FAITHFUL IRREDUCIBLE REPRESENTATIONS OF MODULAR LIE ALGEBRAS

DONALD W. BARNES

Abstract. Let $L$ be a finite-dimensional Lie algebra over a field of characteristic $p \neq 0$. By a theorem of Jacobson, $L$ has a finite-dimensional faithful completely reducible module. We show that if $F$ is not algebraically closed, then $L$ has an irreducible such module.

1. Introduction

Let $L$ be a finite-dimensional Lie algebra over the field $F$ of characteristic $p > 0$. By Jacobson’s Theorem, $L$ has a finite-dimensional faithful completely reducible module. We adapt Jacobson’s proof to show that if $F$ is not algebraically closed, then $L$ has an irreducible such module. We may replace $L$ with a minimal $p$-envelope. Thus without loss of generality, we may assume that $L$ is restricted. Further, by [3, Corollary 2.3], we may assume that the $p$-operation $[p]$ vanishes on $\text{Asoc}(L)$, the abelian socle of $L$. We note that, by the Artin-Schreier Theorem \(^1\) (see [4, Theorem 3.1]), our assumption that $F$ is not algebraically closed implies that the algebraic closure $\overline{F}$ has infinite dimension over $F$.

Jacobson takes an appropriately selected character $c$ and uses the $c$-reduced enveloping algebra $u(L, c)$ to obtain for a given element $x \in L$, an irreducible module on which $x$ acts non-trivially. If $x$ is in some minimal ideal $K$ of $L$, then $K$ is not in the kernel of the representation. For each minimal ideal $K$, we can clearly construct an irreducible module $V_K$ on which $K$ acts non-trivially. We shall choose modules $V_K$ such that their tensor product has a composition factor on which all minimal ideals act non-trivially. It is in the making of this choice that we use the assumption that the dimension of $\overline{F}$ over $F$ is infinite.

2. Diagonals

Let $A_1, \ldots, A_r$ be abelian minimal ideals of $L$ which, as $L$-modules, are isomorphic with isomorphisms $\phi_i : A_1 \to A_i, \phi_1 = \text{id}$. For a given $A_1$, we choose the $A_i$ with $r$ as large as possible subject to their sum being direct. With the $A_i$ so chosen, we say that $A_1$ has multiplicity $r$ in $\text{Asoc}(L)$. For any $\lambda_1, \ldots, \lambda_r$, not all zero, the set $\{ \sum_{i=1}^{r} \lambda_i \phi_i(a) \mid a \in A_1 \}$ is also a minimal ideal and every minimal ideal isomorphic to $A_1$ has this form. Those with more that one of the $\lambda_i$ non-zero are called diagonals. We shall denote the ideal given by $\lambda = (\lambda_1, \ldots, \lambda_r)$ by $A_{\lambda}$.

\(^1\) I wish to thank J. M. Bois for drawing my attention to this theorem.

This work was done while the author was an Honorary Associate of the School of Mathematics and Statistics, University of Sydney.
Under our assumptions, an abelian minimal ideal $A$ acts non-trivially on an irreducible module with character $c$ if and only if $c(A) \neq 0$. If for the above $A$, we have modules $V_i$ with characters $c_i$, then $\bigotimes_{i=1}^r V_i$ has character $c_\otimes = \sum_{i=1}^r c_i$. For $a_\lambda = \sum \lambda_i \phi_i(a) \in A_\lambda$, we have $c_\otimes(a_\lambda) = \sum \lambda_i c_i(\phi_i(a))$. Thus $c_\otimes$ vanishes on some $A_\lambda$ if and only if the $c_i\phi_i$ are linearly dependent.

We shall use generalised characters, linear maps $c : L \to \bar{F}$, the algebraic closure of $F$. If $c$ is a character of a module $V$ then every conjugate of $c$ is also a character. The set of all characters of composition factors of $V = F \otimes V$ is called the character cluster $\text{Cl}(V)$. (See [1].) If the restriction $\text{Cl}(V)|A$ of $\text{Cl}(V)$ to the abelian minimal ideal $A$ does not contain 0, then $A$ acts non-trivially on every composition factor of $V$. By [1] Theorem 3.4, if $V$ is irreducible, then $\text{Cl}(V)$ is simple, that is, the characters in $\text{Cl}(V)$ are all conjugate.

If $C$ is a simple cluster, then we can form the $C$-reduced enveloping algebra $u(L,C)$. For any $x \in L$, the element $x^p - x^{[p]}$ of the universal enveloping algebra is central and on an $\bar{F} \otimes L$-module with character $c$, acts as multiplication by $c(x)^p$. Let $m_x(t) \in F[t]$ be the minimal polynomial of $c(x)^p$. The $C$-reduced enveloping algebra $u(L,C)$ is the quotient of $U(L)$ by the ideal generated by $\{m_x(x^p - x^{[p]}) \mid x \in L\}$ for some $c \in C$. (Since all $c \in C$ are conjugate, they all give the same polynomial $m_x(t)$.) The $C$-reduced enveloping algebra is finite-dimensional. Any $u(L,C)$-module is an $L$-module with cluster $C$. This construction may be found in Farnsteiner [5] or in Barnes [2].

