THE EQUIVALENCE OF SEVERAL CONJECTURES ON INDEPENDENCE OF $\ell$

REMY VAN DOBBEN DE BRUYN

ABSTRACT

We consider several conjectures on the independence of $\ell$ of the étale cohomology of (singular, open) varieties over $\overline{\mathbb{F}}_p$. The main result is that independence of $\ell$ of the Betti numbers $h_i^c(\overline{X}, \mathbb{Q}_\ell)$ for arbitrary varieties is equivalent to independence of $\ell$ of homological equivalence $\sim_{\text{hom},\ell}$ for cycles on smooth projective varieties. We give several other equivalent statements. As a surprising consequence, we prove that independence of $\ell$ of Betti numbers for smooth quasi-projective varieties implies the same result for arbitrary separated finite type $k$-schemes.

INTRODUCTION

Let $k$ be a field, and let $X$ be a $k$-variety. Then for every prime number $\ell$ invertible in $k$, there is an associated étale cohomology group $H^*_\text{ét}(X, \mathbb{Q}_\ell)$ that is defined using the geometry of degree $\ell$ covers of $X$. The main question we want to consider is the following.

Question 1. Given a variety $X$ over a field $k$, is the dimension $h_i^c(X, \mathbb{Q}_\ell)$ of $H^*_\text{ét}(X, \mathbb{Q}_\ell)$ independent of the prime $\ell$?

If $k = \mathbb{C}$ and $X$ is smooth, this easily follows from the functorial comparison isomorphisms [SGA4_{III}, Exp. XI, Thm. 4.4(iii)]

$$H^*_\text{ét}(X, \mathbb{Q}_\ell) \cong H^*_{\text{sing}}(X(\mathbb{C}), \mathbb{Q}) \otimes_{\mathbb{Q}} \mathbb{Q}_\ell.$$  

The result for arbitrary $X$ over $\mathbb{C}$ can be deduced from this using hypercoverings, cf. [Del74b, 6.2.8]. The Lefschetz principle proves the result for any field $k$ of characteristic 0, since étale cohomology is insensitive to extensions of algebraically closed fields [SGA4_{III}, Exp. XVI, Cor. 1.6].

On the other hand, if $k$ is finite and $X$ is smooth and proper, then the Weil conjectures [Del74a], [Del80] imply that $h_i^\text{ét}(X, \mathbb{Q}_\ell)$ can be read off from the zeta function of $X$, and thus does not depend on $\ell$. The question for arbitrary $k$-varieties $X$ is a well-known open problem [Kat94, p. 28, (2a)], [Ill06, 3.5(c)].
Assuming the homological standard conjecture [Gro69, 4, Rmk. (3)], the result is known in the following two cases:

(i) \( X \) is proper;
(ii) \( X \) is the complement of a simple normal crossings divisor \( D \) in a smooth projective variety \( \overline{X} \).

Indeed, (ii) is explained in [Kat94, p. 28–29], and (i) is an application of de Jong’s alterations [dJo96]. Even assuming the homological standard conjecture, the result for general \( X \) does not seem to appear in the literature (although it may have been known to experts). One cannot simply combine the arguments of (i) and (ii); see Remark 5.6.

We improve these conditional results in three ways:

- we replace the homological standard conjecture by a weaker assumption;
- we prove independence of \( \ell \) of \( h^i_c(X, \mathbb{Q}_\ell) \) for every finite type \( k \)-scheme \( X \);
- we prove a converse as well.

Theorem 1. Let \( k = \overline{F}_p \). Then the following are equivalent:

1. For every smooth projective \( k \)-scheme \( X \), the kernel of the cycle class map \( \text{cl}: \text{CH}^*_Q(X) \to H^*_c(X, \mathbb{Q}_\ell) \) is independent of \( \ell \);
2. For all smooth projective \( k \)-schemes \( X \) and \( Y \), and any \( \alpha \in \text{CH}^*_Q(X \times Y) \), the rank of the map \( \alpha_*: H^*(X, \mathbb{Q}_\ell) \to H^*(Y, \mathbb{Q}_\ell) \) is independent of \( \ell \);
3a. For every separated finite type \( k \)-scheme \( X \), the dimension of \( H^*_c(X, \mathbb{Q}_\ell) \) is independent of \( \ell \);
3b. For every smooth quasi-projective \( k \)-scheme \( X \), the dimension of \( H^*_c(X, \mathbb{Q}_\ell) \) is independent of \( \ell \).

This result is given in Theorem 3.5 below. This gives many new angles to the independence of \( \ell \) question. The implication (3b) \( \Rightarrow \) (3a) is particularly surprising; the proof goes through (1) and (2).

We also have an extension to crystalline cohomology. In fact, we work with an arbitrary Weil cohomology theory (see Definition 1.1) satisfying some additional axioms (see Axiom 2.13).

However, our methods do not say anything about independence of \( \ell \) of the dimensions \( h^i(X, \mathbb{Q}_\ell) \) of the (usual) cohomology groups \( H^i(X, \mathbb{Q}_\ell) \), except in the proper (resp. smooth) case where it coincides with (resp. is dual to) compactly supported cohomology.

The idea of (1) \( \Rightarrow \) (2) is that the rank of a linear map \( f: V \to W \) is the largest \( r \in \mathbb{Z}_{\geq 0} \) such that \( \wedge^r f \neq 0 \). Although the functors \( H^*(-, \mathbb{Q}_\ell) \): \text{Mot}_k \to \text{gVec} \) do not preserve wedge products (see Remark 1.10), algebraicity of the Künneth projectors [KM74] decomposes a cycle \( \alpha \in \text{CH}^*_Q(X \times Y) \) as \( \alpha_{\text{even}} \oplus \alpha_{\text{odd}} \). Then \( \wedge^r \alpha_{\text{even}} \) (resp. \( \wedge^r \alpha_{\text{odd}} \)) acts on cohomology as \( \wedge^r \alpha_{\text{even},*} \) (resp. \( \wedge^r \alpha_{\text{odd},*} \)), so the rank of \( \alpha_*: H^*(X, \mathbb{Q}_\ell) \to H^*(Y, \mathbb{Q}_\ell) \) is determined by the vanishing or nonvanishing of \( \text{cl}(\wedge^r \alpha_{\text{even}}) \) and \( \text{cl}(\wedge^r \alpha_{\text{odd}}) \) for various \( r \).
To prove (2) ⇒ (3a), we use a variant of the classical hypercovering argument due to Deligne [Del74b]: if $X_\bullet \to X$ is a proper hypercovering, then there is a hypercohomology spectral sequence

$$E^{p,q}_1 = H^q(X_p, \mathbb{Q}_\ell) \Rightarrow H^{p+q}(X, \mathbb{Q}_\ell). \quad (1)$$

If each $X_p$ is smooth projective, then this degenerates on the $E_2$ page for weight reasons, so the dimension of $H^i(X, \mathbb{Q}_\ell)$ is determined by the ranks of the maps on the $E_1$ page.

However, a proper hypercovering by smooth projective schemes can only exist if $X$ is proper. In general, again using de Jong’s alterations [dJ96], one can construct a proper hypercovering $X_\bullet \to X$ where each $X_i$ is the complement of a simple normal crossings divisor $Z_i$ in a smooth projective $k$-scheme $\bar{X}_i$. There is a different spectral sequence [Kat94, p. 28–29] computing the compactly supported cohomology of $X_i$ in terms of $\bar{X}_i$ and the components of $Z_i$; its dual then computes the cohomology of $X_i$. However, if we then compute (1), the purity argument no longer applies.

Instead, we choose a compactification $X \to \bar{X}$ first, with closed complement $V$, and we produce a morphism of simplicial schemes $v_\bullet : V_\bullet \to X_\bullet$, where $V_\bullet$ (resp. $X_\bullet$) is a hypercovering of $V$ (resp. $X$). Then the simplicial cone of $v_\bullet$ computes the compactly supported cohomology of $X$, by comparing the long exact sequence for the mapping cone with that for the triple $(\bar{X}, X, V)$. This allows us to apply the purity theorem as in the argument above for $X$ proper, which finishes the proof of (2) ⇒ (3a).

Finally, for the implication (3b) ⇒ (1) we prove that any cycle $\alpha \in \text{CH}_d(X)$ can be written as a difference $[Z_1] - [Z_2]$ with the $Z_i$ irreducible; see Corollary 6.5. Letting $U$ be the complement of $Z_1 \cup Z_2$, we relate the vanishing of $\text{cl}(\alpha)$ to the dimension of $H^i_{2d+1}(U, \mathbb{Q}_\ell)$. There are only two possible cases depending on whether $\text{cl}(Z_1)$ and $\text{cl}(Z_2)$ are linearly independent or linearly dependent; in the latter case the linear relation is uniquely determined by certain intersection numbers.

OUTLINE OF THE PAPER

In Section 1 we give a brief review of Weil cohomology theories (Definition 1.1) and pure motives (Definition 1.5). Section 2 contains a review of simplicial schemes and mapping cones, which will play an important role in the proof. We also state the additional axioms on our Weil cohomology theory for the arguments to work; see Axiom 2.13.

The main theorem will be stated in Section 3 (see Theorem 3.5). We then proceed to prove the implications of Theorem 3.5 as outlined in the introduction above, in the following cyclic order:

$$(1) \implies (2) \implies (3a) \implies (3b) \implies (1).$$

The implication (3a) ⇒ (3b) is trivial; each of the others will take up one section (Section 4, Section 5, and Section 6 respectively).
Notation and conventions

A $k$-variety will mean a finite type, separated, geometrically integral $k$-scheme. A pair $(X, H)$ is called a (quasi)projective $k$-scheme if $X$ is a (quasi)projective $k$-scheme and $H$ a very ample divisor on $X$.

The category of smooth projective $k$-varieties will be denoted by $\text{SmPrVar}_k$, and the category of smooth projective $k$-schemes will be denoted by $\text{SmPr}_k$. The latter can be obtained from the former as the category of formal finite coproducts, cf. Example 2.12. The category of Chow motives (with respect to $\sim$) is denoted by $\text{Mot}_k$; its definition will be recalled in Definition 1.5. Morphisms in this category are typically denoted by $\alpha: X \to Y$.

If $K$ is a field, then $\text{Vec}_K$ denotes the category of $K$-vector spaces, $\text{gVec}_K$ the category of $\mathbb{Z}$-graded $K$-vector spaces, and $\text{gAlg}_K$ the category of $\mathbb{Z}$-graded (unital, associative) $K$-algebras. The objects of $\text{gAlg}_K$ we encounter will always be graded-commutative and vanish in negative degrees.

In the main theorems, the base field $k$ will be assumed algebraically closed, because standard references on Weil cohomology theories have this running assumption, and establishing the general framework would take us too far astray. Other than all statements involving Weil cohomology theories, we will not make any assumptions on the ground field $k$, except where necessary for the arguments.

