ON THE NODAL SET OF SOLUTIONS TO A CLASS OF NONLOCAL PARABOLIC REACTION-DIFFUSION EQUATIONS

ALESSANDRO AUDRITO AND SUSANNA TERRACINI

Abstract. We investigate the nodal properties of solutions $u = u(x,t)$ to a nonlocal parabolic reaction-diffusion equation. We characterise the possible blow-ups and we examine the structure of the nodal set of such solutions. More precisely, we prove that their nodal set has at least parabolic Hausdorff codimension one in $\mathbb{R}^N \times \mathbb{R}$, and can be written as the union of a locally smooth part and a singular part, which turns out to possess remarkable stratification properties. Moreover, the asymptotic behaviour of general solutions near their nodal points is classified in terms of a class of explicit polynomials of Hermite and Laguerre type, obtained as eigenfunctions to a Ornstein-Uhlenbeck type operator. Our main results are obtained through a fine blow-up analysis which relies on the monotonicity of an Almgren-Poon type quotient and some new Liouville type results for parabolic equations, combined with more classical results like the Federer Reduction Principle and the Parabolic Whitney Extension.

1. Introduction and structure of the paper

The main purpose of this paper is to give a detailed description of the nodal properties of solutions to the following nonlocal parabolic equation

\( (\partial_t - \Delta)^s u = h(x,t)u, \)

where \( x \in \mathbb{R}^N \) and \( t \in I \subseteq \mathbb{R} \). The fractional power \( 0 < s < 1 \) is fixed and the potential \( h = h(x,t) \) belongs to a suitable class of functions (cfr. with (2.1)). Nonlocal equations involving fractional powers of the Heat operator like (1.1) are of high relevance in pure mathematics as well as in applied fields such as biology, elasticity and finance. We quote Duvalt and Lion [27], Athanasopoulos et al. [3], Danielli et al. [24], and Banerjee et al. [6] for works on the obstacle type problem for \((\partial_t - \Delta)^s\), and Metzler and Klafter [47] for connections with the theory of continuous time random walks.

The present paper can be seen as a natural follow-up of [5] by Banerjee and Garofalo, where the authors proved a space-time strong unique continuation (backward in time) for solutions to (1.1). Their paper is based on the monotonicity of an Almgren-Poon type quotient (cfr. with formula (3.2) below), suitably combined with a fine blow-up analysis and the extension theory for solutions to (1.1), independently developed by Nyström and Sande [52] and Stinga and Torrea [63] (see also [61, 62]) in very recent years (see Caffarelli and Silvestre [19] for the elliptic counterpart).

We note that in comparison with the existing literature, we are mainly concerned with the problem of describing the regularity and the structure of the nodal set of solutions to (1.1). As anticipated, our results will be obtained by combining the use of an Almgren-Poon type monotonicity formula, a blow-up analysis, the classification of tangent maps and and more classical results such as the Federer Reduction Principle (cfr. with Theorem 8.5) and the Whitney Extension Theorem (cfr. with Theorem 8.6). We stress that these methods relies on the spectral analysis of a Ornstein-Uhlenbeck operator type, some new Liouville type results and some Gaussian-Poincaré inequalities, which will be proved together with the main results of the present work.

In this regard, the case \( s = 1 \) has been widely investigated both in the elliptic and in the parabolic framework (cfr. for instance the works of Han and Lin [40, 45], and Chen [20]). Let us mention that there are significative results on nodal properties of solutions to reaction-diffusion systems with strong competition, like Caffarelli et al. [2, 16, 18] and Terracini et al. [22, 23, 51, 65] (local framework) and [17, 67, 68, 72] (nonlocal framework). The parabolic case is less studied and, at least to our knowledge, there is literature for the local setting only (see the papers of Dancer et al. [25, 26]). The elliptic fractional framework has been very recently treated by G. Tortone in his Ph.D. dissertation [69], while the parabolic nonlocal case \( 0 < s < 1 \) is completely open for both systems and single equation.

Below we give an simplified version of our two main results, while the presentation of their precise statements will be postponed to Section 3 after having introduced some auxiliary matter. The first main result is concerned with the asymptotic behaviour of solutions near their nodal points. i.e., points \( p_0 = (x_0, t_0) \in \Gamma(u) := u^{-1}(\{0\}) \). The main fact here is that any solution to (1.1) behaves (near its nodal points) as a parabolically homogeneous polynomial of suitable order, called tangent map of \( u \), belonging to a specific class (cfr. with Definition 3.6 and Theorem 3.9).

**Theorem 1.1.** (Existence and uniqueness of the tangent map at nodal points) Fix \( 0 < s < 1 \). Let \( u = u(x,t) \) be a solution to (1.1) with potential \( h \) satisfying (2.1) below, and set \( u_{p_0}(x,t) = u_{(x_0,t_0)}(x,t) := u(x + x_0, t + t_0) \). Then the following assertions hold true:

(i) For any \( p_0 = (x_0, t_0) \in \Gamma(u) \), there exists a unique half-integer \( \kappa \in \mathbb{N}/2 \) and a unique parabolically \( \kappa \)-homogeneous polynomial \( \vartheta = \vartheta(x,t) \) such that

\[ u_{p_0}(x,t) = \vartheta_{p_0}(x,t) + o(\|u(x,t)\|^{2\kappa}), \]

where \( \vartheta_{p_0}(x,t) \) is the tangent map at \( p_0 \). More specifically:

1. **Existence**: For any \( p_0 \) as above, \( \vartheta_{p_0}(x,t) \) exists and is unique.
2. **Uniqueness**: If \( \vartheta_{p_0}(x,t) \) and \( \vartheta'_{p_0}(x,t) \) are two tangent maps at \( p_0 \), then \( \vartheta_{p_0}(x,t) = \vartheta'_{p_0}(x,t) \).
3. **Continuity**: If \( \vartheta_{p_0}(x,t) \) is the tangent map at \( p_0 \), then it satisfies the continuity condition

\[ \vartheta_{p_0}(x,t) = \vartheta(x,t) + o(\|u(x,t)\|^{2\kappa}), \]

where \( \vartheta(x,t) \) is a parabolically \( \kappa \)-homogeneous polynomial of suitable order.

(ii) For any \( p_0 \) as above, \( \vartheta_{p_0}(x,t) \) is a parabolically \( \kappa \)-homogeneous polynomial of suitable order.

(iii) For any \( p_0 \) as above, \( \vartheta_{p_0}(x,t) \) belongs to a suitable class of functions (cfr. with Definition 3.6 and Theorem 3.9).
for any \(d\) and each set \(\Gamma\) Extension Theorem (cfr. with Theorem 8.5 and Theorem 8.6, respectively).

Analysis is combined with a parabolic version of the Federer Reduction Principle and of the Whitney (cfr. with Definitions 3.10 and 3.11, below).

\[(1.1)\]

denotes the parabolic Hausdorff dimension (cfr. with Definitions \[8.2\]). Here we recall a crucial Hölder bound for the family \(\{u_{\lambda}\}_{\lambda>0}\) (cfr. with Theorem \[3.3\], Theorem \[3.4\] and Lemma \[7.3\]). Here we prove it possesses remarkable Liouville type results (cfr. with Theorems \[3.5\] and \[3.6\] below), then the map

\[
\Gamma_{\kappa}(u) \rightarrow \mathcal{B}_{\kappa}(u) : p_0 \rightarrow \partial p_0
\]
is continuous.

The above theorem relies on a fine analysis of the blow-up sequence

\[
u_{p_0, \lambda}(x, t) = \frac{u_{p_0}(\lambda x, \lambda^2 t)}{\lambda^{2\kappa}},
\]

and some new Liouville type results (cfr. with Theorem \[3.5\], Theorem \[3.6\] and Lemma \[7.3\]). Here we recall a crucial Hölder bound for the family \(\{u_{\lambda}\}_{\lambda>0}\) (cfr. with Theorem \[3.3\] and Corollary \[7.5\]).

**Theorem 1.2. (Uniform Hölder bounds for blow-up families)** Fix \(0 < s < 1\). Let \(u \in \text{dom}(H^s)\) be a solution to \(1.1\) with potential \(\nu\) satisfying \(2.1\) below.

Then for any \(p_0 = (x_0, t_0) \in \Gamma(u)\), there exists a half-integer \(\kappa \in \mathbb{N}/2\) such that for any compact set \(K \subset \mathbb{R}^N \times (-\infty, 0)\), and any \(0 < \nu < \nu_* = \min\{1/2, s\}\), there exists a constant \(C > 0\) not depending on \(\lambda > 0\), such that

\[
\|\nu_{p_0, \lambda}\|_{C^{\nu, \nu}(K)} \leq C,
\]

for any \(\lambda > 0\).

Secondly we state our main result concerning the structure and the regularity of the nodal set of solutions to \(1.1\). In particular, we prove it possesses remarkable non-degeneracy and stratification properties (cfr. with Theorem \[3.7\], Proposition \[3.8\] and Theorem \[3.12\] for the precise statements).

**Theorem 1.3. (Structure and Regularity of the nodal set)** Fix \(0 < s < 1\). Let \(u = u(x, t)\) be a solution to \(1.1\) with potential \(h\) satisfying \(2.1\) below.

(i) The nodal set \(\Gamma(u) := u^{-1}(\{0\})\) has parabolic Hausdorff codimension at least one, i.e.

\[
\text{dim}_{\mathcal{H}}(\Gamma(u)) \leq N + 1,
\]

where \(\text{dim}_{\mathcal{H}}(\cdot)\) denotes the parabolic Hausdorff dimension (cfr. with Definition \[3.2\]).

(ii) \(\Gamma(u)\) can be written as the disjoint union of a regular and singular part, denoted by \(\mathcal{R}(u)\) and \(\mathcal{S}(u)\), respectively. Furthermore:

- \(\mathcal{R}(u) = \Gamma(u) \cap \{|
abla_x u| > 0\}\) is a locally \(C^1\)-manifold of parabolic Hausdorff codimension at least one, i.e.

\[
\text{dim}_{\mathcal{H}}(\mathcal{R}(u)) \leq N + 1.
\]

- \(\mathcal{S}(u) := \Gamma(u) \setminus \mathcal{R}(u)\) can be written as the countable unions

\[
\mathcal{S}(u) = \bigcup_{\kappa\in\mathbb{N}/2} \Gamma_{\kappa}(u) = \bigcup_{\kappa\in\mathbb{N}/2} \bigcup_{d=0,...,N} \Gamma_{\kappa}^d(u),
\]

and each set \(\Gamma_{\kappa}^d(u)\) is contained in a countable union of \((d+1)\)-dimensional space-like \(C^{1,0}\) manifolds for any \(d = 0, \ldots, N - 1\), whilst \(\Gamma_{\kappa}^{N}(u)\) in a countable union of \(N\)-dimensional time-like \(C^1\) manifolds (cfr. with Definitions \[3.10\] and \[3.11\] below).

The proof of this last theorem relies on the validity of the first two ones, in which the blow-up analysis is combined with a parabolic version of the Federer Reduction Principle and of the Whitney Extension Theorem (cfr. with Theorem \[8.5\] and Theorem \[8.6\] respectively).

**Structure of the paper.** The paper is organized in sections as follows.
In Section 2 we review some important notions and definitions which are the basis of the entire work. The main references for this part are [5, 52, 63].

In Section 3 we present the detailed versions of our main results.

In Section 4 we review the proof of some Almgren-Poon type monotonicity formulas, and their immediate consequences.

In Section 5 we prove Theorem 5.2, from which Proposition 3.2 follows as a corollary. As an almost immediate application of the spectral analysis, we show some new Gaussian-Poincaré type inequalities which have a clear self-interest and, furthermore, will be crucially employed in the proof of some Liouville type results.

In Section 6 we start the blow-up analysis and we provide the proof of Theorem 6.3 which, as before, will be obtained as a consequence of a more general result (cfr. with Theorem 6.1). In this first step, we prove the convergence of the blow-up sequence and the uniqueness of the blow-up limit in energy spaces of Gaussian type.

In Section 7 we complete the blow-up analysis by proving Theorem 7.1 which generalizes Theorem 3.4. The main fact here is that we show that the blow-up sequence not only converges in energy space, but also locally uniformly in \( \mathbb{R}^{N+1} \times (0, \infty) \). We stress that, in order to obtain uniform bounds as in (3.14), we employ some new Liouville type results that we show (using again the monotonicity of the Almgren-Poon quotient) in a separate subsection.

Finally, in Section 8 we focus on the nodal set of solutions to equation (1.1) and we prove the main results of the entire work. Theorem 3.7 is obtained by combining the blow-up analysis with the Federer Reduction Principle (cfr. with Theorem 8.5), while the proof of Theorem 3.9 employs the blow-up classification and some Monneau and Weiss monotonicity formulas. Finally, Theorem 3.12 is proved through an application of a parabolic version of the Whitney Extension Theorem 8.6.

2. Preliminaries and known results

In the next paragraphs we collect some known result concerning equation (1.1) and introduce some technical tools which are the basis of this work. Once properly defined the fundamental framework in which we will move, we will be in a position to state in due detail our main results, which presentation is postponed to Section 3.

Equation (1.1): framework and non-locality. Keeping in mind this general ideas, we describe the framework in which equation (1.1) will be studied from now on. First of all, we fix \( 0 < s < 1 \) and we take \( I := (-T, 0) \) for some fixed \( T > 0 \) (the general case can be recovered through a temporal shift and eventually taking \( T = +\infty \)). We assume that the potential \( h : \mathbb{R}^{N+1} \to \mathbb{R} \) satisfies

\[
\begin{align*}
\|h\|_{C^1(\mathbb{R}^{N+1})} & \leq C, & \text{if } 1/2 \leq s < 1 \\
\|h\|_{C^2(\mathbb{R}^{N+1})}, \|x \cdot \nabla x h\|_{L^\infty(\mathbb{R}^{N+1})} & \leq C, & \text{if } 0 < s < 1/2,
\end{align*}
\]

for some constant \( C > 0 \), where

\[
\|f\|_{C^k(\mathbb{R}^{N+1})} := \sum_{|\alpha| + j \leq k} \sup_{(x,t) \in \mathbb{R}^{N+1}} |\partial^\alpha \partial_t^j f(x,t)|.
\]

Note that assumption (2.1) coincides with assumption (1.2) of [5], and it turns out to be crucial in the proof of some regularity results and of the Almgren-Poon monotonicity formula (cfr. with Section 5 and 6 of [5], respectively). As explained in [5], it may be possible to relax it to less a restrictive one. However, we do not insist on this aspect since it goes out of our purposes.
The main new feature of the problem is the presence of a fractional power of the Heat operator $H := \partial_t - \Delta$. Following [52] [63], we define its fractional power in terms of its Fourier transform

$$H^su(\eta, \vartheta) := (i\vartheta + |\eta|^2)^s \hat{u}(\eta, \vartheta),$$

for all functions $u = u(x, t)$ belonging to the natural domain

$$\text{dom}(H^s) := \{ u \in L^2(\mathbb{R}^{N+1}) : (i\vartheta + |\eta|^2)^s \hat{u} \in L^2(\mathbb{R}^{N+1}) \}.$$

We will thus say that a function $u = u(x,t)$ is a solution to (1.1) if $u \in \text{dom}(H^s)$ and (1.1) is satisfied a.e. in $\mathbb{R}^N \times (-T, 0)$ (note that this makes sense since $u \in \text{dom}(H^s)$ implies $H^su \in L^2(\mathbb{R}^{N+1})$ by Plancherel Theorem).

Now, to go deeper into the study of such nonlocal operator, we recall below a pointwise formula for $H^s$ appeared firstly Section 28.3 of [58] (cfr. with formula (28.52)) and then recently presented in [5] [52] [63].

**Theorem.** Let $0 < s < 1$ and $u \in \mathcal{S}(\mathbb{R}^{N+1})$. Then:

$$H^su(x, t) = \frac{1}{|\Gamma(-s)|} \int_0^t \int_{\mathbb{R}^N} [u(x, t) - u(z, \tau)] G_N(x - z, t - \tau) \frac{dzd\tau}{(t - \tau)^{1+s}},$$

for any $x \in \mathbb{R}^N$ and $t \in \mathbb{R}$, where $G_N = G_N(x, t)$ is the standard Gaussian probability density defined in (2.19) below.

The above theorem enlightens the genuine non local nature, both in space and time, of equations like (1.1). In more precise words, “the random jumps are coupled with the random waiting times” (cfr. with p. 3894 of [63]). Moreover, starting from the this pointwise representation, it is not difficult to see that $H^su = (-\Delta)^su$ if $u = u(x)$, while if $u = u(t)$ it reduces to the extended Caputo derivative (or Marchaud derivative) $H^su = (\partial_t)^su$ (cfr. with [10] [58] and the more recent work [12]). We stress that it significantly differs from another interesting model of fractional diffusion (in which jumps and waiting times are independent):

$$\partial_t u + (-\Delta)^su = 0,$$

and its generalizations (see for instance the works of Vázquez et al. [13] [71]). See also the papers of Figalli et al. [8] [14], where the obstacle problem for the above nonlocal parabolic equation is studied and the very recent paper of Fernández-Real and Ros-Oton [32].

**Equation (1.1): extension theory.** Before proceeding further, we need to recall some known facts from [52] [63] which are the fundamentals of our theory. Following Section 3 of [5], we consider a solution $u \in \text{dom}(H^s)$ to

$$(\partial_t - \Delta)^su = \frac{\Gamma(1 - s)}{2^{s-1}\Gamma(s)} h(x, t) u \quad \text{in } \mathbb{R}^N \times \mathbb{R},$$

which differs from (1.1) for the only presence of a normalization constant in front of the potential. Secondly, setting $a := 1 - 2s$ for the only presence of a normalization constant in front of the potential. We introduce the following extension problem:

$$(2.3) \begin{cases} \partial_t U - y^{-a} \nabla \cdot (y^a \nabla U) = 0 & \text{in } \mathbb{R}^{N+1}_+ \times \mathbb{R}, \\ U(x, 0, t) = u(x, t) & \text{in } L^2(\mathbb{R}^{N+1}_+), \end{cases}$$

where $\nabla = \nabla_{x,y}$ and $\nabla \cdot = \nabla_{x,y}$ denotes the gradient and the divergence operator, respectively, and $U = U(x, y, t)$ with $(x,y) \in \mathbb{R}^{N+1}_+ := \mathbb{R}^N \times \mathbb{R}_+$ and $t \in \mathbb{R}$. The theorem below clarifies the connections between the nonlocal operator $H^s$ and the extension problem (2.3), giving also the expression of a solution in terms of the convolution between the boundary data $u = u(x, t)$ and a Poisson kernel type.
Theorem. (Nyström and Sande [52][Theorem 1], Stinga and Torrea [63][Theorem 1.7], Banerjee and Garofalo [5][Section 3]).

Let $0 < s < 1$, $a = 1 - 2s$, $u \in \text{dom}(H^s)$ and consider the function

$$U(x, y, t) := \int_0^{\infty} \int_{\mathbb{R}^N} u(x + z, t - \tau) P_{y}^u(z, \tau) dz d\tau,$$

where the Poisson kernel is defined by

$$P_{y}^u(x, t) = \frac{1}{2^{1-a} \Gamma\left(\frac{1-a}{2}\right)} G_N(x, t) \frac{y^{1-a}}{t^{1+\frac{1-a}{2}}} e^{-\frac{x \cdot y}{t}} \quad (x, y) \in \mathbb{R}^{N+1}, \; t > 0.$$

Then $U = U(x, y, t)$ satisfies $U(\cdot, \cdot, y) \in C^{\infty}((0, \infty), \text{dom}(H^s)) \cap C([0, \infty), L^2(\mathbb{R}^{N+1}))$ and solves the extension problem (2.3). Moreover, $U = U(x, y, t)$ is smooth in $\mathbb{R}^{N+1} \times (-\infty, \infty)$ and

$$-\frac{2^{2s-1} \Gamma(s)}{\Gamma(1 - s)} \partial_y^a U(x, t) = H^s u(x, t) \quad \text{in } L^2(\mathbb{R}^{N+1}),$$

where $\partial_y^a U(x, t) := \lim_{y \to 0^+} y^a \partial_y U(x, y, t)$ in $L^2(\mathbb{R}^{N+1}).$

This last theorem is crucial for the rest of the paper since it explains how to transform a nonlocal problem as (1.1) (and/or (2.2)) into a local one, posed in the extended space $\mathbb{R}^{N+1} \times \mathbb{R}$. Mimicking Section 4 of [5], we thus consider the extended problem:

$$\begin{cases}
\partial_t U - y^{-a} \nabla \cdot (y^a \nabla U) = 0 & \text{in } \mathbb{R}^{N+1} \times \mathbb{R}, \\
U = u & \text{in } \mathbb{R}^N \times \{0\} \times \mathbb{R} \\
-\partial_y^a U = h(x, t)u & \text{in } \mathbb{R}^N \times \{0\} \times \mathbb{R},
\end{cases}$$

(2.7)

where the last to equations have to be intended in the $L^2(\mathbb{R}^{N+1})$ sense (note that, in view of the above theorem, the last equation reads without any additional multiplicative term, thanks to the normalization in (2.2)). Working with the extensions has some technical advantages and, in particular, it allows us to bypass the non-locality of our equation. The main drawback is the presence of an additional, though fictitious variable $y \in \mathbb{R}_+$ that requires the passage to the (nontrivial) limit (2.6), to be eliminated and return to the original nonlocal problem.

**Problem (2.7): weak solutions and regularity theory.** In order to deal with problem (2.7), we have to recall the notion of weak solutions and the subsequent regularity results (cfr. with Section 4 of [5]) adapting them to our setting. Before that, we introduce some notations. If $r > 0$ and $X_0 = (x_0, y_0) \in \mathbb{R}^{N+1}$, we define

$$B_r(x_0) := \{x \in \mathbb{R}^N : |x - x_0| < r\},$$

$$\mathbb{B}_r(X_0) := \{X = (x, y) \in \mathbb{R}^{N+1} : |x - x_0|^2 + |y - y_0|^2 < r^2\},$$

$$\mathbb{B}_r^+(X_0) := \mathbb{B}_r(X_0) \cap \{y > 0\},$$

and we will set $B_r := B_r(0)$, $\mathbb{B}_r := \mathbb{B}_r(0)$ and $\mathbb{B}_r^+ := \mathbb{B}_r^+(0)$ for simplicity.

**Definition. (Banerjee and Garofalo [3][Definition 4.1 and 4.3])**

Let $-1 < a < 1$, $r > 0$, $T_1 < T_2$. We define the space

$$\mathcal{V}^{a, r; T_1, T_2} := L^2((T_1, T_2); W^{1, 2}(\mathbb{B}_r^+, y^a dx dy)).$$

endowed with the norm
\[ \|W\|_{\mathcal{V}^{\alpha,r,t_1,t_2}}^2 := \int_{t_1}^{t_2} \int_{\mathbb{B}_r^+} (W^2 + |\nabla W|^2) y^a \, dx dy dt < \infty. \]
If \( V \in L^\infty(B_r \times (T_1, T_2)) \), we say that a function \( U \in \mathcal{V}^{\alpha,r,t_1,t_2} \) is a weak solution in \( \mathbb{B}_r^+ \times (T_1, T_2) \) to
\[
\begin{aligned}
\partial_t U - y^{-a} \nabla \cdot (y^a \nabla U) &= 0 \\
-\partial_y^a U &= h(x, t)U,
\end{aligned}
\]
if for every \( \eta \in W^{1,2}(\mathbb{B}_r^+ \times (T_1, T_2), y^a dx dy) \) with compact support in \((\mathbb{B}_r^+ \cup B_r) \times [T_1, T_2] \) it holds
\[
\int_{t_1}^{t_2} \int_{\mathbb{B}_r^+} (\nabla U \cdot \nabla \eta - U \partial_y \eta) y^a \, dX dt = \int_{B_r^+} [U(t_1)\eta(t_1) - U(t_2)\eta(t_2)] y^a \, dX dt - \int_{t_1}^{t_2} \int_{B_r} h(x, t)U \eta \, dx dt,
\]
for a.e. \( T_1 < t_1 < t_2 < T_2 \), where \( dX := dx dy \) and \( U(t) \) denotes the function \((x, y) \rightarrow U(x, y, t)\).
If \( h \in L^\infty(\mathbb{R}^N \times (T_1, T_2)) \) and \( U \in L^2((T_1, T_2); W^{1,2}(\mathbb{B}_r^+, y^a dx dy)) \) for any \( r > 0 \) is a weak solution in \( \mathbb{R}_r^{N+1} \times (T_1, T_2) \) to (2.9), if the above integral relation is satisfied for any \( r > 0 \).

We are now in the position to recall some crucial regularity results proved in [5]. Their proofs are based on the De Giorgi-Nash-Moser approach. We stress that equations like (2.3) are included in a wider group of problems studied in the 80’s by Chiarenza and Serapioni [21] (see also [39, 42], and [30] for the elliptic setting), since the weight \( w(y) = y^a \) belongs to the \( A_2 \) Muckenhoupt class (cfr. for instance with [7, 50]).

**Theorem.** (Banerjee and Garofalo [5] [Corollary 4.6])
Fix \(-1 < a < 1 \) and \(-\infty \leq T_1 < T_2 \leq +\infty \). Let \( u \in \text{dom}(H^s) \) be a solution to (2.2) with potential \( h = h(x, t) \) satisfying (2.1) and let \( U = U(x, y, t) \) be the function defined in (2.4). Then \( U \) is a weak solution to the extended problem (2.7) in \( \mathbb{R}_r^{N+1} \times (T_1, T_2) \).

**Theorem.** (Banerjee and Garofalo [5] [Theorem 5.1, Lemma 5.6, Remark 5.7])
Fix \(-1 < a < 1 \), \( r > 0 \) and \(-\infty \leq T_1 < T_2 \leq +\infty \). Let \( U = U(x, y, t) \) be a weak solution to problem (2.9) with potential \( h = h(x, t) \) satisfying (2.1). Then the following statements hold:

(i) Hölder regularity: there exist \( \alpha \in (0, 1) \) depending only on \( a \) and \( N \), such that \( U \) is locally \( \alpha \)-Hölder continuous up to the boundary \( y = 0 \). Moreover, \( u \) is globally \( \alpha \)-Hölder continuous in \( \mathbb{R}_r^{N+1} \) (in particular it is bounded in \( \mathbb{R}_r^{N+1} \)).

(ii) Higher regularity: there exist \( \alpha' \in (0, 1) \) depending only on \( a \) and \( N \), such that \( \nabla_y U, \partial_y U, \) and \( y^a \partial_y U \) are locally \( \alpha' \)-Hölder continuous up to the boundary \( y = 0 \). Moreover, \( u \in C^1(\mathbb{R}_r^{N+1}) \).

The results shown above are the basis of [5] and the present work. We end this paragraph with a remark which introduces the concept of strong solutions, which will be important later. Let \( U = U(x, y, t) \) be a weak solution to problem (2.9) in \( \mathbb{R}_r^{N+1} \times (-T, 0) \), in the special case in which \( h \equiv 0 \) in \( \mathbb{R}_r^N \times (-T, 0) \). Its weak formulation thus reads as
\[
\int_{t_1}^{t_2} \int_{\mathbb{B}_r^+} (\nabla U \cdot \nabla \eta - U \partial_y \eta) y^a \, dX dt = \int_{B_r^+} [U(t_1)\eta(t_1) - U(t_2)\eta(t_2)] y^a \, dX dt,
\]
for any \( r > 0 \), every \( \eta \in W^{1,2}(\mathbb{B}_r^+ \times (-T, 0), y^a dx dy) \) with compact support in \((\mathbb{B}_r^+ \cup B_r) \times [-T, 0] \), and a.e. \(-T < t_1 < t_2 < 0 \). Now, thanks to the regularity results above, we can integrate by parts w.r.t. to time to obtain
\[
-\int_{t_1}^{t_2} \int_{\mathbb{R}_r^{N+1}} \nabla U \cdot \nabla y^a \, dX dt = \int_{t_1}^{t_2} \int_{\mathbb{R}_r^{N+1}} \partial_y U \eta \, y^a \, dX dt,
\]
for every every $\eta \in C_c^0(\mathbb{R}_+^{N+1} \times [-T, 0])$, i.e., the operator $\mathcal{L}_a U := y^{-a} \nabla \cdot (y^a \nabla U) \in L^\infty_{\text{loc}}(\mathbb{R}_+^{N+1} \times [-T, 0])$ and the equation in (2.9) is satisfied a.e. in $\mathbb{R}_+^{N+1} \times (-T, 0)$, i.e. $U = U(x, y, t)$ is a strong solution to (2.9), cfr. with Chapter 7 of [44]. Summing up, the regularity theory developed in [5] shows that weak solutions to (2.9) are indeed solutions in the strong sense.

**Problem (2.7): reduction to the case $h \equiv 0$.** Once introduced all the basic notions concerning equation (1.1) and problem (2.7), we consider the subclass of problems in which the potential is trivial, i.e. $h \equiv 0$. This reduction is a key point of the present paper. We will prevalently work in this easier framework and we will recover our statements for the case $h \neq 0$ by suitably combining our analysis with some techniques developed in [5] (cfr. with formula (3.16) and (3.17) below). This strategy has the advantage to work with independent and less technical methods (cfr. [5]) and, at the same time, to be strong enough to cover the more general case of non trivial potential (cfr. with the crucial comments at the end of the proof of Theorem 3.4 and Theorem 6.1, and the proof of Corollary 7.5).

To motivate this choice from the beginning, we need once more to recall some key results proved in [5]. So, let $u \in \text{dom}(H^s)$ be a solution to (2.2) and let $U = U(x, y, t)$ be defined as in (2.4) (as we have seen it is a weak solution to (2.7)). We consider the quantities (cfr. with formulas (6.3) and (6.4) of [5])

$$k(t, U) := \int_{\mathbb{R}_+^{N+1}} y^a U^2(x, y, t) G_{N+1}(x, y, |t|) \, dx \, dy$$

$$i_h(t, U) := -t \int_{\mathbb{R}_+^{N+1}} y^a |\nabla U|^2(x, y, t) G_{N+1}(x, y, |t|) \, dx \, dy + t \int_{\mathbb{R}_+^{N}} h(x, t) u^2(x, t) G_{N+1}(x, |t|) \, dx$$

$$:= i_0(t, U) + t \int_{\mathbb{R}_+^{N} \times \{0\}} h(x, t) u^2(x, t) G_{N+1}(x, |t|) \, dx,$$

for $t < 0$, where $G_{N+1}(x, y, |t|) = (4\pi |t|)^{-\frac{N+1}{2}} e^{-\frac{|x|^2 + |y|^2}{4|t|}}$ is the fundamental solution the Heat Equation posed in spacial dimension $N + 1$. Then, we consider their averaged versions (cfr. with formulas (6.11), (6.12) and (6.13) of [5]):

$$\overline{H}(\lambda, U) := \frac{1}{\lambda^2} \int_{-\lambda^2}^0 k(t, U) \, dt,$$

(2.10)

$$\overline{T}_h(\lambda, U) := \frac{1}{\lambda^2} \int_{-\lambda^2}^0 i_h(t, U) \, dt, \quad \overline{T}_0(\lambda, U) := \frac{1}{\lambda^2} \int_{-\lambda^2}^0 i_0(t, U) \, dt$$

and the Almgren-Poon quotients (or frequency) of $U$ as

(2.11)

$$\overline{N}_h(\lambda, U) = \frac{\overline{T}_h(\lambda, U)}{\overline{H}(\lambda, U)}, \quad \overline{N}_0(\lambda, U) = \frac{\overline{T}_0(\lambda, U)}{\overline{H}(\lambda, U)},$$

for any $\lambda > 0$ such that $\overline{H}(\lambda, U) \neq 0$. The following theorem is one of the main results proved in [5].

**Theorem 2.1.** (Banerjee and Garofalo [5/Corollary 1.3 and Corollary 6.12])

Fix $0 < s < 1$, $a = 1 - 2s$. Let $u \in \text{dom}(H^s)$ be a solution to (2.2) with potential $h = h(x, t)$ satisfying (2.1) and let $U = U(x, y, t)$ be the function defined in (2.4). Then there exist universal constants $C, t_0 > 0$ such that the function

$$\lambda \to \exp \left\{ C \int_0^\lambda t^{-a} \, dt \right\} \left( \overline{N}_h(\lambda, U) + C \int_0^\lambda t^{-a} \, dt \right)$$
is monotone nondecreasing in \((0, \sqrt{t_0})\). Furthermore, when the potential \(h \equiv 0\), then the constant \(C\) can be taken equal to zero and we have pure monotonicity of the function \(\lambda \to N_h(\lambda, U) = N_0(\lambda, U)\). In such case, \(N_0(\lambda, U) \equiv \kappa\) for \(0 < \lambda < \Lambda\) if and only if \(U\) is parabolically homogeneous of degree \(\kappa\) in \(\mathbb{R}^{N+1}_+ \times (0, \Lambda)\) (cfr. with formula (7.2) of [5] below for the definition). Finally,

\[
\lim_{\lambda \to 0^+} N_h(\lambda, U) = \lim_{\lambda \to 0^+} N_0(\lambda, U) = \kappa.
\]

The above theorem is crucial in the analysis of the asymptotic behaviour of the normalized blow-up family (cfr. with formula (7.2) of [5]):

\[
(2.12) \quad \overline{U}_\lambda(x, y, t) := \frac{U(\lambda x, \lambda y, \lambda^2 t)}{\sqrt{\lambda^{-a} H(\lambda, U)}}.
\]

The main result concerning the limit of (2.12) as \(\lambda \to 0^+\) is resumed in the following theorem.

**Theorem 2.2.** (Banerjee and Garofalo [5][Lemma 7.2, Lemma 7.4 and Proposition 7.5])

Fix \(0 < s < 1, \ a = 1 - 2s\). Let \(u \in \text{dom}(H^s)\) be a solution to (2.2) with potential \(h = h(x, t)\) satisfying (2.1), let \(U = U(x, y, t)\) be the function defined in (2.4) and \(\overline{U}_\lambda = \overline{U}_\lambda(x, y, t)\) be defined as in (2.12). Then there exist a subsequence \(\lambda_j \to 0^+\) as \(j \to +\infty\) and a weak solution \(U_0 = U_0(x, y, t)\) to

\[
(2.13) \quad \begin{cases}
\partial_t U - y^{-a} \nabla \cdot (y^a \nabla U) = 0 & \text{in } \mathbb{R}^{N+1}_+ \times (-1, 0), \\
-\partial_y^a U = 0, & \text{in } \mathbb{R}^N \times \{0\} \times (-1, 0),
\end{cases}
\]

such that \(\overline{U}_{\lambda_j} \to U_0\) uniformly and \(\nabla \overline{U}_{\lambda_j} \to \nabla U_0\) weakly in \(L^2(y^a dx dy dt)\) on compact sets of \(\mathbb{R}^{N+1}_+ \times (-1, 0)\), and

\[
\int_{-R^2}^0 \int_{\mathbb{R}^{N+1}_+} y^a \left( |\overline{U}_{\lambda_j} - U_0|^2 + |t||\nabla \overline{U}_{\lambda_j} - \nabla U_0|^2 \right) G_{N+1}(x, y, t) \, dx \, dy \, dt \to 0,
\]

as \(j \to +\infty\), for any fixed \(0 < R < 1\). Moreover, if we denote with

\[
\kappa := \lim_{\lambda \to 0^+} N_h(\lambda, U) = \lim_{\lambda \to 0^+} N_0(\lambda, U),
\]

then \(U_0 = U_0(x, y, t)\) is parabolically homogeneous of degree \(\kappa\) (cfr. with formula (7.2) below for the definition).

Let us briefly comment this last theorem. First, from the Gaussian type bounds proved in Lemma 8.1 of [5] (see also Chapter 5 of [24] and Section 5 of [6]), it follows that the blow-up limit \(U_0 = U_0(x, y, t)\) is a strong solution to (2.13) (cfr. with Definition 2.3 below). Moreover, we obtain some further and more significant information. Indeed, we obtain that the asymptotic limit of the blow-up sequence \(2.12\) is a function satisfying problem (2.13), i.e. (2.2) with trivial potential \(h \equiv 0\) and, furthermore, it is parabolically homogeneous of degree \(\kappa\), where \(\kappa\) is the limit as \(\lambda \to 0^+\) of the Almgren-Poon quotients introduced above. We will see that these last two properties are the keys that allows us to study the nodal properties of solutions to the nonlocal Heat Equation

\[
(2.14) \quad (\partial_t - \Delta)^s u = 0,
\]

and then to transfer that information to the solutions to the complete equation (1.1).

Keeping this in mind, we fix \(-1 < a < 1, \ T > 0\), and we introduce the Neumann type problem

\[
(2.15) \quad \begin{cases}
\partial_t U - y^{-a} \nabla \cdot (y^a \nabla U) = 0 & \text{in } \mathbb{R}^{N+1}_+ \times (0, T), \\
-\partial_y^a U = 0 & \text{in } \mathbb{R}^N \times \{0\} \times (0, T),
\end{cases}
\]
where we recall that \( \partial_{y}^{a}U := \lim_{y \to 0^{+}} y^{a} \partial_{y}U(x,y,t) \). Note that the above problem corresponds to (2.9) with the time variable inversion \( t \to -t \). This choice is purely formal, but allows us to strongly simplify the future notations. At the same time, we consider also the Dirichlet type version of (2.15):

\[
\begin{cases}
\partial_{t}U + y^{-a} \nabla \cdot (y^{a} \nabla U) = 0 & \text{in } \mathbb{R}^{N+1} \times (0,T) \\
U = 0 & \text{in } \mathbb{R}^{N} \times \{0\} \times (0,T),
\end{cases}
\]

and the one posed in the whole \( \mathbb{R}^{N+1} \):

\[
\partial_{t}U + |y|^{-a} \nabla \cdot (|y|^{a} \nabla U) = 0 \quad \text{in } \mathbb{R}^{N+1} \times (0,T).
\]

Note that solutions \( U = U(x,y,t) \) to (2.15) can be reflected in a even way to build solutions \( W(x,y,t) := U(x,|y|,t) \) to (2.17) (cfr. with Theorem 1 of [52] and Lemma 5.1 of [63]). Viceversa, given a solution \( W = W(x,y,t) \) to (2.17), we have that its even part and its odd part

\[
W_{e}(x,y,t) := \frac{W(x,y,t) + W(x,-y,t)}{2}, \quad W_{o}(x,y,t) := \frac{W(x,y,t) - W(x,-y,t)}{2}
\]

are solutions to (2.15) and (2.16), respectively. These straightforward observations motivate us to describe as precisely as possible the solutions to the more general problem (2.17) and then transfer that information on solutions to (2.15) and (2.16), respectively. This approach is motivated also by other two important reasons. The first one is related to the optimal Hölder regularity of solution to (2.17) that, as we have mentioned above, belongs to a more general class of weighted equations. Chiarenza and Serapioni [21] established a Harnack inequality for weak solutions, together with their Hölder regularity. However, as far as we known, the optimal Hölder exponent is not know even for that special weight \(|y|^{a}\). Combining our methods (cfr. with the proof of Theorem 7.1) with some known results about the elliptic framework (cfr. with [73]), we will give a positive answer to this issue. The second reason is related to some open problems in the field of reaction-diffusion systems with strong competition and nonlocal diffusion in the elliptic setting (cfr. with Terracini et al. [66, 67, 68], see also [72]). Even in this framework, the optimal regularity of solutions is one of the main issues and it is related to the phenomenon of self-segregation, appearing only in the nonlocal setting. Our idea to fully understand the properties of solutions to (2.17), which is fundamental in the blow-up analysis, in order to establish the role played by it, in the reaction-diffusion systems setting. For a wide part of this work we will thus focus on solutions to equation (2.17) and we will automatically obtain information on solutions to (2.15) and (2.16), too (cfr. in particular with Theorem 5.2, Theorem 6.1 and Theorem 7.1), whilst only in the end (cfr. with Section 8) we will come back to solutions to (2.15)-(1.1).

**Fundamental solution.** In the next paragraphs we present the definitions of strong solution to (2.15), (2.16) and (2.17), respectively. To do that, we need to introduce the fundamental solution to problem

\[
\begin{cases}
\partial_{t}U - \mathcal{L}_{a}U = 0 & \text{in } \mathbb{R}^{N+1} \times (0,\infty) \\
-\partial_{y}^{a}U = 0 & \text{in } \mathbb{R}^{N} \times \{0\} \times (0,\infty),
\end{cases}
\]

where, as before, \( \mathcal{L}_{a}U := y^{-a} \nabla \cdot (y^{a} \nabla U) \). As always, \( \nabla \cdot = \nabla_{x,y} \) is the spacial divergence, \( \nabla = \nabla_{x,y} \) is the spacial gradient. Setting

\[
G_{N}(x,t) = \frac{1}{(4\pi t)^{N/2}} e^{-\frac{|x|^{2}}{4t}}
\]
and
\[ G_{a+1}(y,t) = \frac{1}{2^a \Gamma(\frac{1+a}{2})^N} e^{-\frac{|x|^2}{4t}}. \]

we define
\[ G_a(x,y,t) = G_N(x,t)G_{a+1}(y,t) = C_{N,a} \frac{1}{2^a \Gamma(\frac{1+a}{2})} e^{-\frac{|x|^2+y^2}{4t}}, \]

where
\[ C_{N,a} := \frac{1}{2^a \Gamma(\frac{1+a}{2})(4\pi)^{N/2}}. \]

It is straightforward to verify that \( G_a = G_a(x,y,t) \) is a smooth solution to \( (2.18) \), with the following key scaling property
\[ G_a(x,y,t) = t^{-\frac{N+a+1}{2}} G_a\left(t^{-1/2}x, t^{-1/2}y, 1\right). \]

Note that, following [35], we could have proceeded by looking for solutions to \( (2.18) \) with the separate variable form \( (2.20) \). This procedure easily leads to the expressions for \( G_N \) and \( G_{a+1} \), and it is based on the decomposition of the operator \( L_a = \Delta_x + \partial_{yy} + \frac{a}{y} \partial_y \), as the sum of the generator of the Heat and the Bessel semigroup, respectively. We stress that the expression of \( G_a \) was already worked out in Theorem 1.8 and Remark 1.9 of [63], as the function realizing the following identity
\[ -y^{-a} \partial_y G_{-a}(x,y,t) = P^a_y(x,t) \text{ in } \mathbb{R}_+^{N+1} \times (0, \infty), \]

where \( P^a_y \) is the Poisson kernel defined in \( (2.5) \) (cfr. with formula (2.3) of [19] for the elliptic case). Our choice of the normalization constant \( C_{N,a} > 0 \) differs from the one in [63] and makes the family of functions
\[ (x,y) \rightarrow y^a G_a(x,y,t), \]

a family of probability densities for any \( t > 0 \). We thus define the family of probability measures on \( \mathbb{R}_+^{N+1} \)
\[ (2.21) \quad d\mu_t = d\mu_t(x,y) := y^a G_a(x,y,t) \, dx \, dy, \]

shortened, for \( t = 1 \), to \( d\mu := d\mu_1 \). In some cases (cfr. with Section 5), we will use the notations
\[ d\mu_x := G_N(x,1) \, dx = \frac{1}{(4\pi)^{N/2}} e^{-\frac{|x|^2}{4}} \, dx, \quad d\mu_y := \frac{1}{2^a \Gamma(\frac{1+a}{2})} y^a e^{-\frac{y^2}{4}} \, dy, \]

to denote the marginals of the measure \( d\mu = d\mu(x,y) \) w.r.t. to \( x \in \mathbb{R}^N \) and \( y > 0 \), respectively.

We conclude the presentation of the fundamental solution by stressing that, since \( \partial_y^a G_a = 0 \) in \( \mathbb{R}^N \times \{0\} \times (0, \infty) \), it follows that the function
\[ \tilde{G}_a(x,y,t) := \frac{C_{N,a}}{2} t^{-\frac{N+a+1}{2}} e^{-\frac{|x|^2+y^2}{4t}}, \]

is a smooth solution to equation
\[ (2.22) \quad \partial_t U - L_a U = 0 \text{ in } \mathbb{R}_+^{N+1} \times (0, \infty), \]

where now, with some abuse of notation, we set \( L_a U := |y|^{-a} \nabla \cdot (|y|^a \nabla U) \) (cfr. with Lemma 5.1 of [63] or check it directly by repeating the above procedure for \( y < 0 \)). We will call it fundamental
solution to equation (2.23) and, with more abuse of notation, we will denote it with $\mathcal{G}_a = \mathcal{G}_a(x, y, t)$. Of course, it satisfies the same properties of the fundamental solution in the half-space $\mathbb{R}^{N+1}_+$. We will set again

\begin{equation}
(2.24) \quad d\mu_t = d\mu_t(x, y) := |y|^\alpha \mathcal{G}_a(x, y, t) \, dx \, dy,
\end{equation}

which is now a probability measure on $\mathbb{R}^{N+1}$, for all $t > 0$. Again we will shorten with $d\mu$ instead of $d\mu_1$. Also in this case we will indicate with

\begin{equation*}
    d\mu_y := \frac{1}{\Gamma(\frac{1}{2} + a)} |y|^\alpha e^{-\frac{y^2}{2}} \, dy,
\end{equation*}

the marginal of the measure $d\mu = d\mu(x, y)$ w.r.t. to $y > 0$. We have decided not to distinguish between the to kinds of fundamental solutions and related probability measures not to exceed in notations. It will be always clear from the context in which framework we will work.

