Decoupling inequalities and supercritical percolation for the vacant set of random walk loop soup

Caio Alves∗  Artem Sapozhnikov∗

August 6, 2018

Abstract

It has been recently understood [8, 23, 27] that for a general class of percolation models on \( \mathbb{Z}^d \) satisfying suitable decoupling inequalities, which includes i.a. Bernoulli percolation, random interlacements and level sets of the Gaussian free field, large scale geometry of the unique infinite cluster in strongly percolative regime is qualitatively the same; in particular, the random walk on the infinite cluster satisfies the quenched invariance principle, Gaussian heat-kernel bounds and local CLT.

In this paper we consider the random walk loop soup on \( \mathbb{Z}^d \) in dimensions \( d \geq 3 \). An interesting aspect of this model is that despite its similarity and connections to random interlacements and the Gaussian free field, it does not fall into the above mentioned general class of percolation models, since it does not satisfy the required decoupling inequalities.

We identify weaker (and more natural) decoupling inequalities and prove that (a) they do hold for the random walk loop soup and (b) all the results about the large scale geometry of the infinite percolation cluster proved for the above mentioned class of models hold also for models that satisfy the weaker decoupling inequalities. Particularly, all these results are new for the vacant set of the random walk loop soup. (The range of the random walk loop soup has been addressed by Chang [6] by a model specific approximation method, which does not apply to the vacant set.)

Finally, we prove that the strongly supercritical regime for the vacant set of the random walk loop soup is non-trivial. It is expected, but open at the moment, that the strongly supercritical regime coincides with the whole supercritical regime.

1 Introduction

Consider the integer lattice \( \mathbb{Z}^d \) with dimension \( d \geq 3 \). Any nearest neighbor path \( \hat{\ell} = (x_1, \ldots, x_n) \) on \( \mathbb{Z}^d \) with \( x_n \) being a neighbor of \( x_1 \) is called a (non-trivial discrete)
based loop. Two based loops of length $n$ are equivalent if they differ only by a circular permutation of their vertices, i.e., $(x_1, \ldots, x_n)$ is equivalent to $(x_i, x_1, \ldots, x_{i-1})$ for all $i$. Equivalence classes of based loops for this equivalence relation are called loops. Consider the measure $\dot{\mu}$ on based loops defined by
\[
\dot{\mu}(\dot{\ell}) = \frac{1}{n} \left( \frac{1}{2d} \right)^n, \quad \dot{\ell} = (x_1, \ldots, x_n),
\]
and denote the push-forward of $\dot{\mu}$ on the space of loops by $\mu$. For $\alpha > 0$, let $\mathcal{L}^\alpha$ be the Poisson point process of loops with intensity measure $\alpha \mu$ (random walk loop soup).

Poisson ensembles of Markovian loops (loop soups) have been recently actively researched by probabilists and mathematical physicists partly due to their connections to the Gaussian free field, the Schramm-Loewner Evolution and the loop erased random walk, see, e.g., [15, 16, 29, 33, 18, 19, 5, 3, 28]. Although they already appear implicitly in the work of Symanzik [30] on representations of the $\phi^4$ Euclidean field, the first mathematically rigorous definitions were given by Lawler and Werner [15] in the context of planar Brownian motion (Brownian loop soup) and by Lawler and Trujillo Ferreras [14] in discrete setting. Percolation of loop soups was first considered by Lawler and Werner [15] and Sheffield and Werner [29], who identified, in particular, the value of the critical intensity for the planar Brownian loop soup. The existence of percolation phase transition for the random walk loop soup on $\mathbb{Z}^d$ and properties of the critical intensity have been investigated in [17, 18, 7, 20, 6]. Comprehensive analysis of connectivity properties of the random walk loop soup on $\mathbb{Z}^d$ in subcritical regime was achieved by Chang and the second author [7] and in supercritical regime by Chang [6].

One of the main challenges for the study of connectivity properties of the loop soup is the polynomial decay of correlations (see [7]). Models of percolation exhibiting strong spatial correlations have been of immense interest in the last decade, including the random interlacements, the vacant set of random interlacements and the level sets of the Gaussian free field, see, e.g., [31, 32, 26]. Many of the methods (particularly, the coarse graining and Peierls-type arguments) developed for Bernoulli percolation do not apply to these models. The fundamental idea behind the major progress in understanding these models (which are monotone in their intensity parameters) is that the effect of correlations can be well dominated with a slight tilt of the intensity parameter (sprinkling). This idea is formalized in correlation inequalities, known as decoupling inequalities [31, 32, 26, 10, 21, 22, 1]. A general class of percolation models, which satisfy a suitable decoupling inequality and contains the three models mentioned above, was considered in [8, 23, 27], where most of the geometric properties of the infinite percolation cluster, previously only known to hold for Bernoulli percolation, were proven. (See Section 6 for a precise formulation of conditions from [8].) An interesting aspect of the random walk loop soup percolation is that it does not fall into this general class of models, since the decoupling inequalities assumed there are not valid, see, e.g., [6].

The main goal of this paper is the study of geometric properties of connected components of the vacant set of the loop soup $\mathcal{L}^\alpha$ — the vertices of $\mathbb{Z}^d$ that do not belong to any of the loops in $\mathcal{L}^\alpha$ — which we denote by $\mathcal{V}^\alpha$. The vacant set exhibits a non-trivial percolation phase transition: there exists $\alpha_* \in (0, \infty)$ such that
for $\alpha < \alpha_*$ there is almost surely a unique infinite connected component in $\mathcal{V}^\alpha$,

- for $\alpha > \alpha_*$ all the connected components are almost surely finite.

The fact that $\alpha_* < \infty$ is elementary, since $\mathcal{V}^\alpha$ is stochastically dominated by Bernoulli site percolation with parameter $\exp\left(-\frac{\alpha}{4d}\right)$ (by restricting $\mathcal{L}^\alpha$ to loops of length 2), and the positivity of $\alpha_*$ follows from Theorem 1.2. The uniqueness of the infinite cluster is not entirely trivial, since the so-called positive finite energy property fails for $\mathcal{V}^\alpha$, but still can be proved by a direct adaptation of the standard Burton-Keane argument [4], cf. Remark 3.5.

Our main focus is on geometric properties of the unique infinite cluster of $\mathcal{V}^\alpha$. As already mentioned, a unified framework to study infinite clusters of (correlated) percolation models on $\mathbb{Z}^d$ was proposed in [8], within which various results that were previously known only for supercritical Bernoulli percolation have been proven. These include i.a. quenched Gaussian heat kernel bounds, Harnack inequalities, invariance principle and local CLT for the simple random walk on the infinite cluster [23, 27]. The loop soup percolation does not fall into this general class of models, since it does not satisfy condition P3 on spatial correlations (decoupling inequality), c.f. Section 6. However, Chang [6] was able to prove all the above mentioned results for the infinite cluster in the range of the loop soup $\mathcal{L}^\alpha$ by observing that the properties of the infinite cluster are predominantly determined by loops with bounded diameter. In a way, the infinite cluster is a small perturbation on top of the infinite cluster of truncated loops. His analysis relies substantially on the Poisson point process structure of the loop soup and cannot be adapted to the vacant set, which is thus considerably more difficult.

Our first result states that the range of $\mathcal{L}^\alpha$, $\mathcal{R}^\alpha$, does satisfy a decoupling inequality, which is however weaker than the one imposed in [8], cf. conditions P3 and D in Section 6.

**Theorem 1.1.** (Decoupling inequalities) There exist constants $C, c$ such that for any $\alpha > 0$, $\delta \in (0, 1)$, integers $L, s \geq 1$, $x_1, x_2 \in \mathbb{Z}^d$ with $\|x_1 - x_2\| = sL$, and any functions $f_1, f_2 : \{0, 1\}^{\mathbb{Z}^d} \to [0, 1]$ such that $f_i(\omega)$ only depends on values of $\omega_x$ with $\|x - x_i\| \leq L$,

1. if $f_2$ is increasing, then

$$E^\alpha [f_1 f_2] \leq E^\alpha [f_1] E^{\alpha + \delta} [f_2] + C \exp \left(\alpha - c \sqrt{\delta} s^{d-2}\right), \quad (1.1)$$

2. if $f_2$ is decreasing, then

$$E^\alpha [f_1 f_2] \leq E^\alpha [f_1] E^{(\alpha - \delta)+} [f_2] + C \exp \left(\alpha - c \sqrt{\delta} s^{d-2}\right), \quad (1.2)$$

where $E^\alpha$ is the expectation with respect to the distribution of $\{1_{x \in \mathcal{R}^\alpha}\}_{x \in \mathbb{Z}^d}$ on $\{0, 1\}^{\mathbb{Z}^d}$.

It turns out that this decoupling inequality is strong enough to obtain the same results about the infinite cluster of $\mathcal{V}^\alpha$ as those derived for the class of models from [8]. More precisely, in Section 6, after recalling the assumptions from [8], we prove that condition P3 on spatial correlations can be relaxed, cf. condition D in Section 6, without any effect on the conclusions of [8] and of [23, 27] where the framework of [8] was further used, see
Theorem 6.2 and Corollary 6.3. Crucially, even though the vacant set $V^\alpha$ does not satisfy condition $P_3$, it does satisfy the weaker condition $D$ by Theorem 1.1. Furthermore, let us emphasize that condition $D$ is not only weaker than $P_3$, but also more natural, since it postulates decorrelation of local events occurring in large boxes only when the boxes are far apart. All in all, we believe that Theorem 6.2 and Corollary 6.3 are of independent importance beyond their application in the present paper, nevertheless, we postpone their formulation to Section 6 because of a large amount of necessary notation. Incidentally, the results of Chang [6] about the geometry of the infinite cluster in the range of the loop soup can now be directly deduced as a special case of Corollary 6.3 (and Theorem 1.1).

Our next result proves that for small enough values of $\alpha$, the vacant set $V^\alpha$ contains with high probability a unique giant cluster in all large enough boxes. In particular, it implies that the supercritical phase is non-trivial ($\alpha^* > 0$).

**Theorem 1.2.** (Local uniqueness) For any $d \geq 3$ there exist $\alpha_1 > 0$, $c = c(d) > 0$ and $C = C(d) < \infty$ such that for all $0 \leq \alpha \leq \alpha_1$ and $n \geq 1$,

\[
P\left[ \text{the infinite connected component of } V^\alpha \text{ intersects } B(0, n) \right] \geq 1 - Ce^{-nc} \quad (1.3)
\]

and

\[
P\left[ \text{any two connected subsets of } V^\alpha \cap B(0, n) \text{ with diameter } \geq \frac{n}{10} \text{ are connected in } V^\alpha \cap B(0, 2n) \right] \geq 1 - Ce^{-nc} \quad (1.4)
\]

Properties (1.3) and (1.4) appear as assumption $S_1$ in the framework of [8], see Section 6. The remaining conditions (ergodicity, monotonicity, continuity) from [8] are easily verified for $V^\alpha$, see Remark 6.4. As a result, we can summarize the main conclusions about the geometry of the infinite cluster of $V^\alpha$ as follows. (This is an immediate application of Theorem 1.1, Corollary 6.3 and Remark 6.4.)

**Theorem 1.3.** Let $d \geq 3$ and $\alpha_1 > 0$. If (1.3) and (1.4) hold for all $\alpha < \alpha_1$ with constants $c = c(d, \alpha) > 0$ and $C = C(d, \alpha) < \infty$, then the unique infinite cluster of $V^\alpha$ satisfies all the results from [8, 23, 27] for all $\alpha < \alpha_1$, more precisely,

- Theorems 2.3 (chemical distances) and 2.5 (shape theorem) in [8],
- Theorem 1.1 in [23] (quenched invariance principle),
- Theorem 1.13 (Barlow’s ball regularity), Corollary 1.14 (quenched Gaussian heat kernel bounds, elliptic and parabolic Harnack inequalities), Theorem 1.19 (quenched local CLT), as well as Theorems 1.16–1.18, 1.20 in [27].

We refer the reader to the introduction of [27] for the precise statements of these results.

We strongly believe that properties (1.3) and (1.4) with some $c = c(d, \alpha) > 0$ and $C = C(d, \alpha) < \infty$ hold for all $\alpha < \alpha_*$. This has been proven to hold for Bernoulli percolation (for all $p > p_c$, see [11, (7.89)]), the random interlacements (for all $u > 0$, see [25]) and for the range of the loop soup (for all $\alpha > \alpha_c$, see [6]), but is still conjectured for the level sets of the Gaussian free field and for the vacant set of random interlacements (analogues of Theorem 1.2 for these models are proved, in [8], resp., [35](for $d \geq 5$) and [9](for $d \geq 3$)).
Overview of the paper. In Section 2 we collect basic definitions and classical results on random walks. In Section 3 we study the Poisson point process of loops that intersect two disjoint sets. Such loops can be cut into successive excursions between the two sets which are distributed as independent random walk bridges conditioned on their starting and ending points, see Proposition 3.4. In Section 4 we prove Theorem 1.1 and in Section 5 Theorem 1.2. Finally in Section 6, which can be read independently of all the other sections, we recall the general conditions on percolation models from [8], formulate a weaker decoupling inequality $D$ and prove in Theorem 6.2 that the condition $P3$ from [8] can be substituted by $D$ without any loss in conclusions. The punchline of Section 6 is Corollary 6.3, which particularly gives Theorem 1.3.

2 Notation and preliminaries

For $x \in \mathbb{Z}^d$, let $\|x\|$ and $\|x\|_1$ be the $\ell_\infty$-, resp., $\ell_1$-norm of $x$ and denote by $B(x,r)$ the $\ell_\infty$ closed ball in $\mathbb{Z}^d$ of radius $r$ centered in $x$.

For a set $A \subseteq \mathbb{Z}^d$, let $\partial_{in} A = \{ y \in A : \|y' - y\|_1 = 1 \text{ for some } y' \in \mathbb{Z}^d \setminus A \}$ be the interior boundary of $A$ and $\partial_{ext} A = \{ y \notin A : \|y' - y\|_1 = 1 \text{ for some } y' \in A \}$ the exterior boundary of $A$.