We write $\text{Ab}(\mathcal{C})$ for the category of abelian group objects in a category $\mathcal{C}$ with finite products. All topoi\footnote{We work with topoi instead of sites because they have better formal properties, but all arguments could also be carried out using Grothendieck pretopologies. We ignore set-theoretic issues; they can for instance be dealt with by putting bounds on various categories.} will be Grothendieck topoi, i.e. the topos of sheaves (of sets) on a small category with a Grothendieck topology (or pretopology). We write $\text{Topos}$ for the (strict) 2-category of topoi, whose objects are topoi, whose 1-morphisms are (geometric) morphisms of topoi, and whose 2-morphisms are natural transformations between the inverse image functors (equivalently, between the direct image functors).

We write $\text{Shv}$ for the (strict) 2-category whose objects are pairs $(X, \mathbb{F})$ of a topos $X$ with an abelian object $\mathbb{F}$ in $X$, whose 1-morphisms $(X, \mathbb{F}) \to (Y, \mathbb{G})$ are pairs $(f, \phi)$ of a 1-morphism $f: X \to Y$ and a morphism $\phi: f^*\mathbb{G} \to \mathbb{F}$ of abelian objects, and whose 2-morphisms $(f, \phi) \to (g, \psi)$ are given by natural transformations $\eta: f^* \Rightarrow g^*$ such that $\psi \circ \eta \mathbb{G} = 1_{f^*} \circ \phi$. We think of it as a “fibred 2-category” $\text{Shv} \to \text{Topos}$, whose fibre above the topos $X$ is $\text{Ab}(X)^{\text{op}}$ (with only identity 2-morphisms). In a similar way, we define a category $\text{Comp}$ of pairs $(X, K)$ of a topos $X$ with a complex $K$ of abelian objects on $X$.

Acknowledgements

This paper grew out of a conversation with Ashwin Deopurkar on the existence of exterior powers in the category of pure motives. The author also thanks Raymond Cheng, Johan Commelin, and Johan de Jong for helpful conversations.
1. Pure motives and Weil cohomology theories

This is a review of the theory of pure motives, cf. e.g. Kleiman [Kle72], Jannsen [Jan92], or Scholl’s excellent survey [Sch94]. We also give a brief review of Weil cohomology theories; see [Kle94, §3] for more details.

Following standard references, we will assume that \( k \) is algebraically closed. Our setup is slightly more general than that of [Kle94, §3], in that we allow smooth projective \( k \)-schemes with multiple components.

Definition 1.1. A Weil cohomology theory is a functor \( H : \text{SmPr}^\text{op}_k \rightarrow \text{gAlg}_K \) satisfying the following axioms.

(W1) Each \( H^i(X) \) is finite-dimensional and vanishes for \( i < 0 \) and \( i > 2 \dim X \);
(W2) There is a trace map \( \text{tr} : H^{2 \dim X}(X) \rightarrow K \) that is an isomorphism if \( X \) is irreducible. If all components of \( X \) have dimension \( d \), then the natural pairing \( H^i(X) \times H^{2d-i}(X) \rightarrow K \) is perfect;
(W3) The projectors induce an isomorphism \( H^*(X) \otimes_K H^*(Y) \rightarrow H^*(X \times Y) \);
(W4) There are cycle class maps \( \text{cl} : \text{CH}_Q^i(X) \rightarrow H^{2i}(X) \). It is a ring homomorphism functorial for pullback and pushforward, where pushforward for \( H \) is defined using (W2);
(W5) The weak Lefschetz theorem holds;
(W6) The hard Lefschetz theorem holds;
(W7) \( H \) preserves products, i.e. \( H(\coprod X_i) = \prod H(X_i) \).

Example 1.2. For every prime \( \ell \) invertible in \( k \), the \( \ell \)-adic étale cohomology gives a Weil cohomology theory [Del74a; Del80].

Example 1.3. For a perfect field \( k \) of positive characteristic \( p \), Witt ring \( W(k) \) with field of fractions \( K \), the crystalline cohomology \( H_{\text{cris}}^i(X/K) \) is a Weil cohomology theory [Ber74], [KM74, Cor. 1(2)].

Let \( \sim \) be an adequate equivalence relation (cf. [Sam60]) finer than homological equivalence for every Weil cohomology theory, e.g. \( \sim \) is rational, algebraic, or smash-nilpotent equivalence. For a variety \( X \) and \( i \in \mathbb{Z}_{\geq 0} \), we will write \( \text{CH}^i_{\text{Q}}(X) \) for \( \text{CH}^i(X) \otimes Q \).

Definition 1.4. Let \( X \) and \( Y \) be smooth projective \( k \)-schemes, and assume that \( X \) has connected components \( X_1, \ldots, X_m \) of dimensions \( d_1, \ldots, d_m \), respectively. Then the group of correspondences of degree \( r \) from \( X \) to \( Y \) is

\[
\text{Corr}^r(X, Y) := \bigoplus_{i=1}^m \text{CH}^{d_i + r}_{\text{Q}}(X_i \times Y).
\]

An element \( \alpha \in \text{Corr}^r(X, Y) \) is a correspondence from \( X \) to \( Y \), and is denoted \( \alpha : X \rightharpoonup Y \). There is a natural composition of correspondences:

\[
\text{Corr}^r(X, Y) \times \text{Corr}^s(Y, Z) \rightarrow \text{Corr}^{r+s}(X, Z) \quad (\alpha, \beta) \mapsto \beta \circ \alpha.
\]
If the degree $r$ in the superscript is omitted, it will be assumed 0.

**Definition 1.5.** The category of Chow motives (modulo $\sim$) is the category whose objects are triples $(X, p, m)$, where $X$ is a smooth projective $k$-scheme, $p \in \text{Corr}(X, X)$ a projector (i.e., $p^2 = p$), and $m \in \mathbb{Z}$ an integer. Morphisms from $(X, p, m)$ to $(Y, q, n)$ are given by

$$\text{Hom}((X, p, m), (Y, q, n)) = q \text{Corr}^{n-m}(X, Y)p = \{\alpha \in \text{Corr}^{n-m}(X, Y) | \alpha p = \alpha = q\alpha\}.$$ 

We denote the category of Chow motives by $\text{Mot}_k$. The motive $(\text{Spec} k, \text{id}, -1)$ is called the Lefschetz motive, and is denoted by $L$. We write $L^n$ for $L \otimes^n$.

**Remark 1.6.** There is a functor $\text{SmPr}^{\text{op}}_k \to \text{Mot}_k$ associating to every smooth projective $k$-scheme $X$ the motive $(X, \text{id}, 0)$, and to every map $f: X \to Y$ the (class of the) graph $\Gamma_f \in \text{Corr}(Y, X)$.

**Definition 1.7.** If $H$ is a Weil cohomology theory with coefficient field $K$, then Poincaré duality gives an isomorphism

$$H^*(X) \longrightarrow H^*(X)^\vee$$

(1.1)

$$\nu \longmapsto \left(w \mapsto \int v \cup w\right).$$

Together with the Künneth formula this gives isomorphisms

$$H^*(X \times Y) \cong H^*(X) \otimes H^*(Y) \cong H^*(X)^\vee \otimes H^*(Y) = \text{Hom}(H^*(X), H^*(Y)).$$

If $\alpha \in \text{Corr}^r(X, Y)$, then under these isomorphisms $\text{cl}(\alpha)$ induces a pushforward

$$\alpha_*: H^i(X) \to H^{i+2r}(Y).$$

(1.2)

In particular, a projector $p \in \text{Corr}(X, X)$ induces a projector on $H^*$, and we extend $H$ to a functor $\text{Mot}_k \to g\text{Vec}_K$ by setting

$$H^*(X, p, m) := pH^*(X)[2m],$$

where for a graded vector space $V = \bigoplus_i V^i$, we set $V^i[m] = V^{i+m}$.

Given a morphism $\alpha: (X, p, m) \to (Y, q, n)$, we define $H\alpha$ to be the graded map given by the pushforward $\alpha_*: pH^{i+2m}(X) \to qH^{i+2n}(Y)$ as in (1.2).

Some Weil cohomology theories have further structure (e.g., a Hodge structure or a Galois action), and these structures are typically preserved by pushforward along cycles (if everything is given the correct ‘Tate twist’). We will consider this additional structure understood, and we will not use separate notation for the corresponding enriched functor.

**Example 1.8.** The cohomology $H^i(L)$ of the Lefschetz motive is 0 if $i \neq 2$ and one-dimensional if $i = 2$. It’s often thought of as the compactly supported cohomology of $\mathbb{A}^1$, and is equipped with the corresponding Galois action or Hodge structure.
Remark 1.9. The category $\text{Mot}_k$ has binary biproducts given by disjoint union:

$$(X, p, m) \oplus (Y, q, n) = (X \amalg Y, p \oplus q, m + n).$$

However, the category $\text{Mot}_k$ is not in general abelian, and in fact for our choices of $\sim$ this is either false or open. The category $\text{Mot}_k$ is also equipped with a tensor product given by

$$(X, p, m) \otimes (Y, q, n) = (X \times Y, p \otimes q, m + n).$$

Thus, we also get symmetric and alternating products $S^n$ and $\bigwedge^n$ by considering the projectors $\frac{1}{n!} \sum \sigma$ and $\frac{1}{n!} \sum (-1)^\sigma \sigma$ respectively on $X^n$.

Remark 1.10. If $H$ is a Weil cohomology theory with coefficient field $K$, then the functor $H: \text{Mot}_k \to \text{gVec}_K$ is a tensor functor if we equip $\text{gVec}_K$ with the tensor product as in super vector spaces: on objects, it is given by the usual graded tensor product, but the swap is given by

$$\tau_{V,W}: V \otimes W \to W \otimes V$$

$$v_i \otimes w_j \mapsto (-1)^{ij} w_j \otimes v_i,$$

for homogeneous elements $v_i \in V^i, w_j \in W^j$. To see that this makes $H$ into a tensor functor, note that the Künneth isomorphism is given by the map

$$H^*(X) \otimes H^*(Y) \to H^*(X \times Y)$$

$$\alpha \otimes \beta \mapsto \pi_X^* \alpha \cap \pi_Y^* \beta,$$

which under swapping $X$ and $Y$ picks up a factor $(-1)^{\deg \alpha \deg \beta}$.

Remark 1.11. In particular, if $H^*(X) = H^\text{even} \oplus H^\text{odd}$, then

$$H^*(S^r X) = S^r (H^*(X)) = \bigoplus_{i+j=r} S^i H^\text{even} \otimes \bigwedge^j H^\text{odd},$$

and the opposite happens for $\bigwedge^r X$. Indeed, because of the sign in the swap $\tau_{V,W}$, the symmetriser and antisymmetriser get swapped in odd degree.