**Functional setting and strong solutions.** We have seen that the fundamental solution $\mathcal{G}_a = \mathcal{G}_a(x, y, t)$ naturally defines a family of probability measures on $\mathbb{R}^{N+1}_+$. We thus define the family of Hilbert spaces

\begin{equation*}
    L^2(\mathbb{R}^{N+1}_+, d\mu_t) := \left\{ V = V(x, y) \text{ measurable: } \int_{\mathbb{R}^{N+1}_+} V^2(x, y) \, d\mu_t(x, y) < +\infty \right\}, \quad t > 0,
\end{equation*}

where $d\mu_t = d\mu_t(x, y)$ is defined in (2.21), endowed with the natural $L^2$ type norm. We anticipate that, we will often simplify the notation to

\begin{equation*}
    L^2_{\mu_t} := L^2(\mathbb{R}^{N+1}_+, d\mu_t) \quad \text{and} \quad L^2_\mu := L^2(\mathbb{R}^{N+1}_+, d\mu).
\end{equation*}

Then, we introduce the family of weighted Sobolev norms

\begin{equation*}
    \|V\|_{H^1(\mathbb{R}^{N+1}_+, d\mu_t)}^2 := \int_{\mathbb{R}^{N+1}_+} V^2(x, y) \, d\mu_t(x, y) + t \int_{\mathbb{R}^{N+1}_+} |\nabla V|^2(x, y) \, d\mu_t(x, y),
\end{equation*}

and the Hilbert spaces

\begin{equation*}
    H^1(\mathbb{R}^{N+1}_+, d\mu_t) \quad \text{and} \quad H^1_0(\mathbb{R}^{N+1}_+, d\mu_t),
\end{equation*}

obtained as the closure of the spaces $C^\infty_c(\mathbb{R}^{N+1}_+)$ and $C^\infty(\mathbb{R}^{N+1}_+)$ w.r.t. the norm $\|\cdot\|_{H^1(\mathbb{R}^{N+1}_+, d\mu_t)}$ defined above, respectively. Again, we will shorten

\begin{equation*}
    H^1_{\mu_t} := H^1(\mathbb{R}^{N+1}_+, d\mu_t), \quad H^1_{0,\mu_t} := H^1_0(\mathbb{R}^{N+1}_+, d\mu_t), \quad H^1_\mu := H^1(\mathbb{R}^{N+1}_+, d\mu), \quad H^1_{0,\mu} := H^1_0(\mathbb{R}^{N+1}_+, d\mu).
\end{equation*}

Finally, we will need some space-time $L^2$-Sobolev type spaces:

\begin{align*}
    & L^2(0, T; L^2_{\mu_t}) := \left\{ V = V(x, y, t) \text{ measurable: } \int_0^T \|V(t)\|_{L^2_{\mu_t}}^2 \, dt < +\infty \right\}, \\
    & L^2(0, T; H^1_{\mu_t}) := \left\{ V = V(x, y, t) \text{ measurable: } \int_0^T \|V(t)\|_{H^1_{\mu_t}}^2 \, dt < +\infty \right\}, \\
    & L^2(0, T; H^1_{0,\mu_t}) := \left\{ V = V(x, y, t) \text{ measurable: } \int_0^T \|V(t)\|_{H^1_{0,\mu_t}}^2 \, dt < +\infty \right\},
\end{align*}

which are again Hilbert spaces with the natural scalar product and associated norm. In the same way, we consider the family of spaces

\begin{equation*}
    L^2(\mathbb{R}^{N+1}_+, d\mu_t) := \left\{ V = V(x, y) \text{ measurable: } \int_{\mathbb{R}^{N+1}_+} V^2(x, y) \, d\mu_t(x, y) < +\infty \right\}, \quad t > 0,
\end{equation*}
where \( d\mu_t = d\mu_t(x,y) \) is defined in (2.24), for all \( t > 0 \). Again we will use the simplified notations
\[
L^2_{\mu_t} := L^2(\mathbb{R}^{N+1}, d\mu_t) \quad \text{and} \quad L^2_{\mu} := L^2(\mathbb{R}^{N+1}, d\mu).
\]
As before, considering the family of weighted Sobolev norms
\[
\|V\|^2_{H^1(\mathbb{R}^{N+1}, d\mu_t)} := \int_{\mathbb{R}^{N+1}} V^2(x,y) d\mu_t(x,y) + t \int_{\mathbb{R}^{N+1}} |\nabla V|^2(x,y) d\mu_t(x,y),
\]
we can define the family of spaces \( H^1(\mathbb{R}^{N+1}, d\mu_t) \) obtained as the closure of the space \( C_c^\infty(\mathbb{R}^{N+1}) \) w.r.t. the above norm. Also in this case we will shorten \( H^1_{\mu_t} := H^1(\mathbb{R}^{N+1}, d\mu_t) \) and \( H^1_{\mu} := H^1(\mathbb{R}^{N+1}, d\mu) \).

Finally, the Hilbert spaces \( L^2(0,T; L^2_{\mu_t}) \) and \( L^2(0,T; H^1_{\mu_t}) \) are defined as above substituting \( \mathbb{R}^{N+1} \) with \( \mathbb{R}^{N+1} \). We are now ready to introduce the definition of strong solution to (2.15), (2.16) and (2.17).

**Definition 2.3.** A function \( U = U(x,y,t) \) is said to be a strong solution to problem (2.15) if the following properties hold true:

- \( U \in L^2(0,T; H^1_{\mu_t}) \), with \( t\partial_t U + \frac{(x,y)}{2} \cdot \nabla U, \mathcal{L}_a U \in L^2_{\text{loc}}(0,T; L^2_{\mu_t}) \).
- The identity \( \partial_t U + \mathcal{L}_a U = 0 \) is satisfied a.e. in \( \mathbb{R}^{N+1}_+ \times (0,T) \).
- \( -\partial^y_y U(x,y,t) := -\lim_{y \to y_0^+} y^a \partial_a U(x,y,t) = 0 \) in \( L^2(\mathbb{R}^N \times (0,T)) \).

A function \( U = U(x,y,t) \) is said to be a strong solution to problem (2.16) if \( U \in L^2(0,T; H^1_{0,\mu_t}) \), the first two properties above hold true, and the third one is replaced with \( U = 0 \) in \( \mathbb{R}^N \times \{0\} \times (0,T) \).

**Definition 2.4.** A function \( U = U(x,y,t) \) is said to be a strong solution to equation (2.17) if the following properties hold true:

- \( U \in L^2(0,T; H^1_{\mu_t}) \), with \( t\partial_t U + \frac{(x,y)}{2} \cdot \nabla U, \mathcal{L}_a U \in L^2_{\text{loc}}(0,T; L^2_{\mu_t}) \).
- The identity \( \partial_t U + \mathcal{L}_a U = 0 \) is satisfied a.e. in \( \mathbb{R}^{N+1} \times (0,T) \).

The concept of strong solution is well-known in parabolic equations (cfr. for instance with Chapter 7 of [14]). However, before moving forward, we must clarify some aspects of the above definitions. We mainly focus on strong solutions to equation (2.17), specifying which are the main differences with respect to the other two cases.

First of all, we point out that classical solutions (satisfying the first requirements in Definition 2.4) are strong solutions, while smooth strong solutions are in fact classical solutions. This easily follows from the definition. On the other hand, strong solutions are weak solutions in the sense of Definition 2.1 of [21] (or Definitions 4.1 and 4.3 of [3] for the Neumann setting). As we have anticipated before, the substantial difference between weak and strong solutions is that in the second case the time derivative and the diffusion operator are required to belong to the space \( L^2_{\text{loc}}(0,T; L^2_{\mu_t}) \). This is not the case in the weak solutions framework, where these derivatives are allowed to be distributions.

However, the regularity results recalled at the beginning of this introduction show that weak solutions are indeed more regular, justifying our definition of strong solution. Actually, strong solutions satisfies also all the regularity properties recalled above (cfr. with [5]) like Hölder continuity. Note that the requirements like \( U \in L^2(0,T; H^1_{\mu_t}) \) are completely justified by the Gaussian type estimates proved in Lemma 8.1 of [5] for weak solutions to (2.15), which hold also for weak solutions to (2.16) and (2.17) with minor changes (see also Chapter 5 of [24] and Section 5 of [6]).

To end the discussion about strong solutions, we point out that we can replace the second requirement in Definition 2.4 (resp. Definition 2.3) with two equivalent integral formulations. Indeed, multiplying the relation \( \partial_t U + \mathcal{L}_a U = 0 \) by a test function with the form

\[ t|y|^a \mathcal{G}_a(x,y,t) \eta(x,y,t), \]
where $\eta$ belongs to $L^2(0, T; H^1_{\mu})$, and integrating over $\mathbb{R}^{N+1} \times (t_1, t_2)$ (for any choice $0 < t_1 < t_2 < T$), we obtain the identity
\begin{equation}
\int_{t_1}^{t_2} \int_{\mathbb{R}^{N+1}} \left[ t \partial_t U + \frac{(x, y)}{2} \cdot \nabla U \right] \eta \, d\mu(x, y) \, dt = \int_{t_1}^{t_2} \int_{\mathbb{R}^{N+1}} \nabla U \cdot \nabla \eta \, d\mu(x, y) \, dt
\end{equation}
holding for all $\eta \in L^2(0, T; H^1_{\mu})$ (test firstly with $\eta \in C_0^\infty(\mathbb{R}^{N+1} \times (0, T))$ and then use density). Note that, even though it suffices to take $\eta \in L^2_{\text{loc}}(0, T; H^1_{\mu})$ (which is important to widen the set of test functions) we limit ourselves the choice $\eta \in L^2(0, T; H^1_{\mu})$ not to weight down the presentation. Identity (2.25) have the advantage to be easily compared with the definition of weak solutions.

In performing the above integration by parts, we have crucially used the remarkable property of the fundamental solution
\begin{equation}
\nabla_{x,y} G_a(x, y, t) = -\frac{(x, y)}{2t} G_a(x, y, t).
\end{equation}

From the above integral formulation it is thus clear the reason for the requirement $t \partial_t U + \frac{(x, y)}{2} \cdot \nabla U \in L^2_{\text{loc}}(0, T; L^2_{\mu})$. Conversely, having $\mathcal{L}_a U \in L^2_{\text{loc}}(0, T; L^2_{\mu})$ too, and integrating back in (2.25), we easily obtain $\partial_t U + \mathcal{L}_a U = 0$ a.e. in $\mathbb{R}^{N+1} \times (0, T)$ by the Test Lemma (note that we have strongly used the fact that $0 < t_1 < t_2 < T$ are arbitrarily fixed). In the same way, we could have asked that the identity
\begin{equation}
\int_{\mathbb{R}^{N+1}} \left[ \partial_t U + \frac{(x, y)}{2t} \cdot \nabla U \right] \eta \, d\mu(x, y) = \int_{\mathbb{R}^{N+1}} \nabla U \cdot \nabla \eta \, d\mu(x, y),
\end{equation}
holds for a.e. $0 < t < T$ and all $\eta \in L^2(0, T; H^1_{\mu})$ (also in this case the choice $\eta \in L^2_{\text{loc}}(0, T; H^1_{\mu})$ would be enough). This last identity will be very important in the proof of the monotonicity formulas (cfr. with Lemma 3.1 and 4.1). Of course, there are versions of (2.25) and (2.26) for solutions to problems (2.17) and (2.16), which are obtained in the same way, but by integrating on $\mathbb{R}^{N+1}$ instead of $\mathbb{R}^{N+1}$.

We conclude this introduction with some remarks on re-scaled solutions. So, let $U = U(x, y, t)$ be a strong solution to equation (2.17). In the proof of the monotonicity formulas and the blow-up procedure, it will be useful to consider the rescaled version of $U = U(x, y, t)$, defined by
\begin{equation}
\tilde{U}(x, y, t) := U(\sqrt{t}x, \sqrt{t}y, t).
\end{equation}

It is straightforward to see that if we define the Ornstein-Uhlenbeck type operator as
\begin{equation}
-\mathcal{O}_a \tilde{U} := -\frac{1}{|y|^a} \nabla \cdot (|y|^a \nabla \tilde{U}) = -|y|^{-a} \nabla \cdot (|y|^a \nabla \tilde{U}) + \frac{(x, y)}{2} \cdot \nabla \tilde{U},
\end{equation}
then $\tilde{U} = \tilde{U}(x, y, t)$ is a strong solution to
\begin{equation}
t \partial_t \tilde{U} + \mathcal{O}_a \tilde{U} = 0 \quad \text{in } \mathbb{R}^{N+1} \times (0, T),
\end{equation}
in the sense that $\tilde{U} \in L^2(0, T; H^1_{\mu})$ with $t \partial_t \tilde{U}, \mathcal{O}_a \tilde{U} \in L^2_{\text{loc}}(0, T; L^2_{\mu})$ and equation (2.29) is satisfied a.e. $\mathbb{R}^{N+1} \times (0, T)$. Note that, proceeding as before, we obtain the equivalent integral formulations for (2.29). In the first one, we integrate both in space and time, to deduce that for each choice of of times $0 < t_1 < t_2 < T$, the identity
\begin{equation}
\int_{t_1}^{t_2} \int_{\mathbb{R}^{N+1}} \partial_t \tilde{U} \eta \, d\mu(x, y) \, dt = \int_{t_1}^{t_2} \int_{\mathbb{R}^{N+1}} \nabla \tilde{U} \cdot \nabla \eta \, d\mu(x, y) \, dt
\end{equation}
holds for all \( \eta \in L^2(0,T;H^1_\mu) \) (or \( \eta \in L^2_{\text{loc}}(0,T;H^1_\mu) \)). In the second one, we integrate in space to obtain that \( \widetilde{U} = \widetilde{U}(x,y,t) \) satisfies

\[
(2.31) \quad t \int_{\mathbb{R}^{N+1}} \partial_t \tilde{U} \eta \, d\mu(x,y) = \int_{\mathbb{R}^{N+1}} \nabla \tilde{U} \cdot \nabla \eta \, d\mu(x,y),
\]

for a.e. \( 0 < t < T \) and all \( \eta \in L^2(0,T;H^1_\mu) \) (or as always \( \eta \in L^2_{\text{loc}}(0,T;H^1_\mu) \)). It is much important to observe that testing with \( \eta \equiv 1 \), we obtain \( \int_{\mathbb{R}^{N+1}} \partial_t \tilde{U} \, d\mu(x,y) = 0 \) for all \( 0 < t < T \), i.e., the weighted mean of \( \tilde{U} = \tilde{U}(x,y,t) \) is constant in time

\[
(2.32) \quad t \to \int_{\mathbb{R}^{N+1}} \tilde{U}(x,y,t) \, d\mu(x,y) \equiv C,
\]

for some suitable constant \( C \in \mathbb{R} \). On the other hand, if \( U = U(x,y,t) \) is a strong solution to problem \( (2.15) \) (resp. \( (2.16) \)), it follows that its re-scaling \( \tilde{U} = \tilde{U}(x,y,t) \) satisfies \( \tilde{U} \in L^2(0,T;H^1_\mu) \) (resp. \( \tilde{U} \in L^2(0,T;H^1_{0,\mu}) \)), with \( t \partial_t \tilde{U}, \mathcal{O}_a \tilde{U} \in L^2_{\text{loc}}(0,T;L^2_\mu) \), and it satisfies the problem

\[
(2.33) \quad \begin{cases}
  t \partial_t \tilde{U} + \mathcal{O}_a \tilde{U} = 0 & \text{in } \mathbb{R}^{N+1} \times (0,T) \\
  -\partial_y^a \tilde{U} = 0 \ (\text{resp. } \tilde{U} = 0) & \text{in } \mathbb{R}^N \times \{0\} \times (0,T),
\end{cases}
\]

in the sense that the equation is satisfied a.e. in \( \mathbb{R}^{N+1} \times (0,T) \), while the boundary conditions in the sense of Definition \( 2.3 \). Note that in this case, the Ornstein-Uhlenbeck type operator is

\[
-\mathcal{O}_a \tilde{U} := -\frac{1}{y^a \mathcal{G}_a} \nabla \cdot (y^a \mathcal{G}_a \nabla \tilde{U}) = -y^{-a} \nabla \cdot (y^a \nabla \tilde{U}) + \frac{(x,y)}{2} \cdot \nabla \tilde{U}.
\]

Again, we have that for each choice of of times \( 0 < t_1 < t_2 < T \), the identity

\[
(2.34) \quad \int_{t_1}^{t_2} t \int_{\mathbb{R}^{N+1}} \partial_t \tilde{U} \eta \, d\mu(x,y) dt = \int_{t_1}^{t_2} \int_{\mathbb{R}^{N+1}} \nabla \tilde{U} \cdot \nabla \eta \, d\mu(x,y) dt
\]

holds for all \( \eta \in L^2(0,T;H^1_\mu) \) and, similarly,

\[
(2.35) \quad t \int_{\mathbb{R}^{N+1}} \partial_t \tilde{U} \eta \, d\mu(x,y) = \int_{\mathbb{R}^{N+1}} \nabla \tilde{U} \cdot \nabla \eta \, d\mu(x,y),
\]

for a.e. \( 0 < t < T \) and all \( \eta \in L^2(0,T;H^1_\mu) \). For what concerns the time conservation of the weighted mean, note that the function (cfr. with \( 2.32 \))

\[
(2.36) \quad t \to \int_{\mathbb{R}^{N+1}} \tilde{U}(x,y,t) \, d\mu(x,y),
\]

is constant only for solutions to \( (2.15) \) (testing with constant is not allowed in the definition of strong solutions to \( (2.16) \)). This ends the introduction of the main definitions. In the next section we give an extensive presentation of our main results together with the idea of the path we have followed to prove them.
3. Detail of our main results

As mentioned above, we devote the next paragraphs to a complete description of the most significant results of the present work and the main ideas behind them. The first main tool we are going to introduce is an Almgren-Poon type monotonicity formula (cfr. with the classical paper of Poon [53]). As recalled in the first lines of the introduction, this formula has been already proved in Theorem 8.3 of [5] and Theorem 1.15 of [63] (actually, in Theorem 1.3 of [5] the authors proved a stronger monotonicity formula for a more general class of equations). For the sake of completeness we show below the proof, because the technique slightly differs from the previous ones, as is based on the analysis of the rescaled version of $\tilde{U}$ of $U$ (cfr. with (2.27)). The idea to use the rescaled variable $\tilde{U}$ is crucial in the rest part of the work, too.

So, let us fix $-1 < a < 1$, $T > 0$, and let $U = U(x, y, t)$ be a strong solution to problem (2.15). Introducing the set

$$\Sigma := \{(x, y, t) \in \mathbb{R}_+^{N+1} \times (0, T) : y = 0\} = \mathbb{R}^N \times \{0\} \times (0, T),$$

we consider the transformation

$$U_{p_0}(x, y, t) := U(x + x_0, y, t + t_0),$$

where $p_0 = (x_0, 0, t_0) \in \Sigma$. Following [53], we consider the quantities

$$H(p_0, t, U) := \int_{\mathbb{R}_+^N} y^a U^2(x, y, t) G_a^{p_0}(x, y, t) \, dx \, dy,$$

$$I(p_0, t, U) := \int_{\mathbb{R}_+^N} y^a |\nabla U|^2(x, y, t) G_a^{p_0}(x, y, t) \, dx \, dy,$$

where $G_a^{p_0} = G_a(x - x_0, y, t - t_0)$ is the fundamental solution defined in (2.20) centered at $p_0$, and the Almgren-Poon type quotient

$$N(p_0, t, U) := \frac{(t - t_0) I(p_0, t, U)}{H(p_0, t, U)} = \frac{(t - t_0) \int_{\mathbb{R}_+^N} y^a |\nabla U|^2(x, y, t) G_a^{p_0}(x, y, t) \, dx \, dy}{\int_{\mathbb{R}_+^N} y^a U^2(x, y, t) G_a^{p_0}(x, y, t) \, dx \, dy},$$

for all $t > t_0$ such that $H(p_0, t, U) \neq 0$ (cfr. with Corollary 4.4). Note that all the integrals are well defined thanks to our integrability assumptions on $U = U(x, y, t)$ (cfr. with Definition 2.3) and, if $0 = (0, 0, 0)$, setting $H(0, t, U) := H(t, U)$, $I(0, t, U) := I(t, U)$ (and consequently $N(0, t, U) := N(t, U)$), it is immediately seen that

$$H(p_0, t, U) = H(t - t_0, U_{p_0}),$$

$$I(p_0, t, U) = I(t - t_0, U_{p_0}),$$

$$N(p_0, t, U) = N(t - t_0, U_{p_0}), \quad t > t_0.$$

These last relations in particular imply that it suffices to study the case $p_0 = 0$ and then recover the general case by translation. Consequently, we consider the quotient

$$N(t, U) := \frac{t I(t, U)}{H(t, U)} = \frac{t \int_{\mathbb{R}_+^N} |\nabla U|^2(x, y, t) \, d\mu_t(x, y)}{\int_{\mathbb{R}_+^N} U^2(x, y, t) \, d\mu_t(x, y)},$$

for all $t > 0$ such that $H(t, U) \neq 0$, where we recall that $d\mu_t(x, y) := y^a G_a(x, y, t) \, dx \, dy$. Before stating the first fundamental result, we point out that, passing to the rescaled version $\tilde{U} = \tilde{U}(x, y, t)$ defined...
in (2.27) and using the intrinsic scaling of the fundamental solution, it is easy to see that
\[ H(t, U) = \int_{\mathbb{R}^N} y^a \tilde{U}^2(x, y, t) G_a(x, y, 1) \, dx \, dy = \int_{\mathbb{R}^N} \tilde{U}^2(x, y, t) \, d\mu(x, y) := H(1, \tilde{U}), \]
\[ I(t, U) = \frac{1}{t} \int_{\mathbb{R}^N} y^a |\nabla \tilde{U}|^2(x, y, t) G_a(x, y, 1) \, dx \, dy = \frac{1}{t} \int_{\mathbb{R}^N} |\nabla \tilde{U}|^2(x, y, t) \, d\mu(x, y) := \frac{1}{t} I(1, \tilde{U}), \]
and so the quotient has a scaling too:
\[ N(t, U) = \frac{tI(t, U)}{H(t, U)} = \frac{I(1, \tilde{U})}{H(1, \tilde{U})} := N(1, \tilde{U}). \]
These scaling properties are the keys of the majority of our results.

**Lemma 3.1.** (Banerjee and Garofalo [5] [Theorem 8.3], Stinga and Torrea [63] [Theorem 1.15])

Let \( U = U(x, y, t) \) be a function satisfying
- \( U \in L^2(0, T; H^1_{\mu t}) \), with \( t\partial_t U + \frac{(x, y)}{2} \cdot \nabla U \in L^2_{loc}(0, T; L^2_{\mu t}). \)
- The identity
\[
\int_{\mathbb{R}^N} \left[ \partial_t U + \frac{(x, y)}{2} \cdot \nabla U \right] \eta \, d\mu_t(x, y) = \int_{\mathbb{R}^N} \nabla U \cdot \nabla \eta \, d\mu_t(x, y),
\]
holds for a.e. \( 0 < t < T \) and all \( \eta \in L^2(0, T; H^1_{\mu t}) \), and let \( N(t, U) \) be defined as in (3.4). Then the function
\[ t \to N(t, U) \]
is non-decreasing for a.e. \( 0 < t < T \). Moreover, the quotient \( t \to N(t, U) \) is constant if and only if \( U = U(x, y, t) \) is parabolically homogeneous of degree \( \kappa \), for some \( \kappa \geq 0 \).

Some remarks are now in order. First of all, we point out that the same statement holds for functions \( U = U(x, y, t) \) satisfying
- \( U \in L^2(0, T; H^1_{0, \mu t}) \), with \( t\partial_t U + \frac{(x, y)}{2} \cdot \nabla U \in L^2_{loc}(0, T; L^2_{\mu t}). \)
- Identity (3.5) holds for a.e. \( 0 < t < T \) and all \( \eta \in L^2(0, T; H^1_{0, \mu t}) \), i.e. for strong solutions to (2.16) (cfr. in particular with Theorem 1.15 of [63]). Moreover, a very similar result remains valid for strong solutions to (2.17) with a notion of Almgren-Poon quotient adapted to this different kind of problem (cfr. with Lemma 4.1).

The second main fact is that the limit
\[ \lim_{t \to 0^+} N(t, U) = \kappa \geq 0 \]
exists and is finite (if \( \kappa = +\infty \) then \( N(t, U) = +\infty \) for any \( t \in (0, T) \), which is in contradiction with the fact that \( I(t, U) < +\infty \) and \( U \neq 0 \)). This implies that the function
\[ p_0 \to N(p_0, t_0^+, U) := \lim_{t \to t_0^+} N(p_0, t, U), \]
is upper semi-continuous on \( \Sigma \). This easily follows from the fact that \( N(\cdot, t_0^+, U) \) is defined as an infimum of a family of continuous functions \( t \to N(p_0, t, U) \).

Finally, we have to clarify the notion of parabolically homogeneity of degree \( \kappa \). A function \( U = U(x, y, t) \) is said to be parabolically homogeneous of degree \( \kappa \in \mathbb{R} \) if
\[
U(\delta x, \delta y, \delta^2 t) = \delta^{2\kappa} U(x, y, t), \quad \text{for any } \delta > 0.
\]
Under suitable regularity assumptions, the above relation is equivalent to say that $U$ satisfies the following equation

$$t\partial_t U + \frac{(x,y)}{2} \cdot \nabla U = \kappa U \quad \text{in } \mathbb{R}_+^{N+1} \times (0,T),$$

Passing to the rescaled variable $\tilde{U}(x,y,t) := U(\sqrt{t}x,\sqrt{t}y,t)$, we easily see that equation (3.7) is transformed into

$$-\mathcal{O}_a \tilde{U} = \kappa \tilde{U} \quad \text{in } \mathbb{R}_+^{N+1} \times (0,T),$$

where the Ornstein-Uhlenbeck operator in the l.h.s. of the above equation is defined in (2.28). This fact has a crucial consequence. Indeed, from the last part of Lemma 3.1, we deduce that the class of solutions to (2.15), which make the Almgren-Poon quotient (3.4) constant in time, is composed uniquely by parabolically homogeneous solutions of some degree $\kappa \in \mathbb{R}$, i.e., solutions with rescaled $\tilde{U}(x,y,t)$ being the eigenfunctions to the Ornstein-Uhlenbeck eigenvalue problem type (3.8) coupled with Neumann boundary conditions $-\partial_y \tilde{U} = 0$ in $\mathbb{R}^N \times \{0\} \times (0,T)$. We are thus naturally led to the spectral analysis of the following eigenvalue problem

$$\begin{cases} -\mathcal{O}_a V = \kappa V \quad \text{in } \mathbb{R}_+^{N+1} \\ -\partial_y V = 0 \quad \text{in } \mathbb{R}^N \times \{0\}. \end{cases}$$

The complete description of the spectral properties of problem (3.9) is stated in the following proposition.

**Proposition 3.2.** Fix $-1 < a < 1$. Then the set of eigenvalues of the homogeneous Neumann problem (3.9) is

$$\{\tilde{\kappa}_{n,m}\}_{n,m \in \mathbb{N}}, \quad \text{where } \tilde{\kappa}_{n,m} := \frac{n}{2} + m, \quad n,m \in \mathbb{N},$$

with finite geometric multiplicity. For any $n_0,m_0 \in \mathbb{N}$, the eigenspaces are given by

$$V_{n_0,m_0} = \text{span}\left\{ V_{\alpha,m}(x,y) = H_\alpha(x)L_{\frac{a-1}{2},m}(y^2/4) : (\alpha,m) \in \tilde{J}_0 \right\},$$

where

$$\tilde{J}_0 := \left\{ (\alpha,m) \in \mathbb{Z}_0^N \times \mathbb{N} : |\alpha| = n \in \mathbb{N} \text{ and } \tilde{\kappa}_{n,m} = \tilde{\kappa}_{n_0,m_0} \right\},$$

while $H_\alpha(\cdot)$ is a $N$-dimensional Hermite polynomial of order $|\alpha|$, and $L_{\frac{a-1}{2},m}(\cdot)$ is the $m$th Laguerre polynomial of order $(a-1)/2$. Furthermore, the set of eigenfunctions $\{V_{\alpha,m}\}_{\alpha,m}$ is an orthogonal basis of $L^2(\mathbb{R}_+^{N+1},d\mu)$.

The above proposition is decisive since it not only gives the precise values of the discrete spectrum to (3.9), but also the expressions of the eigenfunctions in terms of Hermite and Laguerre polynomials (cfr. with (2.28)). These facts have important consequences in the blow-up analysis and in the description of the nodal set of solutions to equation (1.1). We anticipate that Proposition 3.2 will be obtain as a byproduct of a more general theorem (cfr. with Theorem 5.2), in which we analyse also parabolically homogeneous solutions to (2.16) and (2.17).

Once Proposition 3.2 is established, we turn to the blow-up analysis. So, given a strong solution $U = U(x,y,t)$ to problem (2.15), we denote with

$$\Gamma(U) := \{(x,y,t) \in \mathbb{R}_+^{N+1} \times (0,T) : U(x,y,t) = 0\} = U^{-1}(\{0\}),$$
its nodal set. Now, if \( p_0 = (x_0, 0, t_0) \in \Gamma(U) \cap \Sigma \), we consider the normalized blow-up family

\[
U_{p_0, \lambda}(x, y, t) := \frac{U_{p_0}(\lambda x, \lambda y, \lambda^2 t)}{\sqrt{H(\lambda^2, U_{p_0})}},
\]

and we study its asymptotic behaviour as \( \lambda \to 0^+ \). Indeed, the basic idea of the blow-up technique is to zoom the solution near its nodal points, properly normalizing it in order to avoid the collapse of blow-up sequence. Its limit (the fact that it exists is highly nontrivial) must contain some information about the nodal properties of \( U \). The first main result in that direction is the following theorem.

**Theorem 3.3.** Fix \(-1 < a < 1\), \( p_0 = (x_0, 0, t_0) \in \Gamma(U) \cap \Sigma \), and let \( U = U(x, y, t) \) be a strong solution to problem (2.15). Then there exist \( n_0, m_0 \in \mathbb{N} \) such that the following assertions hold:

(i) The Almgren-Poon quotient \( t \to N(t, U_{p_0}) \) (cfr. with the formula in (3.2)) satisfies

\[
\lim_{t \to 0^+} N(t, U_{p_0}) = \tilde{\kappa}_{n_0, m_0},
\]

where the admissible values for \( \tilde{\kappa}_{n, m} = n/2 + m \) are the eigenvalues to problem (3.9).

(ii) There exists a constant \( L_0 > 0 \) (depending on \( p_0 \) and \( U \)), such that

\[
\lim_{t \to 0^+} t^{-2\tilde{\kappa}_{n_0, m_0}} H(t, U_{p_0}) = L_0,
\]

where the function \( t \to H(t, U_{p_0}) \) is the denominator of the Almgren-Poon quotient.

(iii) For all \( T_\ast > 0 \), the following convergence holds true

\[
U_{p_0, \lambda} \to \Theta_{p_0} \quad \text{in } L^2(0, T_\ast; H^1(\mathbb{R}_+^{N+1}, d\mu_t)) \cap C^0(0, T_\ast; L^2(\mathbb{R}_+^{N+1}, d\mu_t)),
\]

as \( \lambda \to 0^+ \), i.e.:

\[
\lim_{\lambda \to 0^+} \int_0^{T_\ast} \|U_{p_0, \lambda} - \Theta_{p_0}\|^2_{H_{\mu_t}^1} \, dt = \lim_{\lambda \to 0^+} \sup_{t \in [0, T_\ast]} \|U_{p_0, \lambda} - \Theta_{p_0}\|^2_{L^2_{\mu_t}} = 0,
\]

where

\[
\Theta_{p_0}(x, y, t) := t^{\tilde{\kappa}_{n_0, m_0}} \sum_{(\alpha, m) \in \tilde{J}_0} v_{\alpha, m} \nabla_{\alpha, m} \left( \frac{x}{\sqrt{t}}, \frac{y}{\sqrt{t}} \right),
\]

and \( v_{\alpha, m} \) are suitable constants (depending on \( p_0 \) and \( U \)), the sum is done over the set of indices

\[
\tilde{J}_0 := \{ (\alpha, m) \in \mathbb{Z}_0^N \times \mathbb{N} : |\alpha| = n \in \mathbb{N} \text{ and } \tilde{\kappa}_{n, m} = \tilde{\kappa}_{n_0, m_0} \},
\]

and the integration probability measure is defined in (2.21). Moreover,

\[
\nabla_{\alpha, m}(x, y) := \frac{V_{\alpha, m}(x, y)}{\|V_{\alpha, m}\|_{L^2_\mu}}, \quad \alpha \in \mathbb{Z}_0^N, \ m \in \mathbb{N},
\]

are the normalized versions of the eigenfunctions \( V_{\alpha, m} = V_{\alpha, m}(x, y) \) to problem (3.9) corresponding to the eigenvalue \( \tilde{\kappa}_{n, m} \), defined in the statement of Proposition 3.2.

Let us briefly comment the statement of Theorem 3.3. The first crucial fact is that part (i) clarifies the links between the eigenvalue problem (3.9) and the spectrum of the Almgren-Poon quotient (3.2). In particular, it explains that \( N(p_0, t_0^+, U) \) can assume only a countable number of values which, by the way, are the half-integer. This will be very important soon, in the study of the structure of nodal set of solutions to (1.1). Secondly, part (ii) states that the function \( t \to H(t, U_{p_0}) \) has a precise behaviour as \( t \) goes to zero

\[
H(t, U_{p_0}) \sim L_0 t^{2\tilde{\kappa}_{n_0, m_0}} \quad \text{for } t \sim 0^+,
\]
for a suitable constant $L_0 > 0$ (depending on $p_0$ and $U$). This allows us to re-write the limits in (3.13) in a slightly different form, which emphasizes the normalization factor of the blow-up sequence:

$$
\lim_{\lambda \to 0^+} \int_0^{T_*} \left\| \lambda^{-2\kappa_{n_0,ma}} U(x_0 + \lambda x, \lambda y, t_0 + \lambda^2 t) - t^{\kappa_{n_0,ma}} \sum_{(\alpha,m) \in I_0} v_{\alpha,m} \nabla_{\alpha,m} \left( \frac{x}{\sqrt{t}}, \frac{y}{\sqrt{t}} \right) \right\|^2 dt = 0,
$$

$$
\lim_{\lambda \to 0^+} \sup_{t \in (0,T_*)} \left\| \lambda^{-2\kappa_{n_0,ma}} U(x_0 + \lambda x, \lambda y, t_0 + \lambda^2 t) - t^{\kappa_{n_0,ma}} \sum_{(\alpha,m) \in I_0} v_{\alpha,m} \nabla_{\alpha,m} \left( \frac{x}{\sqrt{t}}, \frac{y}{\sqrt{t}} \right) \right\|^2_{L^2_{\mu_t}} = 0,
$$

where we are implicitly absorbing a factor $\sqrt{L_0}$ into the coefficients $v_{\alpha,m}$. This convention will be adopted throughout the paper and we will not distinguish the normalized blow-up sequence defined in (3.10) from the the sequence $\lambda^{-2\kappa_{n_0,ma}} U(x_0 + \lambda x, \lambda y, t_0 + \lambda^2 t)$. Finally, we stress that part (iii) provides relevant (and in some sense sharp) information about the behaviour of the blow-up sequence, in terms of explicit eigenfunctions, given by combinations of $N$-dimensional Hermite polynomials and Laguerre polynomials of different orders, highlighting once more the relevance of the spectral analysis done in the proof of Proposition 3.2.

The second main blow-up result states that the convergence of the blow-up sequence to the blow-up limits is indeed locally uniform.

**Theorem 3.4.** Fix $-1 < a < 1$, $p_0 = (x_0, 0, t_0) \in \Gamma(U) \cap \Sigma$. Let $U = U(x,y,t)$ be a strong solution to problem (2.15) and $U_{p_0,\lambda} = U_{p_0,\lambda}(x,y,t)$ its normalized blow-up sequence defined in (3.10). Then for any compact set $K \subset \mathbb{R}^{N+1}_+ \times (0,\infty)$ and any $0 < \nu < \nu_* := \min\{1,1-a\}/2$, there exists a constant $C > 0$ not depending on $\lambda > 0$, such that

$$
\|U_{p_0,\lambda}\|_{C^{2\nu,\nu}(K)} \leq C,
$$

and, moreover, we have as $\lambda \to 0^+$

$$
U_{p_0,\lambda} \to \Theta_{p_0} \quad \text{uniformly in } K,
$$

where $\Theta_{p_0} = \Theta_{p_0}(x,y,t)$ is the blow-up limit of $U$ at $p_0$, defined in Theorem 2.6.

First of all, we point out that estimate (3.14) remains true, even for solutions to (2.7) (we avoid to state it for expository reasons) as showed in Corollary 7.5. Let us stress that the approach based on the uniform bound of the blow-up sequence parabolic H"older norm, defined by

$$
\|F\|_{C^{2\nu,\nu}(K)} := \|F\|_{L_{\infty}(K)} + [F]_{C^{2\nu,\nu}(K)},
$$

where $X = (x,y)$, $|X|^2 = |x|^2 + |y|^2$, $0 < \nu < 1$ and

$$
[F]_{C^{2\nu,\nu}(K)} := \sup_{(X_1,t_1),(X_2,t_2) \in K} \frac{|F(X_1,t_1) - F(X_2,t_2)|}{(|X_1 - X_2|^2 + |t_1 - t_2|)\nu},
$$

is the main difference in our methods with respect to the techniques employed in [1]. As will be clearer later it has remarkable consequences from both the regularity viewpoint and the blow-up limits uniqueness. Furthermore, the uniform convergence of the blow-up sequences to their blow-up limits will be crucial to estimate the parabolic Hausdorff dimension of the nodal set of solutions to (1.1) and, more precisely, in the application of the Federer Reduction Principle.
Now, to proceed further, we must highlight some connections between our setting and the one of [5]. So, let \( w \in \text{dom}(H^s) \) be a solution to (2.2) in \( \mathbb{R}^N \times (-T, 0) \) and let \( W = W(x,y,\tau) \) its extension (2.4) (it thus satisfies problem (2.7) in \( \mathbb{R}_{\tau}^{N+1} \times (-T, 0) \)). As we have seen (cfr. with the review above), in [5] the authors introduced the Almgren-Poon quotients type \( \lambda \to \overline{N}_h(\lambda,W) \), \( \lambda \to \overline{N}_0(\lambda,W) \) (cfr. formula (2.11)), and showed that

\[
\lim_{\lambda \to 0^+} N_h(\lambda,W) = \lim_{\lambda \to 0^+} N_0(\lambda,W) = \lim_{\lambda \to 0^+} \overline{T}_0(\lambda,W) / \overline{H}(\lambda,W),
\]

where the functions \( \lambda \to \overline{H}(\lambda,W) \) and \( \lambda \to \overline{T}_0(\lambda,W) \) are defined in (2.10). Now, setting \( u(x,t) := w(x,-t) \) and \( U(x,y,t) := W(x,y,-t) \), it is easily seen that

\[
\overline{H}(\lambda,W) = \frac{1}{\lambda^2} \int_0^{\lambda^2} \int_{\mathbb{R}^{N+1}_+} y^a U^2(x,y,t) G_{N+1}(x,y,t) \, dx \, dy \, dt = \frac{c_{N,a}}{\lambda^2} \int_0^{\lambda^2} t^{\frac{2}{a}} H(t, U) \, dt,
\]

\[
\overline{T}_0(\lambda,W) = \frac{1}{\lambda^2} \int_0^{\lambda^2} \int_{\mathbb{R}^{N+1}_+} y^a \nabla U^2(x,y,t) G_{N+1}(x,y,t) \, dx \, dy \, dt = \frac{c_{N,a}}{\lambda^2} \int_0^{\lambda^2} t^{1+\frac{2}{a}} I(t, U) \, dt,
\]

where \( t \to H(U,t) \) and \( t \to I(U,t) \) are defined above (cfr. with formula (3.2)), and we have used the fact that

\[
G_{N+1}(x,y,t) = c_{N,a} t^{\frac{2}{a}} g_a(x,y,t),
\]

for a suitable normalization constant \( c_{N,a} > 0 \). Consequently, if \( 0 \in \Gamma(U) \) (the general case \( p_0 \neq 0 \) follows by translation), we obtain through a simple differentiation

\[
(3.16) \quad \lim_{\lambda \to 0^+} N_0(W,\lambda) = \lim_{\lambda \to 0^+} \frac{\int_0^{\lambda^2} t^{1+\frac{2}{a}} I(t, U) \, dt}{\int_0^{\lambda^2} t^{\frac{2}{a}} H(t, U) \, dt} = \lim_{\lambda \to 0^+} \frac{\lambda^2 I(\lambda^2, U)}{H(\lambda^2, U)} = \lim_{\lambda \to 0^+} N(\lambda^2, U).
\]

It thus follows that the limit of the Almgren-Poon quotient type \( N_h(W,\lambda) \) as \( \lambda \to 0^+ \) does not depend on the presence of the potential (cfr. with Theorem 2.1) and, furthermore, it coincides with the limit of the quotient (3.3). In particular, we deduce that the admissible limits for \( \lambda \to N_h(U,\lambda) \) are the half-integers, as stated in part (i) of Theorem 3.3 for the quotient \( t \to N(t, U) \).

The second key point concerns the convergence of the blow-up sequence \( U_\lambda = \overline{U}_\lambda(x,y,t) \) defined in (2.12). Indeed, as stated in Theorem 2.2, it converges uniformly and in suitable Gaussian spaces to a blow-up limit \( U_0 = W_0(x,y,\tau) \) which satisfies problem (2.13) and is parabolically homogeneous of degree \( \kappa \), where \( \kappa \) is the limit of the Almgren-Poon quotient. Setting as before \( U_0(x,y,t) = W(x,y,-t) \) (which now solves (2.13)), we easily conclude that \( U_0 \) must coincide with a blow-up limit \( \Theta = \Theta(x,y,t) \) defined in Theorem 3.3 (depending of course by \( \kappa \)). In particular, using a translation argument again, we deduce that for any compact set \( K \subset \mathbb{R}^{N+1}_+ \times (0,\infty) \), we have as \( \lambda \to 0^+ \)

\[
(3.17) \quad \overline{U}_{p_0,\lambda} \to \Theta_{p_0} \quad \text{uniformly in} \ K,
\]

where \( \Theta_{p_0} \) is defined in Theorem 3.3. The uniqueness of the above limit is highly not trivial. As we will see, its proof makes use of the equation satisfied by \( \overline{U}_{p_0,\lambda} \), combined with the uniform estimate (3.14) which, as we have anticipated holds true for solutions to (2.7). We stress that the crucial nontrivial fact here is that, compared with Theorem 3.3, the blow-up sequence \( \overline{U}_{p_0,\lambda} \) does not satisfies the homogeneous Neumann problem (2.15), but a nonhomogeneous one, which is the corresponding version of (2.7) (with a time inversion and a \( p_0 \)-translation of the potential). Moreover, with respect to the existing literature (cfr. for instance with [6] [24] [38] where the authors introduced some Monneau and Weiss type monotonicity formulas (cfr. with [38] [49] and [74] [75], respectively), our proof of
the blow-up limit uniqueness strongly relies on the spectral decomposition of the space $L^2(\mathbb{R}_{+}^{N+1}, d\mu)$ stated in Proposition 3.2 and the explicit expression of the eigenfunctions.

In order to state the last main results of the present work, we have to introduce some further notions and definitions. As we have done above, we consider a solution $w \in \text{dom}(H^s)$ to $(2.2)$ in $\mathbb{R}^N \times (-T, 0)$, its extension $W = W(x, y, t)$ and we define $u(x, t) := w(x, -t)$ and $U(x, y, t) := W(x, y, -t)$. Defining the set
\[ \bar{\mathcal{K}} := \{ \bar{\kappa}_{n,m} \}_{n,m \in \mathbb{N}} = \left\{ \frac{n}{2} + m \right\}_{n,m \in \mathbb{N}}, \]
we give the following definition.

**Definition 3.5.** For any $\kappa \in \bar{\mathcal{K}}$, we define
\[ \Gamma_\kappa(U) := \left\{ p_0 \in \Gamma(U) \cap \Sigma : \lim_{t \to 0^+} N(t, U_{p_0}) = \kappa \right\}. \]
In particular, we set $\mathcal{R}(U) := \Gamma_{1/2}(U)$ and $\mathcal{S}(U) := \Gamma(U) \setminus \mathcal{R}(U)$. Finally, we define
\begin{align*}
\Gamma(u) &:= \Gamma(U) \cap \Sigma, \quad \Gamma_\kappa(u) := \Gamma_\kappa(U), \\
\mathcal{R}(u) &:= \Gamma_{1/2}(u), \\
\mathcal{S}(u) &:= \Gamma(u) \setminus \mathcal{R}(u).
\end{align*}

Note that both unions $\Gamma(U) = \mathcal{R}(U) \cap \mathcal{S}(U)$ and $\Gamma(u) = \mathcal{R}(u) \cap \mathcal{S}(u)$ are disjoint by definition. $\mathcal{R}(u)$ and $\mathcal{S}(u)$ are called regular and singular part of $\Gamma(u)$, respectively.