A function $f : \{0,1\}^{\mathbb{Z}^d} \to \mathbb{R}$ is called increasing if $f(\omega) \leq f(\omega')$ for any $\omega, \omega' \in \{0,1\}^{\mathbb{Z}^d}$ such that $\omega_x \leq \omega'_x$ for all $x \in \mathbb{Z}^d$. A subset $E$ of $\{0,1\}^{\mathbb{Z}^d}$ is called increasing if its indicator $1_E$ is increasing ($1_E(\omega) = 1$ if $\omega \in E$ and 0 otherwise). A function $f$, resp., a set $E$, is called decreasing if $-f$, resp., $\{0,1\}^{\mathbb{Z}^d} \setminus E$, is increasing.

Let $W_n$ be the set of all infinite nearest neighbor paths on $\mathbb{Z}^d$ endowed with the $\sigma$-algebra generated by coordinate maps $X_n$, $n \in \mathbb{N}$. Denote by $P_x$ the law of a simple random walk on $\mathbb{Z}^d$ started at $x$ and by $g : \mathbb{Z}^d \times \mathbb{Z}^d \to \mathbb{R}$ the Green function of the simple random walk, $g(x,y) = \sum_{n=0}^{\infty} P_x[X_n = y]$. It is well known, see, e.g., [12, Theorem 1.5.4], that for any $d \geq 3$, there exist $c_g > 0$ and $C_g < \infty$ such that

$$c_g (\|x - y\| + 1)^{2-d} \leq g(x,y) \leq C_g (\|x - y\| + 1)^{2-d}, \quad x, y \in \mathbb{Z}^d. \quad (2.1)$$

For $A \subset \mathbb{Z}^d$ and a nearest neighbor path $w = (w_0, \ldots, w_N)$ on $\mathbb{Z}^d$, where $N \in \mathbb{N}_0 \cup \{+\infty\}$, let $H_A(w) = \inf\{n \geq 0 : w_n \in A\}$ be the entrance time in $A$ and $H_A(w) = \inf\{n \geq 1 : w_n \in A\}$ the hitting time of $A$. The equilibrium measure of a finite set $A$ is defined by $e_A(x) = P_x[H_A = +\infty] \cdot 1_A(x)$. Its total mass is the capacity of $A$, $\text{cap}(A) = \sum_x e_A(x)$. The equilibrium measure of any finite set in dimensions $d \geq 3$ is non-zero and we denote by $\tilde{e}_A$ the normalized equilibrium measure. The following relation between the entrance time probability, the Green function and the equilibrium measure is classical, see, e.g., [31, (1.8)]:

$$P_x[H_A < +\infty] = \sum_{y \in A} g(x,y) e_A(y). \quad (2.2)$$

By taking $x = 0$ and $A = \partial_{in} B(0,n)$ in (2.2) and using (2.1), one easily gets the bounds on the capacity of balls:

$$c_c n^{d-2} \leq \text{cap} (B(0,n)) = \text{cap} (\partial_{in} B(0,n)) \leq C_c n^{d-2}. \quad (2.3)$$
The following lemma and corollary are also standard. They will be used in the proof of Theorem 1.1.

**Lemma 2.1.** There exist constants \( c = c(d) > 0 \) and \( C = C(d) < \infty \) such that
1. for all \( n \geq 1 \) and \( x \notin B(0, n) \),
   \[
   c \left( \frac{n}{\|x\|} \right)^{d-2} \leq P_x \left[ H_{B(0,n)} < \infty \right] \leq C \left( \frac{n}{\|x\|} \right)^{d-2},
   \]
   (2.4)
2. for all \( n \geq 1, m > 2n, A \subset B(0,n) \), \( x \notin B(0, m) \) and \( y \in A \),
   \[
   c \tilde{e}_A(y) \leq P_x \left[ X_{H_A} = y \mid H_A < \infty \right] = C \tilde{e}_A(y).
   \]
(2.5)

**Proof.** The first statement is immediate from (2.1), (2.2) and (2.3). The second follows from [12, Theorem 2.1.3] and the Harnack principle (see, e.g., [12, Theorem 1.7.6]).

**Corollary 2.2.** Let \( L \geq 1, 2 < r \leq \frac{1}{2} \) be integers, \( x_1, x_2 \in \mathbb{Z}^d \) with \( \|x_1 - x_2\| = sL \), and define \( S_i = \partial \text{int} B(x_i, L) \) and \( S'_i = \partial \text{int} B(x_i, rL), \) \( i \in \{1, 2\} \).

There exist constants \( c = c(d) > 0 \) and \( C = C(d) < \infty \) such that for all \( r > C, x \in S'_1 \) and \( y \in S_2 \),

\[
\frac{c}{r^d} P_x \left[ H_{S_2} < \infty \right] \tilde{e}_{S_2}(y) \leq P_x \left[ H_{S_2} < H_{S_1}, X_{H_{S_2}} = y \right] \leq C P_x \left[ H_{S_2} < \infty \right] \tilde{e}_{S_2}(y).
\]
(2.6)

**Proof.** Immediate from Lemma 2.1 and the Markov property of random walk.

For \( A \subset \mathbb{Z}^d, x \notin A, y \in A \), consider the law

\[
P^A_{x,y} = P_x \left[ (X_0, \ldots, X_{H_A}) = \cdot \mid X_{H_A} = y \right]
\]

of a random walk path (bridge) from \( x \) conditioned to enter \( A \) at \( y \).

The set of all based loops is denoted by \( \hat{\mathcal{L}} \) and all loops by \( \mathcal{L} \). For a loop \( \ell \in \mathcal{L} \) and \( A \subset \mathbb{Z}^d \), we write \( \ell \cap A \neq \emptyset \) if some (and hence all) representative from the equivalence class \( \ell \) contains at least one vertex in \( A \). If \( A = \{x\} \), then we instead write \( x \in \ell \). If \( \mathcal{L} \) is a subset of \( \hat{\mathcal{L}} \) and \( x \in \mathbb{Z}^d \), then we write \( x \in \mathcal{L} \) if there exists \( \ell \in \mathcal{L} \) such that \( x \in \ell \).

We denote by \( \pi : \hat{\mathcal{L}} \to \mathcal{L} \) the canonical projection, i.e., \( \pi(\ell) \) is the equivalence class of \( \ell \).

Consider the measure \( \hat{\mu} \) on \( \hat{\mathcal{L}} \) defined by

\[
\hat{\mu}(\ell) = \frac{1}{n} P_{x_1} \left[ (X_0, \ldots, X_n) = \ell, X_n = x_1 \right] = \frac{1}{n} \left( \frac{1}{2d} \right)^n, \quad \ell = (x_1, \ldots, x_n),
\]
(2.7)

and denote by \( \mu \) the push-forward of \( \hat{\mu} \) on \( \mathcal{L} \) by \( \pi \).

For \( \alpha > 0 \) let

- \( \mathcal{L}^\alpha \) be the Poisson point process of loops with intensity measure \( \alpha \mu \),
- \( \mathcal{N}^\alpha \) the field of cumulative local times for the loops in \( \mathcal{L}^\alpha \),
- \( \mathcal{V}^\alpha = \{ x \in \mathbb{Z}^d : \mathcal{N}^\alpha(x) = 0 \} \) the vacant set for \( \mathcal{L}^\alpha \).

We assume that these processes are defined on a probability space \( (\mathcal{X}, \mathcal{F}, \mathbb{P}) \), whose precise description is irrelevant and also use \( \mathbb{P}^\alpha \) and \( \mathbb{E}^\alpha \) to denote the law, resp., expectation, of \( \{1_{x \in \mathcal{L}^\alpha}\}_{x \in \mathbb{Z}^d} \) on \( \{0,1\}^{\mathbb{Z}^d} \).

Constants that only depend on the dimension (and in Section 6 possibly also on \( a \) and \( b \)) are denoted by \( c \) and \( C \). Their value may change from line to line and even within lines.
Decomposition of loops in excursions

In this section we study properties of loops that visit two disjoint sets $A, B \subset \mathbb{Z}^d$. Any such loop can be cut into alternating excursions from $A$ to $B$ and from $B$ to $A$, which, given their starting and ending points, are distributed as independent random walk bridges. This gives a useful way to sample the Poisson point process of loops that visit $A$ and $B$, see Proposition 3.4. Furthermore, the total number of loop excursions is unlikely to be large if $A$ and $B$ are far apart, see Lemma 3.6.

Let $A, B \subset \mathbb{Z}^d$ be disjoint and consider the set of all loops that visit $A$ and $B$:

$$L_{A,B} : = \{ \ell \in \mathcal{L} : \ell \cap A \neq \emptyset, \ell \cap B \neq \emptyset \}.$$ 

We first recall a useful representation of the measure $\mu$ on $L_{A,B}$ from [7].

**Definition 3.1.** For each $\ell \in \mathcal{L}$, let $L(A,B)(\ell)$ be the set of all based loops $\dot{\ell} = (x_1, \ldots, x_n)$ from the equivalence class $\ell$ such that

- $x_1 \in A$,
- there exists $i$ such that $x_i \in B$ and $x_j \notin (A \cup B)$ for all $j > i$.

Note that

- $L(A,B)(\ell) \cap L(A,B)(\ell') = \emptyset$ if $\ell \neq \ell'$,
- $L(A,B)(\ell) \neq \emptyset$ if and only if $\ell \in \mathcal{L}_{A,B}$.

Any loop in $\mathcal{L}_{A,B}$ can be decomposed into alternating nearest neighbor excursions from $A$ to $B$ and from $B$ to $A$. For any $\ell \in \mathcal{L}_{A,B}$ and $\dot{\ell} = (x_1, \ldots, x_n) \in L(A,B)(\ell)$, we define the entrance times

$$\phi_1(\dot{\ell}) = 1,$$

$$\psi_1(\dot{\ell}) = \inf \left\{ j > \phi_1(\dot{\ell}) : x_j \in B \right\},$$

$$\phi_k(\dot{\ell}) = \inf \left\{ j > \psi_{k-1}(\dot{\ell}) : x_j \in A \right\},$$

$$\psi_k(\dot{\ell}) = \inf \left\{ j > \phi_k(\dot{\ell}) : x_j \in B \right\}, \ k \geq 1,$$

with $\inf\{\emptyset\} = \infty$, and let

$$k(\dot{\ell}) = \sup\{n \geq 1 : \phi_n(\dot{\ell}) < \infty\} < \infty.$$

Note that the value of $k(\dot{\ell})$ is the same for all $\dot{\ell} \in L(A,B)(\ell)$ and we denote it by $k(\ell)$.

**Lemma 3.2.** [7, Claim 1] For any loop $\ell \in \mathcal{L}_{A,B}$,

$$\mu(\ell) = \frac{|\ell|}{k(\ell)} \sum_{\dot{\ell} \in L(A,B)(\ell)} \hat{\mu}(\dot{\ell})$$

$$= \frac{1}{k(\ell)} \sum_{x \in A} P_x \left[ (X_0, \ldots, X_{|\ell|-1}) \in L(A,B)(\ell), X_{|\ell|} = x \right] ,$$

where $|\ell|$ is the length of the loop $\ell$.  

7
Let $\mathcal{L}^\alpha_{A,B}$ be the restriction of $\mathcal{L}^\alpha$ to $\mathcal{L}_{A,B}$. It is a Poisson point process with intensity measure $\alpha \mathbb{1}_{\mathcal{L}_{A,B}} \mu$, which is independent from the restriction of $\mathcal{L}^\alpha$ to $\mathcal{L} \setminus \mathcal{L}_{A,B}$. We are interested in the distribution of excursions from $A$ to $B$ of the loops in $\mathcal{L}^\alpha_{A,B}$ (parts of the loop between times $\phi_i$ and $\psi_i$). The set of excursions is only determined up to cyclic permutations, therefore, it is more convenient to work with excursions of based loops. The following lemma identifies $\mathcal{L}^\alpha_{A,B}$ with a projection of a suitable Poisson point process of based loops. Let

$$\hat{\mathcal{L}}_{A,B} = L(A, B)(\mathcal{L}_{A,B}),$$

i.e., the set of all based loops $\hat{\ell} = (x_1, \ldots, x_n)$ such that

- $x_1 \in A$,
- there exists $i$ such that $x_i \in B$ and $x_j \notin (A \cup B)$ for all $j > i$.

(Mind that $\hat{\mathcal{L}}_{A,B}$ is not the set of all based loops that intersect $A$ and $B$, as may be suggested by notation.)

**Lemma 3.3.** Let $\hat{\mathcal{L}}^\alpha_{A,B}$ be a Poisson point process on $\hat{\mathcal{L}}_{A,B}$ with intensity measure $\alpha \hat{\mu}_{A,B}$, where

$$\hat{\mu}_{A,B}(\hat{\ell}) = \frac{1}{k(\hat{\ell})} \mathbb{P}_{|x_1|} \left[ (X_0, \ldots, X_{|\hat{\ell}| - 1}) = \hat{\ell}, X_{|\hat{\ell}|} = x_1 \right], \quad \hat{\ell} = (x_1, \ldots, x_{|\hat{\ell}|}) \in \hat{\mathcal{L}}_{A,B}.$$

Then $\pi \left( \hat{\mathcal{L}}^\alpha_{A,B} \right)$ is a Poisson point process on $\mathcal{L}_{A,B}$ with intensity measure $\alpha \mathbb{1}_{\mathcal{L}_{A,B}} \mu$.

In other words, to sample $\mathcal{L}^\alpha_{A,B}$ one first samples the Poisson point process $\hat{\mathcal{L}}^\alpha_{A,B}$ of based loops and then replaces each based loop by its equivalence class.

**Proof.** This is a direct consequence of Lemma 3.2. Indeed, $\pi \left( \hat{\mathcal{L}}^\alpha_{A,B} \right)$ is a Poisson point process with intensity measure

$$\ell \mapsto \alpha \sum_{\hat{\ell} \in L(A,B)(\ell)} \hat{\mu}_{A,B}(\hat{\ell}) = \alpha \mu(\ell), \quad \ell \in \mathcal{L}_{A,B}.$$

The advantage of based loops in $\hat{\mathcal{L}}^\alpha_{A,B}$ is that their excursions from $A$ to $B$ are naturally ordered. Of course, the range of all based loops in $\hat{\mathcal{L}}^\alpha_{A,B}$ has the same law as the range of all loops in $\mathcal{L}^\alpha_{A,B}$.

