) is distal.