**Definition 3.6.** Fix $\kappa \in \bar{\mathcal{K}}$ and $p_0 \in \Gamma_\kappa(U)$. We define the set of all the possible blow-up limits of $U$ at $p_0$ as
\[ \mathcal{B}_\kappa(U) := \left\{ \Theta_{p_0}(x, y, t) = t^{\kappa_{n_0,m_0}} \sum_{(\alpha, m) \in \hat{J}_0} v_{\alpha,m} \nabla_{\alpha,m} \left( \frac{x}{\sqrt{t}}, \frac{y}{\sqrt{t}} \right) \right\}, \]
where $n_0, m_0 \in \mathbb{N}$ are chosen so that $\kappa = \kappa_{n_0,m_0}$, while $\hat{J}_0$, $v_{\alpha,m}$, and $\nabla_{\alpha,m} = \nabla_{\alpha,m}(\cdot, \cdot)$ are as in Theorem 3.3. Furthermore, the tangent map of $U$ at $p_0$ is the unique $\Theta_{p_0} \in \mathcal{B}_\kappa(U)$ such that for any compact set $K \subset \mathbb{R}_{+}^{N+1} \times [0, \infty)$
\[ U_{p_0,\lambda} \to \Theta_{p_0}(x, y, t) \quad \text{uniformly in } K, \]
as $\lambda \to 0^+$. We are now ready to state the first main theorem concerning the nodal set of solutions to $(1.1)$. In particular, it shows that such set is thin i.e. it has at least codimension 1 in $\mathbb{R}^N \times \mathbb{R}$ w.r.t. to the parabolic Hausdorff dimension. Its proof is based the blow-up theorems stated above and the classical Reduction Principle of Federer (cfr. with Chen [20]).

**Theorem 3.7.** Let $u \in \text{dom}(H^s)$ be a nontrivial solution to $(1.1)$. Then:
\[ \dim \mathcal{P}(\Gamma(u)) \leq N + 1, \]
where $\dim \mathcal{P}(E)$ denotes the parabolic Hausdorff dimension of a set $E \subset \mathbb{R}^N \times \mathbb{R}$.

Once the bound above is established, we move forward with the analysis of the regular set $\mathcal{R}(u) = \Gamma_{1/2}(u)$. In particular, we clarify the relation between regular points and the limit of the Almgren-Poon quotient centered at $p_0$. The main fact here is that the set $\mathcal{R}(u)$, defined in terms of the limit of the quotient $(3.2)$, has some regularity properties that a priori are not immediate.
Proposition 3.8. (Regularity of $R(u)$) Let $u \in \text{dom}(H^s)$ be a nontrivial solution to (1.1). Then the following two assertions hold:

(i) For any $p_0 = (x_0, 0, t_0) \in R(u)$ it holds $|\nabla_x U(p_0)| \neq 0$.

(ii) $R(u)$ is a locally $C^1$-manifold of parabolic Hausdorff codimension at least one.

We are thus left to study the singular set $S(u)$ defined in (3.18):

$$S(u) := \Gamma(u) \setminus R(u) = \bigcup_{\kappa \in 1 + \frac{N}{2}} \Gamma_\kappa(u).$$

This part contains the main novelties with respect to the classical case and, to better understand them, a review of what is known for local diffusion is now in order. In [10], Han and Lin studied the nodal set of solutions $u = u(x, t)$ to

$$\partial_t u = a_{ij}(x, t)\partial_{ij} u + b_i(x, t)\partial_{i} u + c(x, t) u \quad \text{in} \ Q_1 \subset \mathbb{R}^N \times \mathbb{R},$$

where $\partial_i$ and $\partial_{ij}$ indicate the first and second partial derivatives of $U$ w.r.t. to the spacial variables (cfr. with formula (1.1) of [10]), assuming the uniform ellipticity of the diffusion matrix $a_{ij} = a_{ij}(x, t)$ on $Q_1$, and the $\nu$-Hölder regularity of the coefficients in $Q_1$:

$$\|a_{ij}\|_{C^{2\nu, \nu}(Q_1)} + \|b_i\|_{C^{2\nu, \nu}(Q_1)} + \|c\|_{C^{2\nu, \nu}(Q_1)} < +\infty,$$

for all $i, j = 1, \ldots, N$ and some $0 < \nu < 1/2$ (cfr. with formulas (1.2) and (1.3) of Han and Lin paper). Moreover, they worked with smooth solutions satisfying the doubling property (cfr. with formula (1.5)): there exist $C = C(N) > 0$ and a positive integer $d$, such that, setting

$$\|u\|^2_{(x, t), r} := \frac{1}{r^{N+2}} \int_{Q_r(x, t)} u^2, \quad Q_r(x, t) := B_r(x) \times (t - 7r^2/8, t + r^2/8),$$

it holds

$$(3.20) \quad \frac{\|u\|^2_{(x, t), r}}{\|u\|^2_{(x, t), r/2}} \leq C^d, \quad \text{for all} \ (x, t), \ r > 0 \ \text{with} \ Q_r(x, t) \subset Q_1.$$ 

This is a non-degeneracy assumption needed by the authors to exclude solutions vanishing on nonempty open subsets of $\mathbb{R}^N \times \mathbb{R}$ (cfr. with Jones’s example [43]). Then, for this class of functions they proved the following estimates on the Hausdorff dimension of the nodal set of $u$ (cfr. with Theorem 1.1 of [10]):

$$(3.21) \quad \dim_H(\Gamma(u)) \leq N \quad \dim_H(S(u)) \leq N - 1.$$ 

It thus follows that $\Gamma(u) \cap Q_1$ is composed by the union of the locally $C^1$ manifold $\Gamma(u) \cap Q_1 \cap \{\nabla_x u > 0\}$ of Hausdorff dimension not grater than $N$ and the (closed) set $S(u) \cap Q_1$ of Hausdorff dimension not greater than $N - 1$. To our knowledge, these are the first results concerning the parabolic framework. However, as above, we will prevalently use the notion of parabolic Hausdorff dimension (cfr. for instance with [20]) which better adapts to the parabolic scaling. In his remarkable work, Chen [20] considered more general differential parabolic inequalities (which contains the class of equations studied by Han and Lin) and proved estimates corresponding to (3.21), in terms of parabolic Hausdorff...
if $U$ the main deviances occur in the analysis of the singular set possesses similar properties of its corresponding set in the local diffusion framework. As anticipated, holds also for the nonlocal framework while Theorem 3.8 states that the regular part of the nodal set end of Section 6): then its blow up limit must be a linear combination of the right rescaled eigenfunctions (cfr. with the solution to (1.1)

$$\Theta^{A,B}(x,y,t) = A\Theta_{2,0}(x,y,t) + B\Theta_{0,1}(x,y,t) = A(x^2 - 2t) + B\left[\frac{1 + a}{2} t - \frac{y^2}{4}\right]$$

$$= Ax^2 + \left[\frac{1 + a}{2} B - 2A\right] t - B\frac{y^2}{4}.$$ 

In particular, taking $A = 1$, $B = 4/(1 + a)$ and $A = 0$, $B = 4/(1 + a)$, we obtain

$$\Theta^{1,\frac{4}{1+a}}(x,y,t) = x^2 - \frac{y^2}{1 + a}, \quad \Theta^{0,\frac{4}{1+a}}(x,y,t) = 2t - \frac{y^2}{1 + a},$$

with traces on $\mathbb{R}^N \times \mathbb{R}$

$$\vartheta^{1,\frac{4}{1+a}}(x,t) := \Theta^{1,\frac{4}{1+a}}(x,0,t) = x^2, \quad \vartheta^{0,\frac{4}{1+a}}(x,t) := \Theta^{0,\frac{4}{1+a}}(x,0,t) = 2t,$$

respectively. Consequently, since $\dim_P(S(\vartheta^{1,\frac{4}{1+a}})) = \dim_P(S(\vartheta^{0,\frac{4}{1+a}})) = 2 \neq 1$, we understand that the non-locality of the operator $H^s$ plays a central role the description of the singular set properties. Recalling that

$$\mathcal{Z}_t(u) := \{x \in \mathbb{R}^N : u(x,t) = 0\},$$

we note that also $\dim_H(\mathcal{Z}_0(\vartheta^{0,\frac{4}{1+a}})) = 1 \neq 0$ and so all the relations in (3.22) seems not hold. We stress that an explicit counterexample to inequalities (3.22) has been given for the elliptic-nonlocal setting by Tortone in his Ph.D. dissertation [69].

Once clarified this point, we present a first main result concerning the asymptotic behaviour and the differentiability of solutions near singular nodal points in $\Gamma_\kappa(u)$. Furthermore, it establishes the continuity of the tangent map $p_0 \rightarrow \Theta_{p_0}$, seen as a function from $\Gamma_\kappa(U)$ to $\mathcal{B}_\kappa(U)$.

**Theorem 3.9.** (Continuous dependence of the blow-up limits) Let $u \in \text{dom}(H^s)$ be a nontrivial solution to (1.1) and let $U = U(x,y,t)$ its extension (2.24). Let $p_0 \in \Gamma_\kappa(U)$ and $\Theta_{p_0} \in \mathcal{B}_\kappa(U)$ its tangent map at $p_0$ (cfr. with Definition 3.6), for some $\kappa \in \mathbb{K}$. Then the following assertions hold:

(i) We have as $||(x,y,t)||^2 := |x|^2 + y^2 + |t| \rightarrow 0^+$

$$U_{p_0}(x,y,t) = \Theta_{p_0}(x,y,t) + o(||(x,y,t)||^{2\kappa}).$$

(ii) The map $p_0 \rightarrow \Theta_{p_0}$ from $\Gamma_\kappa(U)$ to $\mathcal{B}_\kappa(U)$ is continuous.
(iii) For any compact set $K \subset \Gamma_{\kappa}(U)$ there exists a modulus of continuity $\sigma = \sigma(K)$ with $\sigma(0^+) = 0$, such that as $\|(x, y, t)\|^2 := |x|^2 + y^2 + |t| \to 0^+$,
$$|U_{p_0}(x, y, t) - \Theta_{p_0}(x, y, t)| \leq \sigma(\|(x, y, t)\|) \|(x, y, t)\|^{2\kappa},$$
for any $p_0 \in K$ (the main fact here is that $\sigma$ does not depend on $p_0$, but only on $K$).

Finally, to state the last theorem of this treatise, we must give two more definitions inspired by the work of Danielli et al. \[24\] (cfr. with Definition 12.9 of that paper).

**Definition 3.10.** Let $w \in \text{dom}(H^s)$ be a nontrivial solution to (1.1), $u(x, t) = w(x, -t)$, and $(x_0, t_0) \in \Gamma_{\kappa}(u)$. We define the spatial dimension of $\Gamma_{\kappa}(u)$ at $(x_0, t_0)$ as
$$d^r_{(x_0, t_0)} := \dim \left\{ \xi \in \mathbb{R}^N : \xi \cdot \nabla_x \partial_x^\alpha \partial_t^j \partial_{p_0} = 0, \text{ for any } \alpha \in \mathbb{Z}_{\geq 0}^N, j \in \mathbb{N} \text{ with } |\alpha| + 2j = 2\kappa - 1 \right\},$$
where $p_0 = (x_0, t_0)$, $\partial_{p_0}(x, t) = \Theta_{p_0}(x, 0, t)$ and $\Theta_{p_0} \in \mathcal{B}_{\kappa}(u)$ is the blow-up limit of $U = U(x, y, t)$ at $p_0$.

Finally, for any $d = 0, \ldots, N$, we define
$$\Gamma^d_{\kappa}(u) := \left\{ (x_0, t_0) \in \Gamma_{\kappa}(u) : d^r_{(x_0, t_0)} = d \right\}.$$ 

Finally, we introduce the notion of space-like and time-like manifolds.

**Definition 3.11.** (Definition 12.11 of \[24\])
A $(d + 1)$-dimensional manifold $\mathcal{M} \subset \mathbb{R}^N \times \mathbb{R}$ (with $d = 0, \ldots, N - 1$) is said to be space-like of class $C^{1,0}$ if it can be locally represented as a graph of a $C^{1,0}$ function $g : \mathbb{R}^d \times \mathbb{R} \to \mathbb{R}^{N-d}$
$$(x_{d+1}, \ldots, x_N) = g(x_1, \ldots, x_d, t),$$
up to rotation of coordinate axis in $\mathbb{R}^N$.

A $N$-dimensional manifold $\mathcal{M} \subset \mathbb{R}^N \times \mathbb{R}$ is said to be time-like of class $C^1$ if it can be locally represented as a graph of a $C^1$ function $g : \mathbb{R}^N \to \mathbb{R}$
$$t = g(x_1, \ldots, x_N).$$

We can now state our Structure of the singular set theorem. Its proof relies on a suitable and nontrivial adaptation of some techniques due to Garofalo and Petrosyan \[38\] (local elliptic setting) and Danielli et al. \[24\] (local parabolic setting), based on a ingenious combination of the Implicit Function Theorem and a parabolic version of the Whitney Extension Theorem, which we recall later.

**Theorem 3.12.** (Structure of the singular set) Let $u \in \text{dom}(H^s)$ be a nontrivial solution to (1.1). Then the set $\Gamma^d_{\kappa}(u)$ is contained in a countable union of $(d + 1)$-dimensional space-like $C^{1,0}$ manifolds for any $d = 0, \ldots, N - 1$, while $\Gamma^N_{\kappa}(u)$ is contained in a countable union of $N$-dimensional time-like $C^1$ manifolds.

The above theorem concludes this presentation. Let us stress that its importance is due to the possibility of giving a *stratification* of the singular set $\mathcal{S}(u)$ in terms of the limit of the quotient \[3.2\]. This is possibly one of the most surprising consequences of the study of the monotonicity of Almgren-Poon quotients type.
4. Almgren-Poon type formulas and some immediate applications

In this section, we will derive two parabolic Almgren-Poon type formulas which will be employed later for showing the asymptotic behaviour of strong solutions to equation (2.17), and problems (2.15), (2.16), respectively. As anticipated above, a similar monotonicity formula was firstly proved for more regular functions by Stinga and Torrea in [63] and an averaged version of it by Banerjee and Garofalo in [5] for non-smooth functions and in the more general setting of weak solutions. It is important to stress that in the context of strong solutions, the proofs of the monotonicity formulas are much easier than in the case of weak solutions, where very hard work is required to obtain partial regularity of the weak solutions (cfr. with Section 5 and 6 of [5]). Here we are in the position to assume all these regularity result, as explained in the introduction.

4.1. Poon-Almgren formula for solutions to problems (2.15) and (2.16). Let $-1 < a < 1$ and $0 < T < \infty$ be fixed, and let $U = U(x,y,t)$ be a strong solution to problem (2.15):

$$
\begin{align*}
\partial_t U + L_a U &= 0 \quad \text{in } \mathbb{R}^{N+1}_+ \times (0,T), \\
-\partial_y^a U &= 0 \quad \text{in } \mathbb{R}^N \times \{0\} \times (0,T),
\end{align*}
$$

or (2.16), which is (2.15) with Dirichlet homogeneous boundary conditions replacing the Neumann ones (cfr. with Definition 2.3).

**Proof of Lemma 3.1.** We take $p_0 = 0$ for simplicity (the general case is recovered by translation). The proof is divided in four essential steps as follows.

**Step 1:** Derivative of $H(t,U)$. Let us fix $0 < t_1 < t_2 < T$ and let us use for a moment the rescaled version $\tilde{U} = \tilde{U}(x,y,t)$. Since both $\tilde{U}$ and $\partial_t \tilde{U}$ belong to $L^2_{\text{loc}}(0,T; L^2_\mu)$, it follows that the function $t \to \tilde{U}(\cdot, \cdot, t)$ is absolutely continuous on $[t_1, t_2]$ and, furthermore, it holds

$$
\frac{d}{dt} \|\tilde{U}(t)\|_{L^2_\mu}^2 = 2 \langle \partial_t \tilde{U}(t), \tilde{U}(t) \rangle_{L^2_\mu},
$$

in the weak sense. Consequently, using that $H(t,U) = H(1,\tilde{U}) = \|\tilde{U}(t)\|_{L^2_\mu}^2$, we deduce

$$
H(t_2, U) - H(t_1, U) = \int_{t_1}^{t_2} \frac{d}{dt} \|\tilde{U}(t)\|_{L^2_\mu}^2 dt = 2 \int_{t_1}^{t_2} \langle \partial_t \tilde{U}(t), \tilde{U}(t) \rangle_{L^2_\mu} dt
$$

$$
= 2 \int_{t_1}^{t_2} \int_{\mathbb{R}^{N+1}} \partial_t \tilde{U} \tilde{U} \, d\mu(x,y) dt = 2 \int_{t_1}^{t_2} \frac{1}{t} \int_{\mathbb{R}^{N+1}} |\nabla \tilde{U}|^2 \, d\mu(x,y) dt
$$

$$
= 2 \int_{t_1}^{t_2} \frac{1}{t} I(1,\tilde{U}) dt = 2 \int_{t_1}^{t_2} I(t,U) dt,
$$

where we have employed the integral relation (2.31) in the fourth equality with test $\eta = \tilde{U}$, and the fact that $tI(t,U) = I(1,\tilde{U})$, in the last one. We have thus obtained

$$
H'(t,U) = 2I(t,U) \quad \text{or equivalently} \quad H'(1,\tilde{U}) = \frac{2}{t} I(1,\tilde{U})
$$

in the weak sense. Note that since $H'(1,\tilde{U}) = 2 \int_{\mathbb{R}^{N+1}} \tilde{U} \partial_t \tilde{U} \, d\mu(x,y)$, we easily deduce

$$
(4.1) \quad I(1,\tilde{U}) = t \int_{\mathbb{R}^{N+1}} \tilde{U} \partial_t \tilde{U} \, d\mu(x,y).
$$
Step 2: Derivative of $I(t,U)$. Now, testing the equation of $\tilde{U} = \tilde{U}(x,y,t)$ (cfr. with (2.31)) with test $\eta = \partial_t \tilde{U}$, we see that
\[
\int_{t_1}^{t_2} \int_{\mathbb{R}^N+1} (\partial_t \tilde{U})^2 \, d\mu(x,y) \, dt = \int_{t_1}^{t_2} \int_{\mathbb{R}^N+1} y^a \nabla \tilde{U} \cdot \nabla (\partial_t \tilde{U}) G_a \, dx dy \, dt,
\]
from which we deduce that the r.h.s. is finite thanks to our integrability assumptions on $\partial_t \tilde{U}$ (note that testing with $\eta = \partial_t \tilde{U}$ is not admissible by definition but one can proceed by suitable approximations). On the other hand, from Fubini’s Theorem and well known properties of weak derivatives, we have
\[
\int_{t_1}^{t_2} \int_{\mathbb{R}^N+1} y^a \nabla \tilde{U} \cdot \nabla (\partial_t \tilde{U}) G_a \, dx dy \, dt = \frac{1}{2} \int_{t_1}^{t_2} \int_{\mathbb{R}^N+1} \partial_t (|\nabla \tilde{U}|^2) y^a G_a \, dx dy \, dt
\]
\[
= \frac{1}{2} \int_{\mathbb{R}^N+1} \left( |\nabla \tilde{U}|^2(x,y,t_2) - |\nabla \tilde{U}|^2(x,y,t_1) \right) d\mu(x,y)
\]
\[
= \frac{1}{2} \left[ I(1, \tilde{U}(t_2)) - I(1, \tilde{U}(t_1)) \right].
\]
Consequently, we have obtained that
\[
I'(1,\tilde{U}) = \frac{2}{t} \int_{\mathbb{R}^N+1} (t \partial_t \tilde{U})^2 \, d\mu(x,y),
\]
in the weak sense.

Step 3: Derivative of $N(t,U)$. We are now ready to prove that the function $t \to N(t,U)$ is monotone non-decreasing. Using (4.1) and the expressions for $H'(1, \tilde{U})$ and $I'(1,\tilde{U})$, we deduce
\[
I'(1,\tilde{U})H(1,\tilde{U}) - I(1,\tilde{U})H'(1,\tilde{U})
\]
\[
= \frac{2}{t} \left[ \int_{\mathbb{R}^N+1} \tilde{U}^2 \, d\mu(x,y) \int_{\mathbb{R}^N+1} (t \partial_t \tilde{U})^2 \, d\mu(x,y) - \left( \int_{\mathbb{R}^N+1} \tilde{U} \, t \partial_t \tilde{U} \, d\mu(x,y) \right)^2 \right] \geq 0,
\]
thanks to Cauchy-Schwartz inequality.

Step 4: Final remarks. We are left to prove that the function $t \to N(t,U)$ is constant if and only if $U = U(x,y,t)$ is parabolically homogeneous of some degree. Now, from the Cauchy-Schwartz inequality and the above inequality it follows that
\[
N'(t,U) \equiv 0 \quad \text{for a.e. } 0 < t < T \quad \text{if and only if} \quad t \partial_t \tilde{U} = \kappa(t) \tilde{U} \quad \text{for a.e. } 0 < t < T,
\]
for some real function $\kappa = \kappa(t)$. Consequently, taking $t \partial_t \tilde{U} = \kappa(t) \tilde{U}$ in (2.35), we deduce that $\tilde{U} = \tilde{U}(x,y,t)$ satisfies
\[
\kappa(t) \int_{\mathbb{R}^N+1} \tilde{U} \eta \, d\mu(x,y) = \int_{\mathbb{R}^N+1} \nabla \tilde{U} \cdot \nabla \eta \, d\mu(x,y),
\]
for $0 < t_0 < t < T$ and all $\eta \in L^2(0,T;H^1_\mu)$ and so, the same equation is satisfied by $\tilde{U}_0$. Hence, testing with $\eta = \tilde{U}$, we obtain
\[
\kappa(t) = N(1,\tilde{U}) = N(t,U) \equiv \kappa \quad \text{for all } 0 < 0 \leq t < T,
\]
for some $\kappa \geq 0$. Note that this implies that the function
\begin{equation}
(4.3)
t \to \frac{U(\sqrt{tx}, \sqrt{ty}, t)}{t^\kappa}
\end{equation}
is constant in $(0, T)$. Moreover, $(4.2)$ holds with $\kappa$ replacing of $\kappa(t)$, and so using $(2.35)$:
\begin{equation}
\kappa \int_{\mathbb{R}_+^{N+1}} \tilde{U} \eta d\mu(x, y) = \int_{\mathbb{R}_+^{N+1}} \nabla \tilde{U} \cdot \nabla \eta d\mu(x, y) = t \int_{\mathbb{R}_+^{N+1}} \partial_t \tilde{U} \eta d\mu(x, y),
\end{equation}
for all $\eta \in L^2(0, T; H^1_\mu)$. Changing variables $x \to \sqrt{tx}$ and $y \to \sqrt{ty}$ in the first and the last integral, we obtain
\begin{equation}
\int_{\mathbb{R}_+^{N+1}} \left[ t \partial_t U + \frac{(x, y)}{2} \cdot \nabla U - \kappa U \right] \eta d\mu_t = 0,
\end{equation}
for all $\eta \in L^2(0, T; H^1_\mu)$, and so, by the Test Lemma, it follows
\begin{equation}
t \partial_t U + \frac{(x, y)}{2} \cdot \nabla U = \kappa U \quad \text{a.e. in } \mathbb{R}_+^{N+1} \times (0, T),
\end{equation}
which is equivalent to say that $U = U(x, y, t)$ is parabolically $\kappa$-homogeneous: $U(\delta x, \delta y, \delta^2 t) = \delta^{2\kappa} U(x, y, t)$, for any $\delta > 0$ (cfr. with [5, 63]). Note that we could have obtained relation $(3.7)$ by differentiating (w.r.t. time) the constant function $(4.3)$.

Of course, the same homogeneity property holds also for $\tilde{U} = \tilde{U}(x, y, t)$ which satisfies the problem
\begin{equation}
\begin{cases}
-\mathcal{O}_a \tilde{U} = \kappa \tilde{U} & \text{in } \mathbb{R}_+^{N+1} \times (0, T),

-\partial_y \tilde{U} = 0 & \text{in } \mathbb{R}^N \times \{0\} \times (0, T)
\end{cases}
\end{equation}
where $-\mathcal{O}_a \tilde{U} := -\mathcal{L}_a \tilde{U} + \frac{(x, y)}{2} \cdot \nabla \tilde{U}$ (it is the Ornstein-Uhlenbeck type operator introduced in the introduction), in the sense that the identity
\begin{equation}
\int_{\mathbb{R}_+^{N+1}} \nabla \tilde{U} \cdot \nabla \eta d\mu(x, y) = \kappa \int_{\mathbb{R}_+^{N+1}} \tilde{U} \eta d\mu(x, y),
\end{equation}
is satisfied for a.e. $0 < t < T$ and all $\eta \in L^2(0, T; H^1_\mu)$. Note that, with respect to $(3.7)$, the above equation does not involve time derivatives but second order spacial derivatives. Consequently, the study of the parabolically $\kappa$-homogeneous profiles is equivalent to the study of the Ornstein-Uhlenbeck type problem introduced before, which we will present in detail in the next section. □

4.2. Poon-Almgren formula for solutions to equation $(2.17)$. Let $-1 < a < 1$ and $0 < T < \infty$ be fixed. We now repeat the analysis carried out before, for strong solutions to equation $(2.17)$:
\begin{equation}
\partial_t U + \mathcal{L}_a U = 0 \quad \text{in } \mathbb{R}_+^{N+1} \times (0, T),
\end{equation}
where we recall that in this setting $\mathcal{L}_a U := |y|^{-a} \nabla \cdot (|y|^a \nabla U)$. Following Section $3$, we consider the quantities
\begin{align}
H(t, U) &:= \int_{\mathbb{R}_+^{N+1}} |y|^a U^2(x, y, t) \mathcal{G}_a(x, y, t) \, dx \, dy,

I(t, U) &:= \int_{\mathbb{R}_+^{N+1}} |y|^a |\nabla U|^2(x, y, t) \mathcal{G}_a(x, y, t) \, dx \, dy,
\end{align}
and the quotient
\begin{equation}
N(t, U) := \frac{tI(t, U)}{H(t, U)},
\end{equation}
for a.e. \(0 < t < T\) such that \(H(t, U) \neq 0\). Again, \(H(t, U)\) and \(I(t, U)\) satisfy the scaling properties:

\[
H(t, U) = \int_{\mathbb{R}^{N+1}} |y|^a \tilde{U}^2(x, y, t) \mathcal{G}_a(x, y, 1) \, dx \, dy = \int_{\mathbb{R}^{N+1}} \tilde{U}^2(x, y, t) \, d\mu(x, y) := H(1, \tilde{U}),
\]

\[
I(t, U) = \frac{1}{t} \int_{\mathbb{R}^{N+1}} |y| \, |\nabla \tilde{U}|^2(x, y, t) \mathcal{G}_a(x, y, 1) \, dx \, dy = \frac{1}{t} \int_{\mathbb{R}^{N+1}} |\nabla \tilde{U}|^2(x, y, t) \, d\mu(x, y) := \frac{1}{t} I(1, \tilde{U}),
\]

where \(\tilde{U} = \tilde{U}(x, y, t)\) is defined in (2.27), so that \(N(t, U) = N(1, \tilde{U})\).

**Lemma 4.1.** Let \(U = U(x, y, t)\) be a function satisfying

- \(U \in L^2(0, T; H^0_{\mu_0})\), with \(t \partial_t U + \frac{(x, y)}{2} \cdot \nabla U \in L^2_{loc}(0, T; L^2_{\mu_1})\).
- Identity (2.26):

\[
\int_{\mathbb{R}^{N+1}} [\partial_t U + \frac{(x, y)}{2t} \cdot \nabla U] \eta \, d\mu_t(x, y) = \int_{\mathbb{R}^{N+1}} \nabla U \cdot \nabla \eta \, d\mu_t(x, y),
\]

holds for a.e. \(0 < t < T\) and all \(\eta \in L^2(0, T; H^1_{\mu_1})\),

and let \(N(t, U)\) be defined as in (4.4). Then the function

\[
t \to N(t, U)
\]

is non-decreasing for a.e. \(0 < t < T\). Moreover, the quotient \(t \to N(t, U)\) is constant if and only if \(U = U(x, y, t)\) is parabolically homogeneous of degree \(\kappa\), for some \(\kappa \geq 0\). (We recall that in this framework we use the convention \(L^2_{\mu_0} = L^2(\mathbb{R}^{N+1}, d\mu)\) and \(H^1_{\mu_0} = H^1(\mathbb{R}^{N+1}, d\mu)\)).

**Proof.** The proof is very similar to the previous one and we show it by completeness.

**Step 1:** Derivative of \(H(t, U)\). This step formally coincides with **Step 1** of the proof of Lemma 3.1. We just have to replace \(L^2(\mathbb{R}^{N+1}, d\mu_t)\) by \(L^2(\mathbb{R}^{N+1}, d\mu_t)\), and using identity (2.26) instead of (3.5). Consequently, it follows newly \(H'(t, U) = 2I(t, U)\) (i.e. \(H'(1, \tilde{U}) = 2t^{-1} I(1, \tilde{U})\)) in the weak sense, and from the fact that \(H'(1, \tilde{U}) = 2 \int_{\mathbb{R}^{N+1}} \tilde{U} \partial_t \tilde{U} \, d\mu(x, y)\), we have again

\[
I(1, \tilde{U}) = t \int_{\mathbb{R}^{N+1}} \tilde{U} \partial_t \tilde{U} \, d\mu(x, y).
\]

**Step 2:** Derivative of \(I(t, U)\). Proceeding as before, we test equation (2.26) with \(\eta = \partial_t \tilde{U}\) and we compute

\[
\int_{t_1}^{t_2} t \int_{\mathbb{R}^{N+1}} (\partial_t \tilde{U})^2 \, d\mu(x, y) \, dt = \int_{t_1}^{t_2} \int_{\mathbb{R}^{N+1}} |y|^a \nabla \tilde{U} \cdot \nabla (\partial_t \tilde{U}) \mathcal{G}_a \, dx \, dy \, dt
\]

\[
= \frac{1}{2} \int_{t_1}^{t_2} \int_{\mathbb{R}^{N+1}} \frac{\partial}{\partial t} \left| \nabla \tilde{U} \right|^2 \, y^a \mathcal{G}_a \, dx \, dy \, dt
\]

\[
= \frac{1}{2} \left[ I(1, \tilde{U}(t_2)) - I(1, \tilde{U}(t_1)) \right],
\]

using Fubini Theorem. This implies again

\[
I'(1, \tilde{U}) = \frac{2}{t} \int_{\mathbb{R}^{N+1}} (t \partial_t \tilde{U})^2 \, d\mu(x, y),
\]

in the weak sense.
Step 3: Derivative of $N(t, U)$. Exactly as before it is straightforward to compute

$$I'(1, \bar{U}) H(1, \bar{U}) - I(1, \bar{U}) H'(1, \bar{U})$$

$$= \frac{2}{t} \left[ \int_{\mathbb{R}^{N+1}} \bar{U}^2 d\mu(x, y) - \left( \int_{\mathbb{R}^{N+1}} \bar{U} d\mu(x, y) \right) \right] \geq 0,$$

thanks to Cauchy-Schwartz inequality.

Step 4: Final remarks. This last step coincides with Step 4 of Lemma 3.1. In the same way, we obtain that $N'(t, U) \equiv 0$ if and only if

$$t \partial_t U + \frac{(x, y)}{2} \cdot \nabla U = \kappa U \quad \text{a.e. in } \mathbb{R}^{N+1} \times (0, T),$$

which implies that $U = U(x, y, t)$ is parabolically homogeneous of degree $\kappa \in \mathbb{R}$. This time the equation for $\tilde{U} = \tilde{U}(x, y, t)$ is

$$-\mathcal{O}_a \tilde{U} = \kappa \tilde{U} \quad \text{in } \mathbb{R}^{N+1} \times (0, T),$$

for some $\kappa \in \mathbb{R}$, where $-\mathcal{O}_a \tilde{U} := -\mathcal{L}_a \tilde{U} + \frac{(x, y)}{2} \cdot \nabla \tilde{U}$, in the sense that the identity

$$\int_{\mathbb{R}^{N+1}} \nabla \tilde{U} \cdot \nabla \eta \, d\mu(x, y) = \kappa \int_{\mathbb{R}^{N+1}} \tilde{U} \eta \, d\mu(x, y),$$

is satisfied for a.e. $0 < t < T$ and all $\eta \in L^2(0, T; H^1_{\mu})$. Note that again the study of profiles making constant the Almgren-Poon quotient is equivalent to the study of the above eigenvalue problem. □

4.3. Some immediate applications of the Poon-Almgren monotonicity formula. We now focus on some immediate applications of the monotonicity formula proved in Lemma 3.1 and Lemma 4.1. We will mostly show our results in the setting of Lemma 3.1 since the proof in the other framework is almost identical.

We recall that we have proved that, if $U = U(x, y, t)$ satisfies the assumptions of Lemma 3.1, then the function

$$t \rightarrow N(t, U) = \frac{t I(t, U)}{H(t, U)} = \frac{\int_{\mathbb{R}^{N+1}} y^a |\nabla U|^2(x, y, t) G_a(x, y, t) \, dx \, dy}{\int_{\mathbb{R}^{N+1}} y^a U^2(x, y, t) G_a(x, y, t) \, dx \, dy}$$

is monotone non-decreasing for all $t > 0$ (and a similar result hold for functions $U = U(x, y, t)$ satisfying the assumptions in Lemma 4.1).

Corollary 4.2. Let $U = U(x, y, t)$ be a nontrivial function satisfying the assumptions of Lemma 3.1. Then both limits

$$\lim_{t \rightarrow 0^+} N(t, U) = \kappa \geq 0, \quad \lim_{t \rightarrow 0^+} t^{-2\kappa} H(t, U) \geq 0,$$

exist and are finite (of course, $N(t, U)$ and $H(t, U)$ are defined as in (3.4)).

Proof. The limit $\kappa \in [0, +\infty]$ exists since $N(t, U)$ is non-decreasing. Moreover, if $\kappa = +\infty$, then $N(t, U) \equiv +\infty$ for any $0 < t < T$ and so, since

$$t I(t, U) = \int_{\mathbb{R}^{N+1}} y^a |\nabla U|^2(x, y, t) G_a(x, y, t) \, dx \, dy < +\infty \quad \text{for a.e. } 0 < t < T,$$
it follows that $H(t,U) = 0$ for a.e. $0 < t < T$, i.e. $U \equiv 0$ in $\mathbb{R}^{N+1}_+ \times (0,T)$, which is a contradiction. For what concerns the second limit, we have
\begin{equation}
\frac{d}{dt} \left( t^{-2\kappa}H(t,U) \right) = 2t^{-2\kappa-1}H(t,U)\left[N(t,U) - \kappa\right] \geq 0, \quad t > 0,
\end{equation}
and so the limit $\lim_{t \to 0^+} t^{-2\kappa}H(t,U)$ exists. The fact that it is finite follows as before. □

Corollary 4.3. Let $U = U(x,y,t)$ be a nontrivial function satisfying the assumptions of Lemma 3.1. Then for any $0 < t_0 < T$, the following formulas hold
\begin{equation}
H(t,U) \geq H(t_0,U) \left( \frac{t}{t_0} \right)^{2N(t_0,U)} \quad \text{for all } 0 < t \leq t_0,
\end{equation}
\begin{equation}
H(t,U) \leq H(t_0,U) \left( \frac{t}{t_0} \right)^{2\kappa} \quad \text{for all } 0 < t \leq t_0,
\end{equation}
where as before $\kappa = \lim_{t \to 0^+} N(t,U)$.

Proof. Recall that $H'(t,U) = 2I(t,U)$ (see the proof of Lemma 3.1): $\frac{H'(t,U)}{H(t,U)} = \frac{2I(t,U)}{H(t,U)} = \frac{2N(t,U)}{t} \leq \frac{2N(t_0,U)}{t_0}$, for all $0 < t \leq t_0$, where $0 < t_0 < T$ is arbitrarily fixed. Integrating the previous inequality between $t$ and $t_0$, it is straightforward to obtain (4.6). Similarly,
\begin{equation}
\frac{H'(t,U)}{H(t,U)} = \frac{2I(t,U)}{H(t,U)} = \frac{2N(t,U)}{t} \geq \frac{2\kappa}{t}, \quad \text{for all } t > 0,
\end{equation}
Integrating between $t$ and $t_0$ as before, we obtain (4.7), too. From another view point, we can note that proving (4.7) is equivalent to prove that the function
\begin{equation}
t \to t^{-2\kappa}H(t,U)
\end{equation}
is nondecreasing, and this fact easily follows from (4.5). □

The following corollary (of Lemma 3.1) is classical and we follow the proof done in [32, 53] relying on a doubling type property. See also the end of Section 6 of [5].

Corollary 4.4. (Weak unique continuation property with respect to $t$) Let $U = U(x,y,t)$ be a nontrivial function satisfying the assumptions of Lemma 3.1. If there exists $0 < t_0 < T$ such that
\begin{equation}
U(\cdot,\cdot,t_0) \equiv 0 \quad \text{a.e. in } \mathbb{R}^{N+1}_+,
\end{equation}
then $U \equiv 0$ a.e. in $\mathbb{R}^{N+1}_+ \times (0,T)$.

Proof. We begin the proof by showing that for any $0 < T < \infty$ and any $U = U(x,y,t)$ satisfying our assumptions, it holds
\begin{equation}
U \not\equiv 0 \quad \text{a.e. in } \mathbb{R}^{N+1}_+ \times (0,T) \quad \Rightarrow \quad H(t,U) > 0 \quad \text{for all } 0 < t < T.
\end{equation}
We proceed in three short steps as follows.

Step 1. First, we note that
\begin{equation}
H(t_0,U) = 0 \quad \text{for some } t_0 > 0 \quad \Rightarrow \quad H(t,U) = 0 \quad \text{for all } 0 < t \leq t_0.
\end{equation}
This easily follows from the fact that $H'(t,U) \geq 0$ for all $t > 0$. 

Step 2. Now, we show that

\[ H(\cdot, U) \not\equiv 0 \Rightarrow H(t, U) > 0 \text{ for all } t > 0. \]

Since \( H(\cdot, U) \not\equiv 0 \) there is \( t_0 > 0 \) such that \( H(t_0, U) > 0 \), which implies \( H(t, U) > 0 \) for all \( t \geq t_0 \). Now, let

\[ t_0 := \inf \{ t_0 > 0 : H(t_0, U) > 0 \}. \]

If by contradiction \( t_0 > 0 \), we deduce

\[ 0 = H(t_0, U) \geq H(t_0, U) \left( \frac{t}{t_0} \right)^{2N(t_0, U)} > 0, \]

for some \( t_0 < t_0 \), which rises the desired contradiction.

Step 3. Let \( T > 0 \). We show that

\[ U \not\equiv 0 \text{ a.e in } \mathbb{R}^{N+1} \times (0, T) \Rightarrow H(t, U) > 0 \text{ for all } 0 < t < T. \]

Assume \( U \not\equiv 0 \text{ a.e. in } \mathbb{R}^{N+1} \times (0, T) \). Hence, there is \( 0 < t_0 < T \) such that \( U(\cdot, t_0) \not\equiv 0 \) and so \( H(t_0, U) > 0 \). From the previous step, we conclude \( H(t, U) > 0 \) for all \( 0 < t < T \).

Step 4: Conclusions. If \( U(\cdot, t_0) \equiv 0 \text{ a.e in } \mathbb{R}^{N+1} \times (0, T) \), then obviously follows that \( H(t_0, U) = 0 \), and this contradicts (4.8) unless \( U \equiv 0 \text{ in } \mathbb{R}^{N+1} \times (0, T) \).

Important Remark. The statements of Corollary 4.2, Corollary 4.3 and Corollary 4.4 hold true for functions \( U = U(x, y, t) \) satisfying the assumptions of Lemma 4.1, where \( N(t, U) \) and \( H(t, U) \) are defined in (4.4).

5. Proof of Proposition 3.2

This section is devoted to the proof of Proposition 3.2 which will actually be obtained as a consequence of a more general result (cfr. with Theorem 5.2). To do that, together with the solutions to problem (3.9), we will study also the boundary value problem

\[
\begin{aligned}
-\partial_a V &= \kappa V \quad \text{in } \mathbb{R}_{+}^{N+1} \\
V &= 0 \quad \text{in } \mathbb{R}^N \times \{0\},
\end{aligned}
\]

which is (3.9) with homogeneous Dirichlet boundary conditions, and problem

\[
\begin{aligned}
-|y|^{-a} \nabla \cdot (|y|^a \nabla V) + \frac{(x, y)}{2} \cdot \nabla V &= \kappa V \quad \text{in } \mathbb{R}^{N+1}, \\
- \frac{1}{|y|^a} \nabla \cdot (|y|^a \mathcal{G}_a \nabla V) &= \kappa V \quad \text{in } \mathbb{R}^{N+1},
\end{aligned}
\]

where \( V = V(x, y) \) will belong to a suitable functional space. In what follows it will be useful to keep in mind that (5.2) is equivalent to (for short \( \mathcal{G}_a = \mathcal{G}_a(x, y, 1) \))

\[
(5.3) \quad - \frac{1}{|y|^a} \nabla \cdot (|y|^a \mathcal{G}_a \nabla V) = \kappa V \quad \text{in } \mathbb{R}^{N+1},
\]

and similarly for problems (3.9) and (5.1). The importance of the formulation in (5.3) is clearer in the following fundamental definition.

Definition 5.1. We proceed with three different definitions.

• A nontrivial function \( V \in H^1(\mathbb{R}_+^{N+1}, d\mu) \) is said to be a weak eigenfunction to problem (3.9) with eigenvalue \( \kappa \in \mathbb{R} \) if

\[
\int_{\mathbb{R}_+^{N+1}} \nabla V \cdot \nabla \eta \, d\mu(x, y) = \kappa \int_{\mathbb{R}_+^{N+1}} V \eta \, d\mu(x, y), \quad \text{for all } \eta \in H^1(\mathbb{R}_+^{N+1}, d\mu).
\]
A nontrivial function \( V \in H^1_0(\mathbb{R}^N_+, d\mu) \) is said to be a weak eigenfunction to problem (5.1) with eigenvalue \( \kappa \in \mathbb{R} \) if

\[
\int_{\mathbb{R}^N_+} \nabla V \cdot \nabla \eta \, d\mu(x, y) = \kappa \int_{\mathbb{R}^N_+} V \eta \, d\mu(x, y), \quad \text{for all } \eta \in H^1_0(\mathbb{R}^N_+, d\mu).
\]

A nontrivial function \( V \in H^1(\mathbb{R}^N_+, d\mu) \) is said to be a weak eigenfunction to problem (5.2) with eigenvalue \( \kappa \in \mathbb{R} \) if

\[
\int_{\mathbb{R}^N_+} \nabla V \cdot \nabla \eta \, d\mu(x, y) = \kappa \int_{\mathbb{R}^N_+} V \eta \, d\mu(x, y), \quad \text{for all } \eta \in H^1(\mathbb{R}^N_+, d\mu).
\]

Before moving forward, we stress that using the fact that \( \nabla G_a(x, y, 1) = -\frac{(x, y)}{2} G_a(x, y, 1) \), a simple integration by parts shows that classical eigenfunctions to (3.9), (5.1) and (5.2) are weak eigenfunctions to (3.9), (5.1) and (5.2), respectively. Moreover, it is easily seen that smooth weak eigenfunctions are classical eigenfunctions. Note that in both (3.9)/(5.1) and (5.2) we obtain the classical Ornstein-Uhlenbeck eigenvalue problem by taking \( a = 0 \). As we will see, an interesting fact is that the study of the eigenvalue problems (3.9) and (5.1) will give us enough information for describing the set of eigenvalues and eigenfunctions to the third one. In the following theorem we completely characterize the spectrum of the above problems.

**Theorem 5.2.** Fix \(-1 < a < 1\). Then the following three assertions hold:

(i) The set of eigenvalues of the homogeneous Neumann problem (3.9) is

\[
\{\tilde{\kappa}_{n,m}\}_{n,m \in \mathbb{N}}, \quad \text{where } \tilde{\kappa}_{n,m} := \frac{n}{2} + m, \quad n, m \in \mathbb{N},
\]

with finite geometric multiplicity. For any \( n_0, m_0 \in \mathbb{N} \), the eigenspaces are given by

\[
V_{n_0, m_0} = \text{span} \left\{ V_{\alpha,m}(x, y) = H_{\alpha}(x)L_{(a-1)/2,m}(y^2/4) : (\alpha, m) \in \tilde{J}_0 \right\},
\]

where

\[
\tilde{J}_0 := \left\{ (\alpha, m) \in \mathbb{Z}_+^N \times \mathbb{N} : |\alpha| = n \in \mathbb{N} \text{ and } \tilde{\kappa}_{n,m} = \tilde{\kappa}_{n_0,m_0} \right\},
\]

while \( H_{\alpha}(\cdot) \) is a \( N \)-dimensional Hermite polynomial of order \( |\alpha| \), while \( L_{(a-1)/2,m}(\cdot) \) is the \( m \)-th Laguerre polynomial of order \( (a - 1)/2 \). Furthermore, the set of eigenfunctions \( \{V_{\alpha,m}\}_{\alpha,m} \) is an orthogonal basis of \( L^2(\mathbb{R}^{N+1}_+, d\mu) \).