Next, we decompose the Poisson point process $\hat{\mathcal{L}}^\alpha_{A,B}$ according to the number of excursions that a based loop makes from $A$ to $B$. Namely, for $j \geq 1$, we denote by $\hat{\mathcal{L}}^{\alpha,j}_{A,B}$ the restriction of $\hat{\mathcal{L}}^\alpha_{A,B}$ to $\hat{\mathcal{L}}^j_{A,B} = \{ \hat{\ell} \in \hat{\mathcal{L}}_{A,B} : k(\hat{\ell}) = j \}$. Then,

- $\hat{\mathcal{L}}^{\alpha,j}_{A,B}$, $j \geq 1$, are independent Poisson point processes,
- the intensity measure of $\hat{\mathcal{L}}^{\alpha,j}_{A,B}$ is $\alpha \mathbb{1}_{\mathcal{L}^j_{A,B}} \hat{\mu}_{A,B}$,
- $\hat{\mathcal{L}}^\alpha_{A,B} = \sum_{j=1}^{\infty} \hat{\mathcal{L}}^{\alpha,j}_{A,B}$. 

8
We show in Proposition 3.4 that each loop soup $\hat{L}_{A,B}^{a,j}$ can be constructed by sampling the starting and ending locations of all the excursions from $A$ to $B$ of all the loops in $\hat{L}_{A,B}^{a,j}$ according to a Poisson point process and then joining the endpoints by independent random walk bridges.

Let $j \geq 1$ and recall $\phi_i$ and $\psi_i$ defined in (3.1). For a loop $\dot{\ell} = (x_1, \ldots, x_n) \in \hat{L}_{A,B}^{j}$, denote the starting and ending locations of all the excursions of $\dot{\ell}$ from $A$ to $B$ by

$$\Phi_i(\dot{\ell}) = x_{\phi_i(\dot{\ell})} \in A, \quad \Psi_i(\dot{\ell}) = x_{\psi_i(\dot{\ell})} \in B, \quad 1 \leq i \leq j,$$

the excursions from $A$ to $B$ by

$$\dot{W}_i(\dot{\ell}) = (x_{\phi_i(\dot{\ell})}, \ldots, x_{\psi_i(\dot{\ell})}), \quad 1 \leq i \leq j,$$

and the excursions from $B$ to $A$ by

$$\dot{W}_j(\dot{\ell}) = (x_{\psi_j(\dot{\ell})}, \ldots, x_{\psi_{j+1}(\dot{\ell})}, x_1), \quad 1 \leq i \leq j - 1,$$

see Figure 1 for an illustration; and consider the Poisson point processes (multisets)

$$E_{A,B}^{a,j} = \left\{ \left( (\Phi_1(\dot{\ell}), \Psi_1(\dot{\ell})), \ldots, (\Phi_j(\dot{\ell}), \Psi_j(\dot{\ell})) \right) : \dot{\ell} \in \hat{L}_{A,B}^{a,j} \right\},$$

$$\overline{E}_{A,B}^{a,j} = \left\{ \left( \dot{W}_1(\dot{\ell}), \ldots, \dot{W}_j(\dot{\ell}) \right) : \dot{\ell} \in \hat{L}_{A,B}^{a,j} \right\},$$

Proposition 3.4. Let $A, B$ be disjoint subsets of $\mathbb{Z}^d$, $d \geq 3$. For an infinite path $w = (x_0, x_1, \ldots)$, consider the sequence of times

$$\tau_0(w) = 0,$$

$$\tau_{2j+1}(w) = \inf\{ k > \tau_{2j}(w) : x_k \in B \},$$

$$\tau_{2j+2}(w) = \inf\{ k > \tau_{2j+1}(w) : x_k \in A \}, \quad j \geq 0.$$
Thus, the loops from $\dot{j}$ where in the last line we set $\Phi \geq \inf_1$. the intensity of $V$ to $A$ We end this section with a large deviation bound on the total number of excursions from $\mathcal{L}_{A,B}$.

Proof. Let $j \geq 1$ and $\dot{e} = (x_1, \ldots, x_{|\dot{e}|}) \in \mathcal{L}^j_{A,B}$. The result is immediate from the following representation of $\dot{\mu}_{A,B}$:

$$
\dot{\mu}_{A,B}(\dot{e}) = \frac{1}{j} P_{x_1} \left[ (X_0, \ldots, X_{|\dot{e}|-1} = \dot{e}, X_{|\dot{e}|} = x_1 \right]
$$

$$
= \frac{1}{j} P_{x_1} \left[ \tau_{2j} < \infty, X_{\tau_{2j}} = x_1, X_{\tau_{2j}-1} = \Phi_i(\dot{e}), X_{\tau_{2j-1}} = \Psi_i(\dot{e}),
\right.
$$

$$
\left. (X_{\tau_{2j-1}}, \ldots, X_{\tau_{2j-1}}) = \overrightarrow{W}_i(\dot{e}),
(X_{\tau_{2j-1}}, \ldots, X_{\tau_2}) = \overrightarrow{W}_i(\dot{e}), 1 \leq i \leq j \right]
$$

$$
= \frac{1}{j} P_{x_1} \left[ \tau_{2j} < \infty, X_{\tau_{2j}} = x_1,
X_{\tau_{2j-1}} = \Phi_i(\dot{e}), X_{\tau_{2j-1}} = \Psi_i(\dot{e}), 1 \leq i \leq j \right]
$$

$$
\prod_{i=1}^j \int \int \cdots \int P_{\Phi_i(\dot{e}), \Psi_i(\dot{e})} \left[ \overrightarrow{W}_i(\dot{e}) \right] P_{\phi_i(\dot{e}), \psi_i(\dot{e})} \left[ \overrightarrow{W}_i(\dot{e}) \right]
$$

where in the last line we set $\Phi_{j+1} = \Phi_1$.

Remark 3.5. Proposition 3.4 (applied to $A = \partial_{in} B(0, n)$, $B = \partial_{ext} B(0, n)$) can be used to adapt to $\mathcal{V}^\alpha$ the standard Burton-Keane argument [4] for the uniqueness of the infinite percolation cluster, even though one of the main requirements, the positive finite energy property, is not satisfied by $\mathcal{V}^\alpha$. (The positive finite energy property states that $P[0 \in \mathcal{V}^\alpha | \sigma (1_{x \in \mathcal{V}^\alpha}, x \neq 0)] > 0$ almost surely, which is obviously not the case here, since, for instance, if all the vertices of $B(0, 2) \setminus \{0\}$ are vacant except for one neighbor of the origin, then the origin cannot be vacant.) See, e.g., [34, Theorem 1.1], where the Burton-Keane argument is adapted to prove the uniqueness of the infinite percolation cluster in the vacant set of random interlacements, which also does not satisfy the positive finite energy property.

We end this section with a large deviation bound on the total number of excursions from $A$ to $B$ in all loops from $\mathcal{L}^\alpha_{A,B}$.
Lemma 3.6. Let $A, B$ be (disjoint) subsets of $\mathbb{Z}^d$ such that
\[
\sup_{y \in B} P_y[H_A < \infty] \leq \frac{1}{2e}.
\] (3.3)

Let $Z_{A,B}^\alpha$ be the total number of excursions from $A$ to $B$ of all the loops from $\mathcal{L}^\alpha$. Then,
\[
P[Z_{A,B}^\alpha \geq k] \leq \exp (\alpha - k).
\]

Proof. Let $Z_{A,B}^{\alpha,j}$ be the number of loops in $L_{\alpha,j}^{A,B}$. By Proposition 3.4(1), $Z_{A,B}^{\alpha,j}$ are independent Poisson random variables with intensities
\[
\lambda_j = \frac{\alpha}{j} \sum_{x \in A} P_x \left[ \tau_{2j} < \infty, X_{\tau_{2j}} = x \right] \leq \frac{\alpha}{j} \left( \frac{1}{2e} \right)^j.
\] (3.4)

Furthermore, $Z_{A,B}^\alpha = \sum_{j=1}^{\infty} j Z_{A,B}^{\alpha,j}$. Thus,
\[
\mathbb{E} \left[ \exp \left( Z_{A,B}^\alpha \right) \right] = \prod_{j=1}^{\infty} \mathbb{E} \left[ \exp \left( j Z_{A,B}^{\alpha,j} \right) \right] = \prod_{j=1}^{\infty} \exp \left( \lambda_j \left( e^j - 1 \right) \right) \leq e^\alpha,
\]
and the result follows from the exponential Chebyshev’s inequality. \qed

4 Proof of Theorem 1.1

The proofs of (1.1) and (1.2) are very similar and we only provide here the proof of (1.1). Without loss of generality, we may assume that $s \geq s_0 = s_0(d)$. Let $L \geq 1$ and take $2 < r \leq s/2$ sufficiently large (the ultimate choice of $r$ depends only on the dimension). Let $x_1, x_2 \in \mathbb{Z}^d$ with $\|x_1 - x_2\| = sL$ and define
\[
B_i = B(x_i, L), \quad B'_i = B(x_i, rL), \quad S_i = \partial_{\text{int}} B_i, \quad S'_i = \partial_{\text{int}} B'_i.
\]

Let $f_1, f_2 : \{0, 1\}^{2d} \to [0, 1]$ such that $f_i$ only depends on coordinates of $\omega \in \{0, 1\}^{2d}$ in $B_i$ and assume that $f_2$ is increasing.

We use Proposition 3.4 to decompose the loops from $\mathcal{L}^\alpha$ that intersect $S'_1$ and $S_1$ into excursions. Let $Z = Z_{S'_1,S_1}^\alpha$ be the total number of excursions from $S'_1$ to $S_1$ in $\mathcal{L}^\alpha$ and $\mathcal{E} = \{(X_i, Y_i) : 1 \leq i \leq \mathcal{Z}\}$ the multiset of starting and ending positions of all the excursions (i.e., all the pairs from $\mathcal{E}_{S'_1,S_1}^{\alpha,j}$, $j \geq 1$). Then, by Proposition 3.4, conditioned on $\mathcal{E}$, the excursions are distributed as independent random walk bridges started at $X_i$ and conditioned to hit $S_1$ at $Y_i$.

Let $k \geq 1$ (to be specified later) and consider the event
\[
G_1 = \{ Z \leq k \}.
\]
By the locality of $f_1$ and $f_2$, $f_1$ only depends on the loops from $\mathcal{L}^\alpha$ that are contained in $B'_1$ and on the excursions of the loops intersecting both $S_1$ and $S_1'$ that start on $S_1$ and end on $S_1'$, and $f_2$ is independent of all these loops and excursions given $\mathcal{E}$ by Proposition 3.4 and the definition of Poisson point process. Thus,

$$\mathbb{E}^\alpha [f_1 f_2] \leq \mathbb{E}^\alpha [f_1 1_{G_1} \mathbb{E}^\alpha [f_2 | \mathcal{E}]] + \mathbb{P}^\alpha [G_1^c].$$

Note that on the event $G_1$, by the monotonicity of $f_2$,

$$\mathbb{E}^\alpha [f_2 | \mathcal{E}] \leq \max\{ \mathbb{E}_{\alpha; ((\tilde{x}_i, \tilde{y}_i))_{i=1}^k} [f_2],$$

where $\mathbb{E}_{\alpha; ((\tilde{x}_i, \tilde{y}_i))_{i=1}^k}$ is the expectation with respect to the law of

- the loops from $\mathcal{L}^\alpha$ that do not intersect $S_1$ and
- independent $k$-tuple of independent random walk bridges with the $i$th bridge starting at $\tilde{x}_i$ and conditioned to hit $S_1$ at $\tilde{y}_i$.

Since the maximum is taken over a finite set, it is always attained, and we denote the respective $k$-tuple of start and end points for the bridges by $\{(x_i, y_i)\}_{i=1}^k$.

It now suffices to analyse separately the influence of each bridge on the configuration in $B_2$. We will prove the following lemma, which easily gives the main result.

**Lemma 4.1.** For $x \in S_1'$ and $y \in S_1$, let $\mathcal{R}_{x,y}$ be the range in $B_2$ of a random walk bridge started at $x$ and conditioned to hit $S_1$ at $y$, see Figure 2. For $\delta' \in (0, 1)$, let $\mathcal{R}$ be the range in $B_2$ of the loops from the loop soup $\mathcal{L}^\delta$.

Then for each $r \geq r_0 = r_0(d)$ there exists a coupling $(\mathcal{R}_{x,y}, \mathcal{R})$ of $\mathcal{R}_{x,y}$ and $\mathcal{R}$ such that

$$\mathbb{P} \left[ \mathcal{R}_{x,y} \subseteq \mathcal{R} \right] \geq 1 - C s^{2(2-d)} \exp \left[ -c \delta' s^{2(d-2)} \right],$$

where $C = C(d, r)$ and $c = c(d, r)$.

We first complete the proof of the theorem using the lemma. By taking $\delta' = \frac{\delta}{k}$ in the lemma, it is immediate that

$$\mathbb{E}_{\alpha; ((x_i, y_i))_{i=1}^k} [f_2] \leq \mathbb{E}^{\alpha + \delta} [f_2] + C k s^{2(2-d)} \exp \left[ -c \frac{\delta}{k} s^{2(d-2)} \right].$$

We choose $k = \sqrt{\delta} s^{d-2}$, so that $C k s^{2(2-d)} \exp \left[ -c \frac{\delta}{k} s^{2(d-2)} \right] \leq C \exp[\alpha - c \sqrt{\delta} s^{d-2}]$, and it remains to show that with this choice of $k$, also $\mathbb{P}^\alpha[G_1^c] \leq C \exp[\alpha - c \sqrt{\delta} s^{d-2}]$. This follows from Lemma 3.6. Indeed, by (2.4), $\sup_{x \in S_1'} \mathbb{P}_x \left[ H_{S_1} < \infty \right] \leq C r^{2-d} < \frac{1}{2C}$ for $r$ sufficiently large. Thus, by Lemma 3.6, $\mathbb{P}^\alpha[G_1^c] \leq \exp[\alpha - k] = \exp[\alpha - \sqrt{\delta} s^{d-2}]$.

