Abstract

We consider the $C^*$-algebras $\mathcal{H}_{N,M}$ consisting of $N$-dimensional finite differential operators with $M \times M$-matrix-valued periodic coefficients. We show that any $\mathcal{H}_{N,M}$ is $*$-isomorphic to the universal UHF algebra. In particular, for different $N, M \in \mathbb{N}$ the algebras $\mathcal{H}_{N,M}$ are topologically and algebraically isomorphic to each other. In this sense, there is no difference between multidimensional matrix valued PDEs $\mathcal{H}_{N,M}$ and one-dimensional scalar ODEs $\mathcal{H}_{1,1}$.

Keywords: representation of finite differential operators

1. Introduction

In general, there is an obvious difference between linear continuous ordinary differential equations and partial differential systems, both with non-constant periodic coefficients. While ODEs is a part of PDEs formally, often books are written either about ODEs or PDEs, see, e.g., [1, 2] (at least, the titles). In the continuous case, there are many reasons for this separation. For example, there is no full analogue of the Picard-Lindelöf theorem even for linear PDEs. Nevertheless, we show that if we replace continuous derivatives by their discrete analogues then both generate the same algebra, namely the universal UHF $C^*$-algebra. In this sense, topological and algebraic properties of algebras of finite ODEs and PDEs are identical. Algebras of discrete and continuous PDEs have numerous applications including a development of symbolic and numerical solvers of various differential equations, see, e.g., [3, 4, 5, 6].

Let $N, M \in \mathbb{N}$ be positive integers. Let $L^2_{N,M} = L^2(\mathbb{T}^N \to \mathbb{C}^M)$ be the Hilbert space of periodic vector valued functions defined on the multidimensional torus $\mathbb{T}^N$, where $\mathbb{T} = \mathbb{R}/\mathbb{Z} \simeq [0,1)$. Everywhere in the article, it is assumed the Lebesgue measure in the definition of Hilbert spaces of square-integrable functions. Let $R^\infty_{N,M} = R^\infty(\mathbb{T}^N \to \mathbb{C}^{M \times M})$ be the $C^*$-algebra of matrix-valued regulated functions with rational discontinuities. The regulated functions with possible rational discontinuities are the functions that can be uniformly approximated by the step functions of the form

$$S(x) = \sum_{n=1}^{P} \chi_{J_n}(x)S_n,$$

(1)
where $P \in \mathbb{N}$, $S_n \in \mathbb{C}^{M \times M}$, and $\chi_{J_n}$ is the characteristic function of the parallelepiped $J_n = \prod_{i=1}^{N} [p_{in}, q_{in}]$ with rational ends $p_{in}, q_{in} \in \mathbb{Q}_1 = \mathbb{Q}/\mathbb{Z} \subset \mathbb{T}$. In particular, continuous matrix-valued functions belong to $R_{N,M}^\infty$.

For $S \in R_{N,M}^\infty$, the operator of multiplication by the function $M_S : L^2_{N,M} \to L^2_{N,M}$ is defined by

$$M_S u(x) = S(x)u(x), \quad u(x) \in L^2_{N,M}, \quad x \in \mathbb{T}.$$ 

For $i \in \mathbb{N} = \{1, \ldots, N\}$, $h \in \mathbb{Q}$, the finite derivative $D_{i,h} : L^2_{N,M} \to L^2_{N,M}$ is defined by

$$D_{i,h} u(x) = \frac{u(x + he_i) - u(x)}{h}, \quad u(x) \in L^2_{N,M}, \quad x \in \mathbb{T},$$

where the standard basis vector $e_i = (\delta_{ij})_{j=1}^N$, and $\delta_{ij}$ is the Kronecker delta. The finite partial differential operators have the form

$$A u = \sum_{n=1}^{P} \left( \prod_{j=1}^{P_n} M_{S_n} D_{i_n,h_n} \right) u, \quad u \in L^2_{N,M},$$

where $P, P_n \in \mathbb{N}$, $i_n \in \mathbb{N}_N$, $h_n \in \mathbb{Q}$, and $S_n \in R_{N,M}^\infty$. The algebra of finite PDEs $\mathcal{H}_{N,M}$ is generated by all the possible operators $\mathcal{A}$, i.e.

$$\mathcal{H}_{N,M} = \overline{\text{Alg}}^{\mathcal{B}} \{ D_{i,h}, M_S : i \in \mathbb{N}_N, h \in \mathbb{Q}, S \in R_{N,M}^\infty \},$$

where $\mathcal{B} = \mathcal{B}_{N,M} = \mathcal{B}(L^2_{N,M})$ is the $C^*$-algebra of bounded operators acting on $L^2_{N,M}$. It is seen that $\mathcal{H}_{N,M}$ is the unital $C^*$-sub-algebra in $\mathcal{B}$.