(ii) The set of eigenvalues of the homogeneous Dirichlet problem (5.1) is

\[
\{\tilde{\kappa}_{n,m}\}_{n,m \in \mathbb{N}}, \quad \text{where } \tilde{\kappa}_{n,m} := \frac{n}{2} + m + \frac{1-a}{2}, \quad n, m \in \mathbb{N},
\]

with finite geometric multiplicity. For all \( n_0, m_0 \in \mathbb{N} \), the eigenspaces are given by

\[
V_{n_0, m_0} = \text{span} \left\{ V_{\alpha,m}(x, y) = H_{\alpha}(x)y^{1-a}L_{(1-a)/2,m}(y^2/4) : (\alpha, n) \in J_0 \right\},
\]

where

\[
\tilde{J}_0 := \left\{ (\alpha, m) \in \mathbb{Z}_+^N \times \mathbb{N} : |\alpha| = n \in \mathbb{N} \text{ and } \tilde{\kappa}_{n,m} = \tilde{\kappa}_{n_0,m_0} \right\},
\]

while now \( L_{(1-a)/2,m}(\cdot) \) is the \( m \)-th Laguerre polynomial of order \((1 - a)/2 \). Again, the set of eigenfunctions \( \{V_{\alpha,m}\}_{\alpha,m} \) is an orthogonal basis of \( L^2(\mathbb{R}^{N+1}_+, d\mu) \).

(iii) The set of eigenvalues of problem (5.2) is

\[
\{\kappa_{n,m}\}_{n,m \in \mathbb{N}} = \{\tilde{\kappa}_{n,m}\}_{n,m \in \mathbb{N}} \cup \{\tilde{\kappa}_{n,m}\}_{n,m \in \mathbb{N}},
\]
with finite geometric multiplicity (κ̃_{n,m} and ̂κ_{n,m} are defined in part (i) and (ii), respectively). For any n_0, m_0 ∈ \mathbb{N}, the eigenspaces corresponding to ̃κ_{n_0,m_0} and ̂κ_{n_0,m_0} are given by

\begin{align*}
\tilde{V}_{n_0,m_0} &= \text{span}\{\tilde{V}_{\alpha,m}(x,y) = H_\alpha(x)L_{(\frac{y}{2})^2}(y^2/4) : (\alpha,m) \in \tilde{J}_0\}, \\
\hat{V}_{n_0,m_0} &= \text{span}\{\hat{V}_{\alpha,m}(x,y) = H_\alpha(x)y|y|^{-a}L_{(\frac{y}{2})^2}(y^2/4) : (\alpha,m) \in \hat{J}_0\},
\end{align*}

respectively, where ̃J_0 and ̂J_0 are defined in part (i) and (ii), respectively. Finally, similarly to the previous cases, the set \{\tilde{V}_{\alpha,m}(x,y)\}_{(\alpha,m)} \cup \{\hat{V}_{\alpha,m}(x,y)\}_{(\alpha,m)} is an orthogonal basis of L^2(\mathbb{R}^{N+1},d\mu).

Note that part (i) of the above theorem coincides with the statement of Proposition 3.2. The proof is based on separation of variables together with some known results about Hermite and Laguerre polynomials (cfr. also with [32] from which we borrow some ideas) and will be crucial to characterize the blow-up profiles studied in the next chapter. Furthermore, we mention that we will obtain some Gaussian-Poincaré type inequalities as almost immediate consequences of this spectral analysis. This class of inequalities was known for a long time (cfr. with [9, 50]). However, since they will play an important role in the rest part of the work and we give versions of them with optimal constants, we have decided to devote to them an entire subsection.

In the spectral analysis of problems (3.9), (5.1), and (5.2), the following one-dimensional eigenvalue problem (where we set \psi' = d\psi/dy for simplicity)

\begin{equation}
- \frac{y^{-a}}{y^a G_{a+1}} (y^a \psi')' + \frac{y}{2} \psi' = \sigma \psi, \quad y > 0,
\end{equation}

which, similarly as before, is equivalent to

\begin{equation}
- \frac{1}{y^a G_{a+1}} (y^a \psi')' = \sigma \psi, \quad y > 0,
\end{equation}

will play an important role (here \(G_{a+1} = G_{a+1}(y) = G_a(0,y,1),\) cfr. with the introductions). This is due to the fact that the fundamental solution defines a probability measure that can be written as the product of two marginal measures, which are probabilities on the marginal spaces (cfr. with (2.21)), and the differential Ornstein-Uhlenbeck operators type, defined in (3.9), (5.1) and (5.2) possess a similar property (that we clarify later). For these reasons, we will devote an entire paragraph to the study of equation (5.7).

**Spectral analysis for equation (5.7).** As anticipated before, we now focus on equation (5.7). More precisely, we will obtain information about the following eigenvalue problems (corresponding to (3.9), (5.1) and (5.2)):

\begin{align*}
\begin{cases}
- y^{-a} (y^a \psi')' + \frac{y}{2} \psi' = \sigma \psi, & \text{for } y > 0, \\
- \partial_y \psi = 0 & \text{for } y = 0,
\end{cases}
\end{align*}

(5.9)

\begin{align*}
\begin{cases}
- y^{-a} (y^a \psi')' + \frac{y}{2} \psi' = \sigma \psi, & \text{for } y > 0, \\
\psi = 0 & \text{for } y = 0,
\end{cases}
\end{align*}

(5.10)

and

\begin{align*}
- |y|^{-a} (|y|^a \psi')' + \frac{y}{2} \psi' = \sigma \psi, & \text{for } y \neq 0.
\end{align*}

(5.11)

In the following definition, we introduce the concept of weak eigenfunction to (5.9), (5.10), and (5.11), respectively.
Definition 5.3. Again we proceed in three cases.

• A nontrivial function $\psi \in H^1(\mathbb{R}_+, d\mu_y)$ is said to be a weak eigenfunction to problem (5.9) with eigenvalue $\sigma \in \mathbb{R}$ if

\[
\int_{\mathbb{R}_+} \psi' \eta' \, d\mu_y = \sigma \int_{\mathbb{R}_+} \psi \eta \, d\mu_y, \quad \text{for all } \eta \in H^1(\mathbb{R}_+, d\mu_y).
\]

• A nontrivial function $\psi \in H^1_0(\mathbb{R}_+, d\mu_y)$ is said to be a weak eigenfunction to problem (5.10) with eigenvalue $\sigma \in \mathbb{R}$ if

\[
\int_{\mathbb{R}_+} \psi' \eta' \, d\mu_y = \sigma \int_{\mathbb{R}_+} \psi \eta \, d\mu_y, \quad \text{for all } \eta \in H^1_0(\mathbb{R}_+, d\mu_y).
\]

• A nontrivial function $\psi \in H^1(\mathbb{R}, d\mu_y)$ is said to be a weak eigenfunction to problem (5.11) with eigenvalue $\sigma \in \mathbb{R}$ if

\[
\int_{\mathbb{R}} \psi' \eta' \, d\mu_y = \sigma \int_{\mathbb{R}} \psi \eta \, d\mu_y, \quad \text{for all } \eta \in H^1(\mathbb{R}, d\mu_y).
\]

Note that in the previous definition we employ the probability measure $d\mu_y := G_{a+1}(y)\, dy$ in problems (5.12) and (5.13), while its even extension in (5.14) (cfr. with the introduction again).

We now carry out a detailed analysis of the spectrum of equation (5.7):

\[-y^{-a} (y^a \psi')' + \frac{y}{2} \psi' = \sigma \psi, \quad y > 0.
\]

In order to work in the framework as general as possible, we do not impose boundary conditions at $y = 0$ but only the following integrability conditions (which are necessary to have weak eigenfunctions)

\[
\int_0^\infty \psi^2(y) y^a e^{-\frac{y^2}{4}} \, dy < +\infty, \quad \int_0^\infty |\psi'(y)|^2 y^a e^{-\frac{y^2}{4}} \, dy < +\infty.
\]

Our procedure will naturally distinguish the solutions with Dirichlet and/or Neumann boundary conditions.

So, let us set $\psi(y) = \zeta(y^2/4)$. It is easily seen that the equation for $\zeta = \zeta(r), \ r = y^2/4$ is:

\[
r \frac{d^2 \zeta}{dr^2} + \left(1 + \frac{a-1}{2} - r\right) \frac{d\zeta}{dr} + \sigma \zeta = 0, \quad r > 0,
\]

which can be seen as a Kummer Confluent Hypergeometric type equation, with

\[
b_1 = -\sigma \quad \text{and} \quad b_2 = 1 + \frac{a-1}{2} = \frac{1+a}{2},
\]

and/or a Laguerre equation with

\[
\alpha = \frac{a-1}{2} > -1.
\]

A detail report about these topics is given in [1], see also the classical reference [64]. We know that all solutions are given by

\[
\zeta(r) = A_1 M\left(-\sigma, \frac{1+a}{2}, r\right) + A_2 \tilde{M}\left(-\sigma, \frac{1+a}{2}, r\right), \quad r > 0,
\]

where $A_1, A_2 \in \mathbb{R}$, and $M(\cdot, \cdot, \cdot)$ and $\tilde{M}(\cdot, \cdot, \cdot)$ are the Kummer and the Tricomi functions, as explained in the appendix mentioned above. We divide the analysis in three cases:
• Case $\sigma \in \mathbb{N}$. As explained in [64], when $\sigma = m \in \mathbb{N} = \{0, 1, \ldots\}$, then to each $\sigma = m$ it corresponds a unique solution (up to multiplicative constants) to (5.10) given by the $m$th Laguerre polynomial of order $(a - 1)/2$:

$$\zeta_m(r) = L_{(a - 1)/2,m}(r), \quad r > 0, \quad m \in \mathbb{N},$$

and so, for any $\sigma = m \in \mathbb{N}$, we obtain the solutions to (5.7), given by

$$(5.18) \quad \tilde{\psi}_m(y) = \tilde{A}_m \zeta_m \left(\frac{y^2}{4}\right) = \tilde{A}_m L_{(a - 1)/2,m} \left(\frac{y^2}{4}\right), \quad y > 0,$$

where $\tilde{A}_m$ is an arbitrary real constant. Note that since $\{L_{(a - 1)/2,m}\}_{m \in \mathbb{N}}$ is an orthogonal basis for the space

$$L^2(\mathbb{R}_+, dv) \quad \text{where} \quad dv(r) = r^{a-1} e^{-r} dr,$$

it is immediate to see that $\{\tilde{\psi}_m\}_{m \in \mathbb{N}}$ is an orthogonal basis for $L^2(\mathbb{R}_+, d\mu_y)$.

Similarly, one could have used formula (5.14) for the explicit expression of all solutions to (5.16) and note that for $\sigma = m \in \mathbb{N}$, we have

$$M \left(-m, \frac{1 + a}{2}, r\right) := \tilde{Q}_m(r) = \sum_{j=0}^{m} \frac{(-m)_j r^j}{(1 + a)_j j!}, \quad r > 0,$$

while (cfr. with formula 13.1.3 of [1])

$$\tilde{M} \left(-m, \frac{1 + a}{2}, r\right) = \frac{\pi}{\sin \left(\frac{1 + a}{2} \pi\right)} \left[ M \left(-m, \frac{1 + a}{2}, r\right) \frac{(-1)^a}{\Gamma(1 - m)} \right] = \frac{\Gamma(1 - m)}{\Gamma(1 + a)} \tilde{Q}_m(r), \quad r > 0,$$

where we have used the well-known properties of the Gamma function

$$\frac{1}{\Gamma(-z)} = 0, \quad z \in \mathbb{N} \quad \text{and} \quad \frac{\pi}{\sin (z \pi)} = \Gamma(1 - z) \Gamma(z), \quad z \not\in \mathbb{Z}.$$

Consequently, it follows an equivalent expression for $\tilde{\psi}_m = \tilde{\psi}_m(y)$ given by

$$\tilde{\psi}_m(y) = \tilde{A}_m \tilde{Q}_m \left(\frac{y^2}{4}\right) = \tilde{A}_m \sum_{j=0}^{m} \frac{(-m)_j y^{2j}}{(1 + a)_j j!}, \quad y > 0,$$

which is equivalent to the expression found in (5.18) in view of formula 22.5.54 of [1]. In what follows we will adopt the notation used in (5.18), but always keeping in mind that

$$L_{(a - 1)/2,m} \left(\frac{y^2}{4}\right) = \sum_{j=0}^{m} \frac{(-m)_j y^{2j}}{(1 + a)_j j!}, \quad y > 0,$$

up to a multiplicative constant.

• Case $\sigma \not\in \mathbb{N}$ but $\sigma = (1 - a)/2 \in \mathbb{N}$. If $\sigma = (1 - a)/2 + m$, $m \in \mathbb{N}$, it follows

$$\tilde{M} \left(-\sigma, \frac{1 + a}{2}, r\right) = \frac{\pi}{\sin \left(\frac{1 + a}{2} \pi\right)} \left[ M \left(-\sigma, \frac{1 + a}{2}, r\right) \frac{(-1)^a}{\Gamma(-m) \Gamma(1 + a)} \right] = -\frac{2\Gamma(1 + a)}{(1 - a) \Gamma(-\frac{1 - a}{2} - m)} \frac{(-1)^a}{\Gamma(-\frac{1 - a}{2})} \tilde{P}_m(r), \quad r > 0,$$
where we have employed again the properties of the Gamma function and we have defined

\[ \tilde{P}_m(r) = M\left(-m, 1 + \frac{1 - a}{2}, r\right) = \sum_{j=0}^{\infty} \frac{(-m)_j}{(1 + \frac{1-a}{2})_j j!} r^j, \quad r > 0. \]

On the other hand,

\[ M\left(-\sigma, \frac{1+a}{2}, r\right) = \sum_{j=0}^{\infty} \frac{(-\sigma)_j}{(1 + \frac{1-a}{2})_j j!} \frac{\Gamma\left(\frac{1+a}{2}\right)}{\Gamma(-\sigma)} e^{r - \sigma - \frac{1+a}{2}}, \quad r \sim +\infty, \]

since \( \sigma \not\in \mathbb{N} \) (cfr. with formula 13.1.4 of [1]). From the above asymptotic expansion for \( r \sim +\infty \), it is not difficult to see that the function

\[ y \rightarrow M\left(-\sigma, \frac{1+a}{2}, \frac{y^2}{4}\right) \]

does not satisfy the first bound in (5.15) and so, we have to take \( A_1 = 0 \). Consequently, for \( \sigma = (1-a)/2 + m, m \in \mathbb{N} \), we deduce that

\[ \zeta_{a,m}(r) = \tilde{A}_m r^{\frac{1-a}{2}} \tilde{P}_m(r) = \tilde{A}_m \sum_{j=0}^{\infty} \frac{(-m)_j}{(1 + \frac{1-a}{2})_j j!} r^{\frac{1-a}{2} + j}, \quad r > 0, \]

and so, coming back to the variable \( y \) (we recall that \( r = y^2/4 \)),

\[ \hat{\psi}_m(y) = \tilde{A}_m y^{1-a} \tilde{P}_m \left(\frac{y^2}{4}\right) = \tilde{A}_m \sum_{j=0}^{\infty} \frac{(-m)_j}{4 j!(1 + \frac{1-a}{2})_j} y^{1+2j-a}, \quad y > 0. \]

Exactly as before, we can recall formulas 13.5.6, 13.5.7, 13.5.8 of [1], to deduce \( \hat{L}_{(\frac{1-a}{2}),m}(r) = M(-m, 1 + \frac{1-a}{2}, r) = \tilde{P}_m(r) \) (up to a multiplicative constant), and so

(5.19)

\[ \hat{\psi}_m(y) = \tilde{A}_m y^{1-a} L_{(\frac{1-a}{2}),m} \left(\frac{y^2}{4}\right), \quad y > 0. \]

Again, since \( \{L_{(\frac{1-a}{2}),m}\}_{m \in \mathbb{N}} \) is an orthogonal basis for the space (note the difference in the measure \( \nu \) with respect to the previous case)

\[ L^2(\mathbb{R}_+, d\nu) \quad \text{where now} \quad d\nu(r) = r^{\frac{1-a}{2}} e^{-r} dr, \]

it follows again that \( \{\hat{\psi}_m\}_{m \in \mathbb{N}} \) is an orthogonal basis for \( L^2(\mathbb{R}_+, d\mu_y) \).

- **Case** \( \sigma \not\in \mathbb{N} \) and \( \sigma - (1-a)/2 \not\in \mathbb{N} \). Proceeding as before, we obtain

\[ \zeta(r) = \left(A_1 + \frac{\Gamma\left(\frac{1-a}{2}\right)}{\Gamma\left(\frac{1-a}{2} - \sigma\right) A_2}\right) \sum_{j=0}^{\infty} \frac{(-\sigma)_j}{(1+\frac{1-a}{2})_j j!} r^j - \frac{2\Gamma\left(\frac{1-a}{2}\right)}{(1-a)\Gamma(-\sigma)} A_2 r^{\frac{1-a}{2}} \sum_{j=0}^{\infty} \frac{(\frac{1-a}{2} - \sigma)_j}{(1+\frac{1-a}{2})_j j!} r^j, \]

and so, since the coefficient in front of the first series as to be zero (for the same reason of the above case), we deduce

\[ \zeta(r) = \frac{2\Gamma\left(\frac{1-a}{2}\right)\Gamma\left(\frac{1-a}{2} - \sigma\right)}{(1-a)\Gamma\left(\frac{1-a}{2}ight)\Gamma(-\sigma)} A_2 r^{\frac{1-a}{2}} \sum_{j=0}^{\infty} \frac{(\frac{1-a}{2} - \sigma)_j}{(1+\frac{1-a}{2})_j j!} r^j = \tilde{A}_2 r^{\frac{1-a}{2}} M\left(\frac{1-a}{2} - \sigma, 1 + \frac{1-a}{2}, r\right) \]

\[ \sim \frac{\Gamma\left(1 + \frac{1-a}{2}\right)}{\Gamma\left(\frac{1-a}{2} - \sigma\right)} A_2 e^r r^{-1-\sigma}, \quad r \sim +\infty. \]
Exactly as before, the above expansion for \( r \sim +\infty \) tells us that \( \psi(y) = \zeta(y^2/4) \) does not satisfies the first bound in (5.14) and so we to take \( A_2 = 0 \), i.e. \( A_2 = A_1 = 0 \).

- **Conclusions.** From the analysis carried out, it follows that the set of eigenvalues for equation (5.7) is given by 

\[
\{\tilde{\sigma}_m \}_{m \in \mathbb{N}} \cup \{\hat{\sigma}_m \}_{m \in \mathbb{N}} \quad \text{where} \quad \tilde{\sigma}_m = m, \quad \hat{\sigma}_m = \frac{1-a}{2} + m,
\]

and to the eigenvalue \( \tilde{\sigma}_m = m \) it corresponds (up to multiplicative constants) the eigenfunction 

\[
\tilde{\psi}_m(y) = \tilde{A}_m L_{(\frac{a-1}{2})_m} \left( \frac{y^2}{4} \right), \quad y > 0,
\]

where \( L_{(\frac{a-1}{2})_m}(\cdot) \) it the \( m^{th} \) Laguerre polynomial of order \( (a - 1)/2 \), whilst the eigenvalue \( \hat{\sigma}_m = (1-a)/2 + m \) possesses (up to multiplicative constants) the eigenfunction 

\[
\hat{\psi}_m(y) = y^{1-a} L_{(\frac{1-a}{2})_m} \left( \frac{y^2}{4} \right), \quad y > 0.
\]

We point out that the existence of two distinct orthogonal basis of eigenfunctions of \( L^2(\mathbb{R}_+, d\mu_y) \) comes from the fact that \( \{\tilde{\psi}_m \}_{m \in \mathbb{N}} \) and \( \{\hat{\psi}_m \}_{m \in \mathbb{N}} \) are solutions to different eigenvalue problems. Indeed, for all \( m \in \mathbb{N} \), we have 

\[
\tilde{\psi}_m(0) \neq 0 \quad \text{and} \quad \partial_y^\alpha \tilde{\psi}_m = 0,
\]

while 

\[
\hat{\psi}_m(0) = 0 \quad \text{and} \quad \partial_y^\alpha \hat{\psi}_m \neq 0,
\]

which mean that the functions \( \tilde{\psi}_m \) correspond to the eigenfunctions to equation (5.7) with homogeneous Neumann boundary condition at \( y = 0 \), i.e., to problem (5.5), while \( \hat{\psi}_m \) are the eigenfunctions to equation (5.7) with homogeneous Dirichlet boundary condition at \( y = 0 \), i.e., to problem (5.10). Note that it is not hard to verify that \( \tilde{\psi}_m \) and \( \hat{\psi}_m \) are weak eigenfunctions to (5.9) and (5.10), respectively, i.e. they satisfy (5.12) and (5.13), respectively. This easily follows by an integration by parts and noting that \( \psi_m \) and \( \psi_m \) satisfy both bounds in (5.15). We have thus showed the following lemma.

**Lemma 5.4.** Fix \(-1 < a < 1\). Then the following two assertions hold:

(i) The eigenvalues and the weak eigenfunctions to the homogeneous Neumann problem (5.9) are 

\[
\tilde{\sigma}_m = m \in \mathbb{N}, \quad \tilde{\psi}_m(y) = \tilde{A}_m L_{(\frac{a-1}{2})_m} \left( \frac{y^2}{4} \right), \quad y > 0,
\]

where \( \tilde{A}_m \in \mathbb{R} \) is arbitrary and \( L_{(\frac{a-1}{2})_m}(\cdot) \) is the \( m^{th} \) Laguerre polynomial of order \( (a - 1)/2 \).

(ii) The eigenvalues and the weak eigenfunctions to the homogeneous Dirichlet problem (5.10) are 

\[
\hat{\sigma}_m = \frac{1-a}{2} + m \in \mathbb{N}, \quad \hat{\psi}_m(y) = \hat{A}_m y^{1-a} L_{(\frac{1-a}{2})_m} \left( \frac{y^2}{4} \right), \quad y > 0,
\]

where \( \hat{A}_m \in \mathbb{R} \) is arbitrary and \( L_{(\frac{1-a}{2})_m}(\cdot) \) is the \( m^{th} \) Laguerre polynomial of order \( (1-a)/2 \). Finally, both sets \( \{\tilde{\psi}_m \}_{m \in \mathbb{N}} \) and \( \{\hat{\psi}_m \}_{m \in \mathbb{N}} \) are orthogonal basis of \( L^2(\mathbb{R}_+, d\mu_y) \).

Let us now consider equation (5.11):

\[
-|y|^{-a} (|y|^a \psi')' + \frac{y}{2} \psi' = \sigma \psi, \quad y \neq 0.
\]
We begin our analysis by noting that if \( \psi = \psi(y) \) is a weak eigenfunction to equation (5.11), then \( \hat{\psi}(y) = \psi(-y) \) is a weak eigenfunction too, and so are all their linear combinations. Consequently, it suffices to consider solutions \( \psi^+ = \psi^+(y) \) to equation (5.7) (already analyzed before) and then using their reflections (with respect to \( y = 0 \)) to obtain all solutions to (5.11) defined for all \( y \in \mathbb{R} \).

From the analysis carried out in the proof of Lemma 5.4, we that the only admissible values for \( \sigma \) are

\[
\tilde{\sigma}_m := m \quad \text{with eigenfunctions} \quad \tilde{\psi}^+_m(y) = \tilde{A}_m L_{(\frac{a-1}{2}),m} \left( \frac{y^2}{4} \right), \quad m \in \mathbb{N},
\]
defined for all \( y > 0 \), satisfying \( \partial^a_y \psi^+_m = 0 \) and both bounds in (5.15), and

\[
\tilde{\sigma}_m := 1 - \frac{a}{2} + m \quad \text{with eigenfunctions} \quad \tilde{\psi}^+_m(y) = \tilde{A}_m y^{1-a} L_{(\frac{1-a}{2}),m} \left( \frac{y^2}{4} \right), \quad m \in \mathbb{N},
\]
defined for all \( y > 0 \), satisfying \( \tilde{\psi}^+_m(0) = 0 \) and both bounds in (5.15). As always \( \tilde{A}_m \in \mathbb{R} \) and \( m \in \mathbb{N} \).

We begin by focusing on \( \psi^+_m = \psi^+_m(y) \). Clearly, there are two different ways to build a solution to equation (5.11) with \( \sigma = \tilde{\sigma}_m \), through reflection methods. We can consider both odd and even extensions:

\[
(5.20) \quad \tilde{\psi}^o_m(y) := \begin{cases} \tilde{\psi}^+_m(y) & \text{if } y \geq 0 \\ -\tilde{\psi}^+_m(|y|) & \text{if } y < 0, \end{cases} \quad \tilde{\psi}^e_m(y) := \begin{cases} \tilde{\psi}^+_m(y) & \text{if } y \geq 0 \\ \tilde{\psi}^+_m(|y|) & \text{if } y < 0. \end{cases}
\]

Note that both \( \tilde{\psi}^o_m \) and \( \tilde{\psi}^e_m \) satisfy both bounds in (5.15) (this follows from the analysis done above). However, it is not difficult to see that the even extension (the second formula in (5.20)) produces a candidate eigenfunction \( \tilde{\psi}^e_m = \tilde{\psi}^e_m(y) \) which is not a weak eigenfunction to problem (5.2), i.e., it does not satisfy (5.21).

Indeed, using the equation of \( \tilde{\psi}^e_m = \tilde{\psi}^e_m(y) \) it is not hard to show that

\[
(5.21) \quad \int_{\mathbb{R}} (\tilde{\psi}^e_m)' \eta' \, d\mu_y = \tilde{\sigma}_m \int_{\mathbb{R}} \tilde{\psi}^e_m \eta \, d\mu_y - 2(1-a)\eta(0), \quad \text{for all } \eta \in H^1(\mathbb{R}, d\mu_y),
\]

where we recall that \( d\mu_y := |y|^a G_{a+1}(y)dy \). On the other hand, repeating the same procedure for the odd extension \( \tilde{\psi}^o_m = \tilde{\psi}^o_m(y) \), we obtain that (5.21) holds for \( \tilde{\psi}^o_m \) without the extra term \( 2(1-a)\eta(0) \) (it cancels thanks to the oddness of \( \tilde{\psi}^o_m \)), and so \( \tilde{\psi}^o_m = \tilde{\psi}^o_m(y) \) is an eigenfunction associated to the eigenvalue \( \tilde{\sigma}_m \).

Repeating the same procedure for \( \tilde{\psi}^+_m = \tilde{\psi}^+_m(y) \) it is easily seen that its even reflection is a weak eigenfunction corresponding to the eigenvalue \( \tilde{\sigma}_m = m \), while its odd extension cannot be a weak eigenfunction since it has a jump discontinuity at \( y = 0 \).

Consequently, we can conclude that problem (5.11) has eigenvalues and corresponding weak eigenfunctions defined by

\[
\tilde{\sigma}_m := m \quad \tilde{\psi}^o_m(y) = \tilde{A}_m L_{(\frac{a-1}{2}),m} \left( \frac{y^2}{4} \right), \quad m \in \mathbb{N},
\]

\[
\tilde{\sigma}_m := 1 - \frac{a}{2} + m \quad \tilde{\psi}^o_m(y) = \tilde{A}_m y^{1-a} L_{(\frac{1-a}{2}),m} \left( \frac{y^2}{4} \right), \quad m \in \mathbb{N},
\]
defined for all \( y \in \mathbb{R} \). We stress that, using the parity and the oddness of \( \tilde{\psi}^o_m = \tilde{\psi}^o_m(y) \) and \( \tilde{\psi}^e_m = \tilde{\psi}^e_m(y) \), respectively, we immediately see that (up to multiplicative constants)

\[
\int_{\mathbb{R}} \tilde{\psi}^o_m(y) \tilde{\psi}^o_n(y) \, d\mu_y = \int_{\mathbb{R}} \tilde{\psi}^o_m(y) \tilde{\psi}^e_n(y) \, d\mu_y = \delta_{m,n} \quad \text{for all } m, n \in \mathbb{N},
\]
where
\[ \int_{\mathbb{R}} \tilde{\psi}_m(y) \tilde{\psi}_n(y) d\mu_y = 0 \quad \text{for all } m, n \in \mathbb{N}, \]
so that it follows that the family \( \{ \psi_m \}_{m \in \mathbb{N}} \cup \{ \tilde{\psi}_m \}_{m \in \mathbb{N}} \) is an orthogonal set of \( L^2(\mathbb{R}, d\mu_y) \). The fact that
the family \( \{ \psi_m \}_{m \in \mathbb{N}} \cup \{ \tilde{\psi}_m \}_{m \in \mathbb{N}} \) is a basis of \( L^2(\mathbb{R}, d\mu_y) \) follows since both \( \{ \psi_m \}_{m \in \mathbb{N}} \) and \( \{ \tilde{\psi}_m \}_{m \in \mathbb{N}} \) are orthogonal basis of \( L^2(\mathbb{R}_+, d\mu_y) \). We thus have proved the following lemma.

**Lemma 5.5.** Fix \(-1 < a < 1\). Then the set of eigenvalues of problem \((5.11)\) is
\[ \{ \sigma_{\tilde{m}} \}_{m \in \mathbb{N}} \cup \{ \tilde{\sigma}_m \}_{m \in \mathbb{N}}, \]
where \( \tilde{\sigma}_m \) and \( \tilde{\sigma}_m \) correspond to the eigenvalues of the Neumann problem \((5.9)\) and of the Dirichlet on \((5.10)\), respectively, and are defined in Lemma \(5.4\). Moreover, the eigenfunctions corresponding to \( \tilde{\sigma}_m \) are
\[ \tilde{\psi}_m(y) = \tilde{A}_m L_{(a-1)/2}(y^2/4), \quad y \in \mathbb{R}, \]
where \( \tilde{A}_m \in \mathbb{R} \) is arbitrary and \( L_{(a-1)/2}(\cdot) \) is the \( m \)-th Laguerre polynomial of order \( (a-1)/2 \), while the eigenfunctions corresponding to \( \tilde{\sigma}_m \) are
\[ \tilde{\psi}_m(y) = \tilde{A}_m y|y|^a L_{(1-a)/2}(y^2/4), \quad y \in \mathbb{R}, \]
where \( \tilde{A}_m \in \mathbb{R} \) is arbitrary and \( L_{(1-a)/2}(\cdot) \) is the \( m \)-th Laguerre polynomial of order \( (1-a)/2 \). Finally, the set \( \{ \tilde{\psi}_m \}_{m \in \mathbb{N}} \cup \{ \tilde{\psi}_m \}_{m \in \mathbb{N}} \) is an orthogonal basis of \( L^2(\mathbb{R}, d\mu_y) \).

**End of the proof of Theorem 5.2.** We begin by proving part (i) and (ii). We look for solutions to problems \((3.9)\) and/or \((5.1)\) in separate variables form \( V(x, y) = \varphi(x)\psi(y) \), \( x \in \mathbb{R}^N, y > 0 \). So, substituting into \((3.9)\) and/or \((5.1)\), it is not difficult to see that
\[ (-\Delta_x \varphi + \frac{x}{2} \cdot \nabla_x \varphi) \psi + \left[ -y^{-a} (y^a \psi')' + \frac{y}{2} \psi' \right] \varphi = \kappa \varphi \psi \quad \text{in } \mathbb{R}^{N+1}_+, \]
where, as always, \( \psi' = d\psi/dy \). Hence, we recover the eigenvalue \( \kappa \in \mathbb{R} \) as the sum of \( \nu \in \mathbb{R} \) and \( \sigma \in \mathbb{R} \) eigenvalues to
\[(5.22)\]
\[ -\Delta_x \varphi + \frac{x}{2} \cdot \nabla_x \varphi = \nu \varphi, \quad x \in \mathbb{R}^N \]
and equation \((5.7)\):
\[ -y^{-a} (y^a \psi')' + \frac{y}{2} \psi' = \sigma \psi, \quad y > 0, \]
respectively.

**Step 1: Analysis of \((5.22)\).** Evidently \((5.22)\) is the classical Ornstein-Uhlenbeck eigenvalue problem in the all Euclidean space. It possesses the sequence of eigenvalues
\[ \nu_n = \frac{n}{2}, \quad n \in \mathbb{N} = \{0, 1, \ldots\}, \]
and an eigenfunction basis composed by the so-called Hermite polynomials
\[ H_\alpha(x) = H_{n_1}(x_1) \ldots H_{n_N}(x_N), \quad x = (x_1, \ldots, x_N) \in \mathbb{R}^N, \]
where \( \alpha = (n_1, \ldots, n_N) \in \mathbb{Z}_{\geq 0}^N \) and \( H_{n_j}(\cdot), j = 1, \ldots, N, \) is the \( n_j \)-th 1 dimensional Hermite polynomial (cfr. with \([11][63][70]\)).
Immediate applications: some Gaussian-Poincaré type inequalities. This follows exactly as before. □

Lemma 5.5), where, as always, provides a basis of eigenfunctions \( \{ \psi_{\alpha,m} \}_{\alpha,m} \) which completely characterizes the spectrum of the above equation. In particular, it where the above equation is intended in the weak sense (cfr. with Definition 5.3) and we have proved stressing that the family exactly as before, but in this case we apply Lemma 5.5 instead of Lemma 5.4. We end the proof by Since the analysis of the above equation has already been done, we deduce part (iii) of Theorem 5.2 in the previous section. We end the paragraph by stressing that these kind of inequalities have a self

and for any \( \psi \in H^1(\mathbb{R}, d\mu_y) \), where \( \{\sigma_m\}_{m \in \mathbb{N}} = \{\tilde{\sigma}_m\}_{m \in \mathbb{N}} \cup \{\tilde{\sigma}_m\}_{m \in \mathbb{N}} \) (as in Lemma 5.5). From the above integral characterization, we easily deduce

\[
\int_{\mathbb{R}} \psi'_m \psi'_n d\mu_y = \sigma_m \int_{\mathbb{R}} \psi_m \psi_n d\mu_y = \sigma_m \delta_{m,n}, \quad \text{for all } m, n \in \mathbb{N},
\]

up to normalization, thanks to the \( L^2(\mathbb{R}, d\mu_y) \)-orthogonality of the eigenfunctions (\( \delta_{n,m} \) denotes the Kronecker delta). This means that not only the eigenfunctions \( \psi_m = \psi_m(y) \) are orthogonal in \( L^2(\mathbb{R}, d\mu_y) \), but also in \( H^1(\mathbb{R}, d\mu_y) \). We end this paragraph by recalling that the space \( L^2(\mathbb{R}, d\mu_y) \) is the closure of the space \( C_c(\mathbb{R}) \) with respect to the norm

\[
\|\psi\|_{L^2_y}^2 := \int_{\mathbb{R}} \psi^2(y) d\mu_y,
\]

while \( H^1(\mathbb{R}, d\mu_y) \) is the closure of the same space but with respect to the norm

\[
\|\psi\|_{H^1_y}^2 := \int_{\mathbb{R}} \psi^2(y) d\mu_y + \int_{\mathbb{R}} (\psi')^2(y) d\mu_y.
\]

A natural consequence of the spectral analysis is the following Gaussian Poincaré type inequality.

**Lemma 5.6.** The following three statements hold:

(i) For any \( \psi \in H^1(\mathbb{R}, d\mu_y) \), it holds

\[
\int_{\mathbb{R}} \psi^2 d\mu_y - \left( \int_{\mathbb{R}} \psi d\mu_y \right)^2 \leq \frac{2}{1-a} \int_{\mathbb{R}} (\psi')^2 d\mu_y.
\]

Furthermore, the equality is attained if and only if \( \psi(y) = A \) or \( \psi(y) = Ay|y|^{-a}, A \in \mathbb{R} \).

(ii) For any \( \psi \in H^1_0(\mathbb{R}_+, d\mu_y) \), it holds

\[
\int_{\mathbb{R}_+} \psi^2 d\mu_y - \left( \int_{\mathbb{R}_+} \psi d\mu_y \right)^2 \leq \frac{2}{1-a} \int_{\mathbb{R}_+} (\psi')^2 d\mu_y.
\]

Furthermore, the equality is attained if and only if \( \psi(y) = A \) or \( \psi(y) = Ay^{1-a}, A \in \mathbb{R} \).

(iii) For any \( \psi \in H^1(\mathbb{R}_+, d\mu_y) \), it holds

\[
\int_{\mathbb{R}_+} \psi^2 d\mu_y - \left( \int_{\mathbb{R}_+} \psi d\mu_y \right)^2 \leq \int_{\mathbb{R}_+} (\psi')^2 d\mu_y.
\]

Furthermore, the equality is attained if and only if \( \psi(y) = A \) or \( \psi(y) = A(1 - \frac{1-a}{2} - \frac{\psi^2}{4}), A \in \mathbb{R} \).

**Proof.** Take \( \psi \in H^1(\mathbb{R}, d\mu_y) \) with \( \overline{\psi} := \int_{\mathbb{R}} \psi d\mu_y \), and consider \( \Psi_M := \sum_{m=1}^M c_m \psi_m \) such that

\[
\Psi_M \rightarrow \psi - \overline{\psi} \quad \text{in } L^2(\mathbb{R}, d\mu_y),
\]

where, of course, \( c_m := \int_{\mathbb{R}} \psi \psi_m d\mu_y \). Note that the sum \( \Psi_M \) starts from the first nonconstant eigenfunction, since \( \psi - \overline{\psi} \) is orthogonal to the eigenspace generated by the constants. Now, using the definition of weak eigenfunction and the orthogonality condition in (5.23), it is not difficult to see that

\[
\int_{\mathbb{R}} (\Psi'_M)^2 d\mu_y = \int_{\mathbb{R}} \Psi'_M \psi' d\mu_y \quad \text{for all } M \in \mathbb{N}_0,
\]

i.e. \( \Psi'_M \) and \( \Psi'_M - \psi' \) are orthogonal in \( L^2(\mathbb{R}, d\mu_y) \). Consequently, we have

\[
0 \leq \int_{\mathbb{R}} (\psi' - \Psi'_M)^2 d\mu_y = \int_{\mathbb{R}} (\psi')^2 d\mu_y - 2 \int_{\mathbb{R}} \Psi'_M \psi' d\mu_y + \int_{\mathbb{R}} (\Psi'_M)^2 d\mu_y = \int_{\mathbb{R}} (\psi')^2 d\mu_y - \int_{\mathbb{R}} (\Psi'_M)^2 d\mu_y,
\]
and so \( \int_{\mathbb{R}} (\Psi'_M)^2 d\mu_y \leq \int_{\mathbb{R}} (\psi')^2 d\mu_y < +\infty \), uniformly in \( M \in \mathbb{N}_0 \) (note that here we have used the fact that \( \psi \in H^1(\mathbb{R}, d\mu_y) \)). Finally, from the above bound and employing (5.23) again, we have
\[
\int_{\mathbb{R}} (\psi')^2 d\mu_y = \sum_{m=1}^{M} \sigma_m c_m^2 \int_{\mathbb{R}} \psi_m^2 d\mu_y = \sum_{m=1}^{M} \sigma_m c_m^2 \int_{\mathbb{R}} \psi_m^2 d\mu_y \leq \sigma \int_{\mathbb{R}} \Psi_M^2 d\mu_y,
\]
where we have set \( \sigma : = \min_{m \in \mathbb{N}_0} \{\sigma_m\} = \hat{\sigma}_0 = (1 - a)/2 \). Consequently, passing to the limit as \( M \to +\infty \), we deduce
\[
\int_{\mathbb{R}} (\psi')^2 d\mu_y \geq \int_{\mathbb{R}} (\psi - \bar{\psi})^2 d\mu_y = \int_{\mathbb{R}} \psi^2 d\mu_y - \left( \int_{\mathbb{R}} \psi d\mu_y \right)^2,
\]
obtaining the desired inequality. The last part of the statement follows from the fact that \( \psi(y) = Ay/|y|^{a-1} \) is the first nonconstant eigenfunction to problem (5.11) (with eigenvalue \( \hat{\sigma}_0 = (1 - a)/2 \)).

The proof of (ii) and (iii) is very similar to the one of part (i) and we omit it (note that we just have to use the bases of eigenfunctions \( \{\bar{\psi}_m\}_{m \in \mathbb{N}} \) for (ii) and \( \{\bar{\psi}_m\}_{m \in \mathbb{N}} \) for (iii), instead of \( \{\psi_m\}_{m \in \mathbb{N}} \). We just mention that in (ii) we work with the space \( H^1_0(\mathbb{R}, d\mu_y) \) which does not contain constant functions different from the trivial one (this is the reason because we do not need to employ the average of \( \psi \) in Gaussian Poincaré inequality), while in (iii) it is easily seen that the first nonconstant eigenfunction \( \psi(y) = A(1 - \frac{x^2}{2} - \frac{y^2}{4}) \), \( A \in \mathbb{R} \) has zero mean (with respect to the measure \( d\mu_y \)). Note that since we are now working with functions defined for \( y > 0 \), the normalization constant of the probability measure \( d\mu_y \) is different from the one of Lemma 5.6 (cfr. with the introduction). \( \Box \)

5.3. \((N+1)\text{-dimensional Gaussian Poincaré inequality.} \) For the general case, we proceed as before. We consider problem (5.2):
\[-L_\alpha V + \frac{(x, y)}{2} \cdot \nabla V = \kappa V \quad \text{in } \mathbb{R}^{N+1}.
\]
From Theorem 5.2 we know that it has the set of eigenvalues \( \{\kappa_{n,m}\}_{n, m \in \mathbb{N}} = \{\tilde{\kappa}_{n,m}\}_{n, m \in \mathbb{N}} \cup \{\kappa_{n,m}\}_{n, m \in \mathbb{N}} \) where
\[
\tilde{\kappa}_{n,m} := \frac{n}{2} + m, \quad \kappa_{n,m} := \frac{n}{2} + m + \frac{1 - a}{2} \quad \text{for all } n, m \in \mathbb{N},
\]
while the set of eigenfunctions is \( \{V_{\alpha,m}\}_{(\alpha, m)} = \{\tilde{V}_{\alpha,m}\}_{(\alpha, m)} \cup \{V_{\alpha,m}\}_{(\alpha, m)}, \) where the eigenfunctions can be of two types
\[
\tilde{V}_{\alpha,m}(x, y) = H_\alpha(x)\tilde{\psi}_m(y), \quad \tilde{V}_{\alpha,m}(x, y) = H_\alpha(x)\tilde{\psi}_m(y), \quad \text{for all } (\alpha, m) \in \mathbb{Z}_{\geq 0}^N \times \mathbb{N},
\]
where as before \( \tilde{\psi}_m(y) = L_{\frac{a-1}{2}, m}(y^2/4) \) and \( \tilde{\psi}_m(y) = y_0 y_{1}^{a} L_{\frac{a-1}{2}, m}(y^{2}/4) \) and \( H_\alpha(\cdot) \) is a \( N \)-dimensional Hermite polynomial of order \( |\alpha| \). We recall that similarly to the 1-dimensional case the set \( \{V_{\alpha,m}\}_{(\alpha, m)} \) is an orthogonal basis of \( L^2(\mathbb{R}^{N+1}, d\mu) \), where
\[
d\mu(x, y) = \frac{1}{2^{1+a} \Gamma(\frac{1+a}{2})(4\pi)^{N/2}} |y|^a e^{-\frac{|x|^2+|y|^2}{4}} \, dx \, dy.
\]
Since the sets of eigenvalues and eigenfunctions are countable, we can drop one index and denote by \( \kappa_j \) the \( j \)-th eigenvalue with corresponding eigenfunctions \( V_j, j \in \mathbb{N} \). In this setting, we have that the
first nonzero eigenvalue depends on the parameter $-1 < a < 1$:

$$\nu_* := \min_{j \in \mathbb{N}} \{ \kappa_j \neq 0 \} = \frac{1}{2} \min \{ 1, 1 - a \}.$$ 

This is the unique remarkable difference with respect to the 1-dimensional case. We thus have the following theorem.

**Theorem 5.7.** The following three statements hold:

(i) For any $V \in H^1(\mathbb{R}^{N+1}, d\mu)$, it holds

$$\int_{\mathbb{R}^{N+1}} V^2 d\mu - \left( \int_{\mathbb{R}^{N+1}} V d\mu \right)^2 \leq P_a \int_{\mathbb{R}^{N+1}} |\nabla V|^2 d\mu,$$

where $P_a := 1/\nu_* = 2/\min \{ 1, 1 - a \}$. Furthermore, the equality is attained if and only if $V(x, y) = A$ or, depending on $-1 < a < 1$:

$$V(x, y) = \begin{cases} Ax_j & \text{if } a < 0 \text{ for some } j \in \{ 1, \ldots, N \} \\ Ax_j & \text{if } a = 0 \text{ for some } j \in \{ 1, \ldots, N + 1 \} \\ Ay|y|^{-a} & \text{if } a > 0, \end{cases}$$

where $A \in \mathbb{R}$ and we have used the convention $x_{N+1} = y$.