This completes the proof of Theorem 1.1 subject to Lemma 4.1.

### 4.1 Proof of Lemma 4.1

Fix $x \in S_1'$ and $y \in S_1$. By (2.4), (2.5) and (2.6), the probability that a random walk bridge started at $x$ and conditioned to hit $S_1$ in $y$ visits $B_2$ is bounded by

$$c \left( \frac{r}{s^2} \right)^{d-2} \leq \mathbb{P}_{x,y} \left[ H_{B_2} < \infty \right] \leq C \left( \frac{r}{s^2} \right)^{d-2},$$
Figure 2: The range in $B_2$ of a random walk bridge started at $x$ and conditioned to hit $S_1$ at $y$ is denoted by $\mathcal{R}_{x,y}$.

which is small if $s \geq s_0(d)$ (sufficiently large). In particular,

$$P^{S_1}_{x,y}[H_{B_2} < \infty] \leq 1 - \exp \left[ -2P^{S_1}_{x,y}[H_{B_2} < \infty] \right].$$

Thus, if we denote by $\tilde{\mathcal{R}}_{x,y}$ the range in $B_2$ of the Poisson point process $\eta$ of bridges with intensity $\lambda = 2P^{S_1}_{x,y}$, then $\mathcal{R}_{x,y}$ is stochastically dominated by $\tilde{\mathcal{R}}_{x,y}$, and it suffices to compare $\tilde{\mathcal{R}}_{x,y}$ to $\mathcal{R}$.

Every bridge visits $B_2$ by means of excursions that start on $S_2$ and end on $S'_2$. Let $\eta_m$ be the restriction of $\eta$ to the bridges that make exactly $m$ excursions from $S_2$ to $S'_2$. By properties of Poisson point processes, $\eta_m$ are independent Poisson point processes and

$$\eta = \sum_{m=0}^{\infty} \eta_m.$$

Furthermore, each $\eta_m$ induces a Poisson point process $\sigma_m$ on $m$-tuples of excursions from $S_2$ to $S'_2$, see Figure 3. To describe its intensity measure, let $\mathcal{S}$ be the set of all finite nearest neighbor paths starting on $S_2$ and ending on their first entrance to $S'_2$. For $w_1, \ldots, w_m \in \mathcal{S}$, $w_i = (w_i(0), \ldots, w_i(k_i))$, let

$$\Gamma_m(w_1, \ldots, w_m) = \prod_{i=1}^{m} P_{w_i(0)} [(X_0, \ldots, X_{k_i}) = w_i] \prod_{i=1}^{m-1} P_{w_i(k_i)} [H_{S_2} < H_{S_1}, X_{H_{S_2}} = w_{i+1}(0)]$$

be the probability that the excursions from $S_2$ to $S'_2$ made by a simple random walk started at $w_1(0)$ before it ever visits $S_1$ are precisely $w_1, \ldots, w_m$. Note that $\Gamma_m$ is a measure on $\mathcal{S}^m$. Then, the intensity measure of $\sigma_m$ is

$$\lambda_m(w_1, \ldots, w_m) = 2 \frac{1}{P_x[H_{S_2} < H_{S_1}, X_{H_{S_2}} = w_1(0)]} P_x[H_{S_2} < H_{S_1}, X_{H_{S_2}} = w_1(0)] \Gamma_m(w_1, \ldots, w_m) P_{w_m(k_m)} [H_{S_1} < H_{S_2}, X_{H_{S_1}} = y].$$

13
By (2.4), (2.5) and (2.6), if $s$ and $r$ are sufficiently large, then

$$
C \left( \frac{r}{s^2} \right)^{d-2} \tilde{c}_{S_2}(w_1(0)) \Gamma_m(w_1, \ldots, w_m) \leq \lambda_m(w_1, \ldots, w_m) \leq C \left( \frac{r}{s^2} \right)^{d-2} \tilde{c}_{S_2}(w_1(0)) \Gamma_m(w_1, \ldots, w_m).
$$

(4.1)

We would like to compare $\lambda_m$ with the intensity measure of the Poisson point process of $m$-tuples of excursions from $S_2$ to $S'_2$ induced by the Poisson point process $\mathcal{L}_{S_2, S'_2}$ of loops that visit $S_2$ and $S'_2$. A slight problem is that these loop excursions are only defined up to a cyclic permutation. To avoid this issue, we use Lemma 3.3, which states that the Poisson point process $\mathcal{L}_{S_2, S'_2}$ can be constructed by (a) sampling the Poisson point process $\eta'$ of based loops with intensity measure

$$
\ell \mapsto \frac{1}{k(\ell)} \mathbb{P}_{x_0} \left[ X_i = x_i, 0 \leq i \leq |\ell| \right] \mathbb{1}_{k_{S_2, S'_2}}(\ell), \quad \ell = (x_0, \ldots, x_{|\ell|}),
$$

and (b) “forgetting” the location of the root. In particular, the ranges in $B_2$ of loops from $\mathcal{L}_{S_2}$ that visit both $S_2$ and $S'_2$ and that of loops from $\eta'$ have the same distribution. The excursions of loops in $\eta'$ are naturally ordered. Let $\eta'_m$ be the restriction of $\eta'$ to the loops that make exactly $m$ excursions, then $\eta'_m$ are independent Poisson point processes and $\eta' = \sum_{m=1}^{\infty} \eta'_m$. Furthermore, $\eta'_m$ induces a Poisson point process $\sigma'_m$ on $m$-tuples of excursions (see Figure 3) with intensity measure

$$
\chi'_m(w_1, \ldots, w_m) = \delta' \frac{1}{m} \Gamma'_m(w_1, \ldots, w_m) \mathbb{P}_{w_m(k_m)} \left[ X_{H_{S_2}} = w_1(0) \right],
$$

where

$$
\Gamma'_m(w_1, \ldots, w_m) = \prod_{i=1}^{m} \mathbb{P}_{w_i(0)} \left[ (X_0, \ldots, X_{k_i}) = w_i \right] \prod_{i=1}^{m-1} \mathbb{P}_{w_i(k_i)} \left[ X_{H_{S_2}} = w_{i+1}(0) \right].
$$
In particular, by Lemma 2.1,
\[ cr^{2-d} \delta' \frac{1}{m} \tilde{e}_{S_2}(w_1(0)) \Gamma'_m(w_1, \ldots, w_m) \leq \lambda'_m(w_1, \ldots, w_m) \]
\[ \leq C r^{2-d} \delta' \frac{1}{m} \tilde{e}_{S_2}(w_1(0)) \Gamma'_m(w_1, \ldots, w_m). \] (4.2)

It is immediate that $\Gamma_m \leq \Gamma'_m$. Thus, by (4.1) and (4.2), $\lambda_m \leq \lambda'_m$ if
\[ m \leq c \left( \frac{s}{r} \right)^{2(d-2)} \delta', \]
which implies that for these $m$'s, $\sigma_m$ is stochastically dominated by $\sigma'_m$. In particular, if $\sigma_m = 0$ for all $m > c \left( \frac{s}{r} \right)^{2(d-2)} \delta'$, then $\sum_{m=1}^{\infty} \sigma_m$ is stochastically dominated by $\sum_{m=1}^{\infty} \sigma'_m$.

Let $G_2$ be the event that $\sigma_m = 0$ for all $m > c \left( \frac{s}{r} \right)^{2(d-2)} \delta'$. It follows that there exists a coupling $(\overline{R}_{x,y}, \overline{R})$ of $R_{x,y}$ and $\overline{R}$ such that
\[ \mathbb{P}[\overline{R}_{x,y} \subseteq \overline{R}] \geq \mathbb{P}[G_2]. \]

Finally, for each $m$, using (4.1) and Lemma 2.1,
\[ \mathbb{P}[\sigma_m \neq 0] \leq \lambda_m[S^m] \leq C \left( \frac{r}{s^2} \right)^{d-2} (Cr^{2-d})^{m-1}. \]

Thus, by choosing $r$ sufficiently large (depending only on the dimension),
\[ \mathbb{P}[G_2^c] \leq C s^{2(d-2)} \exp \left[ -c \delta' s^{2(d-2)} \right], \]
which completes the proof of the lemma.

**Remark 4.2.** The arguments of the proof of Theorem 1.1 apply also to loop soups of random walks with general bounded jump distributions considered in [13] as well as to the Brownian loop soup defined in [15], leading to analogous decoupling inequalities for these models.

### 5 Proof of Theorem 1.2

The overall idea of the proof is similar to that of [9], where a result analogous to Theorem 1.2 is proven for the vacant set of random interlacements, although the implementations are quite different. As in [9] we partition the lattice $\mathbb{Z}^d$ into good and bad boxes. Each good box has a vacant “frame” (see Definition 5.1) and uniformly bounded cumulative occupation local times for $L^\alpha$. In Proposition 5.4 and Corollary 5.5 we prove that the set of good boxes typically contains an infinite connected component, whose complement consists only of small holes. When it is the case, any vacant path of big diameter will pass through a large number of good boxes. However, each time the path enters a good box, there is a uniformly positive probability that it locally connects to the frame of the good box, as proved in Lemma 5.6, which makes the existence of long isolated vacant paths unlikely.
An analogue of Proposition 5.4 in [9] is proved relying crucially on a version of decoupling inequalities for random interlacements which is not available in our setting. The decoupling inequality proved in Theorem 1.1 is too weak to be applied here. Instead, for the proof of Proposition 5.4 we use an idea from [35] adapted to our setting to bound the probability that a sufficiently spread out family of boxes consists only of bad ones directly using the decomposition of loops into excursions (Proposition 3.4) and the large deviation bound on the number of excursions (Lemma 3.6).

Fix an integer \( R \geq 1, \) let \( L_0 = 2R + 1 \) and consider the lattice

\[
G_0 = L_0 \mathbb{Z}^d
\]

with edges between any \( \ell_1 \) nearest neighbor vertices of \( G_0. \) If \( x', y' \in G_0 \) are neighbors, we write \( x' \overset{G_0}{\sim} y'. \) For \( n \in \mathbb{N} \) and \( x' \in G_0, \) let \( B_{G_0}(x', n) = \{ y' \in G_0 : \|x' - y'\| \leq L_0n \} \) and \( S_{G_0}(x', n) = \{ y' \in G_0 : \|x' - y'\| = L_0n \} \) be the \( \ell_\infty \) ball, resp., sphere, of radius \( n \) in \( G_0 \) centered at \( x'. \)

For \( x' \in G_0, \) define

\[
Q(x') = B(x', R).
\]

Then, \( \{Q(x'), x' \in G_0\} \) is a partition of \( \mathbb{Z}^d \) into disjoint hypercubes.

**Definition 5.1.** Let \( \square \) be the subset of \( Q(0) \) that consists of all vertices having at least two of their coordinates in the set \( \{ -R, -R + 1, -R + 2, R - 2, R - 1, R \} \) and define

\[
\square(x') = x' + \square, \quad x' \in G_0.
\]

(For \( d = 3, \square(x') \) is just the \( \ell_\infty \) 2-neighborhood of the edges of the cube \( Q(x'). \))

Note that

- the set \( \square \) is connected in \( \mathbb{Z}^d, \)
- for any \( x'_1 \overset{G_0}{\sim} x'_2 \in G_0, \) the set \( \square(x'_1) \cup \square(x'_2) \) is connected in \( \mathbb{Z}^d, \)

Any function \( n : \mathbb{Z}^d \to \mathbb{N}_0 = \{0, 1, \ldots\} \) gives a decomposition of \( G_0 \) into good and bad vertices:

**Definition 5.2.** Let \( n : \mathbb{Z}^d \to \mathbb{N}_0. \) Vertex \( x' \in G_0 \) is \( R \)-good for \( n \) if

1. \( n(x) = 0 \) for all \( x \in \square(x'), \)
2. \( \sum_{x \in \partial_{\text{int}}Q(x')} n(x) \leq R^{d-1}. \)

Otherwise, \( x' \) is \( R \)-bad for \( n. \)

**Remark 5.3.** In our applications, \( \sum_{x \in \partial_{\text{int}}Q(x')} n(x) \) will correspond to the number of times a finite collection of independent random walks visit \( \partial_{\text{int}}Q(x'), \) cf. (5.12). Thus, \( R^{d-1} \) in Definition 5.2(2) could be replaced by any \( f(R) \gg R. \)

We write

\[
G(n) = \{ x' \in G_0 : x' \text{ is } R\text{-good for } n \},
\]

\[
B(n) = \{ x' \in G_0 : x' \text{ is } R\text{-bad for } n \}.
\]

The choice of \( \alpha_1 > 0 \) in Theorem 1.2 is made in the following proposition, which is proven in Section 5.1.
Proposition 5.4. For any $d \geq 3$, there exist $R \geq 1$, $\alpha_1 > 0$, $c > 0$ and $C < \infty$ such that for all $\alpha \leq \alpha_1$ and $N \geq 1$,

$$
\mathbb{P} \left[ 0 \text{ is \#-connected to } S_{G_0}(0, N) \text{ in } B(N^\alpha) \right] \leq C \exp \left( -N^c \right). \tag{5.1}
$$

(Sets $X, Y \subset G_0$ are \#-connected in $Z \subset G_0$ if there exist $z_0, \ldots, z_n \in Z$ such that $z_0 \in X$, $z_n \in Y$ and $\|z_i - z_{i-1}\| = L_0$ for all $1 \leq i \leq n$.)