We finally state two lemmas that we will use later on.

Lemma 1.12. Let $X$ and $Y$ be smooth projective schemes over a field $k$, and let $\alpha \in \text{Corr}(X,Y)$. Then the map $\alpha_*: H^*(X) \to H^*(Y)$ is 0 if and only if $\text{cl}(\alpha) = 0 \in H^*(X \times Y)$.

Proof. This is clear from the definition of $\alpha_*$, cf. Definition 1.7.

Lemma 1.13. Let $X$ be an $n$-dimensional smooth projective $k$-scheme, and let $\alpha \in \text{Corr}(X,X)$. Then

$$\sum_{i=0}^{2n} (-1)^i \text{tr} \left( \alpha_* |_{H^i(X)} \right) = \alpha \cdot [\Delta_X];$$

in particular, it is a rational number that does not depend on $H$. 

7
Corollary 1.14. Let $X$ be a smooth projective $k$-variety such that $\text{K"unn}(X)$ holds (see Definition 3.1). Let $\alpha \in \text{Corr}(X,X)$. Then the characteristic polynomial of $\alpha$ on $H^i(X)$ is in $\mathbb{Q}[t]$, and is independent of the Weil cohomology theory $H$.

Proof. One easily checks that the coefficients of the characteristic polynomial $P_A(t) = \det(t \cdot I - A) = t^n + c_{n-1}t^{n-1} + \ldots + c_1 t + c_0$ of an endomorphism $A$ on an $n$-dimensional vector space $V$ are given by

$$c_j = (-1)^{n-j} \text{tr} \left( A^{n-j} \right).$$

Hence, if $p_i \in \text{Corr}(X,X)$ denotes the $i$-th K"unneth projector, then applying Lemma 1.13 to $\Lambda^{n-j} (p_i \circ \alpha)$ gives the result. \hfill $\Box$

2. Simplicial schemes and mapping cones

We recall the definition of a simplicial object in a category:

Definition 2.1. The category of finite (totally) ordered sets with monotone maps is denoted $\Delta_+$. The full subcategory of nonempty objects is denoted $\Delta$. If $\mathcal{C}$ is a category, then a simplicial object in $\mathcal{C}$ is a functor $X_\bullet \colon \Delta^{\text{op}} \to \mathcal{C}$, and an augmented simplicial object in $\mathcal{C}$ is a functor $X_\bullet \colon \Delta^{\text{op}}_+ \to \mathcal{C}$.

If $X_\bullet$ is an (augmented) simplicial object, then $X_n$ denotes the value of $X_\bullet$ on the set $[n] = \{0, \ldots, n\}$. Giving an augmented simplicial object $(X_n)_{n \geq -1}$ is equivalent to giving a simplicial object $X_\bullet = (X_n)_{n \geq 0}$ together with a map $X_\bullet \to X_{-1}$ to the constant simplicial object with value $X_{-1}$.

Remark 2.2. If $\mathcal{C}$ is a 2-category (e.g. Topos or Shv; see Notation), then the correct definition of a simplicial object is a pseudofunctor $X_\bullet : \Delta^{\text{op}} \to \mathcal{C}$. By the ‘Grothendieck construction’, this should correspond to some sort of fibred object. For example, a simplicial topos corresponds to a functor $F : X \to \Delta$ that is a fibration and cofibration, such that each fibre $X_i$ is a topos, and for any $\phi : [i] \to [j]$ the pair $(f_\ast, f^\ast)$ is a morphism of topos $f : X_j \to X_i$; this is the definition of a simplicial topos of $[\text{SGA4II}, \text{Exp. Vbis}, \text{Df. 1.2.1}].$

By $[\text{SGA4II}, \text{Exp. Vbis}, \text{Df. 1.2.8 and Prop. 1.2.12}]$, this gives rise to a total topos $\Gamma(X)$. Abelian objects in $\Gamma(X)$ correspond to enrichments of the pseudofunctor $X_\bullet : \Delta^{\text{op}} \to \text{Topos}$ through $\Delta^{\text{op}} \to \text{Shv}$, and similarly for complexes\footnote{Note that a complex $K$ on a simplicial topos is bounded below iff the complexes on the components $X_i$ are bounded below uniformly in $i$.}.

Following the notation of simplicial topological spaces, we will write $H^i(X_\bullet, K)$ for $H^i(\Gamma(X), K)$. For a bounded below complex $K$ on $\Gamma(X)$, there is a spectral sequence $[\text{SGA4II}, \text{Exp. Vbis}, \text{Cor. 2.3.7}]$

$$E_1^{p,q} = H^q(X_p, K|_{X_p}) \Rightarrow H^{p+q}(X_\bullet, K),$$

whose $E_1$ page is the alternating face complex on the cosimplicial abelian group $H^q(X_\bullet, K|_{X_\bullet})$. 

Proof. The first statement is well-known, and the second follows. \hfill $\Box$
**Definition 2.3.** Let \( \mathcal{C} \) be a category with finite coproducts and a terminal object \(*\), and let \( f_\bullet : X_\bullet \to Y_\bullet \) be a morphism of simplicial objects in \( \mathcal{C} \). Then the **mapping cone** \( C_\bullet(f_\bullet) \) of \( f_\bullet \) is the simplicial object in \( \mathcal{C} \) constructed as the pushout of the diagram

\[
\begin{array}{ccc}
X_\bullet & \xrightarrow{i_0} & X_\bullet \times \Delta[1] \\
\downarrow{f_\bullet} & & \downarrow{f_\bullet} \\
Y_\bullet & \xleftarrow{i_1} & Y_\bullet,
\end{array}
\]

where \( X_\bullet \times \Delta[1] \) is the simplicial object of \( \mathcal{C} \) defined in [Stacks, Tag 017C]. The mapping cone satisfies

\[
C_n(f_\bullet) = * \amalg X_n \amalg \ldots \amalg X_n \amalg Y_n. \tag{2.1}
\]

A slightly different construction is given in [Del74b, 6.3.1], but the two are homotopy equivalent as simplicial objects in \( \mathcal{C} \). Similarly, the **mapping cylinder** \( \text{cyl}(f_\bullet) \) is the pushout of

\[
\begin{array}{ccc}
X_\bullet & \xrightarrow{f_\bullet} & Y_\bullet \\
\downarrow{i_1} & & \\
X_\bullet \times \Delta[1].
\end{array}
\]

It satisfies

\[
\text{cyl}(f_\bullet)_n = X_n \amalg \ldots \amalg X_n \amalg Y_n, \tag{2.2}
\]

and it is homotopy equivalent to \( Y_\bullet \) as simplicial object in \( \mathcal{C} \).

**Example 2.4.** Let \( f_\bullet : X_\bullet \to Y_\bullet \) be a morphism of simplicial topoi, let \( K \) and \( L \) be abelian objects (resp. complexes) on \( X_\bullet \) and \( Y_\bullet \) respectively, and let \( \phi : f_\bullet^* L \to K \) be a morphism. Then we may view \( (f_\bullet, \phi) \) as a morphism \( (X, K) \to (Y, L) \) of simplicial objects in \( \text{Shv} \) (resp. \( \text{Comp} \)). Thus, there is an abelian object (resp. complex) \( C_\bullet(\phi) \) on \( \Gamma(C_\bullet(f_\bullet)) \) such that \( (C_\bullet(f_\bullet), C_\bullet(\phi)) \) is the mapping cone in \( \text{Shv} \) (resp. \( \text{Comp} \)).

**Remark 2.5.** The terminal object in \( \text{Topos} \) is \( \text{Set} \) [SGA4\_1, Exp. IV, §4.3], whose abelian objects are just abelian groups. Moreover, 2-coproduts in \( \text{Topos} \) are given by the product of categories [SGA4\_1, Exp. IV, Exc. 8.7(bc)]. The terminal object in \( \text{Shv} \) or \( \text{Comp} \) is the pair \( (\text{Set}, 0) \). Thus, in the description of \( (2.1) \), the complex \( C_n(\phi) \) on \( C_n(f_\bullet) \) equals 0 on \( * = \text{Set} \), equals \( K|X_n \) on each of the components \( X_n \), and equals \( L|Y_n \) on the component \( Y_n \).

**Lemma 2.6.** Let \( X_\bullet \) and \( Y_\bullet \) be simplicial topoi, and let \( f_\bullet : X_\bullet \to Y_\bullet \) be a morphism of simplicial topoi. Let \( K \) and \( L \) be bounded below complexes on \( X_\bullet \) and \( Y_\bullet \) respectively, and let \( \phi : f_\bullet^* L \to K \) be a morphism. Then there is a canonical distinguished triangle

\[
R\Gamma(C_\bullet(f_\bullet), C_\bullet(\phi)) \to R\Gamma(Y_\bullet, L) \to R\Gamma(X_\bullet, K) \to R\Gamma(C_\bullet(f_\bullet), C_\bullet(\phi))[1]
\]

in \( D^+(\text{Ab}) \).

In the setting of simplicial topological spaces, this is [Del74b, 6.3.3].
Proof. By [Stacks, Tags 01DN and 01DO], there exists a large enough ordinal $\beta$ such that the functor $J = J_{\beta} : \text{Ab}(X_\bullet) \to \text{Ab}(X_\bullet)$ maps every abelian object of $X_\bullet$ to an injective object, and similarly for the analogous functors on $Y_\bullet, C_\bullet(f_\bullet), \text{and cyl}(f_\bullet)$ (for the same choice of $\beta$).

The functor $J$ also induces a functorial injective resolution $\mathcal{F} \to J^*(\mathcal{F})$. Then applying $J^*$ to $K$ gives a double complex, whose totalisation is a functorial injective resolution of $K$, which we will denote by $J^*(K)$ as well.