(ii) For any $V \in H^1_0(\mathbb{R}^{N+1}, d\mu)$, it holds

$$\int_{\mathbb{R}_+^{N+1}} V^2 d\mu \leq \frac{2}{1 - a} \int_{\mathbb{R}_+^{N+1}} |\nabla V|^2 d\mu.$$

Furthermore, the equality is attained if and only if $V(x, y) = Ay^{1-a}$, $A \in \mathbb{R}$.

(iii) For any $V \in H^1(\mathbb{R}_+^{N+1}, d\mu)$, it holds

$$\int_{\mathbb{R}_+^{N+1}} V^2 d\mu - \left( \int_{\mathbb{R}_+^{N+1}} V d\mu \right)^2 \leq 2 \int_{\mathbb{R}_+^{N+1}} |\nabla V|^2 d\mu.$$

Furthermore, the equality is attained if and only if $V(x, y) = A$ or $V(x, y) = Ax_j$, for some $j \in \{ 1, \ldots, N \}$ and $A \in \mathbb{R}$.

**Remark 5.8.** Note that, since the Gaussian-Poincaré constants do not depend on the spacial dimension $N$, they can be extended to infinite dimensional spaces (cfr. with Beckner [10]).

**Proof.** We begin by proving part (i), following the ideas of the case $N = 1$. Take $V \in H^1(\mathbb{R}^{N+1}, d\mu)$ with $\overline{V} := \int_{\mathbb{R}^{N+1}} V d\mu$, and we approximate it with the sequence $\Psi_J := \sum_{j=1}^{J} c_j V_j$ such that

$$\Psi_J \to V - \overline{V} \quad \text{in } L^2(\mathbb{R}^{N+1}, d\mu), \quad c_j := \int_{\mathbb{R}^{N+1}} V_j V d\mu.$$ 

Proceeding as before, we easily find that

$$\int_{\mathbb{R}^{N+1}} |\nabla \Psi_J|^2 d\mu = \int_{\mathbb{R}^{N+1}} \nabla \Psi_J \nabla V d\mu \quad \text{for all } J \in \mathbb{N}_0,$$
and so \( \int_{\mathbb{R}^{N+1}} |\nabla \Psi_j|^2 \, d\mu \leq \int_{\mathbb{R}^{N+1}} |\nabla V|^2 \, d\mu. \) Hence,

\[
\int_{\mathbb{R}^{N+1}} |\nabla V|^2 \, d\mu \geq \int_{\mathbb{R}^{N+1}} |\nabla \Psi_j|^2 \, d\mu = \sum_{j=1}^J c_j^2 \int_{\mathbb{R}^{N+1}} |\nabla V_j|^2 \, d\mu = \sum_{j=1}^J \sigma_j c_j^2 \int_{\mathbb{R}^{N+1}} V_j^2 \, d\mu \geq \nu_* \sum_{j=1}^J c_j^2 \int_{\mathbb{R}^{N+1}} V_j^2 \, d\mu = \nu_* \int_{\mathbb{R}^{N+1}} \Psi_j^2 \, d\mu,
\]

where now the minimum of the eigenvalues \( \nu_* := \min_j \{ \kappa_j \neq 0 \} = \min \{1, 1 - a\}/2 \). Passing to the limit as \( J \to \infty \) we obtain the inequality of statement (i).

To prove the second part of the statement, let us firstly fix \(-1 < a < 0\). In this case we have \( \nu_* = 1/2 \) and the corresponding eigenfunctions are \( V(x, y) = Ax_j \) for \( j \in \{1, \ldots, N\} \). We thus conclude by the definition of weak eigenfunction and the fact that \( V(x, y) = Ax_j \) has mean zero for any \( j \in \{1, \ldots, N\} \) (with respect to the measure \( d\mu \)). Similarly, if \( 0 < a < 1 \) it turns out that \( \nu_* = (1 - a)/2 \) and the corresponding eigenfunctions are \( V(x, y) = Ay \) for (also in this case they have mean zero). Finally, if \( a = 0 \) we have \( \nu_* = 1/2 \) and the eigenfunctions are \( V(x, y) = Ax_j \) for \( j \in \{1, \ldots, N\} \) and \( V(x, y) = Ay \) (note that we get back the classical statement, cfr. for instance with [10]). This conclude the proof of part (i).

To prove part (ii) and (iii) we employ the bases of eigenfunctions \( \{ \hat{V}_j \}_j = \{ \hat{V}_{(a,m)} \}_{(a,m)} \) for (ii) and \( \{ \tilde{V}_j \}_j = \{ \tilde{V}_{(a,m)} \}_{(a,m)} \) for (iii), instead of \( \{ V_j \}_j = \{ V_{(a,m)} \}_{(a,m)} \). Note that compared with the proof of Lemma 5.6, the first eigenvalue to the Neumann problem (5.1) is \( \nu_* = 1/2 \) with corresponding eigenfunctions \( V(x, y) = Ax_j \) for \( j \in \{1, \ldots, N\} \).

6. Blow-up analysis I: proof of Theorem 3.3

In this chapter the blow-up procedure begins and we prove a first blow-up classification result which is a generalization Theorem 3.3. We focus on the study of the asymptotic behaviour as \( \lambda \to 0^+ \) of the normalized blow-up family

\[
U_{p_0, \lambda}(x, y, t) := \frac{U_{p_0}(\lambda x, \lambda y, \lambda^2 t)}{\sqrt{H(\lambda^2, U_{p_0})}}, \quad \lambda > 0,
\]

defined in (3.10), where \( p_0 = (x_0, 0, t_0) \in \Gamma(U) \) and \( H(\cdot, U) \) is defined in (3.2). In this analysis the parabolically homogeneous profiles studied in Proposition 3.2 and the decomposition of the space \( L^2(\mathbb{R}^{N+1}, d\mu) \) in orthogonal eigenfunctions play a crucial role.

**Theorem 6.1.** Fix \(-1 < a < 1\), \( p_0 = (x_0, 0, t_0) \in \Gamma(U) \cap \Sigma, \) and let \( U = U(x, y, t) \) be a nontrivial strong solution to equation (2.1). Then there exist \( n_0, m_0 \in \mathbb{N} \) such that the following assertions hold:

(i) The Almgren-Poon quotient \( N(t, U_{p_0}) \) (cfr. with the formula in (4.4)) satisfies

\[
\lim_{t \to 0^+} N(t, U_{p_0}) = \kappa_{n_0, m_0},
\]

where the admissible values for \( \kappa_{n,m} \) are

\[
\kappa_{n,m} = \tilde{\kappa}_{n,m} := \frac{n}{2} + m \quad \text{and} \quad \kappa_{n,m} = \tilde{\kappa}_{n,m} := \frac{n}{2} + m + \frac{1 - a}{2},
\]

are the eigenvalues of problem (5.2), for any \( m, n \in \mathbb{N} \).

(ii) There exists a constant \( L_0 > 0 \) (depending on \( p_0 \) and \( U \)), such that

\[
\lim_{\tau \to t_0^+} \tau^{-2\kappa_{n_0, m_0}} H(t, U_{p_0}) = L_0,
\]

where
where the function \( t \to H(t, U_{p_0}) \) is the denominator of the Almgren-Poon quotient.

(iii) For all \( T_* > 0 \), the following convergence holds true
\[
U_{p_0, \lambda} \to \Theta_{p_0} \quad \text{in } L^2(0, T_*; H^1(\mathbb{R}^{N+1}, d\mu_t)) \cap C^0(0, T_*; L^2(\mathbb{R}^{N+1}, d\mu_t)),
\]
as \( \lambda \to 0^+ \), i.e.:
\[
(6.2) \lim_{\lambda \to 0^+} \int_0^{T_*} \| U_{p_0, \lambda} - \Theta_{p_0} \|_{H^1_{\mu t}}^2 \, dt = \lim_{\lambda \to 0^+} \sup_{t \in [0, T_*]} \| U_{p_0, \lambda} - \Theta_{p_0} \|_{L^2_{\mu t}}^2 = 0,
\]
where
\[
\Theta_{p_0}(x, y, t) := t^{\kappa_{n_0, m_0}} \sum_{(\alpha, m) \in J_0} v_{\alpha, m} \nabla_{\alpha, m} \left( \frac{x}{\sqrt{t}}, \frac{y}{\sqrt{t}} \right),
\]
where \( v_{\alpha, m} \) are suitable constants, the sum is done over the set of indices
\[
J_0 := \{ (\alpha, m) \in \mathbb{Z}_{\geq 0}^N \times \mathbb{N} : |\alpha| = n \in \mathbb{N} \text{ and } \kappa_{n, m} = \kappa_{n_0, m_0} \},
\]
and the integration probability measure is defined in (224). Moreover,
\[
\nabla_{\alpha, m}(x, y) := \frac{V_{\alpha, m}(x, y)}{\| V_{\alpha, m} \|_{L^2_{\mu}}}, \quad \alpha \in \mathbb{Z}_{\geq 0}^N, \ m \in \mathbb{N},
\]
are the normalized versions of the eigenfunctions \( V_{\alpha, m} = V_{\alpha, m}(x, y) \) to problem (5.2) corresponding to the eigenvalue \( \kappa_{n, m} \) and defined in the statement of Theorem 5.2.

As the reader can easily guess, we will obtain the statement of Theorem 3.3 with minor changes. Following some ideas of \cite{32}, our approach is based on the monotonicity formulas obtained in Section 4 and a priori compactness results in \( C^0(0, T_*; L^2(\mathbb{R}^{N+1}, d\mu_t)) \) type spaces where \( 0 < t_1 < t_2 < \infty \) and \( B \) is a Banach space (see \cite{10} or Lemma 6.2). Compared with Section 7 of \cite{32} and \cite{24}, where the authors considered averaged versions of \( H(t, U) \) and \( I(t, U) \) (cfr. with Section 3), our methods are possibly naiver but suffice for our purposes. All the proof relies on the following compactness criterion that we recall for clarity.

Lemma 6.2. (Simon \cite{60} Corollary 8) Let \( X \subseteq B \subseteq Y \) be Banach spaces satisfying the following two properties:

- \( X \) is compactly embedded in \( Y \).
- There exist \( 0 < \theta < 1 \) and \( C > 0 \) such that \( \| V \|_B \leq C \| V \|_X^{1-\theta} \| V \|_Y^{\theta} \), for all \( V \in X \cap Y \).

Fix \(-\infty < t_1 < t_2 < +\infty \) and \( 1 \leq p, r \leq \infty \). Let \( \mathcal{F} \) be a bounded family in \( L^p(t_1, t_2; X) \), with \( \partial \mathcal{F}/\partial t \) bounded in \( L^r(t_1, t_2; Y) \). Then the following two assertions hold true:

- If \( \theta(1 - 1/r) \leq (1 - \theta)/p \) then \( \mathcal{F} \) is relatively compact in \( L^p(t_1, t_2; B) \), for all \( p < p_* \), where \( 1/p_* = (1 - \theta)/p - \theta(1 - 1/r) \).
- If \( \theta(1 - 1/r) > (1 - \theta)/p \) then \( \mathcal{F} \) is relatively compact in \( C^0(t_1, t_2; B) \), where we recall that \( C^0(t_1, t_2; B) := \{ V : [t_1, t_2] \to B \text{ continuous } : \| V \|_{C^0(t_1, t_2; B)} < \infty \} \), where
\[
\| V \|_{C^0(t_1, t_2; B)} := \max_{t \in [t_1, t_2]} \| V(t) \|_B.
\]

We will apply the above criterion taking \( X = H^1_\mu = H^1(\mathbb{R}^{N+1}, d\mu) \) and \( B = Y = L^2_\mu = L^2(\mathbb{R}^{N+1}, d\mu) \) and \( p = r = \infty \). To do so, we have to prove the following lemma.

Lemma 6.3. The space \( H^1_\mu = H^1(\mathbb{R}^{N+1}, d\mu) \) is compactly embedded in \( L^2_\mu = L^2(\mathbb{R}^{N+1}, d\mu) \).
Proof. Let \( \{U_j\}_j \) be a bounded sequence in \( H^1_\mu \). Up to subsequences, we can assume the existence of a function \( U \in H^1_\mu \) such that \( U_j \rightharpoonup U \) (weakly) in \( H^1_\mu \) and we must prove that

\[
U_j \rightarrow U \quad \text{(strongly) in } L^2_\mu,
\]
as \( j \rightarrow +\infty \). Let us set \( V_j := U_j - U \). For any \( A > 0 \), we can write

\[
(6.3) \quad \int_{\mathbb{R}^{N+1}} V_j^2 \, d\mu(x,y) = \int_{B_A} V_j^2 \, d\mu(x,y) + \int_{B_A^c} V_j^2 \, d\mu(x,y),
\]
where, following [5], we have defined

\[
B_A := \{(x,y) \in \mathbb{R}^{N+1} : |x|^2 + y^2 < A^2\} \quad \text{with} \quad B_A^c = \mathbb{R}^{N+1} \setminus B_A.
\]

Now, since the measures \( |y|^a \, dx \, dy \) and \( |y|^a G_a(x,y,1) \, dx \, dy \) are equivalent on \( B_A \), we obtain that the first term in the r.h.s. of (6.3) goes to zero as \( j \rightarrow +\infty \), thanks to the well-known \( H^1(B_A,|y|^a) \hookrightarrow L^2(B_A,|y|^a) \) compact immersions type (cfr. for instance with [30]). Consequently, we are left to prove that also the second integral in the r.h.s. of (6.3) is converging to zero as \( j \rightarrow +\infty \).

To do so, we repeat the procedure carried out in [5] (cfr. with Lemma 7.4) with some modifications due to our slightly different framework. Before moving forward, we recall the definition of the fundamental solution and how it splits into the product of two Gaussians:

\[
G_a(x,y,t) = G_N(x,t)G_{a+1}(y,t) = \frac{1}{(4\pi t)^{\frac{N}{2}}} e^{-\frac{|x|^2}{4t}} \frac{1}{2^{1+a+\frac{N}{2}}} \frac{1}{\Gamma\left(\frac{1+a}{2}\right)} \frac{1}{t^{\frac{1+a}{2}}} e^{-\frac{y^2}{4t}},
\]

and that the following two log-Sobolev type inequalities hold (cfr. with Lemma 7.7 of [24] or formulas (7.16)-(7.17) of [5]):

\[
(6.4) \quad \log \left( \frac{1}{\int_{|f|>0} G_a(\cdot,1)} \right) \int_{\mathbb{R}^{N+1}} f^2 G_a(\cdot,1) \leq 2 \int_{\mathbb{R}^{N+1}} |\nabla f|^2 G_a(\cdot,1),
\]

for all \( f \in H^1(\mathbb{R}^{N+1}, d\mu) \), and

\[
(6.5) \quad \log \left( \frac{1}{\int_{|f|>0} G_N(\cdot,1)} \right) \int_{\mathbb{R}^N} f^2 G_N(\cdot,1) \leq 2 \int_{\mathbb{R}^N} |\nabla f|^2 G_N(\cdot,1),
\]

for all \( f \in H^1(\mathbb{R}^N, d\mu_\mu) \). Note that, with respect to [24] and/or [5], in (6.4) we have introduced the quantity \( c_a := 2^{1+a+\frac{N}{2}}\sqrt{4\pi}/\sqrt{\Gamma\left(\frac{1+a}{2}\right)} \) due to the different normalization constant of the fundamental solution (cfr. also with [5]).

Now, fix \( \varepsilon > 0 \), and take \( A > 4 \) large enough such that

\[
(6.6) \quad c_a \int_{B^{A/2}_A} G_a(x,y,1) \, dx \, dy \leq e^{-1/\varepsilon}, \quad \int_{B^{A/2}_A} G_N(x,1) \, dx \leq e^{-1/\varepsilon},
\]

where \( B_A := \{ x \in \mathbb{R}^N : |x| < A \} \) with \( B_A^c = \mathbb{R}^N \setminus B_A \). As explained in [5], (6.4) cannot be directly applied to estimate the integral

\[
\int_{B_A^c} V_j^2 \, d\mu(x,y) = \int_{B_A^c} V_j^2 \, |y|^a G_a(x,y,1) \, dx \, dy,
\]
due to some regularity issues. So, we write

\[
(6.7) \quad \int_{B_A^c} |y|^a V_j^2 \, G_a(x,y,1) \, dx \, dy = \int_{R_A} |y|^a V_j^2 \, G_a(x,y,1) \, dx \, dy + \int_{R_A^c} |y|^a V_j^2 \, G_a(x,y,1) \, dx \, dy,
\]
where
\[ \hat{R}_A := \mathbb{B}_1 \cap (\mathbb{R}^N \times \{|y| \leq A/2\}) \quad \text{and} \quad R_A := \mathbb{B}_1 \cap (\mathbb{R}^N \times \{|y| > A/2\}). \]

Let us start with estimating the first integral in the r.h.s. of (6.7). For any \((x, y) \in \hat{R}_A\), we have both \(|x|^2 + y^2 \geq A^2\) and \(y^2 \leq A^2/4\), so that \(|x| \geq (\sqrt{3}/2)A \geq A/2\). Consequently,
\[
\int_{\hat{R}_A} |y|^a V_j^2(x, y) G_a(x, y, 1) \, dx \, dy \leq \int_{-A/2}^{A/2} |y|^a G_{a+1}(y, 1) \left( \int_{|x| \leq (\sqrt{3}/2)A} V_j^2(x, y) G_N(x, 1) \, dx \right) \, dy.
\]

Now, if \(\varphi \in C_c^\infty(\mathbb{R}^N)\) is a radially decreasing cut-off function satisfying \(\varphi = 1\) in \(B_{A/2}\) and \(\varphi = 0\) outside \(B_A\) with \(|\nabla \varphi| \leq 1\), we firstly observe that
\[
\int_{\{x \geq \sqrt{3}/2, A\}} V_j^2(x, y) G_N(x, 1) \, dx \leq C \int_{\mathbb{R}^N} V_j^2(x, y)[1 - \varphi(x)]^2 G_N(x, 1) \, dx,
\]
for some constant \(C > 0\) depending only on \(\varphi\) and for a.e. \(y \in \mathbb{R}\) (the above inequality can be directly verified using the properties of the cut-off function \(\varphi = \varphi(x)\)). Secondly, observing that the second inequality in (6.6), together with the fact that
\[
\int_{|V_j(1-\varphi)| > 0} G_N(x, 1) \, dx \leq \int_{B_{A/2}} G_N(x, 1) \, dx
\]
implies
\[
\log \left( \frac{1}{\int_{|V_j(1-\varphi)| > 0} G_N(\cdot, 1)} \right) \geq \frac{1}{\varepsilon}
\]
we deduce (by applying (6.5) with \(f = V_j(1 - \varphi)\)):
\[
\int_{\mathbb{R}^N} V_j^2(x, y)[1 - \varphi(x)]^2 G_N(x, 1) \, dx \leq C \int_{\mathbb{R}^N} [V_j^2 + |\nabla V_j|^2] G_N(x, 1) \, dx \leq \varepsilon C,
\]
where \(C > 0\) is constant independent of \(j \in \mathbb{N}\) (this follows from the properties of \(\varphi = \varphi(x)\) and since \(\{V_j\}_j\) is bounded in \(H^1_A\)). Consequently, we obtain
\[
\int_{\hat{R}_A} |y|^a V_j^2(x, y) G_a(x, y, 1) \, dx \, dy \leq \varepsilon C \int_{-A/2}^{A/2} |y|^a G_{a+1}(y, 1) \, dy \leq \varepsilon C,
\]
where \(C > 0\) is new constant not depending on \(j \in \mathbb{N}\). Let us focus the second integral in the r.h.s. of (6.7). We introduce the new cut-off functions
- \(\overline{\varphi} \in C_c^\infty(\mathbb{R}^{N+1})\) with \(\overline{\varphi} = 1\) in \(B_{A/2}\) and \(\overline{\varphi} = 0\) outside \(B_A\) with \(|\nabla x, y \overline{\varphi}| \leq 1 \).
- \(\tilde{\varphi} \in C_c^\infty(\mathbb{R})\) with \(\tilde{\varphi}(y) = 1\) for \(|y| \leq A/4\) and \(\tilde{\varphi}(y) = 0\) for \(|y| \geq A/2\) with \(|\tilde{\varphi}'| \leq 1\),

and we immediately see that
\[
\int_{R_A} |y|^a V_j^2 G_a(x, y, 1) \, dx \, dy \leq \int_{\mathbb{R}^N} |y|^a V_j^2 [1 - \overline{\varphi}(x, y)]^2 (1 - \tilde{\varphi}(y))^2 G_a(x, y, 1) \, dx \, dy.
\]

Now, exactly as in [3] (cfr. with formula (7.24)), we set \(f = |y|^{a/2} V_j(1 - \overline{\varphi})(1 - \tilde{\varphi})\) and we estimate
\[
|\nabla f|^2 \leq C \left[ |y|^a (V_j^2 + |\nabla V_j|^2) + |y|^{a-2} V_j^2 (1 - \overline{\varphi})^2 (1 - \tilde{\varphi})^2 \right] \leq C |y|^a (V_j^2 + |\nabla V_j|^2),
\]
where \(C > 0\) independent of \(j \in \mathbb{N}\). The last inequality follows since for any \(|y| \geq A/4\), we have
\[
|y|^{a-2} V_j^2 (1 - \overline{\varphi})^2 (1 - \tilde{\varphi})^2 \leq |y|^{a-2} V_j^2 \leq |y|^a V_j^2.
\]
where we have used the properties of the support of \( \tilde{\varphi} = \tilde{\varphi}(y) \) and the fact that we have chosen \( A > 4 \) from the beginning. Consequently, applying \( (6.4) \) (with \( f = |y|^{a/2} V_j(1 - \tilde{\varphi})(1 - \tilde{\varphi}) \)), we obtain
\[
\int_{R_A} |y|^a V_j^2 G_a(x, y, 1) \, dx \, dy \leq \varepsilon C \int_{\mathbb{R}^{N+1}} |y|^a \left[ V_j^2 + |\nabla V_j|^2 \right] G_a(x, y, 1) \, dx \, dy \leq \varepsilon C,
\]
where we have used the first inequality in \( (6.6) \) and the uniform \( H^1_\mu \) bound on the \( V_j \)'s. Summing up, from \( (6.7) \) and the above bounds, we have got
\[
\int_{\mathbb{R}_A} |y|^a V_j^2 G_a(x, y, 1) \, dx \, dy \leq \varepsilon C,
\]
which completes the proof, by the arbitrariness of \( \varepsilon > 0 \). \( \square \)

**Remark 6.4.** An almost identical proof allows to show that the space \( H^1_\mu = H^1(\mathbb{R}^{N+1}_+, d\mu) \) is compactly embedded in \( L^2_\mu = L^2(\mathbb{R}^{N+1}_+, d\mu) \).

We are now ready to prove Theorem 6.1. We anticipate that compared with the above mentioned papers, we first obtain a convergence result in the space \( L^2(t_*, T_*; H^1_\mu) \) (and also in \( C^0(t_*, T_*; L^2_\mu) \)) for any \( 0 < t_*, T_* < \infty \), and then, in a second moment, we will improve it obtaining convergence in \( L^2(0, T_*; H^1_\mu) \) and \( C^0(t_*, T_*; L^2_\mu) \), respectively. **Proof of Theorem 6.1.** Take \( p_0 = 0 \) for simplicity. We divide the proof in several steps.

**Step 1: Basic definitions.** For \(-1 < a < 1 \) and \( 0 < T, T_* < \infty \) fixed, we consider a nontrivial strong solution (cfr. with Definition 2.4) \( U = U(x, y, t) \) to \( (2.17) \):
\[
\partial_t U + \mathcal{L}_a U = 0 \quad \text{in} \quad \mathbb{R}^{N+1} \times (0, T).
\]
We recall that in particular \( U = U(x, y, t) \) satisfies \( (2.26) \):
\[
\int_{\mathbb{R}^{N+1}} \left[ \partial_t U + \frac{(x, y)}{2t} \nabla U \right] \eta d\mu(x, y) = \int_{\mathbb{R}^{N+1}} \nabla U \eta d\mu(x, y),
\]
for a.e. \( 0 < t < T \) and all \( \eta \in L^2(0, T; H^1_{\mu_1}) \). We then define the normalized blow-up family
\[
U_\lambda(x, y, t) := \frac{U(\lambda x, \lambda y, \lambda^2 t)}{\sqrt{H(\lambda^2, U)}}, \quad \lambda > 0,
\]
where \( H(\cdot, U) \) is defined at the beginning of Subsection 4.2. As a preliminary observation, it is not difficult to see that for any \( \lambda > 0 \), \( U_\lambda = U_\lambda(x, y, t) \) is a strong solution to equation
\[
\partial_t U_\lambda + \mathcal{L}_a U_\lambda = 0 \quad \text{in} \quad \mathbb{R}^{N+1} \times (0, T/\lambda^2),
\]
and \( (2.26) \) holds for \( U_\lambda = U_\lambda(x, y, t) \), too. Now, we define
\[
H(t, U_\lambda) := \int_{\mathbb{R}^{N+1}} |y|^a U_\lambda^2(x, y, t) G_a(x, y, t) \, dx \, dy,
\]
\[
I(t, U_\lambda) := \int_{\mathbb{R}^{N+1}} |y|^a |\nabla U_\lambda|^2(x, y, t) G_a(x, y, t) \, dx \, dy,
\]
for \( t \in (0, T/\lambda^2) \). By scaling we have
\[
H(t, U_\lambda) = \frac{H(\lambda^2 t, U)}{H(\lambda^2, U)}, \quad I(t, U_\lambda) = \frac{\lambda^2 I(\lambda^2 t, U)}{H(\lambda^2, U)}.
\]
and so the frequency function corresponding to $U_{\lambda}$:

$$N(t, U_{\lambda}) := \frac{t I(t, U_{\lambda})}{H(t, U_{\lambda})},$$

satisfies

$$N(t, U_{\lambda}) = N(\lambda^2 t, U), \quad 0 < t < T/\lambda^2.$$ 

Finally, we consider the family

$$\tilde{U}_{\lambda}(x, y, t) := U_{\lambda}\left(\sqrt{t}x, \sqrt{t}y, t\right), \quad 0 < t < T/\lambda^2, \quad \lambda > 0,$$

which is a normalized and rescaled version of $U_{\lambda} = U_{\lambda}(x, y, t)$. Note that by scaling we have

$$\tilde{U}_{\lambda} \in L^2(0, T/\lambda^2; H^1_{\mu}), \quad \tilde{t}\partial_t \tilde{U}_{\lambda} \in L^2(0, T/\lambda^2; L^2_{\mu}),$$

and moreover, $\tilde{U}_{\lambda} = \tilde{U}_{\lambda}(x, y, t)$ is a strong solution to (2.28):

$$t\partial_t \tilde{U}_{\lambda} + \frac{1}{|y|^a G_a} \nabla \cdot (|y|^a G_a \nabla \tilde{U}_{\lambda}) = 0 \quad \text{in } \mathbb{R}^{N+1} \times (0, T/\lambda^2).$$

In particular, it holds

$$t \int_{\mathbb{R}^{N+1}} \partial_t \tilde{U}_{\lambda} \eta d\mu(x, y) = \int_{\mathbb{R}^{N+1}} \tilde{U}_{\lambda} \nabla \eta d\mu(x, y),$$

for a.e. $0 < t < T/\lambda^2$ and all $\eta \in L^2(0, T/\lambda^2; H^1_{\mu})$. Before moving forward, we need to make an important observation. For a.e. $0 < t < T$, the linear functional

$$\eta(t) \rightarrow \int_{\mathbb{R}^{N+1}} \nabla \tilde{U}_{\lambda}(t) \nabla \eta(t) d\mu(x, y), \quad \eta \in H^1_{\mu},$$

is well-defined and continuous on $H^1_{\mu}$. Consequently, by the Hahn-Banach Theorem it can be continuously extended to a linear functional $F^t_{\lambda}$ defined and continuous on the all $L^2_{\mu}$ with

$$\|F^t_{\lambda}\|_{(L^2_{\mu})'} \leq \|\tilde{U}_{\lambda}(t)\|_{H^1_{\mu}}, \quad \text{for a.e. } 0 < t < T.$$ 

On the other hand, from the Riesz Theorem, there exists a function $f^t_{\lambda} \in L^2_{\mu}$ such that

$$\langle F^t_{\lambda}, \eta(t) \rangle = \int_{\mathbb{R}^{N+1}} f^t_{\lambda} \eta(t) d\mu(x, y), \quad \eta(t) \in L^2_{\mu},$$

and so, matching with (6.9), we obtain $t\partial_t \tilde{U}_{\lambda}(t) = f^t_{\lambda}$ in $L^2_{\mu}$ for a.e. $0 < t < T$. In particular, since $\|F^t_{\lambda}\| = \|f^t_{\lambda}\|$, we obtain

$$\|\partial_t \tilde{U}_{\lambda}(t)\|_{L^2_{\mu}} \leq \frac{1}{t} \|\tilde{U}_{\lambda}(t)\|_{H^1_{\mu}} \quad \text{for a.e. } 0 < t < T/\lambda^2.$$ 

**Step2:** Uniform bounds for $\tilde{U}_{\lambda}$. Let us assume $1 \leq T_* < \infty$ (the case $0 < T_* < 1$ is easier). Using the scaling properties of $G_a = G_a(x, y, t)$, it can be easily seen that

$$\int_{\mathbb{R}^{N+1}} |y|^a \tilde{U}_{\lambda}^2(x, y, t) G_a(x, y, 1) \, dx \, dy = \frac{1}{H(\lambda^2, U)} \int_{\mathbb{R}^{N+1}} |y|^a U^2(x, y, \lambda^2 t) G_a(x, y, \lambda^2 t) \, dx \, dy$$

$$= \frac{H(\lambda^2 t, U)}{H(\lambda^2, U)}, \quad \lambda > 0,$$
and, furthermore,
\[
\int_{\mathbb{R}^{N+1}} |y^a| |\nabla \tilde{U}_\lambda|^2(x, y, t) \mathcal{G}_\alpha(x, y, 1) \, dxdy = \frac{\lambda^2 t}{H^2(U, \lambda)} \int_{\mathbb{R}^{N+1}} |y^a| |\nabla U|^2(x, y, \lambda^2 t) \mathcal{G}_\alpha(x, y, \lambda^2 t) \, dxdy
\]
\[
= \frac{\lambda^2 t H(\lambda^2 t, U)}{H^2(U, \lambda)} = N(\lambda^2 t, U) \frac{H(\lambda^2 t, U)}{H^2(U, \lambda)}, \quad \lambda > 0.
\]

Now, assume both \( t \in (0, T_*) \) and \( \lambda \in (0, 1/\sqrt{T_*}) \). Using the monotonicity of the functions \( t \to H(t, U) \) and \( t \to N(t, U) \) (cfr. with the proof of Lemma 4.1) and formula (4.6) of Corollary 4.3, we obtain
\[
\frac{H(\lambda^2 t, U)}{H^2(U, \lambda)} \leq \frac{H(\lambda^2 T_*, U)}{H^2(U, \lambda)} \leq T_*^{2N(2N^2, T_*, U)} \leq T_*^{2N_1},
\]
where we have set \( N(\lambda^2 t, U) \leq N(1, U) := N_1 < \infty \) and used that \( \lambda^2 t \leq 1 \). Consequently, we deduce
\[
\int_{\mathbb{R}^{N+1}} \tilde{U}_\lambda^2(x, y, t) \, d\mu(x, y) \leq T_*^{2N_1}, \quad \int_{\mathbb{R}^{N+1}} |\nabla \tilde{U}_\lambda|^2(x, y, t) \, d\mu(x, y) \leq N_1 T_*^{2N_1},
\]
for \( 0 < t \leq T_* \) and \( 0 < \lambda \leq 1/\sqrt{T_*} \). The last two formulas imply that the family
(6.12) \( \{\tilde{U}_\lambda\}_{\lambda \in (0, 1/\sqrt{T_*})} \) is uniformly bounded in \( L^\infty(0, T_*; H^1_\mu) \),
where we recall that \( H^1_\mu := H^1(\mathbb{R}^{N+1}, d\mu) \). Furthermore, from (6.10), we obtain that
\[
\|\partial_t \tilde{U}_\lambda(t)\|_{L^2_\mu} \leq \frac{N_1 T_*^{2N_1}}{t} \quad \text{for a.e. } 0 < t \leq T_*, \text{ and all } 0 < \lambda \leq 1/\sqrt{T_*}
\]
From this last bound we deduce that for any \( 0 < t_* < T_* \) the family
(6.13) \( \{\partial_t \tilde{U}_\lambda\}_{\lambda \in (0, 1]} \) is uniformly bounded in \( L^\infty(t_*, T_*; L^2_\mu) \).

So it turns out that the family \( \{\tilde{U}_\lambda\}_{\lambda \in (0, 1]} \) is relatively compact in \( C^0(0, T_*; L^2_\mu) \) for all fixed \( 0 < t_* < T_* \), where \( L^2_\mu := L^2(\mathbb{R}^{N+1}, d\mu) \) (cfr. for instance with Corollary 8 of [60]).

**Step 3: Compactness and properties of the limit.** So, for any \( \lambda_n \to 0^+ \) and any fixed \( 0 < t_* < 1 \), we can extract a sub-sequence \( \lambda_{n_j} \to 0^+ \) (that we rename \( \lambda_j := \lambda_{n_j} \) by convenience) such that
(6.14) \( \tilde{U}_{\lambda_j} \to \tilde{\Theta} \quad \text{in } C^0(0, T_*; L^2_\mu), \) as \( j \to +\infty \),
where \( \tilde{\Theta} \in \bigcap_{t_* \in (0, T_*)} C^0(t_*, T_*; L^2_\mu) \). Note that a priori the sequence \( \lambda_j \) depends on \( 0 < t_* < T_* \). However, an easy diagonal procedure (that we skip not to weight down our presentation) allows us to eliminate this dependence.

Let us now present some important properties of the limit \( \tilde{\Theta} = \tilde{\Theta}(x, y, t) \). First of all, since \( \|\tilde{U}_\lambda(\cdot, \cdot, 1)\|_{L^2_\mu} = 1 \) for all \( \lambda > 0 \) (cfr. (6.11) with \( t = 1 \)), it follows
\[
\|\tilde{\Theta}(\cdot, 1)\|_{L^2_\mu} = 1,
\]
too and so the limit is not trivial (this crucial property follows since we have normalized the blow-up family \( U_\lambda = U_\lambda(x, y, t) \)). Moreover, (6.12) and (6.13) allow us to take the subsequence \( \lambda_j \to 0^+ \) such that
\[
\begin{align*}
\tilde{U}_{\lambda_j} &\to \tilde{\Theta} \quad \text{weakly in } L^2(t_*, T_*; H^1_\mu), \\
\partial_t \tilde{U}_{\lambda_j} &\to \partial_t \tilde{\Theta} \quad \text{weakly in } L^2(t_*, T_*; L^2_\mu),
\end{align*}
\]
for all $0 < t_* < T_*$. This follows from the fact that $L^2(t_*, T_* ; H^1_\mu) \subset L^\infty(t_*, T_* ; H^1_\mu)$ and $L^2(t_*, T_* ; L^2_\mu) \subset L^\infty(t_*, T_* ; L^2_\mu)$, and from the reflexivity of $L^2(t_*, T_* ; H^1_\mu)$ and $L^2(t_*, T_* ; L^2_\mu)$. Consequently, thanks to the previous two convergence properties and the arbitrariness of $0 < t_* < T_*$, it satisfies

$$
t \int_{\mathbb{R}^{N+1}} \partial_t \tilde{\Theta} \eta(t) \, d\mu(x, y) = \int_{\mathbb{R}^{N+1}} \nabla \tilde{\Theta} \nabla \eta(t) \, d\mu(x, y),$$

for $t_* < t < T_*$ and for all $\eta(t) \in H^1_\mu$ (cfr. with [6.9]). Now subtracting the equations of $\tilde{U}_{\lambda_j}$ and $\tilde{\Theta}$, respectively, and testing with $\eta(t) = (\tilde{U}_{\lambda_j} - \tilde{\Theta})(t) \in H^1_\mu$, we obtain

$$
t \left( \partial_t (\tilde{U}_{\lambda_j} - \tilde{\Theta})(t), (\tilde{U}_{\lambda_j} - \tilde{\Theta})(t) \right)_L^2 = \int_{\mathbb{R}^{N+1}} |\nabla (\tilde{U}_{\lambda_j} - \tilde{\Theta})(t)|^2 \, d\mu(x, y), \quad \text{for a.e. } t_* \leq t \leq T_*, \tag{6.15}$$

and so, integrating between $t_*$ and $T_*$, we easily find

$$
\int_{t_*}^{T_*} \| (\tilde{U}_{\lambda_j} - \tilde{\Theta})(t) \|_{L^2_\mu}^2 + \| \nabla (\tilde{U}_{\lambda_j} - \tilde{\Theta})(t) \|_{L^2_\mu}^2 \, dt = \frac{1}{2} \left[ \| (\tilde{U}_{\lambda_j} - \tilde{\Theta})(t_*) \|_{L^2_\mu}^2 + \| (\tilde{U}_{\lambda_j} - \tilde{\Theta})(T_*) \|_{L^2_\mu}^2 \right] \to 0, \quad \text{as } j \to +\infty,
$$

thanks to [6.14]. Note that we have used that $2 \partial_t (\tilde{U}_{\lambda_j} - \tilde{\Theta}), (\tilde{U}_{\lambda_j} - \tilde{\Theta}) \rangle_{L^2_\mu} = \partial_t \| \tilde{U}_{\lambda_j} - \tilde{\Theta} \|_{L^2_\mu}^2$ and integrated by parts (with respect to $t$). This implies

$$
\tilde{U}_{\lambda_j} \to \tilde{\Theta} \quad \text{in } L^2(t_*, T_* ; H^1_\mu), \quad \text{as } j \to +\infty.
$$

**Step 4: Properties of the re-scaling of $\tilde{U}_{\lambda}$.** Consequently, scaling back to $U_{\lambda} = U_{\lambda}(x, y, t)$, for any $0 < t_* < T_*$, it holds

$$
\lim_{j \to +\infty} \int_{t_*}^{T_*} \| U_{\lambda_j}(\cdot, \cdot, t) - \Theta(\cdot, \cdot, t) \|_{H^1(\mathbb{R}^{N+1}, d\mu_t)}^2 \, dt \to 0, \quad \text{as } j \to +\infty, \tag{6.16}
$$

and

$$
\lim_{j \to +\infty} \sup_{t \in [t_*, T_*]} \| U_{\lambda_j}(\cdot, \cdot, t) - \Theta(\cdot, \cdot, t) \|_{L^2(\mathbb{R}^{N+1}, d\mu_t)}^2 \to 0, \quad \text{as } j \to +\infty, \tag{6.17}
$$

where we recall that

$$
U_{\lambda}(x, y, t) := \tilde{U}_{\lambda} \left( \frac{x}{\sqrt{t}}, \frac{y}{\sqrt{t}}, t \right) \quad \text{and} \quad \Theta(x, y, t) := \tilde{\Theta} \left( \frac{x}{\sqrt{t}}, \frac{y}{\sqrt{t}}, t \right).
$$

Note that from weak-strong convergence we obtain also

$$
N(t, U_{\lambda_j}) := \frac{t I(t, U_{\lambda_j})}{H(t, U_{\lambda_j})} = \frac{\int_{\mathbb{R}^{N+1}} |y|^a |\nabla U_{\lambda_j}|^2 (x, y, t) G_a(x, y, t) \, dx \, dy}{\int_{\mathbb{R}^{N+1}} |y|^a U_{\lambda_j}^2 (x, y, t) G_a(x, y, t) \, dx \, dy} \to N(t, \Theta) = \frac{t I(t, \Theta)}{H(t, \Theta)},
$$

for a.e. $t_* < t < T_*$, as $j \to +\infty$, where

$$
H(t, \Theta) := \int_{\mathbb{R}^{N+1}} |y|^a \Theta^2 (x, y, t) G_a(x, y, t) \, dx \, dy,
$$

$$
I(t, \Theta) := \int_{\mathbb{R}^{N+1}} |y|^a |\nabla \Theta|^2 (x, y, t) G_a(x, y, t) \, dx \, dy.
$$

Moreover, by scaling, it turns out that $\Theta = \Theta(x, y, t)$ satisfies

$$
\int_{\mathbb{R}^{N+1}} \left[ \partial_t \Theta + \frac{(x, y)}{2t} \cdot \nabla \Theta \right] \eta \, d\mu_t(x, y) = \int_{\mathbb{R}^{N+1}} \nabla \Theta \cdot \nabla \eta \, d\mu_t(x, y), \quad \eta \text{ smooth and compactly supported}, \tag{6.18}
$$

in $\mathbb{R}^{N+1} \times (t_*, T_*)$. \[226\] \[226\]
for \( t_* < t < T_* \) and all \( \eta(t) \in H^{1}_\mu \). Consequently, the function \( t \to N(t, \Theta) \) is well-defined and non-decreasing in \( (t_*, T_*) \) (recall that \( H(t, \Theta) > 0 \) for all \( t_* < t < T_* \), in view of Corollary 4.4).

**Step 4:** The limit is a rescaled eigenfunction. Now, since \( N(t, U_{\lambda j}) = N(\lambda^2_j t, U) \), we can fix \( t_* < t < T_* \) and take the limit as \( j \to +\infty \) to obtain

\[
N(t, U_{\lambda j}) \to \kappa := \lim_{t \to 0} N(t, U), \quad \text{as} \quad j \to +\infty,
\]

for \( t_* < t < T_* \). Consequently,

\[
(6.19) \quad N(t, \Theta) \equiv \kappa, \quad \text{for} \quad t_* < t < T_* ,
\]

and so, as in the proof of Lemma 4.1 (cfr. with Step 4) the rescaled version \( \tilde{\Theta}(x, y, t) = \Theta(\sqrt{tx}, \sqrt{ty}, t) \) must be a weak eigenfunction to the Ornstein-Uhlenbeck eigenvalue problem type (5.2), in the sense that the identity

\[
(6.20) \quad \int_{\mathbb{R}^{N+1}} \nabla \tilde{\Theta} \cdot \nabla \eta(t) \, d\mu(x, y) = \kappa \int_{\mathbb{R}^{N+1}} \tilde{\Theta} \eta(t) \, d\mu(x, y),
\]

is satisfied for a.e. \( t_* < t < T_* \) and all \( \eta(t) \in H^{1}_\mu \). From the above identity, it thus follows that \( \kappa \) is an eigenvalue of the Ornstein-Uhlenbeck operator \( \mathcal{O}_a \) (cfr. with Section 5) and we complete the proof of part (i).

Note that, from Lemma 3.1 (cfr. with Step 4) we know that the function \( t \to t - \frac{\kappa}{\mu} \tilde{\Theta}(x, y, t) \) is constant in time (cfr. with (4.3)) and so, if

\[
\tilde{\Theta}(x, y, t) = V(x, y),
\]

where of course \( V = V(x, y) \) still satisfies (6.20), we deduce

\[
\Theta(x, y, t) = t^{\kappa} V\left( \frac{x}{\sqrt{t}}, \frac{y}{\sqrt{t}} \right),
\]

for \( (x, y, t) \in \mathbb{R}^{N+1} \times (t_*, T_*) \), obtaining a precise expression for the blow-up limits in terms of linear combinations of rescaled eigenfunctions to problem (5.2).