Proposition 5.4 easily implies the existence of

(a) unique infinite component $G_\infty^\alpha$ in $G(N^\alpha)$ and
(b) ubiquitous connected component $G_N^\alpha$ in $G(N^\alpha) \cap B_{G_0}(0, N)$

(see, e.g., [9, Corollary 3.7] for similar arguments):

Corollary 5.5. Fix $R \geq 1$ and $\alpha_1 > 0$ as in Proposition 5.4. There exist $c' = c'(d) > 0$, and $C' = C'(d) < \infty$ such that for all $\alpha \leq \alpha_1$ and $N \geq 1$,

(a) there exists a unique infinite connected (in $G_0$) component $G_\infty^\alpha$ of $G(N^\alpha)$ and

$$
\mathbb{P} \left[ G_\infty^\alpha \cap B_{G_0}(0, N) \neq \emptyset \right] \geq 1 - C' \exp \left( -N^{c'} \right), \tag{5.2}
$$

(b) if $G_N^\alpha$ denotes a unique connected component of $G(N^\alpha) \cap B_{G_0}(0, N)$ such that any nearest neighbor path in $G_0$ from any $x' \in B_{G_0}(0, \lfloor \frac{2}{3} N \rfloor)$ to $S_{G_0}(x', \lfloor \frac{1}{30} N \rfloor)$ intersects $G_N^\alpha$ at least $\sqrt{N}$ times, or the empty set if such component does not exist, then

$$
\mathbb{P} \left[ G_N^\alpha \neq \emptyset \right] \geq 1 - C' \exp \left( -N^{c'} \right). \tag{5.3}
$$

Since $\bigcup_{x' \in G_\infty^\alpha} \square(x')$ is an infinite connected subset of the vacant set $\mathcal{V}^\alpha$, the first statement of Theorem 1.2, (1.3) is immediate from (5.2).

To prove (1.4), by the union bound, it suffices to show that for each $x \in B(0, L_0 \lfloor \frac{2}{3} N \rfloor)$,

$$
\mathbb{P} \left[ \begin{array}{l}
x \text{ is connected to } \mathbb{Z}^d \setminus B(x, L_0 \lfloor \frac{1}{25} N \rfloor) \text{ in } \mathcal{V}^\alpha, \\
\text{but not to } \bigcup_{x' \in G_\infty^\alpha} \square(x') \text{ in } \mathcal{V}^\alpha \cap B(0, L_0 N + R) \end{array} \right] \leq C'' \exp \left( -N^{c''} \right). \tag{5.4}
$$

(To link (5.4) to (1.4), one can take $N = \lfloor \frac{2n - R}{L_0} \rfloor$, then $L_0 \lfloor \frac{2}{3} N \rfloor \geq n$ and $L_0 \lfloor \frac{1}{25} N \rfloor \leq \frac{1}{10} n$ for all large enough $n$.)

The inequality (5.4) follows from the local connectivity lemma below. To state the lemma, for $R \geq 1$ and $\alpha > 0$, let

$$
\Sigma_G = \sigma \left( I_{x' \in G(\mathcal{V}^\alpha)}, x' \in G_0 \right)
$$

and for $x' \in G_0$,

$$
\mathcal{A}_{x'} = \sigma \left( I_{x \in \mathcal{V}^\alpha}, x \notin Q(x') \right).
$$
Lemma 5.6. Let $d \geq 3$, $R \geq 1$ and $\alpha > 0$. There exists $\gamma = \gamma(d,R,\alpha) > 0$ such that for all $\alpha \in (0,\alpha)$, $x' \in \mathbb{G}_0$, and $y \in \partial_{\text{ext}} \mathbb{Q}(x')$,

$$\mathbb{P} \left[ y \text{ is connected to } \square(x') \text{ in } \mathbb{V}^\alpha \cap \left( \{y\} \cup \mathbb{Q}(x') \right) \right] \geq \gamma \mathbb{1}_{y \in \mathbb{V}^\alpha \setminus \mathbb{Q}(x')} \mathbb{1}_{x' \in \mathbb{G}(\mathbb{V}^\alpha)}, \quad \mathbb{P}\text{-a.s.} \tag{5.5}$$

We postpone the proof of Lemma 5.6 to Section 5.2 and now complete the proof of Theorem 1.2 using the lemma.

Fix $x \in B(0,L_0[\frac{2}{3}N])$. The main idea is to explore the connected component of $x$ in $\mathbb{V}^\alpha$ progressively in boxes $\mathbb{Q}(x')$, $x' \in \mathbb{G}_0$. If the ubiquitous component $\mathbb{G}_N^\alpha$ of good vertices is not empty, then the cluster of $x$ will encounter at least $\sqrt{N}$ boxes centered at vertices from $\mathbb{G}_N^\alpha$, and each time the encounter happens, excluding possibly the very first box, the explored part of the cluster of $x$ connects locally to the set $\bigcup_{x' \in \mathbb{G}_N^\alpha} \square(x')$ with probability at least $\gamma$. This will lead to the upper bound $(1 - \gamma)^{\sqrt{N} - 1}$.

We now define the exploration algorithm. Assume that the vertices of $\mathbb{Z}^d$ are ordered lexicographically.

- Let $x'_0 \in \mathbb{G}_0$ be the unique vertex such that $x \in \mathbb{Q}(x'_0)$ and define $A_0 = \mathbb{Q}(x'_0)$. (Necessarily, $x'_0 \in B_{\mathbb{G}_0}(0,\frac{2}{3}N)$.)
- Let $k \geq 0$ and assume that $x'_k$ and $A_k$ are determined. We stop the algorithm if
  
  (a) $x'_k \in \mathbb{S}_{\mathbb{G}_0}(x'_0, \frac{1}{30}N)$ or (b) $x$ is not connected to $\partial_{\text{int}} A_k$ in $\mathbb{V}^\alpha$, and define $\tau = k$, $y_l = y_k$, $x_l = x'_k$, $A_l = A_k$, for all $l > k$.

  Else, we define
  
  - $y_{k+1} \in \partial_{\text{int}} A_k$ as the smallest vertex such that $x$ is connected to $y_{k+1} \in \mathbb{V}^\alpha \cap A_k$,
  - $x'_{k+1} \in \mathbb{G}_0 \setminus \{x'_0, \ldots, x'_k\}$ as the smallest vertex such that $y_{k+1} \in \partial_{\text{ext}} \mathbb{Q}(x'_{k+1})$,
  - $A_{k+1} = A_k \cup \mathbb{Q}(x'_{k+1})$.

  (See Figure 4 for an illustration.)

The algorithm always stops in a finite time (which we denote by $\tau$), and if $x$ is connected to $\mathbb{Z}^d \setminus B(x, L_0[\frac{1}{27}N])$ in $\mathbb{V}^\alpha$, then the algorithm stops exactly on “reaching” $\mathbb{S}_{\mathbb{G}_0}(x'_0, \frac{1}{30}N)$.

Consider the sigma-algebras

$$\mathcal{A}_k = \sigma \left( A_k, \mathbb{V}^\alpha \cap A_k \right) \quad \text{and} \quad \mathcal{Z}_k = \sigma \left( \sigma(\mathbb{G}_N^\alpha), A_k \right), \quad k \geq 0.$$

Note that the random elements $y_i, x'_i, A_i$, for $1 \leq i \leq k$, are $\mathcal{A}_{k-1}$-measurable, since by revealing the shape of $A_{k-1}$ and the state of $\mathbb{V}^\alpha$ in $A_{k-1}$, one can reconstruct the steps $1, \ldots, k - 1$ of the algorithm uniquely and also uniquely determine $y_k, x'_k$ and $A_k$. Same reasoning gives that the event $\{\tau \geq k\}$ belongs to $\mathcal{A}_{k-1}$.

Consider the events

$$E_k = \{\tau \geq k, x'_k \in \mathbb{G}_N^\alpha, y_k \text{ is connected to } \square(x'_k) \text{ in } \mathbb{V}^\alpha \cap \left( \{y_k\} \cup \mathbb{Q}(x'_k) \right) \}, \quad k \geq 1.$$
Then $E_k \in \mathcal{Z}_k$, $\{\tau \geq k, x'_k \in \mathcal{G}_N^\alpha\} \in \mathcal{Z}_{k-1}$, and
\[
\mathbb{P}\left[ E_k \bigg| \mathcal{Z}_{k-1} \right] \geq \gamma \mathbb{1}_{\tau \geq k, x'_k \in \mathcal{G}_N^\alpha}, \quad \mathbb{P}\text{-a.s.},
\]
with $\gamma$ as in Lemma 5.6 (for $\alpha = \alpha_1$). Indeed, to see that (5.6) holds, fix $k \geq 1$ and for any admissible $G$, $A$ and $V$, define the event $F(G, A, V) = \{\mathcal{G}_N^\alpha = G, A_{k-1} = A, V^a \cap A_{k-1} = V\}$. Note that if $F(G, A, V)$ occurs, then $x'_k = x'$ and $y_k = y$ for some $x'$ and $y$, which are uniquely determined by $A$ and $V$. Thus,
\[
\mathbb{P}\left[ E_k, F(G, A, V) \right] = \mathbb{P}\left[ E_k, F(G, A, V), x'_k = x', y_k = y \right] = \mathbb{E}\left[ \mathbb{P}\left[ E_k, F(G, A, V), x'_k = x', y_k = y \bigg| \Sigma_{\mathcal{G}}, \mathcal{A}_{\mathcal{V}} \right] \right] = \mathbb{E}\left[ F(G, A, V), x'_k = x', y_k = y, \tau \geq k, x'_k \in \mathcal{G}_N^\alpha, y \text{ is connected to } \Box(x') \text{ in } V^a \cap \{y\} \cup Q(x') \bigg| \Sigma_{\mathcal{G}}, \mathcal{A}_{\mathcal{V}} \right] \geq \gamma \mathbb{P}\left[ F(G, A, V), x'_k = x', y_k = y, \tau \geq k, x'_k \in \mathcal{G}_N^\alpha \right],
\]
which proves (5.6).

We can now complete the proof of (5.4). Let
\[
\tau_1 = \inf \{k \geq 1 : x'_k \in \mathcal{G}_N^\alpha\}, \\
\tau_i = \inf \{k > \tau_{i-1} : x'_k \in \mathcal{G}_N^\alpha\}, \text{ for } i \geq 2.
\]
Note that $\{\tau_i = k\} \in \mathcal{Z}_{k-1}$ for all $i$ and $k$. Let $M = \lfloor \sqrt{N} \rfloor - 1$. Then, the probability on
the left hand side of (5.4) is bounded from above by

\[
\leq P[G_N^\alpha = \emptyset] + \sum_{k=1}^{\infty} P\left[ \bigcap_{i=1}^{M} E^c_{\tau_i}, \tau_M = k \leq \tau \right] 
= P[G_N^\alpha = \emptyset] + \sum_{k=1}^{\infty} P\left[ \bigcap_{i=1}^{M-1} E^c_{\tau_i}, \tau_M = k \leq \tau, x'_k \in G_N^\alpha, P\left[E^c_k \mid Z_{k-1}\right] \right] 
\leq P[G_N^\alpha = \emptyset] + (1 - \gamma) \sum_{k=1}^{\infty} P\left[ \bigcap_{i=1}^{M-1} E^c_{\tau_i}, \tau_M = k \leq \tau, x'_k \in G_N^\alpha \right] 
\leq \ldots \leq P[G_N^\alpha = \emptyset] + (1 - \gamma)^M.
\]

An application of (5.3) completes the proof of (5.4).

It remains to prove Proposition 5.4 and Lemma 5.6.

\[\square\]

5.1 Proof of Proposition 5.4

The proof uses a multiscale analysis and embedding of dyadic trees. Its main idea is similar to the proof of [35, Theorem 3.2] about random interlacements, although we use embeddings of dyadic trees as in [32, 24] instead of skeletons as in [35]. Detailed proofs of various properties of such embeddings can be found in [24].

Recall that \(L_0 = 2R+1\). Let \(l \geq 1\) be an integer and consider the sequence of geometrically growing scales \(L_n = L_0^l n, n \geq 0\), and respective lattices \(G_n = L_n \mathbb{Z}^d\).

For \(n \geq 0\), we denote by \(T_n = \bigcup_{k=0}^{n} \{1, 2\}^k\) the dyadic tree of depth \(n\) and write \(T(k) = \{1, 2\}^k\) for the collection of elements of the tree at depth \(k\). Let \(\Lambda_n\) be the set of embeddings \(\mathcal{T} : T_n \rightarrow \mathbb{Z}^d\) such that

- \(\mathcal{T}(\emptyset) = 0\),
- for all \(1 \leq k \leq n\) and \(m \in T(k)\), \(\mathcal{T}(m) \in G_{n-k}\),
- for all \(0 \leq k \leq n-1\), \(m \in T(k)\) and \(i \in \{1, 2\}\),

\[
\|\mathcal{T}(mi) - \mathcal{T}(m)\| = i L_{n-k}.
\]

(Here \(mi \in T(k+1)\) is a descendant of \(m\).)

Lemma 5.7. For all \(n \geq 1, L_0 \geq 1, l \geq 1\),

1. \(|\Lambda_n| \leq \left(2d (2l + 1)^{d-1}\right) \left(2d (4l + 1)^{d-1}\right)^{2n-1} \leq \left((2d)^2 (4l)^{2(d-1)}\right)^{2n-1},
2. for all \(\mathcal{T} \in \Lambda_n, k \geq 0\) and \(m \in T(n)\),

\[
\left| \left\{ m' \in T(n) : \|\mathcal{T}(m') - \mathcal{T}(m)\| \leq \frac{l-5}{l-1} L_{k+1} \right\} \right| \leq 2^k.
\]

20
Proof of Lemma 5.7. Statement 1 follows easily by induction on $n$.
For Statement 2, it suffices to consider $0 \leq k \leq n - 1$ and $l \geq 6$. Take $a \in T_{(n-k-1)}$ and $b', b'' \in \{1, 2\}^k$. Then for the elements $a1b', a2b'' \in T_n$,

$$\|T(a1b') - T(a2b'')\|$$

$$\geq \|T(a1) - T(a2)\| - \|T(a1b') - T(a1)\| - \|T(a2b'') - T(a2)\|$$

$$\geq L_{k+1} - 2(2L_k + 2L_{k-1} + \ldots + 2L_0) > L_{k+1} - 4L_k \frac{l}{l-1} = \frac{l-5}{l-1} L_{k+1}.$$  

Thus, any $m, m' \in T_n$ with $\|T(m') - T(m)\| \leq \frac{l-5}{l-1} L_{k+1}$ can only differ in the last $k$ digits, i.e., there exist $a \in T_{(n-k)}$, $b, b' \in \{1, 2\}^k$ such that $m = ab$ and $m' = ab'$. Since for any $m$ there are at most $2^k$ such $m'$, the result follows.