Note that the construction of $J$ is dimensionwise (because sheafification is computed dimensionwise), i.e. $J(K|_{X_n}) = J(K)|_{X_n}$ for every complex $K$ on $X_\bullet$. This implies that

$$J^*(C_\bullet(\phi)) = C_\bullet(J^*(\phi)),$$

and similarly for cyl($\phi$). Thus, we may replace the complexes $K, L, C_\bullet(\phi)$, and cyl($\phi$) by their functorial injective resolutions to assume that they are all injective. Therefore,

$$R\Gamma(X_\bullet, K) = \text{Tot}((\Gamma(X_\bullet, K^\bullet)).$$

and similarly for $L, C_\bullet(\phi)$, and cyl($\phi$). From the descriptions of (2.1), (2.2), and Remark 2.5, we deduce that the maps $X_\bullet \xrightarrow{\Delta} \text{cyl}(f_\bullet) \to C_\bullet(f_\bullet)$ induce a termwise split exact sequence

$$0 \to \text{Tot}(\Gamma(C_\bullet(f_\bullet), C_\bullet(\phi))) \to \text{Tot}(\Gamma(\text{cyl}(f_\bullet), \text{cyl}(\phi))) \to \text{Tot}(\Gamma(X_\bullet, K)) \to 0. \tag{2.3}$$

The simplicial homotopy equivalence $\text{cyl}(f_\bullet) \simeq Y_\bullet$ induces a chain homotopy equivalence $\text{Tot}(\Gamma(\text{cyl}(f_\bullet), \text{cyl}(\phi))) \simeq \text{Tot}(\Gamma(Y_\bullet, L))$ [Stacks, Tags 019M and 019S]. Thus, the termwise split exact sequence (2.3) gives the desired distinguished triangle. \hfill $\Box$

Example 2.7. We will be interested in the case where $X_\bullet$ is a simplicial scheme, viewed as a simplicial topos with the pro-étale topology [BS15] (resp. the crystalline topology [Ber74]), and $K$ and $L$ are the constant sheaves $Q_\ell$ (resp. the structure sheaf $\mathcal{O}_{X/W(k)}$). Then the recipe above tells us to consider the sheaf on $C_\bullet(f_\bullet)$ given on the components $*$ of $C_\bullet(f_\bullet)$ by 0 and on all other components by $Q_\ell$ (resp. $\mathcal{O}_{-/W(k)}$).

Thus, we need to equip the mapping cone of a morphism of simplicial schemes with a mild motivic structure, interpreting the sheaf 0 on $*$ as a variant of the zero motive. This motivates the following ad hoc notion.

Definition 2.8. An all-or-nothing motive $(X, p)$ is a smooth projective $k$-scheme together with a locally constant function $p : X \to \{0, 1\}$. The set of morphisms $f : (X, p) \to (Y, q)$ of all-or-nothing motives $(X, p), (Y, q)$ whose underlying schemes $X$ and $Y$ are connected is given by

$$\text{Mor}((X, p), (Y, q)) = \begin{cases} \text{Mor}(Y, X), & p = q = 1, \\ \{0\}, & p = 0, \\ \emptyset, & \text{else}, \end{cases}$$

with composition given by $f \circ 0 = 0$. (The contravariance is consistent with the conventions of Section 1.)
In general, if $X = \coprod X_i$ and $Y = \coprod Y_j$ with the $X_i$ and $Y_j$ irreducible, we set

$$\text{Mor}((X,p),(Y,q)) = \prod_j \prod_i \text{Mor}\left(\left(\text{Mor}(X_i,p\mid_{X_i}),\text{Mor}(Y_j,q\mid_{Y_j})\right)\right).$$

The category of all-or-nothing motives is denoted $\text{Mot}_k^{\text{aon}}$.

**Remark 2.9.** If $X_i$ are the components of $X$, then we think of $(X,p)$ as the pure motive $(X,p,0)$ by identifying $p$ with the projector in $\text{Corr}(X,X)$ given by $0 \in \text{CH}^*(X_i \times X_i)$ if $p\mid_{X_i} = 0$ and by $\Delta_{X_i} \in \text{CH}^*(X_i \times X_i)$ if $p\mid_{X_i} = 1$. This gives a factorisation $\text{SmPr}_k^{\text{op}} \to \text{Mot}_k^{\text{aon}} \to \text{Mot}_k$ of the functor $\text{SmPr}_k^{\text{op}} \to \text{Mot}_k$.

If $H$ is a Weil cohomology theory, then the extension $H : \text{Mot}_k \to \text{gVec}_K$ of Definition 1.7 gives functors $H : \text{Mot}_k^{\text{aon}} \to \text{gVec}_K$ as well.

Note that the all-or-nothing motives $(X,0)$ for $X$ irreducible are all isomorphic: the maps $0 : (X,0) \to (Y,0)$ and vice versa are mutual inverses. This gives an alternative construction for $\text{Mot}_k^{\text{aon}}$.

**Definition 2.10.** Let $\mathcal{E}$ be a category. Define the category $\mathcal{E} \amalg \{\ast\}$ whose objects are $\text{ob}\mathcal{E} \amalg \{\ast\}$, and morphisms are given by

$$\text{Mor}_{\mathcal{E}\amalg\{\ast\}}(X,Y) = \begin{cases} \text{Mor}_\mathcal{E}(X,Y), & X,Y \in \text{ob}\mathcal{E}, \\ \{0\}, & Y = \ast, \\ \emptyset, & \text{else}, \end{cases}$$

where $0 \circ f = 0$ whenever this makes sense. If $F : \mathcal{E} \to \mathcal{D}$ is a functor to a category $\mathcal{D}$ with a terminal object $\ast$, then there is a unique extension of $F$ to a functor $F : \mathcal{E} \amalg \{\ast\} \to \mathcal{D}$ with $F(\ast) = \ast$.

**Definition 2.11.** Let $\mathcal{E}$ be a category. Define the category $\text{Coprod}(\mathcal{E})$ of formal finite coproducts in $\mathcal{E}$ whose objects are diagrams $X : I \to \mathcal{E}$ from a finite discrete category $I$, and morphisms from $X : I \to \mathcal{E}$ to $Y : J \to \mathcal{E}$ are given by

$$\text{Mor}(X,Y) = \coprod_{i \in I} \prod_{j \in J} \text{Mor}(X_i,Y_j).$$

If $F : \mathcal{E} \to \mathcal{D}$ is a functor to a category $\mathcal{D}$ with finite coproducts, then there is a unique extension of $F$ to a functor $F : \text{Coprod}(\mathcal{E}) \to \mathcal{D}$ taking $X : I \to \mathcal{E}$ to the coproduct $\coprod_i F(X_i)$.

If $X : I \to \mathcal{E}$ is an object of $\text{Coprod}(\mathcal{E})$, then $X$ is the coproduct of the one-object diagrams $X_i$, so we may write $X = \coprod_i X_i$. An initial object of $\text{Coprod}(\mathcal{E})$ is given by the empty diagram $X : \emptyset \to \mathcal{E}$, and if $\ast$ is a terminal object of $\mathcal{E}$, then it is also terminal in $\text{Coprod}(\mathcal{E})$.

**Example 2.12.** We have an equivalence $\text{SmPr}_k \cong \text{Coprod}(\text{SmPrVar}_k)$, and $\text{Mot}_k^{\text{aon}}$ can be constructed as $\text{Coprod}(\text{SmPrVar}_k \amalg \{\ast\})^{\text{op}}$. In particular, any functor $F : \text{SmPrVar}_k \to \mathcal{D}$ to a category $\mathcal{D}$ with finite coproducts and a terminal object $\ast$ can be uniquely extended to a functor $F : (\text{Mot}_k^{\text{aon}})^{\text{op}} \to \mathcal{D}$ such that $F(X,0) = \ast$ for $X$ irreducible and $F(X,p) = \coprod_i F(X_i,p\mid_{X_i})$ if the $X_i$ are the components of $X$. This gives an alternative method to extend a Weil cohomology $H$ to a functor $H : \text{Mot}_k^{\text{aon}} \to \text{gVec}_K$, cf. Remark 2.9.
Now we are ready to state the additional axioms on our Weil cohomology theory.

**Axiom 2.13.** Consider the following axioms on a Weil cohomology theory $H$.

(A1) The functor $H: \text{SmPr}_k^{op} \to \text{gAlg}_K$ extends to a compactly supported cohomology functor $H_\cdot: \mathcal{C}^{op} \to \text{gVec}_K$ where $\mathcal{C} \subseteq \text{Sch}_{\text{sep. t.i.}/k}$ is the subcategory of proper morphisms. For a closed immersion $Z \to X$ with complementary open $U$, there is a long exact sequence

$$\ldots \to H^i_c(U) \to H^i_c(X) \to H^i_c(Z) \to \ldots$$

functorial for the pair $(X, Z)$. If $X$ is proper, we write $H^i(X)$ for $H^i_c(X)$.

(A2) For a cosimplicial all-or-nothing motive $(X_\bullet, \pi_\bullet)$, there is a graded $K$-vector space $H^*(X_\bullet, \pi_\bullet)$ that is computed by a spectral sequence

$$E^p_{i,q} = H^q(X_p, \pi_p) \Rightarrow H^{p+q}(X_\bullet, \pi_\bullet)$$

that is functorial in $(X_\bullet, \pi_\bullet)$, where $E^p_{i,q}$ is the alternating face complex on the cosimplicial $K$-vector space $H^q(X_p, \pi_p)$. If all $\pi_p$ are equal to the constant function 1, then we write $H^*(X_\bullet)$ for $H^*(X_\bullet, \pi_\bullet)$.

(A3) (Cohomological descent for proper hypercoverings) If $X_\bullet \to X$ is a proper hypercovering of a proper $k$-scheme $X$ such that all $X_n$ are smooth projective $k$-schemes, then the pullback map

$$H^*(X) \to H^*(X_\bullet)$$

is an isomorphism.

(A4) If $\mathcal{f}_\bullet: (Y_\bullet, \beta_\bullet) \to (X_\bullet, \alpha_\bullet)$ is a morphism of cosimplicial all-or-nothing motives, then there is a long exact sequence

$$\ldots \to H^i(C_\bullet(f_\bullet)) \to H^i(Y_\bullet, \beta_\bullet) \to H^i(X_\bullet, \alpha_\bullet) \to \ldots$$

that is functorial in the morphism $f_\bullet$, where $C_\bullet(f_\bullet)$ is the mapping cone of cosimplicial all-or-nothing motives, cf. Definition 2.3.

**Example 2.14.** If $\ell$ is a prime invertible in $k$, then $\ell$-adic étale cohomology is a Weil cohomology theory by Example 1.2. It satisfies additional axiom (A1) by [SGA4III, Exp. XVII, 5.1.16]. By a (pseudofunctor version of) the universal property of Example 2.12, the pseudofunctor

$$(-, Q_\ell): \text{SmPrVar} \to \text{Shv}$$

$$X \mapsto (X_{\text{pro-\acute{e}t}}, Q_\ell)$$

extends uniquely to a pseudofunctor $F: (\text{Mot}_k^{\text{an}})^{op} \to \text{Shv}$ that maps 0 to the pair $(\text{Set}, 0)$ and preserves finite coproducts (see Remark 2.5). This corresponds to a fibred and cofibred category $\mathcal{C} \to \text{Mot}_k^{\text{an}}$ whose fibre $(X, p)_{\text{pro-\acute{e}t}}$ over a connected all-or-nothing motive $(X, p)$ is $X_{\text{pro-\acute{e}t}}$ if $p = 1$ and $\text{Set}$ if $p = 0$, along with a sheaf $\mathcal{F}$ on $\Gamma(\mathcal{C})$ whose restriction to $(X, p)$ is $Q_\ell$ if $p = 1$ and 0 if $p = 0$.