**Step 5:** Uniqueness of the blow-up. We complete the proof of the theorem by showing that (6.16) and (6.17) do not depend on the subsequences \( \lambda_n \) and \( \lambda_{n_j} \). We begin by showing that

\[
\lim_{t \to 0^+} t^{-2\kappa} H(t, U) = L_0 > 0,
\]

which gives us part (ii). Note that from Corollary 4.2 we have that the above limit exists finite and it is nonnegative. Note that it gives an improvement of formula (4.7) for small times, in the sense that

\[
(6.21) \quad H(t, U) \sim L_0 t^{2\kappa} \quad \text{as} \quad t \to 0^+.
\]

In particular, it follows that \( l^{2\kappa} \leq H(t, U) \leq L l^{2\kappa} \) for \( t \to 0 \), for some \( 0 < l < L < \infty \), which will be important later. Now, assume by contradiction \( t^{-2\kappa} H(t, U) \to 0 \) as \( t \to 0^+ \) and consider the family of eigenfunctions

\[\{V_{\alpha, m} = V_{\alpha, m}(x, y) : \alpha \in \mathbb{Z}^{N}_{\geq 0} \text{ with } |\alpha| = n, \ n \in \mathbb{N}, \ m \in \mathbb{N}\},\]

found in Theorem 5.2. We thus obtain an orthonormal basis of \( L^2_\mu \) defining

\[
\nabla\alpha, m(x, y) = \frac{V_{\alpha, m}(x, y)}{|V_{\alpha, m}|_{L^2_\mu}}, \quad \text{as} \quad |\alpha| = n, \ n \in \mathbb{N}, \ m \in \mathbb{N}.
\]
Now, by scaling, we have that the not-normalized blow-up of $U = U(x, y, 1)$:
\[ U^\lambda(x, y, 1) := \sqrt{H(\lambda^2, U)} U_\lambda(x, y, 1) = U(\lambda x, \lambda y, \lambda^2) \]
belongs to $H^1_\mu$ for a.e. $0 < \lambda \leq 1/\sqrt{T^*}$ and so we can write
\[ U^\lambda(x, y, 1) = \sum_{\alpha, m} u_{\alpha, m}(\lambda) \nabla_{\alpha, m}(x, y) \quad \text{in} \ L^2_\mu, \]
where the coefficients are given by
\[ u_{\alpha, m}(\lambda) = \int_{\mathbb{R}^{N+1}} U^\lambda(x, y, 1) \nabla_{\alpha, m}(x, y) \, d\mu(x, y). \]

Note that by the orthonormality of the eigenfunctions $\nabla_{\alpha, m} = \nabla_{\alpha, m}(x, y)$ and the usual scaling properties, it easy to see that
\[ H(\lambda^2, U) = \int_{\mathbb{R}^{N+1}} \left[ \sum_{\alpha, m} u_{\alpha, m}(\lambda) \nabla_{\alpha, m}(x, y) \right]^2 \, d\mu(x, y) \geq u_{\alpha, m}^2(\lambda), \]
for any $\alpha \in \mathbb{Z}^N_{\geq 0}$, $m \in \mathbb{N}$, so that the assumption $t^{-2\kappa} H(t, U) \to 0$ as $t \to 0^+$ implies
\[ \lambda^{-2\kappa} u_{\alpha, m}(\lambda) \to 0 \quad \text{as} \quad \lambda \to 0^+, \]
where we have used the fact that $H(\lambda^2, U) = H(1, U^\lambda)$. Now, from the regularity of $U^\lambda$, we have that
\[ \frac{d}{d\lambda} U^\lambda(x, y, 1) = \sum_{\alpha, m} u'_{\alpha, m}(\lambda) \nabla_{\alpha, m}(x, y) \quad \text{in} \ L^2_\mu. \]

On the other hand,
\[ \frac{d}{d\lambda} U^\lambda(x, y, 1) = (x, y) \cdot \nabla U(\lambda x, \lambda y, \lambda^2) + 2\lambda \partial_t U(\lambda x, \lambda y, \lambda^2) \]

for a.e. $(x, y) \in \mathbb{R}^{N+1}$, and so, testing with $|y|^a \eta(x, y) G_a(x, y, 1)$ we obtain
\[ \int_{\mathbb{R}^{N+1}} \frac{dU^\lambda}{d\lambda} \eta \, d\mu(x, y) = \frac{2}{\lambda} \int_{\mathbb{R}^{N+1}} \nabla U^\lambda \nabla \eta \, d\mu(x, y), \]
for $\eta \in H^1_\mu$. Moreover, since $\nabla_{\alpha, m} = \nabla_{\alpha, m}(x, y)$ are solutions to (5.6) with $\kappa = \kappa_{n, m}$ (defined in the statement of Theorem 5.2), we deduce
\[ \frac{2}{\lambda} \int_{\mathbb{R}^{N+1}} \nabla U^\lambda \nabla \eta \, d\mu = \frac{2}{\lambda} \sum_{\alpha, m} u_{\alpha, m}(\lambda) \int_{\mathbb{R}^{N+1}} \nabla_{\alpha, m} \nabla \eta \, d\mu \]

and so, matching with (6.24) and using the orthogonality of $\nabla_{\alpha, m} = \nabla_{\alpha, m}(x, y)$, we obtain
\[ u'_{\alpha, m}(\lambda) = \frac{2\kappa_{n, m}}{\lambda} u_{\alpha, m}(\lambda) \quad \text{for all} \ \alpha \in \mathbb{Z}^N_{\geq 0} \ \text{with} \ |\alpha| = n, \ n \in \mathbb{N}, \ m \in \mathbb{N}. \]
Thus, integrating between $0 < \lambda < \lambda' \leq 1$, we find
\begin{equation}
\lambda^{-2\kappa_{n,m} u_{\alpha,m}(\lambda)} = \lambda^{-2\kappa_{n,m} u_{\alpha,m}(\lambda)},
\end{equation}
and so, letting $\lambda \to 0^+$ and using (6.23) (recall that $\kappa = \kappa_{n,m}$ for some $n, m \in \mathbb{N}$ as showed in Step 4), it follows $u_{\alpha,m}(\lambda) = 0$ for all $0 < \lambda \leq 1$ which implies $U^\lambda \equiv 0$, getting the desired contradiction.

Now, let us assume (6.21) to be valid and proceed with the second part of the proof. In Step 4 we have showed that if $U = U(x, y, t)$ is a strong solution to equation (2.17), then for any $0 < t_e < T_e < \infty$ and for any sequence $\lambda_n \to 0^+$, there exists a subsequence $\lambda_j = \lambda_{n_j}$ such that (cfr. with (6.16) and (6.17))

\[
\lim_{j \to +\infty} \int_{t_e}^{1} \| U_{\lambda_j} (\cdot, \cdot, t) - \Theta(\cdot, \cdot, t) \|^2_{H^1(\mathbb{R}^{N+1}, d\mu_t)} dt \to 0, \quad \text{as} \quad j \to +\infty,
\]

\[
\lim_{j \to +\infty} \sup_{t \in [t_e, T_e]} \| U_{\lambda_j} (\cdot, \cdot, t) - \Theta(\cdot, \cdot, t) \|^2_{L^2(\mathbb{R}^{N+1}, d\mu_t)} \to 0, \quad \text{as} \quad j \to +\infty,
\]

where
\[
U_{\lambda}(x, y, t) := \frac{U(\lambda x, \lambda y, \lambda^2 t)}{\sqrt{H(\lambda^2 U)}}, \quad \Theta(x, y, t) := t^{\kappa} V \left( \frac{x}{\sqrt{t}}, \frac{y}{\sqrt{t}} \right),
\]
and $V = V(x, y)$ is a weak eigenfunction to (5.2):
\[
-L_0 V + \frac{(x, y)}{2} \cdot \nabla V = \kappa V \quad \text{in} \quad \mathbb{R}^{N+1}.
\]
Moreover, we know that $\kappa = \kappa_{n,m}$ for some $n, m \in \mathbb{N}$ where $\kappa_{n,m}$ are defined in the statement of Theorem 5.2.

Now, if $n_0, m_0 \in \mathbb{N}$ are such that $\kappa = \kappa_{n_0, m_0}$ and $V_{\alpha_0,m_0}$ is the associated eigenspace, and $U_{\alpha,m} = V_{\alpha,m}(x, y)$ are the normalized eigenfunctions, we have that
\[
V(x, y) = \sum_{(\alpha,m) \in J_0} v_{\alpha,m} V_{\alpha,m}(x, y) \quad \text{in} \quad L^2_{\mu},
\]
where $J_0 := \{ (\alpha, m) \in \mathbb{Z}^2_{>0} \times \mathbb{N} : \alpha = n \in \mathbb{N} \text{ and } \kappa_{n,m} = \kappa_{n_0,m_0} \}$. Consequently, in view of (6.21), we can re-write the above convergence properties as

\[
\int_{t_e}^{T_e} \left\| \lambda_j^{-2\kappa_{n,m}} U(\lambda j x, \lambda j y, \lambda_j^2 t) - t^{\kappa} \sum_{(\alpha,m) \in J_0} v_{\alpha,m} V_{\alpha,m} \left( \frac{x}{\sqrt{t}}, \frac{y}{\sqrt{t}} \right) \right\|^2_{H^1(\mathbb{R}^{N+1}, d\mu_t)} dt \to 0,
\]

\[
\sup_{t \in [t_e, T_e]} \left\| \lambda_j^{-2\kappa_{n,m}} U(\lambda j x, \lambda j y, \lambda_j^2 t) - t^{\kappa} \sum_{(\alpha,m) \in J_0} v_{\alpha,m} V_{\alpha,m} \left( \frac{x}{\sqrt{t}}, \frac{y}{\sqrt{t}} \right) \right\|^2_{L^2(\mathbb{R}^{N+1}, d\mu_t)} \to 0,
\]
as $j \to +\infty$. In particular, taking $t = 1$ (recall that we are assuming $T_e \geq 1$ for simplicity), we deduce
\begin{equation}
\lambda_j^{-2\kappa_{n,m}} U(\lambda j x, \lambda j y, \lambda_j^2 t) \to \sum_{(\alpha,m) \in J_0} v_{\alpha,m} V_{\alpha,m}(x, y) \quad \text{in} \quad L^2_{\mu},
\end{equation}

So, in order to prove that (6.28) and (6.29) hold for any subsequence $\lambda_{n_j} \to 0^+$, or, equivalently, hold for $\lambda \to 0^+$, we are left to show that the coefficients $v_{\alpha,m_0}$ are independent from both $\lambda_n$ and its
subsequence $\lambda_n$. Thus, proceeding as in the first part of this step, we expand

$$U(x, y, \lambda^2) = \sum_{\alpha, m} u_{\alpha, m}(\lambda) v_{\alpha, m}(x, y),$$

in series of normalized eigenfunctions. So, multiplying (6.30) by $|y|^a v_{\alpha, m}(x, y) g_a(x, y, 1)$ and integrating on $\mathbb{R}^{N+1}$, we obtain

$$\lambda_j^{-2k} u_{\alpha, m}(\lambda_j) \to v_{\alpha, m}, \quad \text{as } j \to +\infty,$$

where we have used again the orthogonality of the eigenfunctions $v_{\alpha, m} = v_{\alpha, m}(x, y)$. On the other hand, exactly as before (cfr. with (6.27)), it holds

$$\lambda^{-2\kappa_{\alpha, m}} u_{\alpha, m}(\lambda) = \lambda^{-2\kappa_{\alpha, m}} u_{\alpha, m}(\lambda),$$

for all $0 < \lambda < 1/\sqrt{T}$ which means that the function

$$\lambda \to \lambda^{-2k} u_{\alpha, m}(\lambda) = \lambda^{-2k} \int_{\mathbb{R}^{N+1}} U(x, y, \lambda^2) v_{\alpha, m}(x, y) d\mu(x, y),$$

is constantly equal to $v_{\alpha, m}$ for all $0 < \lambda < 1/\sqrt{T}$. It follows in particular that $v_{\alpha, m}$ depends neither on $\lambda_n$ nor on $\lambda_n$. This shows the uniqueness of the blow-up limit.

**Step 6: Improved convergence.** Now, for any $0 < t < T_{\ast}$ and $0 < \lambda < 1/\sqrt{T_{\ast}}$, we consider $U_{\lambda}(x, y, t) = \lambda^{-2\kappa_{n_0, m_0}} U(x, y, \lambda^2 t)$ and

$$\Theta(x, y, t) = t^{\kappa_{n_0, m_0}} \langle x, y \rangle = t^{\kappa_{n_0, m_0}} \sum_{(\alpha, m) \in J_0} v_{\alpha, m} v_{\alpha, m}(x, y),$$

for some $v_{\alpha, m} \in \mathbb{R}$, and $n_0, m_0 \in \mathbb{N}$ are suitably chosen (cfr. with part (i)). So far, we have proved that for all $0 < t_{\ast} < T_{\ast}$, it holds (cfr. with (6.15))

$$\lim_{\lambda \to 0} \int_0^{T_{\ast}} ||U_{\lambda} - \Theta||_{L^2_t}^2 + t ||\nabla U_{\lambda} - \nabla \Theta||_{L^2_t}^2 dt = 0,$$

and we want to obtain

$$\lim_{\lambda \to 0} \int_0^{T_{\ast}} ||U_{\lambda} - \Theta||_{L^2_t}^2 + t ||\nabla U_{\lambda} - \nabla \Theta||_{L^2_t}^2 dt = 0. \quad (6.31)$$

So, we assume by contradiction that there exists $\varepsilon > 0$ and a subsequence $\lambda_j \to 0$ (as $j \to +\infty$), such that

$$\int_0^{T_{\ast}} ||U_{\lambda_j} - \Theta||_{L^2_t}^2 + t ||\nabla U_{\lambda_j} - \nabla \Theta||_{L^2_t}^2 dt \geq \varepsilon, \quad \text{for all large } j \in \mathbb{N}. \quad (6.32)$$

Now, since $S_{\lambda_j} := U_{\lambda_j} - \Theta$ still satisfies the assumptions of Lemma 4.1, we known that (cfr. with Step 1 of the above quoted lemma):

$$2 \int_{t_1}^{t_2} I(t, S_{\lambda_j}) dt = H(t_2, S_{\lambda_j}) - H(t_1, S_{\lambda_j}),$$

for any choice of times $0 < t_1 < t_2 < T_{\ast}$ and so, taking $t_2 = t_{\ast}$ and $t_1 \to 0$, we deduce

$$\int_0^{T_{\ast}} \int_{\mathbb{R}^{N+1}} |
abla S_{\lambda_j}|^2 d\mu_t(x, y) dt \leq \frac{1}{2} \int_{\mathbb{R}^{N+1}} S_{\lambda_j}^2(x, y, t_{\ast}) d\mu_t(x, y) = \frac{1}{2} H(t_{\ast}, S_{\lambda_j}).$$
Furthermore, setting $\nu_s = \min\{1, 1 - a\}/2$ and applying the Gaussian-Poincaré inequality (cfr. Theorem 5.7, part (i)), we obtain
\[
\int_0^{t_s} \int_{\mathbb{R}^{N+1}} S^2 d\mu_t(x, y) dt \leq \frac{1}{\nu_s} \int_0^{t_s} t \int_{\mathbb{R}^{N+1}} |\nabla S_{\lambda_j}|^2 d\mu_t(x, y) dt \\
\leq \frac{t_s}{\nu_s} \int_0^{t_s} \int_{\mathbb{R}^{N+1}} |\nabla S_{\lambda_j}|^2 d\mu_t(x, y) dt \leq \frac{t_s}{2\nu_s} H(t_s, S_{\lambda_j}),
\]
so that it follows
\[
\int_0^{t_s} \|U_{\lambda_j} - \Theta\|^2_{L^2_{\mu_t}} + t \|\nabla U_{\lambda_j} - \nabla \Theta\|^2_{L^2_{\mu_t}} dt \leq t_s \left(\frac{1 + \nu_s}{2\nu_s}\right) H(t_s, S_{\lambda_j}).
\]
Note that, in view of (6.14) we can assume $H(t_s, S_{\lambda_j}) = \|U_{\lambda_j} - \Theta\|_{L^2(\mathbb{R}^{N+1}, d\mu_t)} \leq C$ for all large $j \in \mathbb{N}$, where $C > 0$ is constant not depending on $\lambda_j$. It thus follows
\[
\int_0^{t_s} \|U_{\lambda_j} - \Theta\|^2_{L^2_{\mu_t}} + t \|\nabla U_{\lambda_j} - \nabla \Theta\|^2_{L^2_{\mu_t}} dt \leq C t_s,
\]
for all fixed $0 < t_s < T_*$, where $C > 0$ is a new constant not depending on $\lambda_j$. Consequently, (6.32) begins
\[
\int_{t_s}^{T_*} \|U_{\lambda_j} - \Theta\|^2_{L^2_{\mu_t}} + t \|\nabla U_{\lambda_j} - \nabla \Theta\|^2_{L^2_{\mu_t}} dt \geq \varepsilon - \int_0^{t_s} \|U_{\lambda_j} - \Theta\|^2_{L^2_{\mu_t}} + t \|\nabla U_{\lambda_j} - \nabla \Theta\|^2_{L^2_{\mu_t}} dt \\
\geq \varepsilon - C t_s > \frac{\varepsilon}{2},
\]
if $0 < t_s < \varepsilon/(2C)$, and we obtain the desired contradiction since the l.h.s. must converge to 0 as $\lambda_j \to 0$.

On the other hand, we have proved that
\[
\lim_{\lambda \to 0} \sup_{t \in [t_s, T_*]} \|U_{\lambda} - \Theta\|^2_{L^2_{\mu_t}} = \lim_{\lambda \to 0} \sup_{t \in [t_s, T_*]} H(t, U_{\lambda} - \Theta) = 0.
\]
However, since the function $t \to H(t, U_{\lambda} - \Theta)$ is non-decreasing, it follows $\sup_{t \in [t_s, T_*]} H(t, U_{\lambda} - \Theta) = \sup_{t \in (0, T_*]} H(t, U_{\lambda} - \Theta)$ and so
\[
(6.33) \quad \lim_{\lambda \to 0} \sup_{t \in (0, T_*]} \|U_{\lambda} - \Theta\|^2_{L^2_{\mu_t}} = \lim_{\lambda \to 0} \sup_{t \in (0, T_*]} \|U_{\lambda} - \Theta\|^2_{L^2_{\mu_t}}
\]
The proof is now completed. □

**Uniqueness of the blow-up in the case $h \neq 0$.** Let $w \in \text{dom}(H^s)$ be a solution to (2.2) (with $Vh$ satisfying (2.1)) and $W = W(x, y, t)$ its extension (it satisfies problem (2.7) for $t \in (-T, 0)$). Then define $u(x, t) = w(x, -t)$ and $U(x, y, t) = W(x, y, -t)$, which satisfies problem
\[
(6.34) \quad \begin{cases}
\partial_t U + y^{-a} \nabla \cdot (y^a \nabla U) = 0 & \text{in } \mathbb{R}^{N+1}_+ \times (0, T) \\
-\partial_y^a U = h(x, -t)U & \text{in } \mathbb{R}^N \times \{0\} \times (0, T),
\end{cases}
\]
in the strong sense, i.e., $U$ satisfies the requirements of Definition 2.3', where we replace the homogeneous Neumann boundary condition $-\partial_y^a U = 0$ with the non-homogeneous one $-\partial_y^a U = h(x, -t)U$. 

NODAL SET OF SOLUTIONS TO NONLOCAL PARABOLIC EQUATION 57
In particular, multiplying by a test function \( y^\alpha \eta(x,y,t) G_\alpha(x,y,t) \), we obtain the integral relation
\[
\int_{\mathbb{R}^{N+1}} \left[ \partial_t U + \frac{(x,y)}{2t} \cdot \nabla U \right] \eta \, d\mu(x,y) = \int_{\mathbb{R}^{N+1}} \nabla U \cdot \nabla \eta \, d\mu(x,y) + \int_{\mathbb{R}^N} h(x,-t) u(x,t) \eta(x,0,t) G_\alpha(x,0,t) \, dx,
\]
(6.35)
for a.e. \( 0 < t < T \) and all \( \eta \in L^2(0,T; H^1_{\mu_t}) \). Now, let \( \overline{U}_\lambda = \overline{U}_\lambda(x,y,t) \) be defined as in (2.12) and \( \lambda \to \overline{H}(\lambda,U) \) as in (2.10). As we have recalled in the introduction (cfr. with Theorem 2.2) and explained in Section 3, there exists a sequence \( \lambda_j \to 0^+ \) as \( j \to +\infty \) such that
\[
\overline{U}_{\lambda_j} \to \Theta \quad \text{in} \quad L^2(0,T; H^1(\mathbb{R}^{N+1}, y^\alpha G_{N+1} \, dx \, dy)),
\]
and locally uniformly in \( \mathbb{R}^{N+1} \times (0,\infty) \), where \( \Theta = \Theta(x,y,t) \) is an admissible blow-up profile (cfr. with Theorem 6.1). We now prove that the above convergence does not depend on the sequence \( \lambda_j \), by suitably adapting the methods used in Step 5 of the above proof. So, the crucial fact is to prove (6.21):
\[
\lim_{t \to 0^+} t^{-2\kappa} H(t,U) = L_0 > 0,
\]
for some suitable \( L_0 \), where \( \kappa = \kappa_{n_0,m_0} = n_0/2 + m_0 \). So, as before, we assume by contradiction \( L_0 = 0 \) and, by scaling, we consider the not-normalized blow-up of \( U = U(x,y,1) \) (cfr. with (6.22)):
\[
\overline{U}^\lambda(x,y,1) := \sqrt{\lambda^{-a} \overline{H}(\lambda,U)} \overline{U}_\lambda(x,y,1) = U(\lambda x, \lambda y, \lambda^2),
\]
and we expand it in series of normalized eigenfunctions \( \overline{U}^\lambda(x,y,1) = \sum_{\alpha,m} u_{\alpha,m}(\lambda) \overline{v}_{\alpha,m}(x,y) \) in \( L^2_{\mu_1} \), where the coefficients are given by
\[
u_{\alpha,m}(\lambda) = \int_{\mathbb{R}^{N+1}} \overline{U}^\lambda(x,y,1) \overline{v}_{\alpha,m}(x,y) \, d\mu(x,y).
\]
Exactly as before, we see that the assumption \( L_0 = 0 \) implies (6.23): \( \lambda^{-2\kappa} u_{\alpha,m}(\lambda) \to 0 \) as \( \lambda \to 0^+ \), for any \( \alpha \in \mathbb{Z}_{\geq 0}^N, m \in \mathbb{N} \). Moreover, note that both (6.24) and (6.25) remains valid, while (6.26) becomes
\[
\int_{\mathbb{R}^{N+1}} \frac{dU^\lambda}{d\lambda} \eta \, d\mu = \frac{2}{\lambda} \int_{\mathbb{R}^{N+1}} \nabla U^\lambda \nabla \eta \, d\mu + \frac{\alpha}{\lambda^a} \int_{\mathbb{R}^N} h(\lambda x, -\lambda^2) \overline{U}^\lambda(x,0,1) \eta(x,0) G_\alpha(x,0,1) \, dx,
\]
for any \( \eta \in H^1_{\mu_1} \). Consequently, proceeding as above and testing with \( \eta = \overline{v}_{\alpha,m} \), we deduce
\[
u_{\alpha,m}^\prime(\lambda) = \frac{2\kappa_{n_0,m}}{\lambda} u_{\alpha,m}(\lambda) + \frac{\alpha}{\lambda^a} \sum_{\beta,l} u_{\beta,l}(\lambda) \int_{\mathbb{R}^N} h(\lambda x, -\lambda^2) \overline{v}_{\beta,l}(x,0) \overline{v}_{\alpha,m}(x,0) G_\alpha(x,0,1) \, dx,
\]
for all \( \alpha \in \mathbb{Z}_{\geq 0}^N \) with \( |\alpha| = n, n \in \mathbb{N}, m \in \mathbb{N} \). Let us focus for a moment on the integral in the above expression. From Proposition 3.2 and its proof, we see that
\[
\left| \int_{\mathbb{R}^N} h(\lambda x, -\lambda^2) \overline{v}_{\beta,l}(x,0) \overline{v}_{\alpha,m}(x,0) G_\alpha(x,0,1) \, dx \right| \leq C \| h \|_{L^\infty(\mathbb{R}^{N+1})} \left| \int_{\mathbb{R}^N} H_{\beta}(x) H_{\alpha}(x) G_N(x,1) \, dx \right|,
\]
where we have used the fact that \( G_\alpha(x,0,1) = CG_N(x,1) \) and \( C > 0 \) depends only on \( N \) and \( -1 < a < 1 \). Consequently, since the Hermite polynomials \( H_{\alpha} = H_{\alpha}(x) \) are an orthogonal basis of \( L^2(\mathbb{R}^N, G_N \, dx) \),
Let us put ourselves in the easiest case when the spatial dimension is 2.

\[ u(x,y,t) \] is a blow-up limit in the presence of a nontrivial potential \( h(x,t) \). Integrating between 0 < \( \Delta < \lambda \), it follows

\[ u_{\alpha,m}(\lambda) \leq u_{\alpha,m}(\lambda) \leq \frac{u_{\alpha,m}(\lambda)}{\lambda^{2\kappa_{n,m}}} e^{2C\lambda^{1-a}}(\lambda^{1-a} - \lambda^{1-a}), \]

and so, letting \( \lambda \to 0^+ \), we obtain \( u_{\alpha,m}(\lambda) \equiv 0 \), which is a contradiction since \( U = U(x,y) \) is not trivial. Note that the fact that (6.21) holds also in the case of nontrivial potential has the remarkable consequence that the normalized blow-up sequences \( U_{\lambda} \) and \( U_{\lambda} \) (defined in (3.10) and (2.12), respectively) are asymptotically equivalent, indeed the normalization factor satisfies

\[ \lambda^{-a}H(\lambda,U) = \frac{1}{\lambda^{2+a}} \int_0^\lambda t^a H(t,U) dt \sim C_{N,a} \lambda^{2+2\kappa} dt = \lambda^{4\kappa} \sim H(\lambda^2,U), \]

as \( \lambda \to 0^+ \), where the above relations hold up to a multiplicative positive constant. Now, coming back to the sequence \( U_{\lambda}/U_{\lambda} \), we have that (6.30) holds, i.e.

\[ \lambda_j^{-2\kappa} U(\lambda_j x, \lambda_j y, \lambda_j^2) \to \sum_{(\alpha,m) \in J_0} v_{\alpha,m} V_{\alpha,m}(x,y) \quad \text{in} \quad L^2, \]

where the r.h.s. denotes the expansion of the weak eigenfunction \( V = V(x,y) \) to problem (3.9), satisfying \( \Theta(x,y,t) := t^k V \left( x/\sqrt{t}, y/\sqrt{t} \right) \). Consequently, exactly as before, it follows

\[ \lambda_j^{-2\kappa} u_{\alpha,m}(\lambda_j) \to v_{\alpha,m} \quad \text{as} \quad j \to +\infty, \]

while, at the same time, (6.37) holds with \( \Delta = \lambda_j \) and any \( \lambda > 0 \):

\[ \frac{u_{\alpha,m}(\lambda_j)}{\lambda_j^{2\kappa_{n,m}}} e^{-2C\lambda^{1-a}}(\lambda^{1-a} - \lambda^{1-a}) \leq \frac{u_{\alpha,m}(\lambda)}{\lambda^{2\kappa_{n,m}}} \leq \frac{u_{\alpha,m}(\lambda_j)}{\lambda_j^{2\kappa_{n,m}}} e^{2C\lambda^{1-a}}(\lambda^{1-a} - \lambda^{1-a}). \]

Passing to the limit as \( j \to +\infty \), we thus obtain

\[ v_{\alpha,m} e^{-2C\lambda^{1-a}} \leq \frac{u_{\alpha,m}(\lambda)}{\lambda^{2\kappa_{n,m}}} \leq v_{\alpha,m} e^{2C\lambda^{1-a}}, \]

for any \( \lambda > 0 \), and so (6.38) must hold for any sequence. This conclude the proof of the uniqueness of blow-up limits in the presence of a nontrivial potential \( h \neq 0 \).

**Examples.** Out of clarity, we complete the section with some concrete examples of blow-up profiles.

Let us put ourselves in the easiest case when the spacial dimension is \( N = 1 \) and denote by

\[ \Theta_{\alpha,m}(x,y,t) = t^{\kappa_{n,m}} V_{\alpha,m} \left( \frac{x}{\sqrt{t}}, \frac{y}{\sqrt{t}} \right) = t^{\kappa_{n,m}} H \left( \frac{x}{\sqrt{t}}, \frac{y}{\sqrt{t}} \right) L(\frac{a-1}{2},\sqrt{t}, \left( \frac{y^2}{4t} \right), \]

(cfr. with [64]), any \( u_{\alpha,m} \) satisfies both the following differential inequalities:

\[ \left( \frac{2\kappa_{n,m}}{\lambda} - \frac{2C}{\lambda^a} \right) u_{\alpha,m}(\lambda) \leq u_{\alpha,m}'(\lambda) \leq \left( \frac{2\kappa_{n,m}}{\lambda} + \frac{2C}{\lambda^a} \right) u_{\alpha,m}(\lambda), \]
the blow-up profile corresponding to $\tilde{\kappa}_{n,m} = \frac{n}{2} + m$ (i.e. to the eigenfunction $V_{a,m} = V_{a,m}(x,y)$). Then we have:

\begin{align*}
\tilde{\kappa}_{0,0} &= 0 & \tilde{\Theta}_{0,0}(x,y,t) &= 1 \\
\tilde{\kappa}_{1,0} &= \frac{1}{2} & \tilde{\Theta}_{1,0}(x,y,t) &= x \\
\tilde{\kappa}_{2,0} &= 1 & \tilde{\Theta}_{2,0}(x,y,t) &= x^2 - 2t \\
\tilde{\kappa}_{0,1} &= 1 & \tilde{\Theta}_{0,1}(x,y,t) &= \left(\frac{1+a}{2}\right) t - \frac{y^2}{4} \\
\tilde{\kappa}_{3,0} &= \frac{3}{2} & \tilde{\Theta}_{3,0}(x,y,t) &= x(x^2 - 6t) \\
\tilde{\kappa}_{1,1} &= \frac{3}{2} & \tilde{\Theta}_{1,1}(x,y,t) &= x \left[\left(\frac{1+a}{2}\right) t - \frac{y^2}{4}\right] \\
\tilde{\kappa}_{4,0} &= 2 & \tilde{\Theta}_{4,0}(x,y,t) &= x^4 - 12x^2t + 12t^2 \\
\tilde{\kappa}_{2,1} &= 2 & \tilde{\Theta}_{2,1}(x,y,t) &= (x^2 - 2t) \left[\left(\frac{1+a}{2}\right) t - \frac{y^2}{4}\right] \\
\tilde{\kappa}_{0,2} &= 2 & \tilde{\Theta}_{0,2}(x,y,t) &= \frac{1}{8} \left[(1+a)(3+a)t^2 - (3+a)y^2t + \frac{y^4}{4}\right].
\end{align*}

On the other hand, since the blow-up profiles corresponding to $\tilde{\kappa}_{n,m} = \frac{n}{2} + m + \frac{1-a}{2} = \tilde{\kappa}_{n,m} + \frac{1-a}{2}$ satisfy:

$$\tilde{\Theta}_{a,m}(x,y,t) = \tilde{\kappa}_{n,m} V_{a,m} \left(\frac{x}{\sqrt{t}}, \frac{y}{\sqrt{t}}\right) = \tilde{\kappa}_{n,m} H_n \left(\frac{x}{\sqrt{t}}\right) L_{\frac{1-a}{2},m} \left(\frac{y^2}{4t}\right),$$

we easily see that

\begin{align*}
\tilde{\kappa}_{0,0} &= \frac{1-a}{2} & \tilde{\Theta}_{0,0}(x,y,t) &= y |y|^{-a} \\
\tilde{\kappa}_{1,0} &= \frac{2-a}{2} & \tilde{\Theta}_{1,0}(x,y,t) &= xy |y|^{-a} \\
\tilde{\kappa}_{2,0} &= \frac{3-a}{2} & \tilde{\Theta}_{2,0}(x,y,t) &= y |y|^{-a}(x^2 - 2t) \\
\tilde{\kappa}_{0,1} &= \frac{3-a}{2} & \tilde{\Theta}_{0,1}(x,y,t) &= y |y|^{-a} \left[\left(\frac{3-a}{2}\right) t - \frac{y^2}{4}\right],
\end{align*}

and so on.

7. Blow-up analysis II: proof of Theorem 3.4

As the title suggests, this section is devoted to the proof of Theorem 3.4, which, miming what done in the previous section, will be obtain as a consequence of a more general theorem that we state below.

**Theorem 7.1.** Fix $-1 < a < 1$, $p_0 = (x_0, 0, t_0) \in \Gamma(U) \cap \Sigma$. Let $U = U(x,y,t)$ be a strong solution to equation (2.16) and $U_{p_0,\lambda} = U_{p_0,\lambda}(x,y,t)$ its normalized blow-up sequence defined in (3.10). Then for
any compact set $K \subset \mathbb{R}^{N+1} \times (0, \infty)$ and any $0 < \nu < \nu_* := \min\{1, 1 - a\}/2$, there exists a constant $C > 0$ not depending on $\lambda > 0$, such that
\begin{equation}
\|U_{p_0, \lambda}\|_{C^{2\nu, \nu}(K)} \leq C,
\end{equation}
and, moreover, we have as $\lambda \to 0^+$
\begin{equation}
U_{p_0, \lambda} \to \Theta_{p_0} \text{ uniformly in } K,
\end{equation}
where $\Theta_{p_0} = \Theta_{p_0}(x, y, t)$ is the blow-up limit of $U$ at $p_0$, defined in Theorem 6.1.

The proof of Theorem 7.1 requires some Liouville type results that we present below. The first result will be obtained as an easy application of the monotonicity formulas proved in Lemma 3.1 and Lemma 4.1, the Gaussian Poincaré inequalities proved in Subsection 5.1 and Theorem 6.1, while the second one requires a different monotonicity formula of Alt-Caffarelli-Friedman type, that we prove below. Again this new monotonicity formula easily follows from the Gaussian-Poincaré inequality (cfr. with Theorem 5.7), combined with Theorem 6.1.

7.1. Liouville type theorems. In the next paragraphs we present some Liouville type theorems. The first result will be obtained as an easy application of the monotonicity formulas proved in Lemma 3.1 and Lemma 4.1, the Gaussian Poincaré inequalities proved in Section 5.1 and Theorem 6.1, while the second one requires a different monotonicity formula of Alt-Caffarelli-Friedman type, that we prove below. Again this new monotonicity formula easily follows from the Gaussian-Poincaré inequality (cfr. with Theorem 5.7), combined with Theorem 6.1.

An Alt-Caffarelli-Friedman monotonicity formula type. As anticipated, we prove a monospecies Alt-Caffarelli-Friedman ([2]) monotonicity formula (cfr. for instance with [3, Lemma 5.4], [15, Theorem 1.1.4], [18, Theorem 12.11], [25, Section 2]), which turns out to be an easy consequence of the Gaussian-Poincaré type inequalities proved in Theorem 5.7. As always we set
\[ \nu_* = \frac{1}{2} \min\{1, 1 - a\}, \]
and we prove the following lemma.

**Lemma 7.2.** (Alt-Caffarelli-Friedman monotonicity formula) The following three statements hold:

(i) Let $U = U(x, y, t)$ be a strong solution to equation (2.17). Then the function
\begin{equation}
J(t, U) := \frac{1}{t^{2\nu_*}} \int_0^t \int_{\mathbb{R}^{N+1}} |\nabla U|^2(x, y, \tau) \, d\mu(x, y) \, d\tau
\end{equation}
is nondecreasing for all $0 < t < T$ and it is constant if and only if $U(x, y, t) = A$ or, depending on $-1 < a < 1$:
\[ U(x, y, t) = \begin{cases} Ax_j & \text{if } a \leq 0 \\ Ay_j |y|^{-a} & \text{if } a \geq 0, \end{cases} \]
where $A \in \mathbb{R}$ and we have used the convention $x_{N+1} = y$.

(ii) Let $U = U(x, y, t)$ be a strong solution to problem (2.15). Then the function
\begin{equation}
J(t, U) := \frac{1}{t} \int_0^t \int_{\mathbb{R}^{N+1}} |\nabla U|^2(x, y, \tau) \, d\mu(x, y) \, d\tau
\end{equation}
is nondecreasing for all $0 < t < T$ and it is constant if and only if $U(x, y, t) = A$ or $U(x, y, t) = Ax_j$ for some $j \in \{1, \ldots, N\}$ and $A \in \mathbb{R}$.
(iii) Let $U = U(x,y,t)$ be a strong solution to problem (2.16). Then the function

$$t \to J(t,U) := \frac{1}{t^{1-a}} \int_0^t \int_{\mathbb{R}^{N+1}} |\nabla U|^2(x,y,\tau) \, d\mu(\tau,x,y) \, d\tau$$

is nondecreasing for all $0 < t < T$ and it is constant if and only if $U(x,y,t) = Ay^{1-a}$ and $A \in \mathbb{R}$.

**Proof.** We begin by proving assertion (i). First of all, we have

$$J'(t) = -\frac{2\nu_*}{t^{2\nu_*+1}} \int_0^t \int_{\mathbb{R}^{N+1}} |\nabla U|^2 \, d\mu(\tau,x,y) \, d\tau + \frac{1}{t^{2\nu_*}} \int_{\mathbb{R}^{N+1}} |\nabla U|^2 \, d\mu(\tau,x,y),$$

for all $0 < t < T$. Furthermore, testing the equation with $\eta = U$, we obtain

$$\int_0^t \int_{\mathbb{R}^{N+1}} |\nabla U|^2 \, d\mu(\tau,x,y) \, d\tau = \int_0^t \int_{\mathbb{R}^{N+1}} |y^a \nabla U \cdot \nabla G_a(x,y,\tau) dxdy d\tau = \int_0^t \int_{\mathbb{R}^{N+1}} |y^a U \partial_\tau G_a \, dxdy d\tau - \int_0^t \int_{\mathbb{R}^{N+1}} |y^a U \nabla U \cdot \nabla G_a \, dxdy d\tau = \frac{1}{2} \int_0^t \int_{\mathbb{R}^{N+1}} |y^a \partial_\tau (U^2) \, G_a \, dxdy d\tau + \frac{1}{2} \int_0^t \int_{\mathbb{R}^{N+1}} |y^a U^2 \partial_\tau G_a \, dxdy d\tau \leq \frac{1}{2} \int_{\mathbb{R}^{N+1}} U^2(2,y,t) \, d\mu_t(x,y)$$

where we have used the equations of $U = U(x,y,t)$ and $G_a = G_a(x,y,t)$, and the identity

$$2 \int_{\mathbb{R}^{N+1}} |y^a U \nabla U \cdot \nabla G_a dxdy = \int_{\mathbb{R}^{N+1}} U^2 \nabla \cdot (|y^a \nabla G_a|) dxdy,$$

for a.e. $0 < \tau < T$. Consequently, combining (7.6) and the above estimate, it suffices to prove

$$\frac{1}{t^{2\nu_*+1}} \left\{ t \int_{\mathbb{R}^{N+1}} |\nabla U|^2 \, d\mu_t(x,y) - \nu_* \int_{\mathbb{R}^{N+1}} U^2 \, d\mu_t(x,y) \right\} \geq 0,$$

which can be easily re-written as

$$\frac{t}{\int_{\mathbb{R}^{N+1}} U^2 \, d\mu_t(x,y)} \int_{\mathbb{R}^{N+1}} |\nabla U|^2 \, d\mu_t(x,y) \geq \nu_*,$$

and, passing to the re-normalized variables $\tilde{U}(x,y,t) = U(x/\sqrt{t}, y/\sqrt{t}, t)$, as

$$\frac{\int_{\mathbb{R}^{N+1}} |\nabla \tilde{U}|^2 \, d\mu(x,y) \geq \nu_*,$$

which turns out to be valid by the definition of $\nu_* = \min\{1, 1-a\}/2$ and the Gaussian-Poincaré inequality proved in Theorem 5.7 part (i) (note that we can always assume that $\tilde{U}(\cdot, t)$ has zero mean for all $t > 0$, as in the proof of Lemma 7.3).

To complete the proof, we firstly fix $-1 < a \leq 0$ (so that $\nu_* = 1/2$) and note that Theorem 5.7 implies that the equality is attained in (7.8) if and only if

$$\tilde{U}(x,y,t) = A(t)x_j \quad \text{i.e.} \quad U(x,y,t) = \sqrt{t} A(t) x_j,$$
for some \( j \in \{1, \ldots, N+1\} \) and function \( A = A(t) \) (recall the re-labeling convention \( x_{N+1} = y \)). Since such \( U = U(x,y,t) \) must be a solution to (2.17) and it satisfies \( \nabla \cdot (|y|^a \nabla U) = 0 \), we deduce that \( A(t) = 1/\sqrt{t} \) (up to multiplicative constants), completing the proof in the case \(-1 < a \leq 0\). In the case \( 0 \leq a < 1 \) (\( \nu_\ast = (1-a)/2 \)), we proceed in the same way, noting that the equality is attained in (7.8) if and only if

\[
\bar{U}(x,y,t) = A(t) \frac{y}{t} \quad \text{i.e.} \quad U(x,y,t) = t^{1-a} A(t) \frac{y}{t}.
\]

Consequently, taking \( A(t) = t^{1-a} \) (up to multiplicative constants), we conclude the proof of the case \( 0 \leq a < 1 \), too.

The proofs of part (ii) and (iii) are very similar to the one just presented and we skip them. We just mention that it is enough to repeat the above procedure using the integral formulation for strong solutions to (2.15) and (2.16), and the right Gaussian-Poincaré inequality (cfr. with part (ii) and (iii) of Theorem 5.7). □

Some comments are now in order. Let \( J = J(t, U) \) be defined as in (7.3). Then, from the fact that

\[
\int_0^t \int_{\mathbb{R}^{N+1}} |\nabla U|^2 d\mu^\tau(x,y) d\tau \leq \frac{1}{2} \int_{\mathbb{R}^{N+1}} U^2(x,y,t) d\mu_t(x,y) = \frac{1}{2} H(t,U),
\]

for all \( t > 0 \), it easily follows that \( J = J(t,U) \) is in fact well-defined and positive (except for constant functions), for all \( t > 0 \). Note that, in view of the proof of Theorem 6.1 (cfr. with formula (6.21)), we have \( H(t,U) \sim Ct^{2\nu_\ast} \) for \( t \to 0^+ \) which gives us

\[
\int_0^t \int_{\mathbb{R}^{N+1}} |\nabla U|^2 d\mu^\tau(x,y) d\tau \leq Ct^{2\nu_\ast}, \quad \text{for } t \to 0^+,
\]

and a suitable constant \( C > 0 \). Moreover, the converse inequality in (7.10) holds too, for any nonconstant solutions \( U = U(x,y,t) \) (that, as always, we can assume to have zero mean w.r.t. \( d\mu_t = d\mu_t(x,y) \), for all \( t > 0 \)). Indeed, from (7.7), we obtain

\[
\frac{1}{\nu_\ast} J(t,U) \geq \frac{1}{t^{2\nu_\ast}} \int_0^t \frac{1}{\tau} \int_{\mathbb{R}^{N+1}} U^2(x,y,\tau) d\mu^\tau(x,y) d\tau = \frac{1}{t^{2\nu_\ast}} \int_0^t \frac{H(\tau,U)}{\tau} d\tau \geq \frac{C}{t^{2\nu_\ast+1}} \int_0^t \tau^{2\nu_\ast} \tau d\tau \geq C > 0, \quad \text{for } t \to 0^+,
\]

where we have used formula (6.21) again. Consequently, we have

\[
\int_0^t \int_{\mathbb{R}^{N+1}} |\nabla U|^2 d\mu^\tau(x,y) d\tau \sim Ct^{2\nu_\ast}, \quad \text{for } t \to 0^+,
\]

and as an immediate consequence, we obtain \( \lim_{t \to 0^+} J(t,U) > 0 \) when \( U = U(x,y,t) \) is nonconstant. The very same observations hold if we replace the functional (7.8) with (7.3) and/or (7.5), with simple modifications.

**Liouville type theorems.** Let us now turn to the proof of some Liouville type results. In this context, it is important to stress that we focus on the *global* quantitative behaviour of strong solutions, instead of the *local* one (this is easily seen, for instance, in the interest of the asymptotic behaviour of the quantity \( H(t,U) \) as \( t \to \infty \), instead of \( t \to 0^+ \)). In what follows we employ the following definition of parabolic distance:

\[
d^2(x,y,t) := |x|^2 + |y|^2 + t, \quad \text{for all } (x,y,t) \in \mathbb{R}^{N+1} \times (0, \infty).
\]
Note that it is not a distance in the usual sense, since the triangular inequality does not hold, but it is invariant under parabolic dilatations, in the sense that \( d(x, y, t) = \sqrt{t} d(x/\sqrt{t}, y/\sqrt{t}, 1) \).

**Lemma 7.3.** The following three statements hold.

(i) Let \( U = U(x, y, t) \) be a strong solution to equation (2.17) in \( \mathbb{R}^{N+1} \times (0, \infty) \) (i.e. \( T = \infty \)) and assume it satisfies the bound

\[
U^2(x, y, t) \leq C[1 + d^{2\nu}(x, y, t)],
\]

for some \( C > 0 \) and some exponent \( \nu > 0 \) satisfying

\[0 < \nu < \min\{1, 1 - a\}.
\]

Then \( U \) is constant in \( \mathbb{R}^{N+1} \times (0, \infty) \).

(ii) Let \( U = U(x, y, t) \) be a strong solution to problem (2.15) in \( \mathbb{R}^{N+1} \times (0, \infty) \) (i.e. \( T = \infty \)) and assume it satisfies the bound in (7.11) for some \( C > 0 \) and some exponent \( \nu > 0 \) satisfying

\[0 < \nu < 1.
\]

Then \( U \) is constant in \( \mathbb{R}_+^{N+1} \times (0, \infty) \).

(iii) Let \( U = U(x, y, t) \) be a strong solution to problem (2.16) in \( \mathbb{R}^{N+1} \times (0, \infty) \) (i.e. \( T = \infty \)) and assume it satisfies the bound in (7.11) for some \( C > 0 \) and some exponent \( \nu > 0 \) satisfying

\[0 < \nu < 1 - a.
\]

Then \( U \) is identically zero in \( \mathbb{R}_+^{N+1} \times (0, \infty) \).