For $x' \in G_0$, define

$$C_{x'} = \partial_{\text{int}} B(x', L_0), \quad D_{x'} = \partial_{\text{int}} B(x', \frac{1}{4} L_1)$$

and for $T \in \Lambda_n$, consider

$$C_T = \bigcup_{x' \in \mathcal{T}(T(n))} C_{x'}, \quad D_T = \bigcup_{x' \in \mathcal{T}(T(n))} D_{x'}.$$  

By Lemma 5.7, if $l \geq 10$, then the sets $D_{x'}$ in the above union are pairwise disjoint.

Lemma 5.8. There exists $C_{5,8} = C_{5,8}(d)$ such that for all $n \geq 1$, $T \in \Lambda_n$ and $l \geq C_{5,8}$,

$$\sup_{y \in D_T} P_y[H_{C_T} < \infty] \leq \frac{1}{2e}.$$  

Proof of Lemma 5.8. Let $n \geq 1$, $T \in \Lambda_n$ and $y \in D_T$.
Denote by $S_k$ the set of all $x' \in \mathcal{T}(T(n))$ with $\frac{1}{8} L_k \leq \|x' - y\| \leq \frac{1}{8} L_{k+1}$. By Lemma 5.7(2), if $l \geq 10$, then $|S_k| \leq 2^k$. Also, $S_0 = \emptyset$. Using (2.4), we get

$$P_y[H_{C_T} < \infty] \leq \sum_{k=1}^{\infty} \sum_{x' \in S_k} P_y[H_{C_{x'}} < \infty] \leq \sum_{k=1}^{\infty} |S_k| C L_0^{d-2} L_k^{2-d} \leq C \sum_{k=1}^{\infty} (2l^{2-d})^k \leq \frac{1}{2e},$$

for all $l$ sufficiently large.

The next lemma is the main ingredient for the proof of Proposition 5.4.

Lemma 5.9. Let $d \geq 3$. For any $K \geq 1$, there exist $R_0 = R_0(K)$ and $\alpha_0 = \alpha_0(K, R) > 0$ such that for all $R \geq R_0$, $\alpha \leq \alpha_0$, $l \geq C_{5,8}$, $n \geq 1$ and $T \in \Lambda_n$,

$$\mathbb{P} \left[ \mathcal{T}(T(n)) \subseteq B(N^n) \right] \leq \exp(-K 2^n).$$
Proof of Lemma 5.9. Let \( n \geq 1 \) and \( \mathcal{T} \in \Lambda_n \). Take \( l \geq C_{5,8} \), \( \alpha \leq 1 \) and \( M = K + 2 \). Recall that for two disjoint sets \( A, B \), \( Z_{A,B}^\alpha \) denotes the number of excursions of all loops from \( L^\alpha \) from \( A \) to \( B \). Then,

\[
\mathbb{P} \left[ \mathcal{T}(T(n)) \subseteq B(N^\alpha) \right] \leq \mathbb{P} \left[ Z_{C_T,D_T}^\alpha \geq M 2^n \right] + \mathbb{P} \left[ Z_{C_T,D_T}^\alpha \leq M 2^n, \mathcal{T}(T(n)) \subset B(N^\alpha) \right]. \tag{5.8}
\]

By the choice of \( l \), Lemma 5.8 and Lemma 3.6,

\[
\mathbb{P} \left[ Z_{C_T,D_T}^\alpha \geq M 2^n \right] \leq \exp (\alpha - M 2^n) \leq \frac{1}{2} \exp (-K 2^n), \tag{5.9}
\]

where in the second inequality we used \( \alpha \leq 1 \) and \( M = K + 2 \).

To bound the second term in (5.8), recall that by the choice of \( l \), the sets \( D'_{x'}, x' \in \mathcal{T}(T(n)) \), are pairwise disjoint. Thus,

\[
Z_{C_T,D_T}^\alpha = \sum_{x' \in \mathcal{T}(T(n))} Z_{C_{x'},D_{x'}}^\alpha.
\]

In particular, if \( Z_{C_T,D_T}^\alpha \leq M 2^n \), then there exists a subset \( S \) of \( \mathcal{T}(T(n)) \) with cardinality \( 2^{n-1} \) such that \( Z_{C_{x'},D_{x'}}^\alpha \leq 2M \) for all \( x' \in S \). As the number of possible subsets of \( \mathcal{T}(T(n)) \) with cardinality \( 2^{n-1} \) is at most \( 2^{2n} \), we obtain that

\[
\mathbb{P} \left[ Z_{C_T,D_T}^\alpha \leq M 2^n, \mathcal{T}(T(n)) \subset B(N^\alpha) \right] \leq 2^{2n} \sup_S \mathbb{P} \left[ Z_{C_{x'},D_{x'}}^\alpha \leq 2M \text{ and } x' \in B(N^\alpha) \text{ for all } x' \in S \right],
\]

where the supremum is over all subsets \( S \) of \( \mathcal{T}(T(n)) \) with cardinality \( 2^{n-1} \).

The event that \( x' \) is \( R \)-bad only depends on the restriction of \( N^\alpha \) to \( Q(x') \). Thus, if we denote by \( N_{x'}^\alpha \) the total local time of all loops from \( L^\alpha \) that intersect \( Q(x') \) but not \( D'_{x'} \), then for all \( z \in Q(x') \), \( N^\alpha(z) \) is the sum of \( N_{x'}^\alpha(z) \) and the total number of visits to \( z \) of all the excursions of \( L^\alpha \) from \( C_{x'} \) to \( D_{x'} \). Note that

- \( N_{x'}^\alpha \), \( x' \in S \), are independent,
- the excursions of \( L^\alpha \) from \( C_{x'} \) to \( D_{x'} \), conditioned on their starting and ending locations, are distributed as independent random walk bridges (see Proposition 3.4),
- the event that \( x' \) is \( R \)-bad for \( n : \mathbb{Z}^d \rightarrow \mathbb{N} \) is increasing in \( n \).

Thus, if we denote by \( N' \) the total local time of \( 2M \) random walk excursions from \( C_0 \) to \( D_0 \), then

\[
\mathbb{P} \left[ Z_{C_{x'},D_{x'}}^\alpha \leq 2M \text{ and } x' \in B(N^\alpha) \text{ for all } x' \in S \right] \leq \left( \max_{(y_i,z_i)} \mathbb{P} \otimes \bigotimes_{i=1}^{2M} P_{y_i,z_i}^{D_0} [0 \text{ is } R \text{-bad for } (N^\alpha + N')] \right)^{2n-1}
\]

\[
\leq \left( \mathbb{P} \left[ \sum_{z \in Q(0)} N^\alpha(z) \geq 1 \right] + \max_{(y_i,z_i)} \mathbb{P} \otimes \bigotimes_{i=1}^{2M} P_{y_i,z_i}^{D_0} [0 \text{ is } R \text{-bad for } N'] \right)^{2n-1},
\]

22
where the maximum is over all $2M$-tuples of pairs $(y_i, z_i) \in C_0 \times D_0$—the starting and ending locations of excursions from $C_0$ to $D_0$.

It remains to prove that for a suitable choice of $\alpha$ and $R$,

$$\Pr \left[ \sum_{z \in Q(0)} \mathcal{N}^{\alpha}(z) \geq 1 \right] \leq \frac{1}{16} \exp(-2K) \tag{5.10}$$

and

$$\max_{(y_i, z_i)_{i=1}^{2M}} \prod_{i=1}^{2M} \Pr_{y_i, z_i}^{D_0} \left[ 0 \text{ is } R\text{-bad for } \mathcal{N}' \right] \leq \frac{1}{16} \exp(-2K). \tag{5.11}$$

Indeed, if (5.10) and (5.11) hold, then the second summand in (5.8) is bounded from above by

$$2^{2n} \left( \frac{1}{8} \exp(-2K) \right)^{2^{n-1}} \leq \frac{1}{2} \exp(-K2^n)$$

and, combined with (5.9), this gives the result.

We begin with (5.11). Let $(y_i, z_i)_{i=1}^{2M}$ be the $2M$-tuple for which the maximum is attained. By the definition of $R$-bad vertex, the probability in (5.11) is bounded from above by

$$2^{2M} \sum_{i=1}^{2M} \Pr_{y_i, z_i}^{D_0} \left[ H_\Box < \infty \right] + \sum_{i=1}^{2M} \Pr_{y_i, z_i}^{D_0} \left[ \sum_n \sum_{x \in \partial \text{int } Q(0)} 1_{X_n=x} > \frac{1}{2M} R^{d-1} \right], \tag{5.12}$$

which can be estimated using standard results for random walks and the fact that for any $d \geq 3$, there exists $C < \infty$ such that

$$\text{cap}(\Box) \leq \frac{C R^{d-2}}{\log R}, \quad R \geq 2, \quad (\text{cf. } [9, \text{Lemma 3.2}]). \tag{5.13}$$

Indeed, by (5.13), (2.2), (2.1) and the Harnack principle, the first sum is bounded from above by $C \frac{M}{\log R}$. By the Markov inequality, (2.1) and the Harnack principle, the second sum is bounded from above by $CM^2R^{2-d}$. Thus, if $R \geq R_0 = R_0(K)$, then (5.11) holds.

It remains to show that for $\alpha \leq \alpha_0 = \alpha_0(K, R)$, (5.10) holds, but this is immediate, since by properties of $\mathcal{L}^\alpha$, the probability in (5.10) is bounded from above by $CR^d \alpha$. \hfill $\square$

**Proof of Proposition 5.4.** First note that it suffices to prove that for some $R \geq 1$, $l \geq 1$ and $\alpha > 0$,

$$\Pr \left[ B(0, L_n) \text{ is } \ast\text{-connected to } \partial_{\text{int}} B(0, 2L_n) \text{ in } B(\mathcal{N}^{\alpha}) \right] \leq 2^{-2^n} \tag{5.14}$$

for all $n \geq 1$. Indeed, let $N \geq 1$ and choose $n$ so that $2L_n \leq L_0 N \leq 2L_{n+1}$. Then, the event in (5.1) implies the event in (5.14) and $N \leq \frac{2L_{n+1}}{L_0} = 2^{n+1} \leq 2^{Cn}$ for some $C = C(l)$. 

23
Claim (5.14) easily follows from Lemma 5.9 and the observation that the event in (5.14) implies the existence of an embedding $T \in \Lambda_n$ such that the images of all leaves $T(n)$ are $R$-bad for $N^\alpha$ (see, e.g., [32, (3.24)] or [24, Lemma 3.3]). Namely,

$$\mathbb{P}[B(0, L_n) \text{ is } \star\text{-connected to } \partial_{\text{int}} B(0, 2L_n) \text{ in } B(N^\alpha)]$$

$$\leq \mathbb{P} \left[ \text{there exists } T \in \Lambda_n \text{ such that } T(T(n)) \subset B(N^\alpha) \right]$$

$$\leq \left( (2d)^2 (4l)^{2(d-1)} \right)^{2^n-1} \sup_{T \in \Lambda_n} \mathbb{P} \left[ T(T(n)) \subset B(N^\alpha) \right].$$

Let $l \geq C_{5.8}$ and choose $K = K(l)$ so that

$$\left( (2d)^2 (4l)^{2(d-1)} \right)^{2^n-1} \exp \left( -K2^n \right) \leq 2^{-2n}.$$

Finally, choose $R = R_0(K)$ and $\alpha = \alpha_0(R, K) > 0$ as in Lemma 5.9. Then, by Lemma 5.9,

$$\sup_{T \in \Lambda_n} \mathbb{P} \left[ T(T(n)) \subset B(N^\alpha) \right] \leq \exp \left( -K2^n \right),$$

and (5.14) follows for this choice of $l$, $R$ and $\alpha$. 

5.2 Proof of Lemma 5.6

Let $x' \in G_0$ and $y \in \partial_{\text{ext}} Q(x')$. Define

$$A = \partial_{\text{int}} Q(x'), \quad B = \partial_{\text{ext}} Q(x'),$$

and recall from (3.2) the definition of Poisson point processes $\mathcal{E}_{A,B}^{\alpha,j}$, $\mathcal{E}_{A,B}^{\alpha,j}$, and $\mathcal{E}_{A,B}^{\alpha,j}$, $j \geq 1$, of pairs of loop entrance points in $A$ and $B$, inner and outer bridges, respectively. Define sigma-algebras

$$\mathcal{E} = \sigma \left( \mathcal{E}_{A,B}^{\alpha,j}, j \geq 1 \right), \quad \mathcal{E} = \sigma \left( \mathcal{E}_{A,B}^{\alpha,j}, j \geq 1 \right), \quad \mathcal{E} = \sigma \left( \mathcal{E}_{A,B}^{\alpha,j}, j \geq 1 \right),$$

and the sigma-algebra $\mathcal{F}_{\text{ext}}$ generated by the loops from $\mathcal{L}^\alpha$ that do not intersect $Q(x')$.

Let $x$ be the unique neighbor of $y$ in $\partial_{\text{int}} Q(x')$ and consider the event $D$ that $x$ is connected to $\square(x')$ in $V^\alpha \cap Q(x')$. Then,

$$\{ y \text{ is connected to } \square(x') \text{ in } V^\alpha \cap \{y\} \cup Q(x') \} = D \cap \{ y \in V^\alpha \}.$$ 

Finally, let $\mathcal{E}(\tilde{x}, \tilde{y})$ be the event that none of the loop excursions from $A$ to $B$ starts at $x$ and none of them ends at $y$, namely, for all the pairs of points in $\mathcal{E}_{A,B}^{\alpha,j}$, $j \geq 1$, the first point is not $x$ and the second is not $y$. Note that $\{ y \in V^\alpha \} \subseteq \mathcal{E}(\tilde{x}, \tilde{y})$.