Let us introduce the universal UHF $C^*$-algebra $\mathcal{U}$. One of the definitions is based on the inductive limit

$$\mathbb{C}^{1 \times 1} \xrightarrow{\varphi_1} \mathbb{C}^{2 \times 2} \xrightarrow{\varphi_2} \mathbb{C}^{6 \times 6} \ldots \xrightarrow{\varphi_n} \mathbb{C}^{n! \times n!} \ldots \rightarrow \mathcal{U},$$

where $\varphi_n$ are the unital $*$-embeddings, or, formally,

$$\mathcal{U} = \mathbb{C}^{1 \times 1} \otimes \mathbb{C}^{2 \times 2} \otimes \mathbb{C}^{3 \times 3} \otimes \ldots \mathbb{C}^{n \times n} \otimes \ldots$$

The corresponding supernatural number $N_\mathcal{U}$ contains all prime numbers infinitely many times. Hence, any UHF algebra is a sub-algebra of $\mathcal{U}$, see, e.g., [7, 8]. Let us formulate our main result.

**Theorem 1.1.** For any $N, M \in \mathbb{N}$, the $C^*$-algebra $\mathcal{H}_{N,M}$ is $*$-isomorphic to $\mathcal{U}$.

This means that there is no difference between $\mathcal{H}_{N,M}$ for different $N, M$. For example, if $\mathcal{A} \in \mathcal{H}_{N,M}$ then there is $\mathcal{B} \in \mathcal{H}_{1,1}$ with the same spectrum $\text{sp}_{\mathcal{B}_{N,M}}(\mathcal{A}) = \text{sp}_{\mathcal{B}_{1,1}}(\mathcal{B})$, and the $C^\infty$-algebras generated by $\mathcal{A}$ and $\mathcal{B}$ are $*$-isomorphic

$$\overline{\text{Alg}}_{\mathcal{H}_{N,M}}^{\mathcal{B}_{N,M}} \{ \mathcal{A}, \mathcal{A}^* \} \simeq \overline{\text{Alg}}_{\mathcal{B}_{1,1}}^{\mathcal{B}_{1,1}} \{ \mathcal{B}, \mathcal{B}^* \}. $$
Thus, there are no special difficulties in the studying of finite PDEs in comparison with finite ODEs. In fact,\
\[ H_{N,M} \cong \mathbb{C}^{M \times M} \otimes H_{1,1}^N \cong \mathbb{C}^{M \times M} \otimes U^N \cong U \cong H_{1,1}, \]
since \( U \otimes \mathcal{V} \cong U \) for any UHF algebra \( \mathcal{V} \), see [7].

What about other UHF algebras? Let \( N_{\mathcal{V}} = \prod_{n=1}^{P} p_n^{N_n} \) be some supernatural number corresponding to the UHF algebra \( \mathcal{V} \). Some of \( N_n \) and \( P \) can be infinite. We use the notation \( N_{\infty} = N \). Then
\[ \mathcal{V} \cong \text{Alg} \left\{ D_{i,h}, \mathcal{M}_S : h = p_n^{j}, j \in \mathbb{N}, n \in \mathbb{N}_P, S \in R_{i,1}^\infty(N_{\mathcal{V}}) \right\}, \tag{4} \]
where \( R_{i,1}^\infty(N_{\mathcal{V}}) \) is the \( C^* \)-algebra of scalar (\( M = 1 \)) one dimensional (\( N = 1 \)) regulated functions which can be uniformly approximated by step functions of the form (1) but with \( q_{1n}, p_{1n}^{s} \) equal to some \( p_{r,n}^{s} \) for any \( r \in \mathbb{N}_P, s \in \mathbb{N}_N \). In particular, the CAR-algebra is generated by the dyadic derivatives \( D_{i,h} \), \( n \in \mathbb{N} \) and dyadic regulated functions. The proof of (4) is similar to the proof of Theorem 1.1.