Given a cosimplicial all-or-nothing motive $(X_\bullet, \pi_\bullet): \Delta \to \text{Mot}_k^{\text{an}}$, the fibre product $\mathcal{C} \times_{\text{Mot}_k^{\text{an}}} \Delta \to \Delta$ is a simplicial topos [SGA4III, Exp. V_{\text{bis}}, 1.2.5], which we will denote by $(X_\bullet, \pi_\bullet)_{\text{pro-\acute{e}t}}$. 

12
The sheaf $\mathcal{F}$ on $\Gamma(\mathcal{C})$ pulls back to $\Gamma((X_{\bullet}, \pi_{\bullet})_{\text{pro-\acute et}})$, and the spectral sequence of Remark 2.2 then reads

$$E_{p,q}^1 = H^q((X_p, \pi_p)_{\text{pro-\acute et}}, \mathcal{F}) \Rightarrow H^{p+q}((X_{\bullet}, \pi_{\bullet}), \mathcal{F}).$$

For any all-or-nothing motive $(X, \pi)$, we have $H^q((X, \pi)_{\text{pro-\acute et}}, \mathcal{F}) = H^q((X, \pi))$, where the right hand side is defined by Remark 2.9. This gives the required spectral sequence of (A2). Moreover, (A4) holds by Lemma 2.6, since all (pseudo)functors involved preserve terminal objects and finite coproducts, hence preserve the construction of the mapping cone. Finally, (A3) follows from [SGA4 II, Exp. V bis, Prop. 4.3.2, Thm. 3.3.3, and Prop. 2.5.7].

**Example 2.15.** If $k$ is a perfect field of positive characteristic $p$ with Witt ring $W(k)$ with field of fractions $K$, then crystalline cohomology $H^i_{\text{cris}}(X/K)$ is a Weil cohomology theory by Example 1.3. Moreover, (A1) is provided by rigid cohomology with compact support [Ber86, 3.1(iii)]. The proofs of axioms (A2) and (A4) are analogous to the étale case of Example 2.14, and (A3) is proven in [Tsu03].

### 3. Independence of Weil cohomology theory

From now on, we will fix Weil cohomology theories $H$ and $\mathcal{H}$ (see Definition 1.1) with coefficient fields $K$ and $\mathcal{K}$ respectively. We will always assume that $H$ and $\mathcal{H}$ satisfy the additional properties (A1–4) of Axiom 2.13.

**Definition 3.1.** Let $X$ and $Y$ are $k$-schemes. We will consider the following statements on independence of Weil cohomology theory:

- **Cl($X$):** the kernels of the cycle class maps $cl: CH^*_Q(X) \to H^*_c(X)$ and $cl: CH^*_Q(X) \to H^*_c(X)$ agree.
- **Rk($X, Y$):** for any $\alpha \in \text{Corr}^r(X, Y)$ and any $i$, the ranks of $\alpha_*$ on $H^i$ and $H^i_c$ agree. (If $r = 0$, the superscript $r$ is dropped.)
- **Rk($X, Y$):** $\text{Rk}^r(X, Y)$ holds for all $r \in \mathbb{Z}$.
- **Rk($X, Y$):** for any proper morphism $f: Y \to X$ and any $i$, the ranks of $f_*$ on $H^i_c$ and $H^i_c$ agree.
- **Dim$(X)$:** for each $i$, the dimensions of $H^i_c(X)$ and $H^i_c(X)$ agree.
- **Kun($X$):** for each $i$, there exists a cycle $p \in \text{Corr}(X, X)$ inducing the $i^{th}$ Künneth projector on both $H^*$ and $H^*$.

The reliance of these properties on the chosen Weil cohomology theories $H$ and $\mathcal{H}$ will be implicit, and we will make no further mention of it. For properties Cl($X$), Rk($X, Y$), Rk($X, Y$), and Kun($X$), we assume $X$ and $Y$ are smooth projective, so that $CH^*(X)$ and Corr($X, Y$) are defined.

**Remark 3.2.** For Kun($X$), note that such a cycle $p$ need not be a projector in Corr($X, X$). We only know that the cycle class map sends it to a projector in Hom($H^*(X), H^*(X)$) (and the same for $\mathcal{H}$).
Remark 3.3. If \( k \) is a finite field and \( X \) is smooth proper, then we know \( \text{Dim}_c(X) \) (for any Weil cohomology theories \( H, \mathcal{H} \)), because the dimension can be read off from the zeta function. On the other hand, \( \text{Rk}(X, Y) \) is still unknown even when \( X \) and \( Y \) are smooth and projective.

We also know \( K\text{un}(X) \) for \( X \) smooth projective over a finite field, by [KM74]. Hence by Corollary 1.14, the characteristic polynomial of \( \alpha \in \text{Corr}(X, X) \) is independent of the Weil cohomology theory.

Remark 3.4. If \( \text{char} \ k = 0 \), then for all known cohomology theories \( H \) and \( \mathcal{H} \), all the statements \( \text{Cl}(X) \) and \( \text{Rk}^*(X, Y) \) for \( X \) and \( Y \) smooth projective, as well as \( \text{Dim}_c(X) \) for an arbitrary finite type \( k \)-scheme \( X \) are known. On the other hand, \( K\text{un}(X) \) is still open, even for (smooth projective) varieties over \( \mathbb{C} \).

The main theorem is the following.

**Theorem 3.5.** Let \( k = \overline{\mathbb{F}}_p \). Then the following are equivalent:

1. For all smooth projective \( k \)-schemes \( X \), we have \( \text{Cl}(X) \).
2. For all smooth projective \( k \)-schemes \( X \) and \( Y \), we have \( \text{Rk}^*(X, Y) \).
3. For all smooth projective \( k \)-schemes \( X \) and \( Y \), we have \( \text{Rk}(X, Y) \).

The outline of the rest of the article is as follows. In each of the following sections, we will prove one of the implications, often in a more refined version. We will prove the implications in the following cyclic order:

\[
(1) < (2a) > (2b) > (3a) > (3b) > (1) \quad \wedge \quad (2c)
\]

Implications \((2a) \Rightarrow (2b) \Rightarrow (2c)\) and \((3a) \Rightarrow (3b)\) are trivial. For \((2c) \Rightarrow (2b)\), note that \( X \times Y \) is the biproduct in \( \text{Mot}_k \), so \( \text{Rk}(X \times Y, X \times Y) \) implies \( \text{Rk}(X, Y) \).

The implications \((1) \Leftrightarrow (2a), (2b) \Rightarrow (3a),\) and \((3b) \Rightarrow (1)\) will be the contents of the following three sections (Section 4, Section 5, Section 6) respectively.

Remark 3.6. The arguments do not generalise to other algebraically closed fields \( k \). For example, implication \((1) \Rightarrow (2a)\) relies on \( K\text{un}(X) \), which currently is known only for finite fields and algebraic extensions thereof. Implication \((2b) \Rightarrow (3a)\) uses the Weil conjectures and a hypercovering argument, so also does not generalise to other fields.

On the other hand, if the Weil cohomology theories \( H \) and \( \mathcal{H} \) have a good specialisation theory (such as the smooth and proper base change theorems in étale cohomology), then statements \((1)\) and \((2abc)\) for smooth projective varieties over any field \( k \) can be deduced from the statements over \( \overline{\mathbb{F}}_p \).
Moreover, in this case the argument in (2b) ⇒ (3a) can be refined to deduce (3a) over arbitrary fields from (2b) over \( \overline{F}_p \) by a standard spreading out argument. Thus, the case of \( k = \overline{F}_p \) is the essential case.

Remark 3.7. If \( X \) is smooth projective over \( k \), then we get a ring isomorphism

\[
\text{ch}: \quad KQ(X) \to \text{CH}_Q(X). \tag{3.1}
\]

Thus, \( \text{Cl}(X) \) is equivalent to the following statement:

\( \text{Cl}'(X): \) the kernels of the Chern character maps \( \text{ch}: KQ(X) \to H^*(X) \) and \( \text{ch}: KQ(X) \to \mathcal{H}^*(X) \) agree.

To study the vanishing of \( \text{ch}_H(\alpha) \) for \( \alpha \in KQ(X) \), the splitting principle plus injectivity of pullbacks for dominant maps \([\text{Kle}68, \text{Prop. 1.2.4}]\) reduces us to the case where \( \alpha \) is in the subring of \( KQ(X) \) generated by classes of the form \( [\mathcal{L}] \) for \( L \) a line bundle on \( X \). Under the isomorphism (3.1), this corresponds to the subalgebra of \( \text{CH}_Q(X) \) generated by divisors (but note that \( \text{ch}([D]) \neq [\mathcal{O}(\pm D)] \)). Although \( \text{Cl}(X) \) is known for divisors, it seems that this cannot be used to deduce the statement in general.

4. Cycle classes and ranks

In this section, the ground field \( k \) is an arbitrary algebraically closed field. However, we will soon assume that \( \text{K"{u}n} \) holds; this is currently only known over algebraic extensions of \( F_p \) \([\text{KM}74]\).

Theorem 4.1. Let \( X \) and \( Y \) be smooth projective \( k \)-schemes.

(1) Assume \( \text{Rk}^*(\text{Spec } k, X) \). Then \( \text{Cl}(X) \) holds.

(2) Assume \( \text{K"{u}n}(X) \), \( \text{K"{u}n}(Y) \), and \( \text{Cl}((X \times Y)^n) \) for all \( n \). Then \( \text{Rk}^*(X,Y) \) holds.

Proof. We have \( \text{Corr}^r(\text{Spec } k, X) = \text{CH}_Q(X) \), and a cycle \( \alpha \in \text{CH}_Q(X) \) maps to zero under \( \text{cl}: \text{CH}_Q(X) \to H^{2r}(X) \) if and only if \( \alpha_*: H^*(\text{Spec } k) \to H^*(X) \) is zero (and similarly for \( \mathcal{H}^* \)); see Lemma 1.12. Now (1) follows from the observation that \( H^*(\text{Spec } k) \) is 1-dimensional, so the only possibilities for the rank of \( \alpha_* \) are 0 and 1, corresponding to \( \alpha_* = 0 \) and \( \alpha_* \neq 0 \) respectively.