To prove (5.5) it suffices to show that

$$\mathbb{P} \left[ D \left| \mathcal{E} \left( 1_{x' \in G(N^\alpha)}, \mathcal{F}_{\text{ext}} \right) \geq \gamma 1_{\mathcal{E}(\tilde{x}, \tilde{y}), x' \in G(N^\alpha)}, \mathbb{P} \right.-\text{a.s.} \right. \right. \tag{5.15}$$

24
Indeed,

\[ \mathbb{P} \left[ y \text{ is connected to } \square(x') \text{ in } \mathcal{V}^\alpha \cap \{y\} \cup Q(x') \right], x' \in G(\mathcal{N}^\alpha) \mid \Sigma_{\overline{G}}, A_{x'} \]

\[ = \mathbb{P} \left[ D, y \in \mathcal{V}^\alpha, x' \in G(\mathcal{N}^\alpha) \mid \Sigma_{\overline{G}}, A_{x'} \right] \]

\[ = \mathbb{E} \left[ \mathbb{P} \left[ D, y \in \mathcal{V}^\alpha, x' \in G(\mathcal{N}^\alpha) \mid \sigma(1_{x' \in G(\mathcal{N}^\alpha)}), \overline{E}, \mathcal{F}_{\text{ext}} \right] \mid \Sigma_{\overline{G}}, A_{x'} \right] \]

\[ = 1_{y \in \mathcal{V}^\alpha, x' \in G(\mathcal{N}^\alpha)} \mathbb{E} \left[ \mathbb{P} \left[ D \mid \sigma(1_{x' \in G(\mathcal{N}^\alpha)}), \overline{E}, \mathcal{F}_{\text{ext}} \right] \right] \mid \Sigma_{\overline{G}}, A_{x'} \]

\[ \geq \gamma 1_{y \in \mathcal{V}^\alpha, x' \in G(\mathcal{N}^\alpha)} \mathbb{E} \left[ 1_{\mathcal{E}(\bar{x}, \bar{y}), x' \in G(\mathcal{N}^\alpha)} \mid \Sigma_{\overline{G}}, A_{x'} \right] \]

which gives (5.5).

By the definition of Poisson point process, the sigma-algebras \( \mathcal{F}_{\text{ext}} \) and \( \sigma(\mathcal{E}, \overline{\mathcal{E}}_1, \overline{\mathcal{E}}_2) \) are independent. Furthermore, by Proposition 3.4, the sigma-algebras \( \overline{\mathcal{E}}_1 \) and \( \overline{\mathcal{E}}_2 \) are conditionally independent given \( \mathcal{E} \). Thus,

\[ \mathbb{P} \left[ D \left| \sigma(1_{x' \in G(\mathcal{N}^\alpha)}), \overline{E}, \mathcal{F}_{\text{ext}} \right. \right] = \mathbb{P} \left[ D \left| \sigma(1_{x' \in G(\mathcal{N}^\alpha)}), \mathcal{E} \right. \right], \quad \text{P.a.s.} \quad (5.16) \]

Indeed, by Dynkin’s \( \pi-\lambda \) lemma, it suffices to show that for any admissible \( e \), \( \overline{\mathcal{E}}_1 \), and \( F \in \mathcal{F}_{\text{ext}} \),

\[ \mathbb{P} \left[ D, x' \in G(\mathcal{N}^\alpha), \mathcal{E}_{A,B}^{\alpha,j} \geq 1, e \right] \]

\[ = \mathbb{E} \left[ x' \in G(\mathcal{N}^\alpha), \mathcal{E}_{A,B}^{\alpha,j} \geq 1, e \mid \overline{\mathcal{E}}_1 = e, F, \mathbb{P} \left[ D \mid \sigma(1_{x' \in G(\mathcal{N}^\alpha)}), \mathcal{E} \right] \right], \]

which is immediate, since by the (conditional) independence of sigma-algebras,

\[ \mathbb{P} \left[ D, x' \in G(\mathcal{N}^\alpha), \mathcal{E}_{A,B}^{\alpha,j} \geq 1, e \right] \]

\[ = \mathbb{P} \left[ D, x' \in G(\mathcal{N}^\alpha), \mathcal{E}_{A,B}^{\alpha,j} \geq 1, e \right] \mathbb{P} \left[ \{ \overline{\mathcal{E}}_{A,B}^{\alpha,j} \geq 1 \mid \overline{\mathcal{E}}_1 = e, F \right] \{ \mathcal{E}_{A,B}^{\alpha,j} \geq 1 \mid e \}

\[ = \mathbb{E} \left[ x' \in G(\mathcal{N}^\alpha), \mathcal{E}_{A,B}^{\alpha,j} \geq 1, e \mid \overline{\mathcal{E}}_1 = e, F, \mathbb{P} \left[ D \mid \sigma(1_{x' \in G(\mathcal{N}^\alpha)}), \mathcal{E} \right] \right], \]

for all compatible \( e \) and \( \overline{\mathcal{E}}_1 \).

Thus, by (5.15) and (5.16), it suffices to prove that

\[ \mathbb{P} \left[ D \left| \sigma(1_{x' \in G(\mathcal{N}^\alpha)}), \mathcal{E} \right. \right] \geq \gamma 1_{\mathcal{E}(\bar{x}, \bar{y}), x' \in G(\mathcal{N}^\alpha)} \], \quad \text{P.a.s.,} \]

in other words, that for all \( e \) such that \( \{ \mathcal{E}_{A,B}^{\alpha,j} \geq 1 \} \subset \mathcal{E}(\bar{x}, \bar{y}) \),

\[ \mathbb{P} \left[ D, x' \in G(\mathcal{N}^\alpha), \mathcal{E}_{A,B}^{\alpha,j} \geq 1 \right] \geq \gamma \mathbb{P} \left[ x' \in G(\mathcal{N}^\alpha), \mathcal{E}_{A,B}^{\alpha,j} \geq 1 \right]. \quad (5.17) \]
In particular, we may and will assume from now on that
\[ x \notin \square(x'), \]
since otherwise the claim is trivial.

In fact, we will show a stronger statement. Let \( F_{\text{int},\emptyset} \) be the event that the set of loops from \( \mathcal{L}^\alpha \) contained in \( Q(x') \) is empty, then
\[
\Pr\left[ D, x' \in G(\mathcal{N}^\alpha), \{\mathcal{E}^\alpha_{A,B}\}_{j \geq 1} = e, F_{\text{int},\emptyset}\right] \geq \gamma \Pr\left[ \{\mathcal{E}^\alpha_{A,B}\}_{j \geq 1} = e \right] \tag{5.18}
\]
for all \( e \) as in (5.17) and satisfying additionally \( \{\mathcal{E}^\alpha_{A,B}\}_{j \geq 1} = e \cap \{x' \in G(\mathcal{N}^\alpha)\} \neq \emptyset \). (This basically means that none of the loop excursions can start from \( \square(x') \) or end in a neighbor of \( \square(x') \) and that the total number of excursions does not exceed \( \frac{1}{2} R^{d-1} \), cf. Definition 5.2.)

Let \( \mathcal{N}^\alpha \) be the field of cumulative occupation local times in \( Q(x') \) of all the excursions from \( \{\mathcal{E}^\alpha_{A,B}\}_{j \geq 1} \), that is, for \( z \in Q(x') \), \( \mathcal{N}^\alpha(z) \) is the total number of times \( z \) is visited by the bridges \( \{\mathcal{E}^\alpha_{A,B}\}_{j \geq 1} \). Also, let \( \mathcal{V}^\alpha = \{z \in Q(x') : \mathcal{N}^\alpha(z) = 0\} \). Note that
\[
\{D, x' \in G(\mathcal{N}^\alpha), F_{\text{int},\emptyset}\} = \{x \text{ is connected to } \square(x') \text{ in } \mathcal{V}^\alpha, x' \in G(\mathcal{N}^\alpha)\} \cap F_{\text{int},\emptyset},
\]
and the two events on the right are independent. Since the number of loops from \( \mathcal{L}^\alpha \) contained in \( Q(x') \) is a Poisson random variable with parameter \( \alpha c \), for \( c = c(R) \),
\[
\Pr[F_{\text{int},\emptyset}] = e^{-\alpha c} \geq e^{-\alpha c} > 0,
\]
and to finish the proof of (5.18) it suffices to show that for all \( e \) as before and some \( \gamma_1 = \gamma_1(d, R) > 0 \),
\[
\Pr\left[ x \text{ is connected to } \square(x') \text{ in } \mathcal{V}^\alpha, x' \in G(\mathcal{N}^\alpha), \{\mathcal{E}^\alpha_{A,B}\}_{j \geq 1} = e \right] \geq \gamma_1 \Pr\left[ \{\mathcal{E}^\alpha_{A,B}\}_{j \geq 1} = e \right],
\]
or, equivalently, that
\[
\Pr\left[ x \text{ is connected to } \square(x') \text{ in } \mathcal{V}^\alpha, x' \in G(\mathcal{N}^\alpha), \{\mathcal{E}^\alpha_{A,B}\}_{j \geq 1} = e \right] \geq \gamma_1. \tag{5.19}
\]
Let \( e = \{(x_i, y_i) \in A \times B, 1 \leq i \leq N\} \) be a multiset of all starting and ending locations of all the excursions of loops from \( \mathcal{L}^\alpha \) from \( A \) to \( B \), which satisfies all the above assumptions on \( e \). By Proposition 3.4, the law of the excursions \( \{\mathcal{E}^\alpha_{A,B}\}_{j \geq 1} \), conditioned on \( \{\mathcal{E}^\alpha_{A,B}\}_{j \geq 1} = e \), is the law of independent random walk bridges from \( x_i \) conditioned to enter \( B \) in \( y_i \), that is \( \bigotimes_{i=1}^{N} P_{x_i,y_i}^B \).

Let \( \{X_i\}_{i=1}^{N} \) be a family of independent random walk bridges distributed according to \( \bigotimes_{i=1}^{N} P_{x_i,y_i}^B \). Let \( \mathcal{N} \) be the field of cumulative occupation local times in \( Q(x') \) of all the bridges \( X_i \), that is, for \( z \in Q(x') \), \( \mathcal{N}(z) \) is the total number of times \( z \) is visited by the bridges \( X_i \). Also, let \( \mathcal{V} = \{z \in Q(x') : \mathcal{N}(z) = 0\} \). Then, (5.19) is equivalent to
\[
\bigotimes_{i=1}^{N} P_{x_i,y_i}^B \left[ x \text{ is connected to } \square(x') \text{ in } \mathcal{V}, x' \in G(\mathcal{N}) \right] \geq \gamma_1. \tag{5.20}
\]
for any choice of \{(x_i, y_i) \in A \times B, 1 \leq i \leq N\} such that \(N \leq \frac{1}{2}R^{d-1}\) and for all \(i, x_i \not\in \{x\} \cup \Box(x')\) and \(y_i \not\in \{y\} \cup \partial \Box(x')\).

We prove that there exist \(N\) simple (deterministic) paths \(\rho_i\) from \(x_i\) to \(y_i\), such that

\[(a) \bigotimes_{i=1}^{N} P^{B}_{x_i, y_i} \left[ X_i = \rho_i, 1 \leq i \leq N \right] \geq \gamma_1 \text{ and } \\
(b) \text{ event } \{X_i = \rho_i, 1 \leq i \leq N\} \text{ implies the event inside probability in (5.20)}. \tag{5.21}\]

Once the existence of such paths \(\rho_i\) is shown, (5.20) is immediate.

Recall that we assume \(x \not\in \Box(x')\). Thus, precisely one of the coordinates, say coordinate \(i\), of the vector \(x - x'\) equals \(-R\) or \(R\), and the other coordinates take values between \(-R + 3\) and \(R - 3\). Let \(j\) be the first coordinate which is not equal to \(i\) and denote by \(e_s\) the \(s\)th coordinate unit vector. We define the set \(\Pi\) in \(Q(x')\) as

\[
\begin{align*}
\{x, x + e_i, x + 2e_i\} &\cup (\{x + 2e_i + te_j : t \geq 0\} \cap Q(x')) \\
\{x, x - e_i, x - 2e_i\} &\cup (\{x - 2e_i + te_j : t \geq 0\} \cap Q(x'))
\end{align*}
\]

if the \(i\)th coordinate of \(x - x'\) equals \(-R\), and as

\[
\begin{align*}
\{x, x + e_i, x + 2e_i\} &\cup (\{x + 2e_i + te_j : t \geq 0\} \cap Q(x')) \\
\{x, x - e_i, x - 2e_i\} &\cup (\{x - 2e_i + te_j : t \geq 0\} \cap Q(x'))
\end{align*}
\]

if the \(i\)th coordinate of \(x - x'\) equals \(R\), see Figure 5. Note that for \(R \geq 4\),

- \(\Pi \cap \Box(x') \neq \emptyset\),
- \(Q = Q(x') \setminus (\partial_{\text{int}} Q(x') \cup \Box(x') \cup \Pi)\) is a connected subset of \(Q(x')\),
- every \(z \in \partial_{\text{int}} Q(x') \setminus (\Box(x') \cup \{x\})\) has a neighbor in \(\overline{Q}\).

Coming back to the random walk bridges, for each \(x_i\) and \(y_i\), let \(\overline{x}_i\) be the unique neighbor of \(x_i\) in \(\overline{Q}\) (note that \(x_i \in \partial_{\text{int}} Q(x') \setminus (\Box(x') \cup \{x\})\) by assumptions), \(y'_i\) the unique neighbor of

\[27\]
of \( y_i \) in \( Q(x') \) (note that \( y_i' \in \partial_{\text{int}} Q(x') \setminus (\square(x') \cup \{x\}) \)) and \( \overline{y}_i \), the unique neighbor of \( y_i' \) in \( \overline{Q} \). Let \( \overline{p}_i \) be an arbitrary simple path from \( \overline{x}_i \) to \( \overline{y}_i \) in \( \overline{Q} \), see Figure 5.