**Proof.** We begin by proving part (i). First of all, we note that for any \( \nu > 0 \), if \( U = U(x, y, t) \) satisfies the point-wise bound (7.11), it holds

\[
H(t, U) = \int_{\mathbb{R}^{N+1}} |y|^a U^2(x, y, t) G_a(x, y, t) \, dx \, dy
\]

\[
\leq C \int_{\mathbb{R}^{N+1}} |y|^a \left[ \left( |x|^2 + |y|^2 + t\right)^\nu + 1 \right] G_a(x, y, t) \, dx \, dy
\]

\[
= C + t^\nu \int_{\mathbb{R}^{N+1}} |y|^a \left( |x|^2 + |y|^2 + 1\right)^\nu G_a(x, y, 1) \, dx \, dy \leq Ct^\nu,
\]

for a suitable constant \( C > 0 \) and \( t > 0 \) large. Now, set as always \( \kappa := \lim_{t \to 0^+} N(t, U) \) and assume by contradiction that \( U = U(x, y, t) \) is non constant. Let us start with the case \( \kappa > 0 \). In this case, it must be

\[
\kappa \geq \frac{1}{2} \min\{1, 1 - a\} := \nu_*,
\]

since \( \kappa > 0 \) has to be an eigenvalue of problem (5.2) (cfr. with Theorem 6.1) and 1/2 and \((1 - a)/2\) are the first nontrivial eigenvalue depending on \(-1 < a < 0\) or \(0 < a < 1\), respectively (cfr. with Theorem 5.2). Now, in part (ii) of Theorem 6.1 we have shown that

\[
\lim_{t \to 0^+} t^{-2\kappa} H(t, U) = L_0,
\]

for some positive constant \( L_0 > 0 \). Moreover, proceeding as in Corollary 4.3 it holds

\[
\frac{H'(t, U)}{H(t, U)} \geq \frac{2\kappa}{t}, \quad \text{for all } t > 0,
\]
and so, integrating between $0 < t_0 < t$ and $t$, we obtain
\[ H(t, U) \geq t_0^{-2\kappa} H(t_0, U)t^{2\kappa}, \quad \text{for all } 0 < t_0 < t. \]
Consequently, taking the limit as $t_0 \to 0^+$ we finally obtain $H(t, U) \geq Ct^{2\kappa}$ for all $t > 0$ and so, thanks to (7.13), we deduce
\[ H(t, U) \geq Ct^{\min\{1, 1-a\}} = Ct^{2\nu_*}, \]
for $t > 0$ large enough, which is in contradiction with the bound from above in 7.12 unless $U = U(x, y, t)$ is constant.

Now, assume that $\kappa = 0$. In this case, the bound in (7.12) is still true, but instead of the last bound from below, we just obtain $H(t, U) \geq C$ for all $t > 0$, which is not enough to immediately deduce the desired contradiction. So, we pass to the re-scaling $\tilde{U}(x, y, t) = U(\sqrt{t}x, \sqrt{t}y, t)$ and we recall that $\tilde{U}(t) \in H^1(\mathbb{R}^{N+1}, d\mu)$ for all $t > 0$. Consequently, we can apply the Gaussian Poincaré inequality of Theorem 5.7, part (i), to deduce
\[ \int_{\mathbb{R}^{N+1}} \tilde{U}^2(t) d\mu - \left( \int_{\mathbb{R}^{N+1}} \tilde{U}(t) d\mu \right)^2 \leq \frac{1}{\nu_*} \int_{\mathbb{R}^{N+1}} |\nabla \tilde{U}|^2(t) d\mu, \quad \text{for all } t > 0, \]
where $P_a := 1/\nu_* = 2/\min\{1, 1-a\}$. Note that we can assume $\int_{\mathbb{R}^{N+1}} \tilde{U}(t) d\mu = 0$ for all $t > 0$. Indeed, we have already seen that the function
\[ t \to \int_{\mathbb{R}^{N+1}} \tilde{U}(t) d\mu \]
is constant (cfr. with (2.32)) and, since $\tilde{U} = \tilde{U}(x, y, t)$ satisfies a linear equation, we can replace $\tilde{U}$ by
\[ \tilde{U}(x, y, t) - \int_{\mathbb{R}^{N+1}} \tilde{U}(t) d\mu, \]
to obtain a strong solution to equation (2.17) with zero mean for all $t > 0$. Consequently, (7.14) can be easily re-written as
\[ \nu_* = \frac{1}{2} \min\{1, 1-a\} \leq N(1, \tilde{U}), \]
and, since the l.h.s. is strictly positive, while the r.h.s. is converging to zero as $t \to 0^+$, we obtain a contradiction unless $\tilde{U} \equiv 0$ and we conclude the proof of part (i) (note that we infer $\tilde{U} \equiv 0$ since we have assumed that $\tilde{U}$ has zero mean for any $t > 0$)

For what concerns part (ii) and (iii), it is easily seen that the proof of part (i) works also in these different settings with straightforward modifications. The most significative is that we have to employ the right Gaussian Poincaré inequality proved in Theorem 5.7 depending on the problem (Neuman or Dirichlet) satisfied by $U = U(x, y, t)$. □

We now prove a second Liouville type result of a quite different nature. In the first one, we impose a critical growth condition one the function $U = U(x, y, t)$, whilst, in the second, a sort of decaying property of the norm of the gradient is required.

Lemma 7.4. The following three statements hold.

(i) Let $U = U(x, y, t)$ be a strong solution to equation (2.17) in $\mathbb{R}^{N+1} \times (0, \infty)$ (i.e. $T = \infty$) and assume it satisfies the bound
\[ |\nabla U(x, y, t)|^2 \leq C d^{2\nu}(x, y, t), \]

where $d(x, y, t)$ is defined as $(|x|^2 + |y|^2 + t^2)^{\frac{1}{2}}$. Then, $U \equiv 0$.
for some $C > 0$ and some exponent $v \in \mathbb{R}$ satisfying 

$$
\nu < \min\{0, -a\}.
$$

Then $U$ is constant in $\mathbb{R}^{n+1}_+ \times (0, \infty)$.

(ii) Let $U = U(x, y, t)$ be a strong solution to problem (2.15) in $\mathbb{R}^{n+1}_+ \times (0, \infty)$ (i.e. $T = \infty$) and assume it satisfies the bound in (7.15) for some $C > 0$ and some exponent $\nu \in \mathbb{R}$ satisfying 

$$
\nu < 0.
$$

Then $U$ is constant in $\mathbb{R}^{n+1}_+ \times (0, \infty)$.

(iii) Let $U = U(x, y, t)$ be a strong solution to problem (2.16) in $\mathbb{R}^{n+1}_+ \times (0, \infty)$ (i.e. $T = \infty$) and assume it satisfies the bound in (7.15) for some $C > 0$ and some exponent $\nu \in \mathbb{R}$ satisfying 

$$
\nu < -a.
$$

Then $U$ is identically zero in $\mathbb{R}^{n+1}_+ \times (0, \infty)$.

**Proof.** As before, we prove part (i), while (ii) and (iii) follow similarly. Compared with the above proof, the present one is based on the monotonicity of the functional $t \to J(t, U)$ defined in (7.2) instead of the Almgren-Poon quotient $t \to N(t, U)$. So, if (7.15) holds true, then

$$
J(t, U) = \frac{1}{t^{2\nu}} \int_0^t \int_{\mathbb{R}^{n+1}} |\nabla U|^2(x, y, \tau) \, d\mu(x, y) \, d\tau 
$$

as $t \to +\infty$, thanks to the assumption on $\nu \in \mathbb{R}$. From Lemma 7.2 it thus follows that $J(t, U) = 0$ for any $t > 0$, and so, since the measure $d\mu_t = d\mu_t(x, y)$ is nonnegative, it follows $|\nabla U| = 0$ a.e. in $\mathbb{R}^{n+1}_+ \times (0, \infty)$, i.e. $U = U(x, y, t)$ is constant. □

**Proof of Theorem 7.1** In this proof, we adapt some technique employed in (67), (68) (see also (69), (73)) in the elliptic framework, to the parabolic one. The method is based on a blow-up-of-the-blow-up sequence and on the construction of two auxiliary sequences combined with the application of Liouville type results proved in Lemma 7.3.

Now, let $U = U(x, y, t)$ be a strong solution to equation (2.17) and $p_0 = 0$. We consider the blow-up sequence

$$
U_\lambda(x, y, t) = U(\lambda x, \lambda y, \lambda^2 t), \quad \kappa := \lim_{t \to 0^+} N(t, U),
$$

so that $U_\lambda = U_\lambda(x, y, t)$ satisfies the same equation in $\mathbb{R}^{n+1} \times (0, T/\lambda^2)$, $\lambda > 0$. Moreover, we fix a time $T_\ast > 0$ and a compact set $K \subset \mathbb{R}^{n+1} \times (0, T_\ast)$ (note that since $\lambda \to 0$, we can assume also $T_\ast < T/\lambda^2$).

The first step of the proof consists in showing that the family $\{U_\lambda\}$ is uniformly bounded in the Hölder space $C^{2\nu, \nu}(K)$ for any $0 < \nu < \nu_\ast = \min\{1, 1-a\}/2$, i.e.,

$$
\|U_\lambda\|_{L^\infty(K)} + [U_\lambda]_{C^{2\nu, \nu}(K)} \leq C,
$$

for some constant $C > 0$ independent of $\lambda > 0$, where the symbol $[\cdot]_{C^{2\nu, \nu}(K)}$ denotes the Hölder semi-norm. Note that it suffices to prove the above bound with $K = Q_{1/2} := \mathbb{B}_{1/2} \times (3/4, 1)$ and deduce the general case through standard covering arguments. Furthermore, a uniform bound for $\|U_\lambda\|_{L^\infty(Q_{1/2})}$
can be obtained through the Harnack inequality proved by Chiarenza and Serapioni in Theorem 2.1 of [21] (note that from $L^2 - L^\infty$ estimates we already know that $U_\lambda$ is locally bounded, cfr. with Lemma 2.1 of [21] and/or formula (5.7) of [5]).

For what concerns the H"{o}lder semi-norm, we assume the uniform bound of $\|U_\lambda\|_{L^\infty(Q_1)}$, and we show that for any $0 < \nu < \nu_* = \min\{1, 1 - a\}/2$, there exists a constant $C > 0$ (independent of $\lambda > 0$), such that

$$\tag{7.16} [U_\lambda]_{C^{2,\nu}(Q_{1/2})} := \sup_{Q_{1/2}} \frac{|U_\lambda(X_1, t_1) - U_\lambda(X_2, t_2)|}{(|X_1 - X_2|^2 + |t_1 - t_2|)^{\nu}} \leq C,$$

where we have set by convenience $X := (x, y) \in \mathbb{R}^{N+1}$ and $|X| = \sqrt{|x|^2 + y^2}$. More precisely, for any $0 < \nu < \nu_* := \min\{1, 1 - a\}/2$, we will show

$$\tag{7.17} [\eta U_\lambda]_{C^{2,\nu}(Q_1)} \leq C,$$

where $Q_1 := B_1 \times (0, 1)$ and $\eta = \eta(X, t)$ is a smooth function satisfying

$$\begin{align*}
\eta(X, t) &= 1 \quad \text{for } (X, t) \in Q_{1/2} \\
0 < \eta(X, t) &\leq 1 \quad \text{for } (X, t) \in Q_1 \setminus Q_{1/2} \\
\eta(X, t) &= 0 \quad \text{for } (X, t) \in \partial Q_1,
\end{align*}$$

where $\partial Q_1 := \partial B_1 \times (0, 1)] \cup [B_1 \times \{0\}]$. From the definition of $\eta = \eta(X, t)$, (7.16) easily follows from (7.17).

**Step 1:** *Reductio ad absurdum and first definitions.* Assume by contradiction that (7.17) does not hold, i.e. there exists $0 < \nu < \nu_*$ and a sequence $\lambda_j \to 0^+$ as $j \to +\infty$ such that

$$[\eta U_{\lambda_j}]_{C^{2,\nu}(Q_1)} = \sup_{Q_1} \frac{|\eta(X_1, t_1)U_{\lambda_j}(X_1, t_1) - \eta(X_2, t_2)U_{\lambda_j}(X_2, t_2)|}{(|X_1 - X_2|^2 + |t_1 - t_2|)^{\nu}} := L_j \to +\infty,$$

as $j \to +\infty$. We may assume that for any $j \in \mathbb{N}$, $L_j$ is achieved by $(X_{1,j}, t_{1,j}), (X_{2,j}, t_{2,j}) \in Q_1$, i.e.

$$\tag{7.18} L_j := \frac{|\eta(X_{1,j}, t_{1,j})U_{\lambda_j}(X_{1,j}, t_{1,j}) - \eta(X_{2,j}, t_{2,j})U_{\lambda_j}(X_{2,j}, t_{2,j})|}{r_j^{2\nu}},$$

for any index $j \in \mathbb{N}$, where, for future simplicity, we have defined

$$r_j := (|X_{1,j} - X_{2,j}|^2 + |t_{1,j} - t_{2,j}|)^{\frac{1}{2}}, \quad j \in \mathbb{N}.$$

From (7.18), we immediately deduce the bound

$$L_j \leq \frac{\|U_{\lambda_j}\|_{L^\infty(Q_1)}}{r_j^{2\nu}}[|\eta(X_{1,j}, t_{1,j})| + |\eta(X_{2,j}, t_{2,j})|],$$

and so, since we know that $U_{\lambda_j}$ is uniformly bounded in $Q_1$, we obtain that $r_j \to 0$ as $j \to +\infty$. Furthermore, from the same bound on $L_j$ and the smoothness of $\eta = \eta(X, t)$, it is easily seen that

$$\frac{\text{dist}((X_{1,j}, t_{1,j}), \partial Q_1)}{r_j} + \frac{\text{dist}((X_{2,j}, t_{2,j}), \partial Q_1)}{r_j} \geq \frac{L_j r_j^{2\nu - 1}}{\|U_{\lambda_j}\|_{L^\infty(Q_1)}},$$

where $L > 0$ is taken such that $|\eta(X_1, t_1) - \eta(X_2, t_2)| \leq L(|X_1 - X_2|^2 + |t_1 - t_2|)^{\frac{1}{2}}$. Consequently, since $0 < 2\nu < 1$, we obtain

$$\tag{7.19} \frac{\text{dist}((X_{1,j}, t_{1,j}), \partial Q_1)}{r_j} + \frac{\text{dist}((X_{2,j}, t_{2,j}), \partial Q_1)}{r_j} \to +\infty,$$
as \( j \to +\infty \).

**Step 2: Auxiliary sequences.** Following the ideas of \([67, \text{Section } 6]\) and \([68, \text{Section } 4]\), the remaining part of the proof is based on the analysis of two different sequences:

\[
W_j(X, t) := \eta(\hat{X}_j, \hat{t}_j) \frac{U_{\lambda_j}(\hat{X}_j + r_j X, \hat{t}_j + r_j^2 t)}{L_j r_j^{2\nu}},
\]

(7.20)

\[
\overline{W}_j(X, t) := \frac{(\eta U_{\lambda_j})(\hat{X}_j + r_j X, \hat{t}_j + r_j^2 t)}{L_j r_j^{2\nu}},
\]

where \( \hat{P}_j = (\hat{X}_j, \hat{t}_j) \in Q_1 \) will be chosen later and

\[
(X, t) \in Q' = (Q_1 - \hat{P}_j)/r_j = \mathbb{B}_1/r_j(\hat{X}_j) \times (-\hat{t}_j/r_j, (1 - \hat{t}_j)/r_j), \quad j \in \mathbb{N}.
\]

The definitions of the new sequences in (7.20) are motivated by two crucial facts.

The first one is that the Hölder semi-norm of order \( 0 < \nu < \nu_* \) of \( \overline{W}_j = \overline{W}_j(X, t) \) is bounded independently of \( j \in \mathbb{N} \):

\[
|\overline{W}_j|_{C^{2\nu, \nu}(Q_j)} = 1 \quad \text{for all } j \in \mathbb{N}.
\]

This easily follows by the definition of \( \overline{W}_j = \overline{W}_j(X, t) \), \( L_j \) and \( r_j \). On the other hand, the first sequence satisfies the notable equation

(7.21)

\[
\partial_t W_j + L_j^d W_j = 0 \quad \text{in } \mathbb{R}^{N+1} \times (-\hat{t}_j/r_j, (1 - \hat{t}_j)/r_j),
\]

where \( L_j^d W = |\tilde{y}_j r_j^{-1} + y|^{-a} \nabla \cdot ((\tilde{y}_j r_j^{-1} + y)^a \nabla W_j) \) and \( \hat{X}_j = (\tilde{x}_j, \tilde{y}_j) \), for all \( j \in \mathbb{N} \), with \( W_j(0) = \overline{W}_j(0) \).

A second important feature of these two sequences is that they are asymptotically equivalent on compact sets of \( \mathbb{R}^{N+1} \times \mathbb{R} \). Indeed, if \( K \subset \mathbb{R}^{N+1} \times \mathbb{R} \) is compact and \( (X, t) \in K \), we have

\[
|W_j(X, t) - \overline{W}_j(X, t)| \leq \frac{\|\eta U_{\lambda_j}\|_{L^\infty(Q_1)}}{r_j^{2\nu} L_j} |\eta(\hat{X}_j + r_j X, \hat{t}_j + r_j^2 t) - \eta(\hat{X}_j, \hat{t}_j)|
\]

\[
\leq L \frac{\|\eta U_{\lambda_j}\|_{L^\infty(Q_1)}}{r_j^{2\nu-1} L_j} \left(|X|^2 + t\right)^{\frac{\nu}{2}} \to 0,
\]

as \( j \to +\infty \) (recall that \( r_j \to 0 \), \( L_j \to +\infty \), and \( 2\nu < 1 \)). In particular, it follows

(7.22)

\[
\|W_j - \overline{W}_j\|_{L^\infty(K \cap Q_j)} \to 0 \quad \text{as } j \to +\infty.
\]

Furthermore, from the bound above and recalling that \( \overline{W}_j = \overline{W}_j(X, t) \) is \( \nu \)-Hölder continuous with \( \overline{W}_j(0) = W_j(0) \), it is easily seen that

\[
|W_j(X, t) - W_j(0)| \leq |W_j(X, t) - \overline{W}_j(X, t)| + |\overline{W}_j(X, t) - \overline{W}_j(0)|
\]

\[
\leq C \left(\frac{1}{r_j^{2\nu-1} L_j} \left(|X|^2 + t\right)^{\frac{\nu}{2}} + \left(|X|^2 + t\right)^\nu\right),
\]

from which we deduce the existence of a constant \( C > 0 \) depending on the compact set \( K \subset \mathbb{R}^{N+1} \times \mathbb{R} \) such that

(7.23)

\[
\sup_{(X, t) \in K \cap Q_j} |W_j(X, t) - W_j(0)| \leq C.
\]

These last two properties will be crucial in the next step.
Step 3: Asymptotic behaviour of \((X_{1,j}, t_{1,j})\) and \((X_{2,j}, t_{2,j})\). We now show that the sequences \((X_{1,j}, t_{1,j})\) and \((X_{2,j}, t_{2,j})\) approach the characteristic manifold \(\Sigma = \{(x, y) \in \mathbb{R}^{N+1} : y = 0\}\) as \(j \to +\infty\). More precisely, we prove the existence of a constant \(C > 0\) such that

\[
\frac{\text{dist}((X_{1,j}, t_{1,j}), Q_1 \cap \Sigma)}{r_j} + \frac{\text{dist}((X_{2,j}, t_{2,j}), Q_1 \cap \Sigma)}{r_j} \leq C,
\]

for \(j \in \mathbb{N}\) large enough. Arguing by contradiction, we assume that

\[
\frac{\text{dist}((X_{1,j}, t_{1,j}), Q_1 \cap \Sigma)}{r_j} + \frac{\text{dist}((X_{2,j}, t_{2,j}), Q_1 \cap \Sigma)}{r_j} \to +\infty \quad \text{as} \quad j \to +\infty.
\]

Let us take \((\widehat{X}_j, \widehat{t}_j) = (X_{1,j}, t_{1,j})\) in the definition of \(W_j = W_j(X, t)\) and \(\overline{W}_j = \overline{W}_j(X, t)\), so that, thanks to (7.19),

\[
Q^j \to \mathbb{R}^{N+1} \times \mathbb{R} \quad \text{or} \quad Q^j \to \mathbb{R}^{N+1} \times (0, \infty) \quad \text{as} \quad j \to +\infty.
\]

In what follows, we will assume \(Q^j \to \mathbb{R}^{N+1} \times \mathbb{R}\) since the other case can be treated similarly. Now, consider the new sequences

\[
Z_j(X, t) := W_j(X, t) - W_j(0),
\]

\[
\overline{Z}_j(X, t) := \overline{W}_j(X, t) - \overline{W}_j(0),
\]

and let \(j \in \mathbb{N}\) be large enough such that \(K \subset Q^j\), where \(K \subset \mathbb{R}^{N+1} \times \mathbb{R}\) is a fixed compact set. Since the sequence \(\{\overline{Z}_j\}_{j \in \mathbb{N}}\) is uniformly bounded in \(K\) (cfr. with (7.22) and (7.23)) with uniformly bounded \(\nu\)-Hölder semi-norm, we can apply Ascoli-Arzelà Theorem to deduce the existence of a continuous function \(Z \in C(K)\), uniform limit of \(\overline{Z}_j = \overline{Z}_j(X, t)\) as \(j \to +\infty\).

Note that, using a standard diagonal procedure, we obtain that \(\overline{Z}_j \to Z\) uniformly on compact sets of \(\mathbb{R}^{N+1} \times \mathbb{R}\) and, by (7.22) and (7.23), we obtain \(Z_j \to Z\) uniformly on compact sets of \(\mathbb{R}^{N+1} \times \mathbb{R}\), too. Furthermore, from the definition of \(\overline{Z}_j = \overline{Z}_j(X, t)\)

\[
|\overline{Z}_j(X_1, t_1) - \overline{Z}_j(X_2, t_2)| = |\overline{W}_j(X_1, t_1) - \overline{W}_j(X_2, t_2)| \leq (|X_1 - X_2|^2 + |t_1 - t_2|)^\nu,
\]

for any choice \((X_1, t_1), (X_2, t_2) \in \mathbb{R}^{N+1} \times \mathbb{R}\) and \(j \in \mathbb{N}\) large enough. Consequently, taking \(j \to +\infty\) in the above inequality, we obtain \(Z \in C^{2\nu}(\mathbb{R}^{N+1} \times \mathbb{R})\), for any \(0 < \nu < \nu_* = \min\{1, 1 - a\}/2\). In particular, it satisfies

\[
|Z(x, y, t)| \leq C(1 + (|X|^2 + |t|)^\nu) \leq C(1 + d^{2\nu}(x, y, t))
\]

for any \((x, y, t) \in \mathbb{R}^{N+1} \times \mathbb{R}_+\), \(0 < 2\nu < \min\{1, 1 - a\}\), and some \(C > 0\).

Now, multiplying the equation of \(Z_j = Z_j(X, t)\) by \(|\widehat{y}_j r_j^{-1} + y| a \varphi\) (note that \(Z_j\) satisfies the same equation of \(W_j\)), where \(\varphi = \varphi(X, t)\) is any test function belonging to \(C_0^\infty(\mathbb{R}^{N+1} \times \mathbb{R})\), and integrating by parts both in space and time, we easily see that

\[
\int_{\mathbb{R}} \int_{\mathbb{R}^{N+1}} \left[ |1 + r_j |\widehat{y}_j|^{-1} y| a \partial_t \varphi - \nabla \cdot \left( |1 + r_j |\widehat{y}_j|^{-1} y| a \nabla \varphi \right) \right] Z_j \, dx \, dy \, dt = 0.
\]

Hence, exploiting the fact that \(|1 + r_j |\widehat{y}_j|^{-1} y| a \to 1\) on any compact set of \(\mathbb{R}^{N+1} \times \mathbb{R}\) \(\left( r_j |\widehat{y}_j|^{-1} \to 0 \right. \text{thanks to (7.25)}\) and using the uniform convergence of the sequence \(Z_j = Z_j(X, t)\), we pass to the limit as \(j \to +\infty\) in the above relation to conclude

\[
\int_{\mathbb{R}} \int_{\mathbb{R}^{N+1}} (\partial_t \varphi - \Delta_{x,y} \varphi) Z \, dx \, dy \, dt = 0,
\]
for any $\varphi \in C_0^\infty(\mathbb{R}^{N+1} \times \mathbb{R})$. In particular, this implies that $Z = Z(X,t)$ is a backward caloric function in $\mathbb{R}^{N+1} \times \mathbb{R}_+$, in the very weak sense. Consequently, from the classical regularity theory of the Heat Equation, the bound in (7.27), and the Liouville type theorem proved in Lemma 7.3 (part (i) with $a = 0$, see also the classical Hirschman’s paper [41]), we immediately deduce that $Z = Z(X,t)$ must be constant.

At this point, since we have chosen $(\tilde{X}_j, \tilde{t}_j) = (X_{1,j}, t_{1,j})$, it follows

$$
\frac{(X_{2,j}, t_{2,j}) - (\tilde{X}_j, \tilde{t}_j)}{r_j} = \frac{(X_{2,j}, t_{2,j}) - (X_{1,j}, t_{1,j})}{(|X_{1,j} - X_{2,j}|^2 + |t_{1,j} - t_{2,j}|)^{\frac{1}{2}}} \rightarrow (X_2, t_2),
$$

for some $(X_2, t_2) \in Q_1$, up to subsequences, and so, using the uniform convergence and the uniform Hölder bound on $W_j = W_j(X,t)$, we obtain

$$
1 = |W_j \left( \frac{X_{2,j} - \tilde{X}_j}{r_j}, \frac{t_{2,j} - \tilde{t}_j}{r_j} \right) - W_j \left( \frac{X_{1,j} - \tilde{X}_j}{r_j}, \frac{t_{1,j} - \tilde{t}_j}{r_j} \right)|
$$

$$
= Z_j \left( \frac{X_{2,j} - \tilde{X}_j}{r_j}, \frac{t_{2,j} - \tilde{t}_j}{r_j} \right) - Z_j \left( \frac{X_{1,j} - \tilde{X}_j}{r_j}, \frac{t_{1,j} - \tilde{t}_j}{r_j} \right)
$$

$$
= Z_j \left( \frac{X_{2,j} - \tilde{X}_j}{r_j}, \frac{t_{2,j} - \tilde{t}_j}{r_j} \right) - Z_j(0) \rightarrow |Z(X_2, t_2) - Z(0)| = 1,
$$

as $j \rightarrow +\infty$, i.e. $Z = Z(x,t)$ is nonconstant, in contradiction with the Liouville type theorem. This conclude the proof of (7.24).

**Step4: Final part of the proof of (7.24)**. In view of (7.24) and the arbitrariness of $\hat{P}_j = (\hat{X}_j, \hat{t}_j) \in Q_1$ in the definition of $W_j = W_j(X,t)$ and $\bar{W}_j = \bar{W}_j(X,t)$ (cfr. with (7.20)), we can choose $\hat{P}_j = (X_{1,j}, t_{1,j}) = (x_{1,j}, 0, t_{1,j}) \in \Sigma$, for all $j \in \mathbb{N}$. Consequently, it follows that $W_j = W_j(X,t)$ is a strong solution to the equation (instead of (7.21)):

$$
(\hat{X})_{j,t} W_j + \mathcal{L}_a W_j = 0 \quad \text{in} \quad \mathbb{R}^{N+1} \times (-\hat{t}_j/r_j^2, (1 - \hat{t}_j)/r_j^2)
$$

and, repeating the procedure followed in **Step3** together with the $L^2(0, T; H^1_{\mu_t})$ type convergence proved in Theorem 6.1 we deduce that the limit function $Z = Z(X,t)$ (of the sequences in (7.26)) satisfies

$$
\int_{\mathbb{R}^{N+1}} \left[ \partial_t Z + \frac{(x,y)}{2t} \cdot \nabla Z \right] \eta \, d\mu_t(x,y) = \int_{\mathbb{R}^{N+1}} \nabla Z \cdot \nabla \eta \, d\mu_t(x,y),
$$

for a.e. $0 < t < T$ and all $\eta \in L^2_{\text{loc}}(0, T; H^1_{\mu_t})$, together with the global bound (7.27). It thus follows that $Z = Z(X,t)$ must be constant (it suffices to apply Lemma 7.3 again) while (7.28) holds also in this case. This gives the final contradiction.

**Step5: Uniqueness of the blow-up limit.** Having shown (7.16), we can assume that there exists a subsequence $\lambda_j \rightarrow 0^+$ and a locally bounded continuous function $\Theta = \Theta(x,y,t)$ such that for any $T_0 > 0$ and compact set $K \subset \mathbb{R}^{N+1} \times (0, T_0)$, it holds

$$
\|U_{\lambda_j} - \Theta\|_{L^\infty(K)} \rightarrow 0,
$$

as $j \rightarrow +\infty$. On the other hand, setting as always

$$
\Theta(x,y,t) = t^{\kappa_0, m_0} \sum_{(\alpha, m) \in J_0} v_{\alpha, m} \nabla_{\alpha, m} \left( \frac{x}{\sqrt{t}}, \frac{y}{\sqrt{t}} \right),
$$
where \( v_{\alpha,m} \in \mathbb{R} \), \( \nabla_{\alpha,m} = \nabla_{\alpha,m}(x,y) \) and \( J_0 \) are defined as in the statement of Theorem 6.1 and \( n_0, m_0 \in \mathbb{N} \) are chosen such that \( \kappa = \kappa_{n_0,m_0} \), we have
\[
\| U_\lambda - \Theta \|_{L^2(0,T_*, H^1_{\mu t})} \to 0,
\]
as \( \lambda \to 0^+ \). Now, we note that
\[
\int_K |\Theta - \Theta|^2 d\mu_t(x,y) dt \leq \| U_{\lambda_j} - \Theta \|_{L^\infty(K)}^2 \int_0^{T_*} \int_{\mathbb{R}^{N+1}} d\mu_t(x,y) dt + \| U_{\lambda_j} - \Theta \|_{L^2(0,T_*, L^2_{\mu t})}^2
\]
\[
= T_* \| U_{\lambda_j} - \Theta \|_{L^\infty(K)}^2 + \| U_{\lambda_j} - \Theta \|_{L^2(0,T_*, L^2_{\mu t})}^2 \to 0,
\]
as \( j \to +\infty \), from which we deduce \( \Theta = \overline{\Theta} \) on any compact set \( K \subset \mathbb{R}^{N+1} \times (0,T_*) \) (note that the continuity of the limit profiles is used) and conclude the proof of the theorem. \( \square \)

**Important remark.** As mentioned in the introduction, Theorem 7.1 has an interesting consequence. If \( U = U(x,y,t) \) is a locally bounded solution to equation (2.17) (let us say \( \| U \|_{L^\infty(Q)} \leq C \)), then \( U = U(x,y,t) \) is uniformly bounded in some Hölder space

\[(7.30) \quad [U]_{C^{2,\nu}(Q_{1/2})} \leq C \quad \text{for all } 0 < \nu < \nu_* := \frac{1}{2} \min\{1, 1-a\},\]

and some constant \( C > 0 \) not depending on \( U = U(x,y,t) \). This fact can be easily obtained by repeating the above proof, replacing \( U \) by \( U_\lambda \) and it is very significative since it is the first quantitative Hölder estimate of solutions to (2.17). We stress that Hölder continuity of solutions to (2.17) was already proved by Chiarenza and Serapioni in [21] and by Banerjee and Garofalo in [5], but in those cases the best Hölder exponent was not explicit. Note that the above bound is almost optimal, in the sense that there are strong solutions to (2.17) satisfying (7.30) with \( \nu = \nu_* \). A simple example for the case \( 0 < a < 1 \) is given by the function \( U(x,y,t) = y|y|^{-a} \), while, for \( -1 < a \leq 0 \), \( U(x,y,t) = x \) (cfr. with the elliptic case [73]).

**Proof of Theorem 3.4.** In the case in which \( U = U(x,y,t) \) is a strong solution to the homogeneous Neumann problem (2.15) (and \( p_0 = 0 \)), we can repeat the above proof with minor changes. We basically have to work in \( \mathbb{R}^{N+1}_+ \) instead of \( \mathbb{R}^{N+1}_0 \) and in order to bound \( \| U_{\lambda} \|_{L^\infty(Q_{1/2})} \) uniformly w.r.t. \( \lambda > 0 \), we do not employ the Harnack inequality of Chiarenza and Serapioni (Theorem 2.1 of [21]) but the one of Banerjee and Garofalo (formula (5.12) of [5]). Secondly, we obtain that the function \( W_j = W_j(X,t) \), defined in (7.20), satisfies
\[
\begin{align*}
\partial_t W_j + \mathcal{L}_j W_j &= 0 \quad \text{in } \mathbb{R}^N \times \{ y > -\hat{y}_j/r_j \} \times (-\hat{t}_j/r_j^2, (1 - \hat{t}_j)/r_j^2), \\
-\partial_{y}^{a}j W_j &= 0 \quad \text{in } \mathbb{R}^N \times \{ y > -\hat{y}_j/r_j \} \times (-\hat{t}_j/r_j^2, (1 - \hat{t}_j)/r_j^2)
\end{align*}
\]
instead of (7.21), where
\[-\partial_{y}^{a}j W_j = \lim_{y \to (\hat{y}_j, r_j)^+} \left( \frac{\hat{y}_j}{r_j} + y \right)^a \partial_y W_j.\]

The last part of the proof is almost identical, except for the fact that, in the application of the Liouville result in Step 4, we employ part (ii) of Lemma 7.3 instead of part (i). \( \square \)

**Corollary 7.5.** Fix \( 0 < s < 1 \), \( a = 1 - 2s \). Let \( u \in \text{dom}(H^s) \) be a solution to (2.2) with potential \( h = h(x,t) \) satisfying (2.1) and let \( U = U(x,y,t) \) be its extension defined in (2.4) and satisfying (2.7). Let \( p_0 = (x_0, 0, t_0) \in \Gamma(U) \cap \Sigma \) and \( U_{p_0, \lambda} = U_{p_0, \lambda}(x,y,t) \) its normalized blow-up sequence defined in...
Then for any compact set $K \subset \mathbb{R}^{N+1}_+ \times (-\infty,0)$ and any $0 < \nu < \nu_* := \min\{1, 1 - a\}/2$, there exists a constant $C > 0$ not depending on $\lambda > 0$, such that

$$\|U_{p_0,\lambda}\|_{C^{2\nu,\nu}(K)} \leq C,$$

and, moreover, we have as $\lambda \to 0^+$

$$U_{p_0,\lambda} \to \Theta_{p_0} \quad \text{uniformly in } K,$$

where $\Theta_{p_0} = \Theta_{p_0}(x, y, t)$ is the blow-up limit of $U$ at $p_0$, defined in Theorem 7.3.

**Proof.** Let $w \in \text{dom}(H^s)$ be a solution to (2.2) (with $h$ satisfying (2.1)) and $W = W(x, y, t)$ its extension (it satisfies problem (2.7) for $t \in (-T, 0)$). Then define $u(x, t) = w(x, -t)$ and $U(x, y, t) = W(x, y, -t)$, which satisfies problem (6.34) in the strong sense. So (6.35) holds, and $U_\lambda$ (defined as in (3.10)) satisfies problem

$$\begin{cases}
\partial_t U_\lambda + y^{-a} \nabla \cdot (y^a \nabla U_\lambda) = 0 & \text{in } \mathbb{R}^{N+1}_+ \times (0, T/\lambda^2) \\
-\partial_y^a U_\lambda = \lambda^{1-a}h(\lambda x, -\lambda^2 t)U_\lambda & \text{in } \mathbb{R}^N \times \{0\} \times (0, T/\lambda^2),
\end{cases}$$

for any $\lambda > 0$. In particular, setting $u_\lambda(x, t) = u(\lambda x, \lambda^2 t)$, it satisfies

$$\int_{\mathbb{R}^{N+1}^+} \left[ \frac{(x, y)}{2t} \cdot \nabla U_\lambda \right] \eta \frac{d\mu_t(x, y)}{\mu_t(x, y)} = \int_{\mathbb{R}^{N+1}^+} \nabla U_\lambda \cdot \nabla \eta \frac{d\mu_t(x, y)}{\mu_t(x, y)} + \lambda^{1-a} \int_{\mathbb{R}^N} h(\lambda x, -\lambda^2 t)u_\lambda(x, t)\eta(x, 0, t)G_a(x, 0, t) \, dx,$$

for a.e. $0 < t < T$ and all $\eta \in L^2(0, T/\lambda^2; H^s_{\mu_t})$, which is the corresponding version of (6.35) (cfr. with formula (7.9) of [5]). Now, for what concerns the uniform bound of $\|U_\lambda\|_{L^\infty(Q^+_t)}$, we can use again the Harnack inequality proved in [5] (cfr. with formula (5.12)), exactly has in the case $h \equiv 0$.

The bound of the Hölder semi-norm of $U_\lambda$ requires some further work. As in the proof of Theorem 7.1 we assume there is a sequence $\lambda_j \to 0^+$ such that $[\eta U_{\lambda_j}]_{C^{2\nu,\nu}(Q^+_t)} \to +\infty$, for some $0 < \nu < 1/2$. Then we repeat what done in Step 2 and Step 3. The only significative change is that the auxiliary function $W_j = W_j(X, t)$ solves

$$\begin{cases}
\partial_t W_j + \mathcal{L}_a \partial_t W_j = 0 & \text{in } \mathbb{R}^N \times \{y > -\tilde{y}_j/r_j\} \times (-\tilde{t}_j/r_j^2, (1 - \tilde{t}_j)/r_j^2), \\
-\partial_y^a W_j = (r_j \lambda_j)^{-a}h_j(x, -t)W_j & \text{in } \mathbb{R}^N \times \{y > -\tilde{y}_j/r_j\} \times (-\tilde{t}_j/r_j^2, (1 - \tilde{t}_j)/r_j^2),
\end{cases}$$

where $h_j(x, -t) := h_{\lambda_j}(\tilde{x}_j + r_j x, -\tilde{t}_j - r_j^2 t)$, instead of (7.21). To show that (7.24) holds in this case too, we introduce that functions $Z_j$ and $\overline{Z}_j$ as in (7.20) and we fix a compact $K \subset \mathbb{R}^{N+1} \times \mathbb{R}$. The main difference with respect to the previous case is that $Z_j$ satisfies

$$\begin{cases}
\partial_t Z_j + \mathcal{L}_a Z_j = 0 & \text{in } \mathbb{R}^N \times \{y > -\tilde{y}_j/r_j\} \times (-\tilde{t}_j/r_j^2, (1 - \tilde{t}_j)/r_j^2), \\
-\partial_y^a Z_j = (r_j \lambda_j)^{-a}h_j(x, -t)(Z_j + W_j(0, 0)) & \text{in } \mathbb{R}^N \times \{y > -\tilde{y}_j/r_j\} \times (-\tilde{t}_j/r_j^2, (1 - \tilde{t}_j)/r_j^2),
\end{cases}$$

instead of (7.33). Now, testing the first equation of the above problem with $|\tilde{y}_j/r_j^2 + y|^a \varphi$, where $\varphi \in C_c^\infty(\mathbb{R}^{N+1} \times \mathbb{R})$, and assuming

$$\text{supp}(\varphi) \subseteq \mathbb{R}^N \times \{y > -\tilde{y}_j/r_j\} \times (-\tilde{t}_j/r_j^2, (1 - \tilde{t}_j)/r_j^2) \to \mathbb{R}^{N+1} \times \mathbb{R},$$

we have

$$\int_{\mathbb{R}^N} \left[ \frac{(x, y)}{2t} \cdot \partial_t Z_j \right] \varphi \frac{d\mu_t(x, y)}{\mu_t(x, y)} = \int_{\mathbb{R}^N} \nabla Z_j \cdot \nabla \varphi \frac{d\mu_t(x, y)}{\mu_t(x, y)} + \int_{\mathbb{R}^N} h_j(x, -t)W_j(0, 0) \varphi \frac{d\mu_t(x, y)}{\mu_t(x, y)}.
we deduce that
\[
\int_\mathbb{R} \int_{\mathbb{R}^{N+1}} \left[ |1 + r_j \tilde{y}_j^{-1} y|^{a} \partial_t \varphi - \nabla \cdot \left( |1 + r_j \tilde{y}_j^{-1} y|^a \nabla \varphi \right) \right] Z_j \, dx \, dy \, dt
\]
\[
= - \left( \frac{r_j}{\tilde{y}_j} \right)^a (r_j \lambda_j)^{1-a} \int_\mathbb{R} \int_{\mathbb{R}^{N+1}} h_j(x,-t)(Z_j(x,0,t) + W_j(0,0))\varphi(x,0,t) \, dx \, dt.
\]
Now, the r.h.s. can be written as the sum of the two terms
\[
\frac{r_j}{\tilde{y}_j} \lambda_j^{1-a} \int_\mathbb{R} \int_{\mathbb{R}^{N+1}} h_j(x,-t)Z_j(x,0,t)\varphi(x,0,t) \, dx \, dt,
\]
and
\[
\frac{r_j}{\tilde{y}_j} \lambda_j^{1-a} \int_\mathbb{R} \int_{\mathbb{R}^{N+1}} h_j(x,-t)\varphi(x,0,t) \, dx \, dt.
\]
Assume now \( \tilde{y}_j \to 0 \) (if not what come next is trivial due to the fact that \( r_j \to 0 \)). Thanks to the assumptions on the potential \( h \) and the fact that \( Z_j \) is uniformly bounded, we obtain that the first term converges to zero as \( j \to +\infty \) since \( r_j/\tilde{y}_j^a \leq r_j/\tilde{y}_j \to 0 \) when \( 0 < a < 1 \) (the case \( -1 < a \leq 0 \) is trivial). The second term converges to zero too. Indeed, the sequence
\[
\frac{r_j}{\tilde{y}_j} \lambda_j^{1-a} \int_\mathbb{R} \int_{\mathbb{R}^{N+1}} h_j(x,-t)\varphi(x,0,t) \, dx \, dt.
\]
since \( 2\nu < \min\{1,1-a\} \) and the fact that \( r_j/\tilde{y}_j \to 0 \) as \( j \to +\infty \), while the rest is bounded thanks to the uniform \( L^\infty \) bound on \( U_{\lambda_j} \). Consequently, \( Z_j \to Z \) uniformly on compact sets of \( \mathbb{R}^{N+1} \times \mathbb{R} \), where \( Z = Z(X,t) \) is a backward caloric function in \( \mathbb{R}^{N+1} \times (0,\infty) \), and so, we conclude that it must be constant, thanks to the Liouville theorem. The last part of the proof is an immediate adaptation of the previous one and we skip it. \( \square \)

We end this section by mentioning that the above theorems can be used to prove strong unique continuation properties of solutions to (1.1) (already proved in Theorem 1.2 of [5]) and/or (2.17). Strong unique continuation properties have a long history and have been intensively studied in both the elliptic and parabolic framework, for both local and nonlocal equations. In the elliptic case we quote the works of Garofalo and Lin [36-37] for the local framework, and Fall and Felli [31] for the nonlocal one (see also Rüland [56]). As far as the parabolic framework is concerned, the first result was given by Poon in [53] (see also more recent results in [28, 29] and [76]) for the local case. We do not insist further on these aspect and we quote [4] (cfr. with Chapter 5) for more details.

8. Nodal Properties of Solutions to Equation (1.1)

In this final part of the work, we employ the theory developed in the previous sections to obtain information about the Hausdorff dimension, regularity and structure of the nodal set of solutions to equation (1.1). As we have mentioned in the introduction, the decisive tools turn out to be the blow-up classification of Section 6 and Section 7 and classical theorems as Federer’s Reduction Principle (cfr. with Theorem 8.5) and Whitney’s Extension Theorem (cfr. with Theorem 8.6), together with some independent technical results.

We begin with a preliminary result, and we prove that \( \Gamma_\kappa(U) \) is \( F_\sigma \). This fact will turn out to be crucial in the proof of Theorem 8.12.
Lemma 8.1. Fix $0 < s < 1$, $a = 1 - 2s$. Let $u \in \text{dom}(H^s)$ a solution to (1.1) and let $U = U(x, y, t)$ be its extension defined in (2.3) (satisfying (2.7)). Then:

(i) The set $\mathcal{R}(U)$ is relatively open in $\Gamma(U)$.

(ii) For any $\kappa = 1, 3, 2, \ldots$, the set $\Gamma_\kappa(U)$ is a union of countably many closed sets.