For (2), let \( i \) and \( r \) be given, and let \( p \in \text{Corr}(X, X) \) (resp. \( q \in \text{Corr}(Y, Y) \)) be an element acting on \( H^* \) and \( \mathcal{H}^* \) as the \( i^{\text{th}} \) (resp. \( i + 2r^{\text{th}} \)) K"unneth projector. For \( \alpha \in \text{Corr}^r(X, Y) \), we get an induced element

\[ q \circ \alpha \circ p \in \text{Corr}^r(X, Y). \]

Moreover, the map \( (q \circ p)_*: H^i(X) \to H^{i+2r}(Y) \) agrees with the map induced by \( \alpha \) (and the same holds for \( \mathcal{H}^i(X) \to \mathcal{H}^{i+2r}(Y) \)). Denote this map by \( \alpha_* \) (on both \( H^i \) and \( \mathcal{H}^i \)). First assume \( i \) is even, and consider the induced maps

\[
\wedge^j(q \circ p)_*: \wedge^j X \mapsto \wedge^j Y
\]

for various \( j \).
By Remark 1.11, we have a decomposition
\[ H^*(\Lambda^i X) = \bigoplus_{a+b=j} \Lambda^a H^{\text{even}}(X) \otimes S^b H^{\text{odd}}(X). \]

The map \( H^*(\Lambda^i X) \to H^*(\Lambda^j Y) \) induced by \( \Lambda^i(qap) \) is \( \Lambda^j \alpha_i \) on \( \Lambda^i H^*(X) \), and 0 on all other components of \( H^*(\Lambda^i X) \). In particular, it is nonzero if and only if \( j \leq \text{rk}(\alpha_i|_H) \). Similarly, the map on \( H^*(X) \) induced by \( \Lambda^i(qap) \) is nonzero on \( H^*(X) \) if and only if \( j \leq \text{rk}(\alpha_i|_H) \). Thus, the rank of \( \alpha_i \) only depends on the vanishing or nonvanishing of the cycles \( \Lambda^i(qap) \) under the cycle class map, by Lemma 1.12. But we assumed that the kernels of the cycle class maps are the same for \( H^*((X \times Y)^j) \) and \( H^*((X \times Y)^j) \). This proves the claim if \( i \) is even. If \( i \) is odd, we have to use \( S^j \) instead of \( \Lambda^j \) (see Remark 1.11).

**Corollary 4.2.** Let \( k \) be a field such that \( \text{K"un}(X) \) holds for all smooth projective \( k \)-schemes \( X \) (e.g. \( k = \mathbb{F}_p \) [KM74]). Then the following are equivalent:

1. \( \text{Cl}(X) \) holds for all smooth projective \( k \)-schemes \( X \);
2. \( \text{Rk}^*(X,Y) \) holds for all smooth projective \( k \)-schemes \( X \) and \( Y \).

5. **RANKS AND DIMENSIONS**

In this section, \( k \) will denote an arbitrary field. The main theorem of this section (Theorem 5.5) assumes that \( k = \mathbb{F}_p \), because its proof relies on the Weil conjectures. The idea is to use alterations to produce smooth hypercoverings that compute the cohomology of arbitrary separated finite type \( k \)-schemes.

**Lemma 5.1.** Let \( X \) and \( Y \) be separated finite type \( k \)-schemes, and \( f: Y \to X \) a morphism. Then there exist proper \( k \)-schemes \( \tilde{X}, \tilde{Y} \) along with dense open immersions \( X \to \tilde{X} \) and \( Y \to \tilde{Y} \) and a morphism \( \tilde{f}: \tilde{Y} \to \tilde{X} \) such that the diagram

\[
\begin{array}{c c c}
Y & \longrightarrow & \tilde{Y} \\
\downarrow f & & \downarrow \tilde{f} \\
X & \longrightarrow & \tilde{X}
\end{array}
\]

commutes. If \( f \) is proper, then \( Y = \tilde{f}^{-1}(X) \).

**Proof.** Let \( X \to \tilde{X} \) be a Nagata compactification [Nag62]. Replacing \( \tilde{X} \) by the closure of \( X \) in \( \tilde{X} \), we may assume that \( X \) is dense in \( \tilde{X} \). Let \( \tilde{Y} \) be a relative Nagata compactification of \( Y \to \tilde{X} \) [Nag63]. Again, we may assume that \( Y \) is dense in \( \tilde{Y} \). Then \( \tilde{Y} \) is proper over \( \tilde{X} \), hence proper over \( k \) since \( X \) is. This proves the first statement. The second statement follows because the scheme theoretic image of the morphism of proper \( X \)-schemes \( Y \to \tilde{f}^{-1}(X) \) is closed. Since \( Y \) is also dense in \( \tilde{f}^{-1}(X) \) (in fact, in \( \tilde{Y} \)), this forces equality.

**Lemma 5.2.** Let \( (\mathcal{J}, \leq) \) be a poset (viewed as category) such that for every \( i \in \mathcal{J} \), there are only finitely many \( j \in \mathcal{J} \) with \( j \leq i \). Let \( D: \mathcal{J}^{op} \to \text{Sch}/k \) be a diagram of separated finite type \( k \)-schemes. Then there exists a diagram \( D_*: \mathcal{J}^{op} \times \Delta^1_k \to \text{Sch}/k \) such that the following hold.
(1) \( D_{-1} = D \);
(2) For each \( i \in \mathcal{I} \), the diagram \( D_{\bullet}(i) \) is a proper hypercovering of \( D(i) \);
(3) For each \( i \in \mathcal{I} \) and each \( n \in \mathbb{Z}_{>0} \), the scheme \( D_n(i) \) is quasi-projective over \( k \) and regular.

Proof. We construct \( D_{\bullet}(i) \) by induction on the size of \( \mathcal{I}_{\leq i} = \{ j \in \mathcal{I} \mid j \leq i \} \).

If \( i \) is minimal, then we take \( D_{\bullet}(i) \to D(i) \) to be any proper hypercovering by regular quasi-projective \( k \)-schemes, which is possible by [Del74b, 6.2.8], using [Dlo96] instead of resolution of singularities.

Now let \( i \in \mathcal{I} \) be given, and write \( \mathcal{I}_{\leq i} = \{ i, j_1, \ldots, j_r \} \). If \( D_{\bullet}(j) \) has been defined for all \( j \) with \( |\mathcal{I}_{\leq j}| < |\mathcal{I}_{\leq i}| \), then it has been defined for \( j = j_1, \ldots, j_r \).

To define \( D_{\bullet}(i) \), we follow the procedure of [SGA4I, Exp. V\textsuperscript{bis}, 5.1.4–5.1.7], but when constructing \( N(D_{n+1}(i)) \) we first replace \( C_{n+1}(i) := \cosk_n sk_n(D_{\bullet}(i))_{n+1} \) by

\[
C_{n+1}(i) \times_{C_{n+1}(j_1)} N(D_{n+1}(j_1)) \times_{C_{n+1}(j_2)} \ldots \times_{C_{n+1}(j_r)} N(D_{n+1}(j_r)),
\]

before using an alteration to make it regular. This ensures that \( N(D_{n+1}(i)) \) maps to all \( N(D_{n+1}(j)) \) for \( j < i \) making the necessary diagrams commute, which proves the required functoriality.

**Lemma 5.3.** Let \( 0 \to A^\bullet \to B^\bullet \to C^\bullet \to 0 \) be a short exact sequence of chain complexes of finite dimensional vector spaces. Then

\[
\text{rk} \left( \delta^i : H^i(C^\bullet) \to H^{i+1}(A^\bullet) \right) = \text{rk}(d^i_B) - \text{rk}(d^i_A) - \text{rk}(d^i_C).
\]

Proof. All ranks in question only depend on the stupid truncations \( \sigma_{\geq i}, \sigma_{\leq i+1} \) of the complexes. For \( d_A^i, d_B^i, \) and \( d_C^i \), this is clear, and for \( \delta^i \) this follows because of the factorisation

\[
H^i(\sigma_{\geq i} C^\bullet) \to H^i(C^\bullet) \xrightarrow{\delta^i} H^{i+1}(A^\bullet) \to H^{i+1}(\sigma_{\leq i+1} A^\bullet),
\]

noting that precomposing by surjections and postcomposing by injections does not alter ranks. Now the snake lemma gives a long exact sequence

\[
0 \to \ker d_A^i \to \ker d_B^i \to \ker d_C^i \xrightarrow{\delta^i} \coker d_A^i \to \coker d_B^i \to \coker d_C^i \to 0.
\]

Additivity of dimension in short exact sequences gives

\[
\dim(\ker d_A^i) - \dim(\ker d_B^i) + \dim(\ker d_C^i) - \text{rk}(\delta^i) = 0. \tag{5.1}
\]

On the other hand, exactness of \( 0 \to A^\bullet \to B^\bullet \to C^\bullet \to 0 \) gives

\[
\dim A^i - \dim B^i + \dim C^i = 0. \tag{5.2}
\]

Subtracting (5.1) from (5.2) gives the result. \( \square \)

**Corollary 5.4.** Let \( f : A^\bullet \to B^\bullet \) be a morphism of chain complexes of finite dimensional vector spaces. Then

\[
\text{rk} \left( H^i(f) \right) = \text{rk} \left( \begin{pmatrix} d_A^i & 0 \\ f & d_B^{i-1} \end{pmatrix} : A^i \oplus B^{i-1} \to A^{i+1} \oplus B^i \right) - \text{rk}(d_A^i) - \text{rk}(d_B^{i-1}).
\]
Proof. Apply Lemma 5.3 to the short exact sequence
\[ 0 \to B^\bullet \to C^\bullet(f) \to A^\bullet[1] \to 0, \]
noting that the boundary homomorphism of this sequence is \( H^{i+1}(f) \).

\[ \square \]

**Theorem 5.5.** Let \( k = \overline{F}_p \). If \( \text{Rk}(X,Y) \) holds for all smooth projective \( k \)-schemes \( X \) and \( Y \), then

1. \( \text{Dim}_c(X) \) holds for every separated finite type \( k \)-scheme \( X \);
2. \( \text{Rk}_c(X,Y) \) holds for all separated finite type \( k \)-schemes \( X \) and \( Y \).

**Proof.** Let \( X \) and \( Y \) be separated \( k \)-schemes of finite type, and let \( f: Y \to X \) be a proper morphism. Choose a commutative diagram as in Lemma 5.1
\[ \begin{array}{ccc}
Y & \xleftarrow{w} & W \\
\downarrow{f} & & \downarrow{g} \\
X & \xleftarrow{v} & V,
\end{array} \tag{5.3} \]
where, \( \bar{X} \) and \( \bar{Y} \) are compatible compactifications of \( X \) and \( Y \) respectively such that \( X \) (resp. \( Y \)) is dense in \( \bar{X} \) (resp. \( \bar{Y} \)) with complement \( V \) (resp. \( W \)), and \( g \) denotes \( \bar{f}|_W \).

Note that all vertical maps in (5.3) are proper, so by Axiom 2.13(A1) we get a commutative diagram with exact rows
\[ \ldots \to H^i_c(X) \to H^i_c(\bar{X}) \xrightarrow{v^*} H^i_c(V) \to \ldots \]
\[ \ldots \to H^i_c(Y) \to H^i_c(\bar{Y}) \xrightarrow{w^*} H^i_c(W) \to \ldots. \tag{5.4} \]

Applying Lemma 5.2 to the right hand square of (5.3), we get a commutative diagram
\[ \begin{array}{ccc}
W_\bullet & \xrightarrow{w^\bullet} & \bar{Y}_\bullet \\
\downarrow{f^\bullet} & & \downarrow{g^\bullet} \\
V_\bullet & \xrightarrow{v^\bullet} & \bar{X}_\bullet, \tag{5.5}
\end{array} \]
of augmented simplicial schemes such that each \( W_i \) is smooth projective for \( i \geq 0 \) and \( W_\bullet \) is a proper hypercover of \( W_{-1} = W \), and similarly for \( V, \bar{X}, \) and \( \bar{Y} \).