**Lemma 2.1.** For any simple cluster $C$, there exists a finite-dimensional irreducible $L$-module with cluster $C$.

**Proof.** As $u(L,C)$ is a $u(L,C)$-module, any $L$-module composition factor of $u(L,C)$ is an irreducible module with cluster $C$. $\square$

**Lemma 2.2.** Let $K$ be an ideal of $L$ and let $V, W$ be irreducible $L$-modules. Suppose that $K$ acts non-trivially on $V$ and trivially on $W$. Then $K$ acts non-trivially on every composition factor of $V \otimes W$.

**Proof.** Regarded as $K$-module, $V \otimes W$ is a direct sum of copies of $V$. Thus any composition factor of $V \otimes W$ is as $K$-module, a direct sum of copies of $V$. $\square$

**Lemma 2.3.** There exists an irreducible $L$-module $V_0$ on which every abelian minimal ideal acts non-trivially.

**Proof.** Let $A_1, \ldots, A_r$ be abelian minimal ideals of $L$ which are isomorphic with isomorphisms $\phi_i : A_1 \to A_i$, $\phi_1 = \text{id}$, chosen as above. Let $B_1$ be a maximal subspace of $A_1$ and let $a_1 \in A_1, a_1 \notin B_1$. Put $B_i = \phi_i(B_1)$ and $a_i = \phi_i(a_1)$. Let $K$ be a subspace of $L$ complementing $\text{Asoc}(L)$. We define a character $c_1$ by setting $c_1(a_1) = 1, c_1(B_1) = 0, c_1(K) = 0, c_1(A_i) = 0$ for $i \neq 1$ and $c_1(A) = 0$ for all abelian minimal ideals not isomorphic to $A_1$. By Lemma 2.1 there exists an irreducible $L$-module $W_1$ with cluster $\{c_1\}$. We proceed similarly to define $c_i$, choosing $c_i(a_i)$ not in the field generated by the earlier $c_j(a_j)$ and their conjugates, obtaining irreducible modules $W_i$. (This is always possible since the dimension of $\bar{F}$ over $F$ is infinite.) Let $W$ be a composition factor of $\bigotimes_{i=1}^r W_i$. Every character of the tensor product is a sum over $i$ of the $c_i$ or a conjugate of $c_i$. Thus the characters of $W$ are all of this form. By our choice of the $c_i$, no non-trivial linear combination of these characters is zero, thus every minimal ideal in $\sum A_i$ acts non-trivially on $W$. The abelian minimal ideals not isomorphic to $A_1$ all act trivially on $W$. 

We construct such a module $W$ for each of the isomorphism types of abelian minimal ideal and let $V$ be the tensor product of these. Let $V_0$ be a composition factor of $V$. The result follows by Lemma 2.2.

3. The main result

**Theorem 3.1.** Let $L$ be a finite-dimensional Lie algebra over a field $F$ of characteristic $p \neq 0$. Suppose that $F$ is not algebraically closed. Then there exists a finite-dimensional faithful irreducible $L$-module.

**Proof.** Let $K_1, \ldots, K_s$ be the non-abelian minimal ideals of $L$. Then $K_i$ is an irreducible $L$-module on which $K_i$ acts non-trivially and on which every other minimal ideal acts trivially. We start with $V_0$ given by Lemma 2.3 and construct inductively irreducible modules $V_i$ on which the abelian minimal ideals and the $K_j$ for $j \leq i$ all act non-trivially.

We suppose that we have constructed $V_{i-1}$. If $K_i$ acts non-trivially on $V_{i-1}$, we set $V_i = V_{i-1}$. If not, then we take for $V_i$ any composition factor of $V_{i-1} \otimes K_i$. By Lemma 2.2 this satisfies the requirements.

Put $V = V_s$. Then $V$ is a finite-dimensional irreducible $L$-module on which every minimal ideal of $L$ acts non-trivially. Since the kernel of the representation cannot contain any minimal ideal, the representation is faithful.

**Remark 3.2.** Even over an algebraically closed field $F$, there are many algebras for which the argument works. In this case, the $\phi_i$ are determined up to scalar multiples. For isomorphic $A_1, \ldots, A_r$, we require $r$ linearly independent linear maps $c_i : A_1 \rightarrow F$. These exist if and only if $r \leq \dim(A_1)$. Any algebra where each isomorphism type of abelian minimal ideal satisfies this condition has a faithful irreducible module.