Proof. Recalling the setting already introduced in the introduction, we can assume that $U = U(x, y, t)$ is a strong solution to problem (2.15). Part (i) directly follows from the upper semi-continuity of the map

$$p_0 \to N(p_0, t_0^+, U) := \lim_{t \to t_0^+} N(p_0, t, U),$$

and the gap condition given by Theorem 3.3 which yields

$$\mathcal{R}(U) = \left\{ p_0 \in \Gamma(U) \cap \Sigma : \lim_{t \to t_0^+} N(p_0, t, U) = \frac{1}{2} \right\} = \left\{ p_0 \in \Gamma(U) \cap \Sigma : N(p_0, t_0^+, U) < 1 \right\}.$$

Turning to point (ii) we note that, thanks to formula (6.21), we have

$$\Gamma_\kappa(U) = \bigcup_{j=1}^{\infty} E_j \quad E_j := \left\{ p_0 \in \Gamma_\kappa(U) : \frac{1}{j} t^{2\kappa} \leq H(p_0, t, U) < j t^{2\kappa}, \text{ as } t \to 0 \right\},$$

for any $1 \leq j \in \mathbb{N}$. Consequently, it is enough to show that all the $E_j$’s are closed sets. We show that for any fixed $1 \leq j \in \mathbb{N}$ and $p_0 \in E_j$, it holds $p_0 \in E_j$. It is instantly seen that for such $p_0$, the inequalities in (8.1) hold by continuity, while, since the function $p_0 \to N(p_0, t_0^+, U)$ (cfr. with (3.3)) is upper semi-continuous, we infer $N(p_0, t_0^+, U) \geq \kappa$. Finally, if by contradiction $N(p_0, t_0^+, U) = \kappa > \kappa$, combining formula (6.21) with $\kappa = \kappa$ and (8.1), we easily obtain

$$\frac{1}{j} t^{2\kappa} \leq H(p_0, t, U) < j t^{2\kappa}, \text{ as } t \to 0,$$

which is contradiction. Consequently, $p_0 \in \Gamma_\kappa(U)$ and so $p_0 \in E_j$. □

We are now ready to turn to the problem of estimating the Hausdorff dimension of the nodal set of solutions to (1.1). The analysis will be performed by applying Federer Reduction Principle (cfr. for instance with Simon [59, Appendix A], or Lin [45, Section 2]). Its parabolic version of it is less employed in literature and so, out of completeness, we review its main steps in the next paragraphs. We follow the notable work of Chen [20, Section 8], simplifying its quite general setting to our more specific framework. We begin with the definition of Hausdorff and parabolic Hausdorff dimension.

Definition 8.2. (Parabolic Hausdorff dimension, [20, Definition 8.1])

For any $E \subset \mathbb{R}^N \times \mathbb{R}$, any real number $d \geq 0$, and $0 < \delta \leq \infty$, we define

$$\mathcal{P}_\delta^d(E) := \inf \left\{ \sum_{j=1}^{\infty} r_j^d : E \subset \bigcup_{j=1}^{\infty} Q_{r_j}(x_j, t_j) \text{ with } 0 < r_j < \delta \right\},$$

where, as always

$$Q_r(x, t) := \left\{ (x', t') : (x', t') \in \mathbb{R}^N \times \mathbb{R} : |x - x'| < r, |t - t'| < r^2 \right\}.$$

Then we define the $d$-dimensional cylindrical Hausdorff measure by

$$\mathcal{P}^d(E) := \lim_{\delta \to 0^+} \mathcal{P}_\delta^d(E) = \sup_{\delta > 0} \mathcal{P}_\delta^d(E).$$
We call parabolic Hausdorff dimension of $E$, the number

$$\dim_P(E) := \inf \left\{ d \geq 0 : \mathcal{P}^d(E) = 0 \right\} = \sup \left\{ d \geq 0 : \mathcal{P}^d(E) = +\infty \right\}.$$  

Before moving forward, we recall that the above definition is just a parabolic version of the more classical spherical Hausdorff measure (Hausdorff dimension, resp.). Indeed, if $E \subset \mathbb{R}^N$, $d \geq 0$, and $0 < \delta \leq \infty$, we define

$$\mathcal{H}^d_\delta(E) := \inf \left\{ \sum_{j=1}^{\infty} r_j^d : E \subset \bigcup_{j=1}^{\infty} B_{r_j}(x_j) \text{ with } 0 < r_j < \delta \right\},$$

where now $B_r(x)$ is the ball of radius $r > 0$, centered at $x$. Consequently, the $d$-dimensional spherical Hausdorff measure can be defined as

$$\mathcal{H}^d(E) := \lim_{\delta \to 0^+} \mathcal{H}^d_\delta(E) = \sup_{\delta > 0} \mathcal{H}^d_\delta(E).$$

The Hausdorff dimension of $E$ is the number

$$\dim_H(E) := \inf \left\{ d \geq 0 : \mathcal{H}^d(E) = 0 \right\} = \sup \left\{ d \geq 0 : \mathcal{H}^d(E) = +\infty \right\}.$$  

To better understand the statement of Theorem 3.7, we recall the following lemma.

Lemma 8.3. ([20, Lemma 8.2])

The following two assertions hold:

(i) For any linear subspace $E \subset \mathbb{R}^N$ and any $-\infty \leq a < b \leq +\infty$, it holds

$$\dim_P(E \times (a, b)) = \dim_H(E) + 2.$$  

In particular, $\dim_P(\mathbb{R}^N \times \mathbb{R}) = N + 2$.

(ii) For any set $E \subset \mathbb{R}^N \times \mathbb{R}$, any point $p_0 = (x_0, t_0) \in \mathbb{R}^N \times \mathbb{R}$, and $\lambda > 0$, define

$$E_{p_0, \lambda} = \frac{E - p_0}{\lambda} := \left\{ (x, t) \in \mathbb{R}^N \times \mathbb{R} : (x_0 + \lambda x, t_0 + \lambda^2 t) \in E \right\}.$$  

Then

$$\mathcal{P}^d_\delta(E_{p_0, \lambda}) = \lambda^{-d} \mathcal{P}^d_\delta(E),$$

for any $d \geq 0$ and $\delta > 0$.

The above lemma clarifies the relation between the more natural Hausdorff dimension and the little bit more ambiguous parabolic Hausdorff dimension (for which $\dim_P(\mathbb{R}^N \times \mathbb{R}) = N + 2!$). This (maybe strange) fact is actually quite natural if the natural parabolic scaling is taken into account.

Definition 8.4. (Locally asymptotically self-similar family, cfr. with [20, Definition 8.3])

Let $\mathcal{F} \subset L^\infty_{loc}(\mathbb{R}^N \times \mathbb{R})$ be a family of functions and consider a map

$$\mathcal{S} : \mathcal{F} \to C := \{ C \subset \mathbb{R}^N \times \mathbb{R} : C \text{ is closed} \}.$$  

Moreover, define the blow-up family

$$u_{p_0, \lambda, \varphi}(x, t) = \frac{u(x_0 + \lambda x, t_0 + \lambda^2 t)}{\varphi},$$

for any $p_0 = (x_0, t_0) \in \mathbb{R}^N \times \mathbb{R}$ and $\lambda, \varphi > 0$. We say that the pair $(\mathcal{F}, \mathcal{S})$ is a locally asymptotically self-similar family if it satisfies the properties (A1), (A2) and (A3) below.
(A1) (Closure under re-scaling, translation and normalization) For any \( Q_\lambda(x_0, t_0) \subset Q_1(0, 0) \), \( \varrho > 0 \) and \( u \in \mathcal{F} \), it holds
\[
    u_{p_0, \lambda_0} \in \mathcal{F}.
\]

(A2) (Convergence of the normalized blow-up sequence) For any \( p_0 \in Q_1(0, 0) \), \( u \in \mathcal{F} \) and \( \lambda_j \to 0^+ \), there exist a number \( \kappa \in \mathbb{R} \) and a function \( \vartheta_{p_0} \in \mathcal{F} \) parabolically \( \kappa \)-homogeneous such that as \( j \to +\infty \), up to extracting a subsequence of \( \lambda_j \), it holds
\[
    u_{p_0, \lambda_j} \to \vartheta_{p_0} \text{ locally uniformly in } \mathbb{R}^N \times \mathbb{R}.
\]
Moreover, if \( u_{p_0, \lambda_j} \to \vartheta_{p_0} \) and \( u_{p_0, \lambda_j} \to \vartheta_{p_0} \), then \( \kappa = k \) and \( \vartheta = \theta \).

(A3) (Singular Set assumptions) The map \( S : \mathcal{F} \to C \) satisfies the following properties:
(i) For any \( Q_\lambda(x_0, t_0) \subset Q_1(0, 0) \), \( \varrho > 0 \) and \( u \in \mathcal{F} \), it holds
\[
    S(u_{p_0, \lambda, \varrho}) = (S(u))_{p_0, \lambda, \varrho}.
\]
(ii) For any \( p_0 \in Q_1(0, 0) \), \( u, \vartheta_{p_0} \in \mathcal{F} \), \( \kappa \in \mathbb{R} \) and \( \lambda_j \to 0^+ \) such that \( u_{p_0, \lambda_j, \lambda_j^{2\kappa}} \to \vartheta_{p_0} \) uniformly on compact sets of \( \mathbb{R}^N \times \mathbb{R} \), the following continuity property holds: for any \( \varepsilon > 0 \), there exists \( j_\varepsilon > 0 \) such that
\[
    S(u_{p_0, \lambda, \lambda_j^{2\kappa}}) \cap Q_1(0, 0) \subseteq \{ p \in \mathbb{R}^N \times \mathbb{R} : \text{dist}(p, S(\vartheta_{p_0})) < \varepsilon \}, \quad \text{for all } j \geq j_\varepsilon.
\]
(iii) If \( u \in \mathcal{F} \) and \( \kappa \in \mathbb{R} \) are such that \( u_{p_0, \lambda, \lambda_j^{2\kappa}} = u \) for all \( (x_0, t_0) \in \mathbb{R}^N \times \mathbb{R} \) and \( \lambda > 0 \), then \( S(u) = \emptyset \).

Remark. Some comments are now in order. In Definition 8.3 of [20], the author gives a far more general definition that we have decided to adapt to our specific context. Note in particular that we have replaced the heavy notation \( g(x_0, t_0; \lambda, 1/\varrho)u \) with the simpler one \( u_{p_0, \lambda, \varrho} \). Moreover, we have dropped the assumptions (A1.1), (A1.2), and (A3.2) of [20] since they are immediate in our case. Moreover, the second part of (A1.3) and (A1.4) of [20] corresponds to (i) and (iii) of (A3), respectively, and finally, (A2), (A3.1) and (A3.3) of [20], corresponds to our assumption (A2). We are now ready to state Federer Reduction Principle.

**Theorem 8.5.** (Federer Reduction Principle, Chen [20], Theorem 8.5) Let \( (\mathcal{F}, S) \) be a locally asymptotically self-similar family and assume there exists at least one \( u \in \mathcal{F} \) such that \( S(u) \cap Q_1(0, 0) \neq \emptyset \). Then:

(i) There exists an integer \( 0 \leq d \leq N + 1 \) such that for all \( u \in \mathcal{F} \) it holds
\[
    \dim^p [S(u) \cap Q_1(0, 0)] \leq d.
\]

(ii) There exist \( u \in \mathcal{F} \), \( \kappa \in \mathbb{R} \) and a linear subspace of \( \mathbb{R}^N \times \mathbb{R} \) such that
\[
    E_{(0, 0), \lambda} = E, \quad \text{for any } \lambda > 0, \quad S(u) = E, \quad \dim E = d,
\]
and
\[
    u_{p_0, \lambda, \lambda_j^{2\kappa}} = u \quad \text{for any } \lambda > 0 \text{ and } p_0 \in E.
\]

**Proof of Theorem 3.7.** The statement is obtained as by product of Federer’s theorem and the blow-up classification of Sections 6 and 7. So, if \( w \in \text{dom}(H^s) \) is a nontrivial solution to \([11]\) and \( u(x, t) = w(x, -t) \), we define
\[
    \mathcal{F} := \{ u \in \text{dom}(H^s) : w \text{ is a non trivial solution to equation } [11] \} \subset L^\infty_{\text{loc}}(\mathbb{R}^N \times \mathbb{R}).
\]
Note that the family $F$ satisfies assumption $(A_1)$ of Definition 3.8 thanks to the properties of the operator $(\partial_x - \Delta)^s$ such as linearity. Now, let $U(x, y, t) = W(x, y, -t)$, where $W$ is the extension of $w = w(x, t)$ defined as in (2.3). From Theorem 3.1 we have

$$U_{p_0, \lambda_j} \to \Theta_{p_0} \quad \text{locally uniformly in } \mathbb{R}^{N+1}_+ \times \mathbb{R}_+,$$

as $j \to +\infty$, where $\Theta_{p_0} \in \mathcal{B}_\kappa(U)$ is the unique (parabolically $\kappa$-homogeneous) tangent map of $U$ at $p_0 \in \Gamma(U) \cap \Sigma = \Gamma(u)$ (see Definitions 3.6 and 3.7) and $\lambda_j \to 0$. Consequently,

$$u_{p_0, \lambda_j} \to \partial_{p_0} \quad \text{locally uniformly in } \mathbb{R}^N \times \mathbb{R}_+,$$

as $j \to +\infty$, where $\partial_{p_0}(x, t) := \Theta_{p_0}(x, 0, t)$ and $u_{p_0, \lambda_j}(x, t) = U_{p_0, \lambda_j}(x, 0, t)$. Since $\Theta_{p_0}$ is parabolically $\kappa$-homogeneous for some $\kappa \geq 0$, we deduce that assumption $(A_2)$ Definition 3.4 is satisfied too, by taking

$$u_{p_0, \lambda_j, \theta_j}(x, t) = u_{p_0, \lambda_j}(x, t) \quad \text{(with } \theta_j := \lambda_j^{2\kappa}).$$

Now, let us consider the map

$$\mathcal{S} : u \to \mathcal{S}(u) := \Gamma(u) \in \mathcal{C},$$

since $\Gamma(U) \cap Q_1 \cap \Sigma$ is closed by the continuity of $U = U(x, y, t)$. Moreover, by the uniform convergence of $U_{p_0, \lambda}$ towards their tangent maps $\Theta_{p_0}$ (cfr. with Theorem 7.1), we easily see that also the assumption $(A_3)$ (of Definition 3.4) is satisfied and so, $(\mathcal{F}, \mathcal{S})$ is a locally asymptotically self-similar family. Hence, in view of Federer’s Reduction Principle, we conclude the proof since $d \leq N + 1$. □

**Proof of Theorem 3.8** From the blow up classification of Corollary 3.4 and the spectral Theorem 3.2, we know that as $\lambda \to 0$

$$U_{p_0, \lambda} = \frac{U(x_0 + \lambda x, \lambda y, t_0 + \lambda^2 t)}{\lambda} \to \Theta_{p_0}(x, y, t) = \sum_{i=1}^{N} v_j x_j$$

uniformly on compact sets of $\mathbb{R}^{N+1}_+ \times (0, T)$, where $v_j \neq 0$ at least for some $j = 1, \ldots, N$. Consequently, if $(e_j)_{i=1}^{N+1}$ is the standard basis of $\mathbb{R}^{N+1}$ and $v_j \neq 0$, it holds

$$\partial_{x_i} U(p_0) = \lim_{\lambda \to 0^+} \frac{U(p_0 + \lambda e_i) - U(p_0)}{\lambda} = v_i,$$

thanks to the above convergence and that $U(p_0) = 0$ (here $\delta_{ij}$ is the Kronecker delta). It thus follows $\nabla_x U(p_0) \neq 0$ (note that however $\partial_t U(p_0) = 0$). Part (i) is thus proved. For what concerns part (ii), it is enough to apply the Implicit function theorem at point $p_0 \in \mathcal{R}(U)$ and use part (i). □

We now prove the last two main theorems of this paper. We begin with the proof of Theorem 3.9 which will play an important role in the application of Whitney theorem, in the proof of Theorem 3.12.

**Proof of Theorem 3.9** Part (i) easily follows from Theorem 7.1. Indeed, assuming for simplicity $p_0 = 0 \in \Gamma_\kappa(U)$ and taking $K = Q_1^+ = \mathbb{B}_1^+ \times (0, 1)$, we have as $\lambda \to 0^+$

$$o(1) = \sup_{(x, y, t) \in Q_1^+} |U_\lambda(x, y, t) - \Theta(x, y, t)| = \sup_{(x, y, t) \in Q_1^+} \left| \frac{U(\lambda x, \lambda y, \lambda^2 t)}{\lambda^{2\kappa}} - \Theta(\lambda x, \lambda y, \lambda^2 t) \right|$$

$$= \lambda^{-2\kappa} \sup_{(x, y, t) \in Q_1^+} |U(x, y, t) - \Theta(x, y, t)|,$$

where $Q_1^+ := \mathbb{B}_1^+ \times (0, \lambda^2)$. 

\[\]
To prove part (ii) we follow the ideas of Theorem 14.4 of \[24\]. As in Remark 12.7 of that paper, we point out that since \( \mathfrak{B}_\kappa(U) \) is a finite dimensional space composed by parabolically \( \kappa \)-homogeneous polynomials, the continuity of the function \( p_0 \to \Theta_{p_0} \) can be verified with respect to any norm on \( \mathfrak{B}_\kappa(U) \). We proceed in two separate steps.

**Step 1: Monneau’s and Weiss’ type monotonicity formulas.** Taking the norm \( C^0(0,1; L^2_{\mu_t}) \) \( \text{(cfr. with Lemma 6.12)} \) and repeating the above scaling procedure using the \( C^0(0,1; L^2_{\mu_t}) \) convergence \( \text{(instead of the uniform one)} \), we have that for any \( p_0 \in \Gamma_\kappa(U) \) \( \text{(cfr. with [6, 33] with } T_* = 1) \):

\[
\frac{1}{\lambda^{4\kappa}} \max_{t \in [0,\lambda^2]} \| U_{p_0}(t) - \Theta_{p_0}(t) \|^2_{L^2_{\mu_t}} = \frac{1}{\lambda^{4\kappa}} \max_{t \in [0,\lambda^2]} H(t, U_{p_0} - \Theta_{p_0}) \rightarrow 0 \quad \text{as } \lambda \to 0^+.
\]

On the other hand, we easily see that

\[
\frac{1}{\lambda^{4\kappa}} \max_{t \in [0,\lambda^2]} H(t, U_{p_0} - \Theta_{p_0}) = \frac{H(\lambda^2, U_{p_0} - \Theta_{p_0})}{\lambda^{4\kappa}}, \quad \lambda > 0,
\]

thanks to the monotonicity of the function \( t \to H(t, U_{p_0} - \Theta_{p_0}) \) \( \text{(cfr. with Section 4)} \). Now, we claim that the function

\[
(8.2) \quad t \to M^\kappa_{U_{p_0}, \Theta_{p_0}}(t) := \frac{H(t, U_{p_0} - \Theta_{p_0})}{t^{2\kappa}},
\]

is monotone non-decreasing \( \text{(note that this does not follows immediately from [4, 77] since we are replacing } U_{p_0} \text{ with } U_{p_0} - \Theta_{p_0} \text{). The map } t \to M^\kappa_{U_{p_0}, \Theta_{p_0}}(t) \text{ defined in (8.2) is a Monneau type function (cfr. with [48, 49]) and its derivative can be easily computed as follows}

\[
\frac{d}{dt} M^\kappa_{U_{p_0}, \Theta_{p_0}}(t) = -2\kappa t^{-2\kappa - 1} H(t, U^*_p) + 2t^{-2\kappa} I(t, U^*_p)
\]

\[
= \frac{2}{t^{2\kappa + 1}} \left[ tI(t, U^*_p) - \kappa H(t, U^*_p) \right] = \frac{2}{t} M^\kappa_{U_{p_0}, \Theta_{p_0}}(t) \left[ N(t, U^*_p) - \kappa \right]
\]

\[
= \frac{2}{t} W^\kappa_{U_{p_0}, \Theta_{p_0}}(t),
\]

where we have set \( U^*_p := U_{p_0} - \Theta_{p_0} \) and used the fact that \( H'(t, U^*_p) = 2I(t, U^*_p) \). The map \( t \to W^\kappa_{U_{p_0}, \Theta_{p_0}}(t) \) is known in literature as Weiss type function \( \text{(cfr. with [74, 75])}. \)

We point out that in Theorem 13.4 of \[24\] and \[6\] the authors introduced Monneau and Weiss type functions which are a sort of averaged versions of ours. In this framework, these averaged versions are not needed.

Now, as the reader can easily see, if \( U = U(x, y, t) \) has Almgren-Poon limit \( \kappa \) at \( p_0 \) and tangent map \( \Theta_{p_0} \in \mathfrak{B}_\kappa(U) \), we have that the Weiss type function

\[
t \to W^\kappa_{U_{p_0}, \Theta_{p_0}}(t) := M^\kappa_{U_{p_0}, \Theta_{p_0}}(t) \left[ N(t, U_{p_0}) - \kappa \right] = \frac{H(t, U_{p_0})}{t^{2\kappa}} \left[ N(t, U_{p_0}) - \kappa \right],
\]

is monotone non-decreasing \( \text{(since it is the product of two non-decreasing functions, cfr. with [4, 77]} \) and Lemma 3.1, nonnegative and \( W^\kappa_{\Theta_{p_0}, \Theta} \equiv 0 \) \( \text{(cfr. with Lemma 3.1 again and use the homogeneity of } \Theta_{p_0} \text{). Consequently, if we show that}

\[
W^\kappa_{U_{p_0}, \Theta_{p_0}}(t) = W^\kappa_{U_{p_0}, \Theta_{p_0}}(0) \quad \text{for all } 0 < t < 1,
\]
we deduce that the Monneau’s function \( t \to W_{U_{p_0}, \Theta_{p_0}}^\kappa (t) \) is monotone non-decreasing, as claimed. So, we have

\[
t^{2\kappa}W_{U_{p_0}, \Theta_{p_0}}^\kappa (t) = t^{2\kappa} \left[ W_{U_{p_0}, \Theta_{p_0}}^\kappa (t) + W_{\tilde{U}_{0}, \Theta_{p_0}}^\kappa (t) \right]
\]

as desired. Note that we have passed to the re-scaled variables \( \tilde{U}(x, y, t) = U(\sqrt{t}x, \sqrt{t}y, t) \) and \( \tilde{\Theta}(x, y, t) = \Theta(\sqrt{t}x, \sqrt{t}y, t) \), and used the definition of weak eigenfunction as in Definition 5.1 (recall that we can test with \( \tilde{U} \) since \( \tilde{U}(t) \in H^1_\mu \) for any \( 0 < t < 1 \)). We can thus conclude that the function

\[
\lambda \to \frac{1}{\lambda^{2\kappa}} \max_{t \in [0, \lambda^2]} H(t, U_{p_0} - \Theta_{p_0}) = \frac{H(\lambda^2, U_{p_0} - \Theta_{p_0})}{\lambda^{4\kappa}} = M_{U_{p_0}, \Theta_{p_0}}^{\kappa}(\lambda^2),
\]

is monotone non-decreasing for \( 0 < \lambda < 1 \).

**Step 2:** End of the proof of part (ii). For \( \varepsilon > 0 \) fixed, we take \( \lambda_\varepsilon > 0 \) such that

\[
M_{U_{p_0}, \Theta_{p_0}}^{\kappa}(\lambda_\varepsilon) = \frac{H(\lambda_\varepsilon^2, U_{p_0} - \Theta_{p_0})}{\lambda_\varepsilon^{4\kappa}} < \frac{\varepsilon}{2}, \quad M_{U_{p_0}, U_{p_1}}^{\kappa}(\lambda_\varepsilon) = \frac{H(\lambda_\varepsilon^2, U_{p_0} - U_{p_1})}{\lambda_\varepsilon^{4\kappa}} < \frac{\varepsilon}{2},
\]

where \( p_1 \in \Gamma_\kappa(U) \) satisfies \( |p_0 - p_1| < \delta_\varepsilon \) and \( \delta_\varepsilon > 0 \) is small enough depending on \( \varepsilon > 0 \) and \( p_0 \) (here we have simply used the \( C^0(0, 1; L^2_\mu) \) continuous dependence \( U_{p_0} \) on \( p_0 \in \Gamma(U) \)). Consequently,

\[
H_{U_{p_1}, \Theta_{p_0}}^{\kappa}(\lambda_\varepsilon) = \frac{H(\lambda_\varepsilon^2, U_{p_1} - \Theta_{p_0})}{\lambda_\varepsilon^{4\kappa}} \leq \frac{H(\lambda_\varepsilon^2, U_{p_1} - U_{p_0})}{\lambda_\varepsilon^{4\kappa}} + \frac{H(\lambda_\varepsilon^2, U_{p_0} - \Theta_{p_0})}{\lambda_\varepsilon^{4\kappa}} < \varepsilon,
\]

where, similar to [24], we have used the continuity of the map \( \Gamma(U) \ni p \to U_p \) with respect to the norm \( C^0(0, 1; L^2_\mu) \). Thus, from the monotonicity of \( \lambda \to H_{U_{p_0}, \Theta_{p_0}}^{\kappa}(\lambda) \) and the fact the both \( p_0, p_1 \in \Gamma_\kappa(U) \), it follows

\[
\max_{t \in [0, 1]} \| U_{p_1, \lambda}(t) - \Theta_{p_0}(t) \|_{L^2_{\mu_\varepsilon}}^2 \leq H_{U_{p_1}, \Theta_{p_0}}^{\kappa}(\lambda_\varepsilon) < \varepsilon, \quad \text{for all } 0 < \lambda < \lambda_\varepsilon,
\]

and so, taking the limit as \( \lambda \to 0^+ \), we obtain

\[
\max_{t \in [0, 1]} \| \Theta_{p_1}(t) - \Theta_{p_0}(t) \|_{L^2_{\mu_\varepsilon}}^2 < \varepsilon,
\]

which completes the proof of part (ii).

Finally, to prove part (iii) we combine what showed in the above part and a standard diagonal procedure. So, we fix a compact set \( K \subset \Gamma_\kappa(U), \varepsilon > 0 \) and \( p_0 \in K \) and we take \( \lambda_\varepsilon, \delta_\varepsilon > 0 \) such that

\[
\| U_{p, \lambda} - \Theta_p \|_{C^0(0, 1; L^2_\mu)}^2 < \varepsilon, \quad \text{for all } 0 < \lambda < \lambda_\varepsilon,
\]

for any \( p \in K \) satisfying \( |p_0 - p| \leq \delta_\varepsilon \) (this immediately follows from part (ii)). Now, covering \( K \) with a finite union of cylinders \( Q_{\delta_\varepsilon}(p_i) \) with \( p_i \in K \), we deduce the existence of a constant \( C = C_K > 0 \)
such that
\[ \|U_{p,\lambda} - \Theta_p\|_{L^2(0,1;L^2_{\mu_1})}^2 \leq \|U_{p,\lambda} - \Theta_p\|_{C^0(0,1;L^2_{\mu_1})}^2 < C\varepsilon \quad \text{for all } 0 < \lambda < \lambda_v, \]
for all \( p \in K \), since \( C^0(0,1;L^2_{\mu_1}) \subset L^2(0,1;L^2_{\mu_1}) \). On the other hand, from formula (5.7) of [5] we have the \( L^2 - L^\infty \) bound
\[ (8.3) \quad \sup_{B_{1/2}^+ \times (0,1/4)} |U_{p,\lambda} - \Theta_p|^2 \leq C \int_{B_1^+ \times (0,1)} y^n |U_{p,\lambda} - \Theta_p|^2 dxdydt, \]
where \( C > 0 \) is a universal constant. Using the fact that \( \|U_{p,\lambda} - \Theta_p\|_{L^2(0,1;L^2_{\mu_1})} \to 0 \) as \( \lambda \to 0^+ \), we deduce that the r.h.s. of (8.3) converges to zero as \( \lambda \to 0^+ \). This follows from the fact that the function \( G_a = G_a(x,y,t) \) is bounded above and below on \( B_{1}^+ \times (\delta,1) \), for any \( \delta > 0 \). Next, noting that \( B_{1/2}^+ \times (\delta,1) \to B_{1/2}^+ \times (0,1) \) as \( \delta \to 0^+ \), we can use a Cantor diagonal procedure combined with (8.3), to infer that
\[ \sup_{B_{1/2}^+ \times (0,1/4)} |U_{p,\lambda} - \Theta_p|^2 \leq C\varepsilon, \quad \text{for all } 0 < \lambda < \lambda_v, \]
where \( C > 0 \) depends only on \( K \). The last part of thesis thus follows. □

We are almost ready to prove our Structure of the singular set theorem. Its proof relies on the techniques due to Garofalo and Petrosyan [38] (elliptic setting) and Danielli, Garofalo, Petrosyan and To [21] (parabolic setting). They are based on a ingenious combination of the Implicit function theorem and a version of the Whitney’s extension theorem tailored for the parabolic case, which we recall here for completeness.

**Theorem 8.6. (Parabolic Whitney extension, [21] Theorem B.1)**
Let \( E \) be a compact subset of \( \mathbb{R}^N \times \mathbb{R} \), \( f : E \to \mathbb{R} \) a continuous function, and \( \{f_{\alpha,j}\}_{|\alpha|+2j\leq 2m} \) with \( f_{0,0} = f \) and \( m \in \mathbb{N}, \alpha \in \mathbb{Z}^N_0 \) a multi-index. Assume that there exist a family of moduli of continuity \( \{\omega_{\alpha,j}\}_{|\alpha|+2j\leq 2m} \) such that
\[ f_{\alpha,j}(x,t) = \sum_{|\beta|+2\ell \leq 2m-|\alpha|-2j} \frac{f_{\alpha+\beta,j+\ell}(x_0,t_0)}{\beta!\ell!} (x-x_0)^\beta (t-t_0)^\ell + R_{\alpha,j}(x,t;x_0,t_0) \]
and
\[ |R_{\alpha,j}(x,t;x_0,t_0)| \leq \omega_{\alpha,j}((x-x_0,t-t_0)) \|x-x_0,t-t_0\|^{2m-|\alpha|-2j}. \]
Then there exists a function \( F \in C^{2m,m}(\mathbb{R}^N \times \mathbb{R}) \) such that \( F = f \) on \( E \) and \( \partial_x^n \partial_t^\ell F = f_{\alpha,j} \) on \( E \), for \( |\alpha|+2j \leq 2m \).

Together with the above result, we will use the following lemma, which explains the importance of having introduced the notion of time-like manifold (cfr. with Definition 3.11).

**Lemma 8.7. (Time-like singular points)** Let \( u \in \text{dom}(H^s) \) be a nontrivial solution to (1.1), \( (x_0,t_0) \in \Gamma_N^K(u) \). Then
\[ \vartheta_{p_0}(x,t) = C|t|^{|\alpha|}, \]
for some nonzero \( C \in \mathbb{R} \), where the symbol \( |\cdot| \) denotes the floor function and, as always, \( \vartheta_{p_0}(x,t) = \Theta_{p_0}(x,0,t) \) and \( \Theta_{p_0} \in \mathcal{B}_K(U) \) is the blow-up limit of \( U = U(x,y,t) \) at \( (x_0,0,t_0) \).
Proof. Assume for simplicity \((x_0, t_0) = (0, 0)\) and set \(\vartheta := \vartheta_{p_0}\). From the homogeneity of \(\vartheta = \vartheta(x,t)\), we can write

\[
\vartheta(x,t) = \sum_{|\alpha|+2j=2\kappa} \frac{a_{\alpha,j}(x_0,t_0)}{\alpha!j!} x^\alpha t^j, \quad \text{with} \quad a_{\alpha,j} = \partial_x^\alpha \partial_t^j \vartheta(0,0).
\]

(8.4)

On the other hand, the fact that \((0, 0) \in \Gamma_\kappa^N(u)\) means that

\[
\partial_x^\alpha \partial_t^j \vartheta(0,0) = 0,
\]

for any multi-index \(\alpha \in \mathbb{Z}_\geq 0^N\) and \(j = 0, \ldots, |\kappa|\) such that \(|\alpha| + 2j = 2\kappa - 1\), and all \(i = 1, \ldots, N\). Consequently, it follows

\[
\partial^\beta_x \partial_t^j \vartheta(0,0) = 0,
\]

for any multi-index \(\beta \in \mathbb{Z}_\geq 0^N\) and \(j = 0, \ldots, |\kappa|\) such that \(|\beta| + 2j = 2\kappa\) and \(|\beta| = |\alpha| + 1\), and so, the unique nonzero coefficient in the sum (8.4) turns out to be \(a_{\alpha,j}(x,t)\) and proof is completed. \(\square\)

Proof of Theorem 3.12. Let \(w \in \text{dom}(H^s)\) be a solution to (2.22) (with \(h\) satisfying (2.1)) and \(W = W(x,y,t)\) its extension (it satisfies problem (2.7) for \(t \in (-T,0)\)). Then define \(u(x,t) = w(x,-t)\) and \(U(x,y,t) = W(x,y,-t)\), which satisfies problem (6.31) in the strong sense. Following Theorem 12.12 of [24], we divide the proof in two steps.

Step 1: Parabolic Whitney’s extension. Let \(p_0 = (x_0, t_0) \in \Gamma_\kappa(u)\) (cfr. with (3.18)) and let \(\vartheta_{p_0}(x,t) := \Theta_{p_0}(x,0,t)\), where, as always, \(\Theta_{p_0} = \Theta_{p_0}(x,y,t) \in \mathcal{B}_\kappa(U)\) is the blow-up limit of \(U = U(x,y,t)\) at \(p_0 = (x_0,0,t_0)\). Since, \(\vartheta_{p_0}\) is a parabolically \(\kappa\)-homogeneous polynomial of degree \(2\kappa\), we can write it in the form

\[
\vartheta_{p_0}(x,t) = \sum_{|\alpha|+2j=\kappa} \frac{a_{\alpha,j}(x_0,t_0)}{\alpha!j!} x^\alpha t^j,
\]

(8.5)

where \(\alpha \in \mathbb{Z}_\geq 0^N\), \(j = 0,1,\ldots, \kappa\), and the coefficient functions \(p_0 \to a_{\alpha,j}(p_0)\) are continuous on \(\Gamma_\kappa(u)\), thanks to part (ii) of Theorem 3.9. Now, we define

\[
f_{\alpha,j}(x,t) := \begin{cases} 0 & \text{if } |\alpha| + 2j < 2\kappa \\ a_{\alpha,j}(x,t) & \text{if } |\alpha| + 2j = 2\kappa, \end{cases}
\]

for any \(\alpha \in \mathbb{Z}_\geq 0^N\) and \(j = 0,1,\ldots, \kappa\). We proceed by proving the following claim.

CLAIM: Let \(K = E_h\) for some \(h \in \mathbb{N}\), where \(E_h\) is defined in (8.1). Then for any \((x_0,t_0),(x,t) \in K\),

\[
f_{\alpha,j}(x,t) = \sum_{|\beta|+2r < \kappa - |\alpha| - 2j} \frac{f_{\alpha+\beta,j+r}(x_0,t_0)}{\beta!r!} (x-x_0)^\beta (t-t_0)^r + R_{\alpha,j}(x,t;x_0,t_0),
\]

(8.6)

with

\[
|R_{\alpha,j}(x,t;x_0,t_0)| \leq \sigma_{\alpha,j}(\|x-x_0\|,|t-t_0|)\|x-x_0\|^{2\kappa-|\alpha|+2j},
\]

(8.7)

where \(\sigma_{\alpha,j}\) are suitable modulus of continuity (depending on \(K\)).

CLAIM’s proof. The case \(|\alpha| + 2j = 2\kappa\) follows from the continuity of the functions \(p_0 \to a_{\alpha,j}(p_0)\) on \(\Gamma_\kappa(u)\), by taking

\[
R_{\alpha,j}(x,t;x_0,t_0) = a_{\alpha,j}(x,t) - a_{\alpha,j}(x_0,t_0).
\]
The case $0 \leq |\alpha| + 2j < 2\kappa$ is harder. According to Taylor expansion theory, we define

$$R_{\alpha,j}(x, t; x_0, t_0) := - \sum_{(\beta, i) \geq (\alpha, j): |\beta| + 2i = 2\kappa} \frac{a_{\beta,i}(x_0, t_0)}{(\beta - \alpha)! (i - j)!} (x - x_0)^{\beta - \alpha} (t - t_0)^{i - j}$$

$$= -\partial_x^\alpha \partial_t^j \vartheta p_0 (x - x_0, t - t_0), \quad t \geq t_0.$$  \hspace{1cm} (8.10)

Now, assume by contradiction, there is no modulus of continuity $\sigma_{\alpha,j} = \sigma_{\alpha,j} (\cdot)$ such that (8.7) is satisfied, i.e., there are sequences $p_l := (x_l, t_l), p_{0l} := (x_{0l}, t_{0l}) \in K,$

$$\delta_l := \max \{|x_l - x_{0l}|, \sqrt{|t_l - t_{0l}|}\} \to 0 \quad \text{as} \quad l \to +\infty,$$

such that

$$|R_{\alpha,j}(x_l, t_l; x_{0l}, t_{0l})|$$

$$\geq |\partial_x^\alpha \partial_t^j \vartheta p_0 (x_l - x_{0l}, t_l - t_{0l})| = \sum_{(\beta, i) \geq (\alpha, j): |\beta| + 2i = 2\kappa} \frac{a_{\beta,i}(x_0, t_0)}{(\beta - \alpha)! (i - j)!} (x_l - x_{0l})^{\beta - \alpha} (t_l - t_{0l})^{i - j}$$

$$\geq \sigma\|(x_l - x_{0l}, t_l - t_{0l})\|^{2\kappa - |\alpha| - 2j},$$

for some suitable $\sigma > 0$ and all $l \geq 0.$ Defining the families

$$u_{p_{0l}, \delta_l} (x, t) = \frac{u_{p_{0l}} (\delta_l x, \delta_l^2 t)}{\delta_l^{2\kappa}}, \quad (\xi_l, \theta_l) := \left( \frac{x_l - x_{0l}}{\delta_l}, \frac{t_l - t_{0l}}{\delta_l^2} \right),$$

we may assume (up to subsequences) $(x_{0l}, t_{0l}) \to (x_0, t_0) \in K$ and $(\xi_l, \theta_l) \to (\xi_0, \theta_0) \in \partial(B_1 \times (-1, 1)),$ and so, from Theorem 3.4 it follows

$$\|u_{p_{0l}, \delta_l} - \vartheta p_{0l}\|_{L^\infty(Q_R)} \leq \|u_{p_{0l}, \delta_l} - u_{p_{0l}, \delta_l}\|_{L^\infty(Q_R)} + \|u_{p_{0l}, \delta_l} - \vartheta p_0\|_{L^\infty(Q_R)} \to 0,$$

as $l \to \infty,$ for any $Q_R = B_R \times (0, R^2).$ The same holds true for the sequence

$$u_{p_l, \delta_l} (x, t) = \frac{u_{p_l} (\delta_l x, \delta_l^2 t)}{\delta_l^{2\kappa}},$$

so that

$$u_{p_{0l}, \delta_l} \to \vartheta p_{0l} \quad \text{in} \quad L^\infty(Q_R)$$

$$u_{p_l, \delta_l} \to \vartheta p_0 \quad \text{in} \quad L^\infty(Q_R),$$

and, consequently,

$$\|u_{p_{0l}, \delta_l} (\cdot + \xi_l, \cdot + \theta_l) - u_{p_l, \delta_l} (\cdot + \xi_l, \cdot + \theta_l)\|_{L^\infty(B_R \times (-R^2, R^2))} \to 0$$

$$\|u_{p_l, \delta_l} (\cdot, \cdot) - u_{p_{0l}, \delta_l} (\cdot - \xi_l, \cdot - \theta_l)\|_{L^\infty(B_R \times (-R^2, R^2))} \to 0,$$

for any $R > 0.$ Now, as in [24], we proceed by splitting the remaining part of the proof in two cases:

(i) There are infinitely many indexes $l \in \mathbb{N}$ such $\theta_l \geq 0.$

(ii) There are infinitely many indexes $l \in \mathbb{N}$ such $\theta_l \leq 0.$
Let us prove (ii). After passing to a subsequence, we can assume \( \theta_l \leq 0 \) for any \( l \in \mathbb{N} \). So, since \( \theta_l \leq 0 \), for any \( (x, t) \in Q_1 \) we have \( (x - \xi_l, t - \theta_l) \in Q_2 := B_2 \times (0, 4) \) and, furthermore,
\[
\| \vartheta_{p_0}(\cdot, \cdot) - \vartheta_{p_0}(\cdot - \xi_0, \cdot - \theta_0) \|_{L^\infty(Q_1)} \leq \| \vartheta_{p_0} - \vartheta_{p_0, \delta} \|_{L^\infty(Q_1)} \\
+ \| \vartheta_{p_0, \delta}(\cdot, \cdot) - \vartheta_{p_0, \delta}(\cdot - \xi_0, \cdot - \theta_0) \|_{L^\infty(Q_1)} \\
+ \| \vartheta_{p_0, \delta}(\cdot - \xi_0, \cdot - \theta_0) - \vartheta_{p_0}(\cdot - \xi_0, \cdot - \theta_0) \|_{L^\infty(Q_1)} \to 0,
\]
as \( l \to +\infty \), thanks to (8.9) and (8.10). Consequently, using the real analyticity of the polynomial \( \vartheta_{p_0} = \vartheta_{p_0}(x, t) \), it follows
\[
\vartheta_{p_0}(x + \xi_0, t + \theta_0) = \vartheta_{p_0}(x, t) \quad \text{for all } (x, t) \in \mathbb{R}^N \times \mathbb{R},
\]
and so
\[
\partial_x^\alpha \partial_t^j \vartheta_{p_0}(\xi_0, \theta_0) = \partial_x^\alpha \partial_t^j \vartheta_{p_0}(0, 0) = 0 \quad \text{for all } |\alpha| + 2j < 2\kappa.
\]
On the other hand, diving both sides of (8.8) by \( \delta_l^{2\kappa - |\alpha| - 2j} \) ad taking the limit as \( l \to +\infty \), we obtain
\[
|\partial_x^\alpha \partial_t^j \vartheta_{p_0}(\xi_0, \theta_0)| = \left| \sum_{(\beta, i) \geq (\alpha, j): \frac{\beta}{\alpha} + \frac{i}{j} = 2\kappa} a_{\beta, i}(x_0, t_0) \frac{\xi_0^{\beta - \alpha} \theta_0^{i-j}}{\beta! \alpha! \cdot \theta_0^{i-j}} \right| > 0,
\]
in contradiction with the computation above. The proof of case (i) is almost identical to the previous one and we skip it (we just have to using the first convergence in (8.10) instead of the second one).

We have thus verified the assumptions of Whitney’s Theorem. Consequently, we deduce the existence of a function \( F \in C^{2\kappa, [\kappa]}(\mathbb{R}^N \times \mathbb{R}) \) such that
\[
\partial_x^\alpha \partial_t^j F = f_{\alpha, j} \quad \text{in } K,
\]
for all \( |\alpha| + 2j < 2\kappa \), where \( [\cdot] \) denotes the floor function.

**Step2: Implicit function theorem.** Let \((x_0, t_0) \in \Gamma^d_\kappa \cap K \) and \( d = 0, \ldots, N \). As in Theorem 12.12 of [24] we consider two subcases.

Let us begin by assuming \( d = 0, \ldots, N - 1 \). For these choices of the dimension, we have that there are multi-indexes \( \alpha_i \) and nonnegative integers \( j_i \) with \( |\alpha_i| + j_i = 2\kappa - 1 \) such that
\[
v_i = \nabla_x \partial_x^{\alpha_i} \partial_t^{j_i} \vartheta_{p_0} = \nabla_x \partial_x^{\alpha_i} \partial_t^{j_i} F(x_0, t_0) \quad \text{for } i = 1, \ldots, N - d,
\]
are linearly independent vectors. At the same time, in view of part (i) of Theorem 3.9 and Whitney Extension Theorem, we have
\[
\Gamma^d_{\kappa}(u) \cap K \subset \bigcap_{i=1}^{N-d} \{(x, t) \in \mathbb{R}^N \times \mathbb{R} : \partial_x^{\alpha_i} \partial_t^{j_i} F(x, t) = 0 \},
\]
and so, using the linear independence of the \( v_i \)’s and the Implicit function theorem, we immediately conclude that \( \Gamma^d_{\kappa}(u) \cap K \) is contained in a \( (d + 1) \)-dimensional space-like \( C^{1,0} \) manifold (cfr. with Definition [3.11]). Finally, recalling that we have chosen \( K = E_h \) (for some arbitrary \( h \in \mathbb{N} \)) and since \( \Gamma_{\kappa}(u) = \bigcup_{h \in \mathbb{N}} E_h \) (cfr. with Lemma [8.1]), the proof in the case \( d = 0, \ldots, N - 1 \) is ended.

Assume now \( d = N \) and \((x_0, t_0) \in \Gamma^N_{\kappa}(u) \cap K \). Hence from Lemma [8.7] we deduce
\[
\partial_t^{[\kappa]} F(x_0, t_0) = \partial_t^{[\kappa]} \vartheta_{p_0} \neq 0,
\]
while
\[
\Gamma^N_{\kappa}(u) \cap K \subset \{(x, t) \in \mathbb{R}^N \times \mathbb{R} : \partial_t^{[\kappa]-1} F(x, t) = 0 \},
\]
and so, for the Implicit function theorem we obtain that $\Gamma^N_\kappa \cap K$ is contained in a $N$-dimensional time-like $C^1$ manifold. The proof is then completed. □