2. Proof of Theorem 1.1

We fix \( N, M \in \mathbb{N} \) and, for convenience, we will omit these indices below. Let \( h = 1/p \) for some \( p \in \mathbb{N} \). Denote \( R^h \) the \( C^* \)-sub-algebra of \( R^\infty \) consisting of step functions constant on each \( J = \prod_{i=1}^{N} [h p_i, h p_i + h) \subset \mathbb{T}^{N} \), where \( p_i \in \mathbb{Z}_p = \{0, \ldots, p - 1\} \). Consider the finite-dimensional \( C^* \)-sub-algebra \( \mathcal{H}^h \subset \mathcal{H} \) defined by
\[ \mathcal{H}^h = \text{Alg} \left\{ D_{i,h}, \mathcal{M}_S : i \in \mathbb{N}_N, \ S \in R^h \right\}. \]
It is seen that any operator \( \mathcal{A} \in \mathcal{H}^h \) has the form
\[ \mathcal{A} u(x) = \sum_{j \in \mathbb{Z}_p^N} A_j(x) u(x + h j), \quad u \in L^2_{N,M}, \tag{5} \]
with some \( A_j(x) \in R^h \). This is because all such \( \mathcal{A} \) belongs to \( \mathcal{H}^h \), since \( D_{i,h} \) is generated by shift operators, and all such \( \mathcal{A} \) form an algebra which contains \( D_{i,h} \) and \( \mathcal{M}_S \) for \( S \in R^h \). The next step is to find the convenient representation of \( \mathcal{H}^h \). Using (5), we have
\[ \mathcal{A} u(y + hr) = \sum_{j \in \mathbb{Z}_p^N} A_j(y + hr) u(y + h j + hr) = \sum_{j \in \mathbb{Z}_p^N} A_{j-r}(y + hr) u(y + h j), \quad y \in I_h = [0, h)^N, \ r \in \mathbb{Z}_p^N. \tag{6} \]
The Hilbert space \( L^2 \) is naturally isomorphic to the direct sum of Hilbert spaces of functions defined on shifted cubes \( I_h \):
\[ L^2 \cong L^2_h = \bigoplus_{r \in \mathbb{Z}_p^N} L^2(I_h \rightarrow \mathbb{C}^M) \]
with the isomorphism \( \mathcal{F}_h : L^2 \to L^2_h \) defined by

\[
\mathbf{u}(\mathbf{x}) \leftrightarrow (\mathbf{u}(\mathbf{y} + h\mathbf{j}))_{\mathbf{j} \in \mathbb{Z}_p^N}, \quad \mathbf{u} \in L^2, \quad \mathbf{x} \in \mathbb{T}^N, \quad \mathbf{y} \in I_h.
\]

Then, by (6) the operator \( \mathcal{F}_h A \mathcal{F}_h^{-1} : L^2_h \to L^2_h \) is the operator of multiplication by \( Mp^N \times Mp^N \)-matrix-valued function \( B_A(\mathbf{y}), \mathbf{y} \in I_h \) of the form

\[
B_A(\mathbf{y}) = (A_{j-r}(\mathbf{y} + h\mathbf{r}))_{r, \mathbf{j} \in \mathbb{Z}_p^N}.
\]

(8)

It is easy to see that

\[
B_{\alpha A + \beta B} = \alpha B_A + \beta B_B, \quad B_{AB} = B_A B_B, \quad B_A^* = B_A^*.
\]

(9)

Moreover, \( B_A(\mathbf{y}) \) is constant for \( \mathbf{y} \in I_h \), since all \( A_j \in \mathcal{R}^h \). Finally, note that for any \( \mathbf{B} \in \mathbb{C}^{Mp^N \times Mp^N} \) there is a unique \( \mathcal{A} \in \mathcal{H}^h \), such that \( \mathbf{B} = \mathcal{B}_A \). We can explicitly and uniquely recover \( \mathcal{A} \) from \( \mathcal{B}_A \), using (8) and (6). Thus, \( \mathcal{A} \mapsto \mathcal{B}_A \) is \( * \)-isomorphism between \( \mathcal{H}^h \) and \( \mathbb{C}^{Mp^N \times Mp^N} \).

Taking \( h_n = 1/n! \), \( n \in \mathbb{N} \), we can write

\[
\mathcal{H}^h_{n_1} \xrightarrow{\varphi_1} \mathcal{H}^h_{n_2} \xrightarrow{\varphi_2} \mathcal{H}^h_{n_3} \xrightarrow{\varphi_3} \ldots \to \mathcal{H},
\]

(10)

where \( \varphi_n \) is the natural embedding \( \mathcal{H}^h_{n_1} \) into \( \mathcal{H}^h_{n_1+1} \). Such embedding exists, since the partition of \( \mathbb{T}^N \) onto \( ((n+1)!)^N \) identical cubes for \( \mathcal{H}^{h_{n+1}} \) contains the partition of \( \mathbb{T}^N \) onto \( (n!)^N \) identical cubes for \( \mathcal{H}^{h_n} \). The inductive limit in (10) is \( \mathcal{H} \), since any \( \mathcal{D}_{t,h} \) with \( h = p/q \in \mathbb{Q} \) \( (q \in \mathbb{N}) \) belongs to \( \mathcal{H}^{h_q} \), and \( \mathcal{R}^\infty \) can be uniformly approximated by \( \mathcal{R}^{h_n} \) following the definition of regulated functions. Remembering \( \mathcal{H}^{h_n} \simeq \mathbb{C}^{M((n!)^N \times M((n!)^N)} \), we can conclude that the supernatural number \( N_{\mathcal{H}} \) for the UHF algebra \( \mathcal{H} \) contains all prime numbers infinitely many times. Hence, \( \mathcal{H} \) is \( * \)-isomorphic to the universal UHF algebra \( \mathcal{U} \).