We will view \( V_\bullet, W_\bullet, \bar{X}_\bullet, \) and \( \bar{Y}_\bullet \) as simplicial schemes \( \Delta^{op} \to \text{Sch}/k \) together with a map to the constant simplicial schemes \( V, W, \bar{X}, \) and \( \bar{Y} \) respectively.

By Axiom 2.13(A4), we have a long exact sequence
\[ \ldots \to H^i(C_\bullet(v_\bullet)) \to H^i(\bar{X}_\bullet) \to H^i(V_\bullet) \to \ldots. \]

Moreover, \( H^i(\bar{X}_\bullet) \) equals \( H^i(\bar{X}) = H^i_c(\bar{X}) \) by Axiom 2.13(A3), and similarly for \( Y_\bullet, V_\bullet, \) and \( W_\bullet \). Under this identification, the map \( v^\bullet: H^i(\bar{X}_\bullet) \to H^i(V_\bullet) \) becomes \( v^* : H^i_c(\bar{X}) \to H^i_c(V) \). Comparing with the bottom row of (5.4), we conclude that
\[ H^i(C_\bullet(v_\bullet)) \cong H^i_c(X). \tag{5.6} \]

18
But the left hand side is computed by a hypercohomology spectral sequence

\[ E_1^{p,q} = H^q(C_p(v_*)) \Rightarrow H^{p+q}(C_*(v_*)). \]

If \( \bar{X}_p \) and \( V_p \) are defined over some finite field \( k_0 \) for all \( p \leq i + 1 \), then the computation of \( H^i(C_*(v_*)) \) only involves maps between cohomology groups of smooth projective varieties defined over \( k_0 \). Moreover, the action of the \( |k_0| \)-power Frobenius\(^1\) on \( H^q(C_p(v_*)) \) is pure of weight \( q \) [KM74, Cor. 1(2)]. Therefore, the spectral sequence degenerates on the \( E_2 \) page, because all maps are between spaces of different weights. We conclude that

\[ \dim H^i_c(X) = \sum_{p+q=i} \dim E_2^{p,q}, \]

where \( E_2^{p,q} \) is given as

\[ E_2^{p,q} = \frac{\ker (d^p : H^q(C_p(v_*)) \to H^q(C_{p+1}(v_*)))}{\operatorname{im} (d^{p-1} : H^q(C_{p-1}(v_*)) \to H^q(C_p(v_*)))}. \]

A dimension count gives

\[ \dim E_2^{p,q} = \dim(\ker d^p) - \dim(\operatorname{im} d^{p-1}) = \dim(H^q(C_p(v_*))) - \dim(H^q(C_{p+1}(v_*))) = \dim E_2^{p,q}. \]

By assumption, each of these numbers is independent of the Weil cohomology theory \( H \). Hence, the same holds for \( \dim E_2^{p,q} \) and therefore also for \( \dim H^i_c(X) \), which proves (1) for \( X \).

To prove (2), note that (5.5) shows that \( \bar{f}_* \) and \( g_* \) induce a natural map \( f_* : C_*(v_*) \to C_*(w_*) \). This induces a morphism of spectral sequences

\[ f_*^* : E_2^{p,q}(X) \to E_2^{p,q}(Y). \]

On the \( E_1 \) pages, this gives commutative diagrams

\[ \cdots \to H^q(C_p(v_*)) \xrightarrow{d^p} H^q(C_{p+1}(v_*)) \to \cdots \]

\[ \xrightarrow{f_*^*} \]

\[ \cdots \to H^q(C_p(w_*)) \xrightarrow{d^p} H^q(C_{p+1}(w_*)) \to \cdots . \]

By Corollary 5.4, we get

\[ \operatorname{rk} E_2^{p,q}(f^*) = \operatorname{rk} \left( \begin{array}{cc} d^p & 0 \\ f_* & d_{w_*}^p \\ d_{w_*}^{p-1} & \end{array} \right) \to \operatorname{rk} (d^p) - \operatorname{rk} (d_{w_*}^{p-1}). \]

By assumption, the right hand side is independent of the Weil cohomology theory \( H \), hence so is the left hand side. Hence, the same holds for the rank of \( f_*^* : H^i(C_*(v_*)) \to H^i(C_*(w_*)), \) which proves (2) by the isomorphism (5.6).

**Remark 5.6.** Instead of the diagrammatic argument given above, one would be tempted to use the strong version of the alterations result [dJo96].

---

\(^1\)There is no natural Galois action, but the geometric Frobenius acts as a cycle.
This gives a proper hypercover $X_\bullet \to X$ along with an embedding $X_\bullet \to \bar{X}_\bullet$ such that each $X_m$ is smooth projective, and the complement of $X_m \subseteq \bar{X}_m$ is a simple normal crossings divisor $D_m$.

Assuming $\text{Rk}(Y, Z)$ holds for smooth projective $k$-schemes $Y$ and $Z$, a simplicial argument for $D_m$ shows that the dimension of $H^i_c(X_m)$ (hence also $H^i(X_m)$) is independent of the Weil cohomology theory [Kat94, p. 29]. This again uses the Weil conjectures to conclude degeneration of a spectral sequence.

Then the spectral sequence for the hypercovering $X_\bullet \to X$ computes $H^i(X)$ in terms of $H^i_c(X_m)$. However, now the purity argument no longer applies, and we have no idea on what page the spectral sequence might degenerate. So even knowing $\text{Rk}(Y, Z)$ for smooth quasi-projective $k$-schemes $Y$ and $Z$ does not imply $\text{Dim}_c(X)$ (or its variant $\text{Dim}(X)$ for cohomology $H^i$) through this method.

The above argument is a way around this problem. It does not seem to appear anywhere in the literature, although variants of it might have been known to experts.

6. Dimensions and cycle class maps

In this section, the ground field $k$ is allowed to be arbitrary again. We start with a Bertini irreducibility theorem. We do some extra work in Lemma 6.2 to avoid extending the base field, using the Bertini irreducibility theorem of Charles–Poonen [CP16] as well as the classical one [Jou83, Thm. 6.3(4)].

The main application of these Bertini theorems is Corollary 6.5, which we use to prove the implication (3b) ⇒ (1) of Theorem 3.5. The idea is that if $Z \subseteq X$ is an effective codimension $m$ cycle on a smooth projective variety $(X, H)$, then for $m$ general sections $H_1, \ldots, H_m \in |H|$ containing $Z$, the intersection $H_1 \cap \ldots \cap H_m$ contains only one new component $Z'$, which is smooth away from $Z$ (in particular reduced). Therefore,

$$[Z] = H^m - [Z'] \in \text{CH}^m(X),$$

which realises $[Z]$ as a difference of two irreducible divisors. We do something similar for an arbitrary (not necessarily effective) cycle $\alpha \in \text{CH}^m(X)$.

We suggest the reader skip ahead to Corollary 6.5 on a first reading.

Definition 6.1. Let $X$ be a separated $k$-scheme of finite type. Consider the following condition on a closed subscheme $Z \subseteq X$:

(Irr): For every irreducible component $X_i$ of $X_k$, there exists a unique irreducible component $Z_i$ of $Z_k$ contained in $X_k$, and moreover $Z_i = X_i \cap Z_k$.

If $X$ is geometrically normal, then $X_i \cap X_j = \emptyset$ for $i \neq j$. In this case, the final statement of (Irr) is automatic: we clearly have $Z_i \subseteq X_i \cap Z_k$, and all other components $Z_j$ of $Z_k$ are disjoint from $X_i \cap Z_k$. 20
Lemma 6.2. Let $(X, H)$ be a quasi-projective $k$-scheme all of whose components have dimension $n \geq 2$, let $Z \subseteq X$ be a geometrically reduced closed subscheme of pure dimension $\ell \neq 0, n$, and let $Y_1, \ldots, Y_s \subseteq X$ be integral subschemes of dimension $< n$ that are not contained in $Z$. Assume that $X$ is smooth away from $Z$ and at the generic points of $Z$. Then for $d \gg 0$, there exists an element $D \in |dH|$ containing $Z$ such that

- $D$ is smooth away from $Z$;
- $D$ is smooth at the generic points of $Z$;
- the divisor $D \setminus Z$ of $X \setminus Z$ satisfies $(\text{Irr})$;
- $D$ does not contain any of the $Y_j$.

Proof. Let $U \subseteq X$ be the smooth locus. By assumption, it contains $X \setminus Z$, as well as the generic points of $Z$. Since $Z$ is geometrically reduced, the singular locus $V \subseteq Z$ has dense open complement $Z \setminus V \subseteq Z$.

Let $W = U \setminus V$ be the complement in $X$ of the singular loci of $X$ and $Z$. Then $W$ is smooth of dimension $n$ and contains $X \setminus Z$, and $W \cap Z$ is smooth. Let $Y$ be the union of the zero-dimensional $Y_j$, and note that $Y \cap Z = \emptyset$.

If $k$ is finite, we apply [Wut17, Thm. 2.1], where Wutz’s $X, Y, Z, k, \ell, m$ are our $W, Y, Z, \ell - 1, \ell, n$ respectively. This shows that the set

$$\left\{ D \in |dH| \left| \begin{array}{l}
Z \subseteq D \text{ and } Y \cap D = \emptyset, \\
\dim(D \cap W)_{\text{sing}} \leq \ell - 1, \\
D \cap (X \setminus Z) \text{ is smooth of dimension } n - 1.
\end{array} \right. \right\}$$

has positive density $\mu > 0$ as $d \to \infty$. In particular, such $D$ are smooth at the generic points of $Z$, since $Z$ has dimension $\ell$. Applying Bertini’s irreducibility theorem [CP16, Thm. 1.2] to $X \setminus Z$ shows that the set of $D$ such that $D \setminus Z$ satisfies $(\text{Irr})$ in $X \setminus Z$ has density 1.

Finally, if $Y_j$ is positive-dimensional, then the ideal sheaf $\mathcal{I}_{Z \cap Y_j} \subseteq \mathcal{O}_{Y_j}$ is nonzero because $Y_j \not\subseteq Z$. The map $\mathcal{I}_Z \to \mathcal{I}_{Z \setminus Y_j}$ is surjective by the second and third isomorphisms theorems. Hence, for $d \gg 0$, the map

$$\phi_d: H^0(X, \mathcal{I}_Z(d)) \to H^0(Y_j, \mathcal{I}_{Z \setminus Y_j}(d))$$

is surjective. The dimension of the right hand side grows as $d^{\dim Y_j}$, so

$$\text{codim ker}(\phi_d) \to \infty \quad \text{as } d \to \infty.$$ 

Hence, the functions that vanish on $Y_j$ have density 0 as $d \to \infty$. Therefore, the intersection of the three sets has positive density $\mu$.

If $k$ is infinite, then the usual Bertini theorems [Jou83, Thm. 6.10(2,3)] imply that the first three conditions are satisfied on nonempty open subsets of $|dH|$ for any $d \geq 1$, hence their intersection is nonempty open as well. Finally, we may also avoid the $Y_j$, which finishes the proof.

Lemma 6.3. Let $k$ be a perfect field, and let $(X, H)$ be a smooth quasi-projective $k$-scheme all of whose components have dimension $n$. Let $Z_1, \ldots, Z_r \subseteq X$ and $Y_1, \ldots, Y_s \subseteq X$ be pairwise distinct integral subschemes of codimension $m \neq 0, n$.  

21
Then for all \( d_1, \ldots, d_m \gg 0 \), there exist sections \( D_1, \ldots, D_m \) of \( |d_1H|, \ldots, |d_mH| \) intersecting properly such that

\[
\bigcap_{i=1}^m D_i = \sum_{i=1}^r [Z_i] + [Z],
\]

where \( Z \subseteq X \) satisfies (Irr), \( Z \setminus \bigcup Z_i \) is smooth, and \( Z \) does not contain any of the \( Y_j \).

**Proof.** Let \( Z' = \bigcup Z_i \). We apply Lemma 6.2 inductively on the codimension \( m \) of the \( Z_i \) to find sections \( D_i \) of \( |d_iH| \) containing \( Z' \) such that \( \bigcap D_i \) is smooth away from \( Z' \) and at the generic points of \( Z' \) and does not contain any of the \( Y_j \), and \( \bigcap D_i \setminus Z' \) satisfies (Irr). Hence

\[
\bigcap_{i=1}^m D_i = \sum_{i=1}^r [Z_i] + \alpha,
\]

where \( \alpha \) is an effective cycle none of whose components is contained in \( Z' \).

If \( Z \) is the closure of \( \bigcap D_i \setminus Z' \), then restricting to \( X \setminus Z' \), we find that \( \alpha = [Z] \), where all coefficients are 1 since \( \bigcap D_i \setminus Z' \) is smooth. Finally, \( Z \) satisfies (Irr) because \( \bigcap D_i \setminus Z' \) does, and it does not contain any of the \( Y_j \) since \( \bigcap D_i \setminus Z' \) does not.

**Theorem 6.4.** Let \( k \) be a perfect field, let \((X, H)\) be a smooth projective \( k \)-scheme of equidimension \( n \), and let \( \alpha \in CH^m(X) \) be a pure dimensional cycle. If \( m \neq 0, n \), then there exists subscheme \( Z \subseteq X \) satisfying (Irr) and \( e \in \mathbb{Z} \) such that

\[
\alpha = [Z] - eH^m \in CH^m(X).
\]

**Proof.** Write \( \alpha = \sum n_i [Z_i] - \sum n'_i [Z'_i] - eH^m \), where \( Z_i, Z'_i \subseteq X \) are pairwise distinct integral subschemes of codimension \( m \), and \( n_i, n'_i \in \mathbb{Z}_{\geq 0} \) (to start with, we may take \( e = 0 \)). We will apply Lemma 6.3 a few times.

First, by induction on \( z = \sum (n_i - 1) + \sum (n'_i - 1) \), we will reduce to the case where \( z = 0 \). Indeed, if \( z > 0 \), then one of the \( n_i \) or \( n'_i \) is \( \geq 2 \). Say \( n_1 \geq 2 \); the case \( n'_i \geq 2 \) is similar. Applying Lemma 6.3 to \( Z_1 \) where the \( Y_j \) are the \( Z_i \) and \( Z'_i \), we can write \([Z_1] = dH^m - [Z']\), where \( Z' \) does not contain any of the \( Z_i \) and \( Z'_i \), and \( Z' \) is generically smooth (in particular reduced).

Adjoining the irreducible components of \( Z' \) to the \( Z'_i \) and changing \( e \) to \( e - d \), we have reduced \( z \) by one, because the new components coming from \( Z' \) all have coefficient 1. After finitely many steps, we get \( z = 0 \), so all \( n_i \) and \( n'_i \) are equal to 1.

Now applying Lemma 6.3 to the \( Z_i \) while avoiding the \( Z'_i \), we get a generically smooth subscheme \( Z' \subseteq X \) of codimension \( m \) and such that \( \sum [Z_i] = dH^m - [Z'] \). Adjoining the components of \( Z' \) to the \( Z'_i \) and replacing \( e \) by \( e - d \), we can write

\[
\alpha = - \sum [Z'_i] - eH^m.
\]

22
Finally, applying Lemma 6.3 to the $Z_i$, for every $d_1, \ldots, d_m \gg 0$ we get a subscheme $Z$ of codimension $m$ satisfying (Irr) such that $dH^m = \sum_i [Z_i] + [Z]$, where $d = \prod d_i$. Thus, 

$$\alpha = [Z] - (e+d)H^m.$$  

Replacing $e$ by $e+d$ gives the result. \[ \square \]

**Corollary 6.5.** Let $k$ be a perfect field, let $(X, H)$ be a smooth projective $k$-scheme of equidimension $n$, and let $\alpha \in CH^m(X)$. If $m \neq 0, n$, then there exist subschemes $Z_1, Z_2 \subseteq X$ satisfying (Irr) such that 

$$\alpha = [Z_1] - [Z_2] \in CH^m(X).$$

**Proof.** By Theorem 6.4, we may write $\alpha = [Z_1] - eH^m$, where $Z_1$ satisfies (Irr). Moreover, from the final step of the proof of Theorem 6.4, we see that we may take $e$ arbitrarily large. Applying the usual Bertini irreducibility theorem [Jou83, Thm. 6.10(4)]; [CP16, Cor. 1.4] inductively, we find a subscheme $Z_2 \subseteq X$ satisfying (Irr) with $[Z_2] = eH^m$. Indeed, over an infinite field we can do this for any $e$, whereas over a finite field the definition of the density shows that if the density is positive, there exists $e_0$ such that for all $e \geq e_0$ we can find a member satisfying (Irr). \[ \square \]

**Theorem 6.6.** Let $k$ be an algebraically closed field. Assume that Dim$e(X)$ holds for every smooth, quasi-projective $k$-scheme $X$. Then Cl$^e(X)$ holds for every smooth projective $k$-scheme $X$.

**Proof.** Since $CH^e_Q(X \times Y) = CH^e_Q(X) \times CH^e_Q(Y)$, and the same statement holds for the cohomology ring, we may assume $X$ is irreducible of dimension $n$, hence (geometrically) integral. Let $\alpha \in CH^e_Q(X)$ be given. Because the cycle class map is homogeneous, it suffices to treat the case $\alpha \in CH^m_Q(X)$ of pure dimension $d = n - m$. If $m = 0$ or $m = n$, then clearly the kernels of the cycle class maps to $H^m(X)$ and $H^m(X)$ agree.

Now assume $m \neq 0, n$. Then by Corollary 6.5, we may write $\alpha = [Z_1] - [Z_2]$, where $Z_1$ and $Z_2$ satisfy (Irr); since $X$ is integral this just means that $Z_1$ and $Z_2$ are integral as well. Let $Z = Z_1 \cup Z_2 \subseteq X$, let $U = X \setminus Z$, and consider the long exact cohomology sequence with compact support (Axiom 2.13(A1))

$$\ldots \to H^i_c(U) \to H^i_c(X) \to H^i_c(Z) \to \ldots .$$

We have $\dim H^d_c(Z) = 2$, since $Z$ has two components of the same dimension $d$, and $H^i_c(Z) = 0$ for $i > 2d$. Thus, we have an exact sequence

$$\ldots \to H^d_c(X) \xrightarrow{i^*} H^d_c(Z) \to H^{d+1}_c(U) \to H^{d+1}_c(X) \to 0. \tag{6.1}$$

The maps $H^d_c(X) \to H^d_c(Z_i) \cong K$ are the Poincaré duals of the cycle classes $[Z_i]$. The pullbacks and the trace maps give isomorphisms

$$H^d_c(Z) \cong H^d_c(Z_1) \oplus H^d_c(Z_2) \cong K \oplus K,$$

and under this identification the map $i^*: H^d_c(X) \to K \oplus K$ is the dual of

$$(i^*)^\vee: K \oplus K \to H^2m(X) \quad (\lambda, \mu) \mapsto \lambda \cdot cl(Z_1) + \mu \cdot cl(Z_2).$$
If \( h \) is an ample divisor class on \( X \), then \( h^d \cdot Z_i > 0 \). Therefore, \( \text{cl}(Z_i) \neq 0 \), so the rank of \( i^* \) is either 1 or 2. Additivity of dimensions in (6.1) gives

\[
\text{rk}(i^*) = \dim H^d_c(Z) - \dim H^{d+1}_c(U) + \dim H^{d+1}_c(X).
\]

By assumption, \( \dim H^{d+1}_c(U) \) is independent of the Weil cohomology theory \( H \), hence so is the rank of \( i^* \).

We now claim that \( \text{cl}_H(\alpha) = 0 \) if and only if \( \text{rk}(i^*) = 1 \) and \( h^d \cdot Z_1 = h^d \cdot Z_2 \).

Indeed, if \( \text{cl}(\alpha) = 0 \), then \( (i^*)^\dagger \) has a kernel, so \( i^* \) cannot have rank 2. Moreover, cupping the relation \( \text{cl}(Z_1) = \text{cl}(Z_2) \) with \( h^d \) gives \( h^d \cdot Z_1 = h^d \cdot Z_2 \).

Conversely, if \( \text{rk}(i^*) = 1 \) and \( h^d \cdot Z_1 = h^d \cdot Z_2 \), then there is a unique \([\lambda_H : \mu_H] \in \mathbf{P}^1(K)\) such that

\[
\lambda_H \cdot \text{cl}_H(Z_1) = \mu_H \cdot \text{cl}_H(Z_2).
\]

Again, cupping with \( h^d \) gives \( \lambda_H Z_1 \cdot h^d = \mu_H Z_2 \cdot h^d \), forcing \([\lambda_H : \mu_H] = [1 : 1]\), so that \( \text{cl}_H(\alpha) = 0 \).

Because the rank of \( i^* \) and the intersection numbers \( h^d \cdot Z_i \) are independent of the Weil cohomology theory \( H \), this shows that the vanishing of \( \text{cl}_H(\alpha) \) is also independent of \( H \).