We define \( \rho_i \) as the path \( (x_i, \overline{p}_i, y_i', y_i) \). Then, each \( \rho_i \) is a simple path from \( x_i \) to \( y_i \) that avoids \( \Pi \), visits \( \partial \rho \) exactly twice and stops on entering \( B \) (at \( y_i \)). Thus,

- for each \( i \), \( P^B_{x_i,y_i} [X_i = \rho_i] \geq (2d)^{-|\rho_i|} \geq (2d)^{-|Q(x')|} = c(d,R) \) and
- the total number of visits of all \( \rho_i \) to \( \partial_{\text{int}} Q(x') \) is not bigger than \( R^{d-1} \).

In other words, the collection of paths \( \rho_i \) satisfies the desired properties (5.21).

This way, the proof of (5.20) (hence of Lemma 5.6) is complete. \( \square \)

6 General approach to correlated percolation models

For \( d \geq 2 \), let \( \Omega = \{0,1\}^{Z^d} \) and \( S = S(\omega) = \{x \in Z^d : \omega(x) = 1\} \) the subgraph of \( Z^d \)
induced by \( \omega \in \Omega \). Let \( \mathcal{F} \) be the sigma-algebra on \( \Omega \) generated by the coordinate maps \( \Psi_x, x \in Z^d \), and let \( \mathbb{P}^u, u \in (a,b) \), be a family of probability measures on \( (\Omega, \mathcal{F}) \), for some (fixed) \( 0 < a < b < \infty \).

Under general assumptions on the family \( \{\mathbb{P}^u\}_{u \in (a,b)} \) introduced in [8] it has been proven that for each \( u \in (a,b) \), the random set \( S \) contains a unique infinite connected component \( S_\infty \), which on large scales “looks like \( Z^d \)”, for instance, for \( \mathbb{P}^u \)-almost every \( \omega \in \Omega \), balls in \( S_\infty \) have asymptotic deterministic shape [8], the simple random walk on \( S_\infty \) converges to a Brownian motion with a deterministic positive diffusion constant [23], its transition probabilities satisfy quenched Gaussian heat kernel bounds and the local CLT, etc. [27].

These assumptions on \( \{\mathbb{P}^u\}_{u \in (a,b)} \) are the following.

P1 (Ergodicity) For each \( u \in (a,b) \), every lattice shift is measure preserving and ergodic on \( (\Omega, \mathcal{F}, \mathbb{P}^u) \).

P2 (Monotonicity) For any \( a < u < u' < b \) and increasing event \( G \in \mathcal{F} \), \( \mathbb{P}^u[G] \leq \mathbb{P}^{u'}[G] \).

P3 (Decoupling) There exist \( R_\nu, L_\nu < \infty \) and \( \varepsilon_\nu, \chi_\nu > 0 \) such that for any integers \( L \geq L_\nu \) and \( R \geq R_\nu \), if \( a < \hat{u} < u < b \) satisfy \( u \geq (1 + R^{-\nu}) \hat{u} \), \( x_1, x_2 \in Z^d \) satisfy \( \|x_1 - x_2\| \geq RL \), \( A_1, A_2 \in \sigma(\Psi_y, y \in B(x_i, 10L)) \) are increasing events and \( B_1, B_2 \in \sigma(\Psi_y, y \in B(x_i, 10L)) \) are decreasing, then

\[
\mathbb{P}^u [A_1 \cap A_2] \leq \mathbb{P}^u [A_1] \cdot \mathbb{P}^u [A_2] + \exp \left( -e^{(\log L)^{\nu}} \right),
\]

and

\[
\mathbb{P}^u [B_1 \cap B_2] \leq \mathbb{P}^u [B_1] \cdot \mathbb{P}^u [B_2] + \exp \left( -e^{(\log L)^{\nu}} \right).
\]

S1 (Local uniqueness) For each \( u \in (a,b) \), there exist \( \Delta_\delta > 0 \) and \( R_\delta < \infty \) so that for all \( R \geq R_\delta \),

\[
\mathbb{P}^u [S_\infty \cap B(0, R) \neq \emptyset] \geq 1 - \exp \left( -(\log R)^{1+\Delta_\delta} \right),
\]

and

\[
\mathbb{P}^u \left[ \text{any two connected subsets of } S \cap B(0, R) \text{ with diameter } \geq \frac{R}{10} \text{ are connected in } S \cap B(0, 2R) \right] \geq 1 - \exp \left( -(\log R)^{1+\Delta_\delta} \right).
\]
While properties $P_1$ and $S_1$ are rather natural and have been extensively used in the analysis of supercritical percolation models, conditions $P_2$, $P_3$ and $S_2$ represent the novelty of this framework and serve as a substitute to independence. (In fact, $P_2$ easily follows from $P_3$ and is stated separately only for convenience.) They provide a connection between the measures $P^u$ with different values of the parameter and serve only to prove the likeliness of certain patterns in $S_\infty$, cf. [27, Remark 1.9(1)]. More precisely, if an increasing, resp. decreasing, (seed) event is unlikely with respect to measure $P^u$, then by applying $P_3$ recursively, one concludes that a family of $2^n$ translates of the event sufficiently spread out on $\mathbb{Z}^d$ in a certain hierarchical manner (cascading events) occur with probability $\leq 2^{-2^n}$ with respect to $\mathbb{F}^u$, cf. [8, Theorem 4.1]. Then, one uses $S_2$ to show that the probabilities of suitable seed events (cf. [8, Section 5]) with respect to measures $P^{u+\delta}$, resp. $P^{u-\delta}$, and $P^u$ are close for small enough $\delta$, cf. [8, Lemmas 5.2 and 5.4]. In other words, one starts with a suitable increasing, resp. decreasing, seed event unlikely with respect to $P^u$, concludes that it is also unlikely with respect to $P^{u+\delta}$, resp. $P^{u-\delta}$, for small $\delta > 0$, and obtains that sufficiently spread out translates of the seed event are unlikely with respect to $P^u$, but now with an explicit bound on the probability. All the other arguments in [8], as well as in [23, 27], do not require comparison of probability laws with different parameters and go through for each fixed $u$ if $P^u$ satisfies $P_1$ and $S_1$.

In this section we prove in Theorem 6.2 that the result of [8, Theorem 4.1] holds for families of probability measures $P^u$ that satisfy condition $D$, which is weaker than $P_3$. As $P_3$ is only used in [8, 23, 27] to derive [8, Theorem 4.1], all the results about geometric properties of $S_\infty$ proved in [8, 23, 27] hold for families of probability measures $P^u$ that satisfy $P_1$, $P_2$, $D$, $S_1$, $S_2$, see Corollary 6.3. This weakening is crucial in the study of the vacant set of the random walk loop soup, since it does not satisfy $P_3$, as shown by Chang [6], but it does satisfy $D$, as we prove in this paper.

The family of probability measures $P^u$, $u \in (a, b)$, satisfies condition $D$ if

$D$ There exist constants $C, c$ and $\beta, \gamma, \chi, \zeta > 0$ such that $\xi := \gamma - \beta \chi > 0$ and for all $L, s \geq 1$, $x_1, x_2 \in \mathbb{R}^d$ with $\|x_1 - x_2\| = sL$ and $u, u' \in (a, b)$ with $u' - u \geq s^{-\chi}$,

(a) if $A_i \in \sigma(\Psi_y : y \in B(x_i, L))$ are increasing events, then

$$P^u[A_1 \cap A_2] \leq P^{u'}[A_1] P^{u'}[A_2] + C \exp \left(-c \min \left\{(u' - u)\beta s^\gamma, e^{(\log L)^{\chi}}\right\}\right), \quad (6.1)$$

(b) if $B_i \in \sigma(\Psi_y : y \in B(x_i, L))$ are decreasing events, then

$$P^{u'}[B_1 \cap B_2] \leq P^u[B_1] P^u[B_2] + C \exp \left(-c \min \left\{(u' - u)\beta s^\gamma, e^{(\log L)^{\chi}}\right\}\right). \quad (6.2)$$

Let us emphasize that condition $D$ is not only weaker than $P_3$, but also more natural, since it postulates decorrelation of local events occurring in large boxes only when the boxes are far apart.
Remark 6.1. It is easy to see that the measures $P_u$ that satisfy $D(a)$ or $D(b)$ are stochastically monotone, i.e., satisfy $P_2$. The condition is particularly interesting for $\zeta \in (0, 1)$, since in this case $e^{(\log L)^\zeta} = o(L^p)$ for any $p > 0$. Furthermore, if $\zeta > \frac{1}{2}$, then the error term in (6.1) and (6.2) can be replaced by $C \exp \left( -c \min \left\{ (u' - u)^\beta \sigma^\gamma, (u' - u)^\rho e^{(\log L)^\zeta} \right\} \right)$ with an arbitrary $\rho > 0$ (see Remark 6.5).

6.1 Cascading events

Let $l_k, r_k, L_k, k \geq 0$ be sequences of positive integers such that

$$L_k = l_{k-1} \cdot L_{k-1}, \quad k \geq 1.$$ 

Consider renormalized lattices

$$G_k = L_k \mathbb{Z}^d = \{L_k x : x \in \mathbb{Z}^d\}, \quad k \geq 0,$$

and define

$$\Lambda_{x,k} = G_k = \{x : x \in \mathbb{Z}^d\}, \quad k \geq 1, x \in G_k.$$ (6.3)

(Note that $|\Lambda_{x,k}| = (l_{k-1})^d$.)

For $L_0 \geq 1$ and $x \in G_0$, any event $\overline{G}_x = \overline{G}_{x,0} \in \sigma(\Psi_y, y \in x + [-L_0, 3L_0]^d)$ is called a seed event. (For simplicity, we omit from notation the dependence of seed events on $L_0$.) The family of seed events $(\overline{G}_x : L_0 \geq 1, x \in G_0)$ is denoted by $\overline{G}$.

For $k \geq 1$ and $x \in G_k$, we recursively define the events

$$\overline{G}_{x,k} = \bigcup_{x_1, x_2 \in \Lambda_{x,k} \cap (x + [0, L_k]^d)} \overline{G}_{x_1,k-1} \cap \overline{G}_{x_2,k-1}.$$ (6.4)

The main result of this section is the following theorem, which states that the result of [8, Theorem 4.1] holds if the family of probability measures $P_u$ satisfies assumption $D$. Its proof is given in Section 6.2.

Theorem 6.2. Let $\theta > 1$ such that $(\theta + 1)\zeta > 1$ and consider the scales

$$l_0, r_0, L_0 \geq 1, \quad l_k = l_0 4^{[k^\theta]}, \quad r_k = r_0 2^{[k^\theta]}, \quad L_k = l_{k-1} L_{k-1}, \quad k \geq 1.$$ (6.5)

Let $P^u, u \in (a, b)$, be a family of probability measures on $(\Omega, \mathcal{F})$. Let $\overline{G}$ be a family of seed events such that for some $u' \in (a, b)$,

$$\liminf_{L_0 \to \infty} \sup_{x \in G_0} P^u \left[ \overline{G}_x \right] = 0.$$ (6.6)

(a) If all $\overline{G}_x$ are increasing and the family $P^u$ satisfies $D(a)$, then for any $u \in (a, u')$, there exists $C = C(u, u')$ such that for all $l_0 \geq 1$, $r_0 \geq C(1 + \log l_0)^\frac{1}{2}$ and some $L_0 \geq 1$,

$$\sup_{x \in G_k} P^u \left[ \overline{G}_{x,k} \right] \leq 2^{-2k}, \quad k \geq 0.$$ (6.7)
(b) If all $\mathcal{G}_x$ are decreasing and the family $\mathbb{P}^u$ satisfies $D(b)$, then for any $u \in (u', b)$, there exists $C = C(u, u')$ such that for all $l_0 \geq 1$, $r_0 \geq C(1 + \log l_0)^{\frac{1}{2}}$ and some $L_0 \geq 1$, (6.7) holds.

Furthermore, if the limit (as $L_0 \to \infty$) in (6.6) exists (and equals 0), then there exists $C'(u, u', l_0, G)$ such that the statements (a) and (b) hold for all $L_0 \geq C'$.

To study geometric properties of the unique infinite percolation cluster $S_\infty$ as in [8, 23, 27], one needs to impose further conditions on the scales $l_k, r_k$, namely, that for all $k \geq 0$, $r_k$ divides $l_k$, $l_k > 16r_k$ and $\sum_{k=0}^{\infty} \frac{l_k}{l_k}$ is sufficiently small, see, e.g., below [27, (37)]. This can be easily achieved, for instance, by taking in (6.5) $l_0 = r_0^2$ and $r_0$ large enough. We briefly summarize the main consequences of Theorem 6.2:

**Corollary 6.3.** Assume that a family of probability measures $\mathbb{P}^u$, $u \in (a, b)$, satisfies assumptions $P_1, P_2, D, S_1, S_2$. Then all the results on geometry of $S_\infty$ from [8, 23, 27] hold for all $u \in (a, b)$, more precisely,

- Theorems 2.3 (chemical distances) and 2.5 (shape theorem) in [8],
- Theorem 1.1 in [23] (quenched invariance principle),
- Theorem 1.13 (Barlow’s ball regularity), Corollary 1.14 (quenched Gaussian heat kernel bounds, elliptic and parabolic Harnack inequalities), Theorem 1.19 (quenched local CLT), as well as Theorems 1.16–1.18, 1.20 in [27].

We refer the reader to the introduction of [27] for the precise statements of these results and relevant discussion.

**Remark 6.4.** Theorem 1.1 implies that $\mathcal{V}^\alpha$, the vacant set of random walk loop soup, satisfies condition $D$ for all $\alpha > 0$. Theorem 1.2 proves that $\mathcal{V}^\alpha$ satisfies condition $S_1$ for small enough positive $\alpha$. (It is believed that $S_1$ holds for all $\alpha < \alpha^*$, see text below Theorem 1.3.) Condition $P_1$ holds for $\mathcal{V}^\alpha$ due to [7, Proposition 3.2]. Condition $P_2$ follows from $D$, but also directly follows from the definition of $\mathcal{V}^\alpha$. Condition $S_2$ holds for $\mathcal{V}^\alpha$ for all $\alpha < \alpha^*$ by standard arguments of van den Berg and Keane [2] — the probability that 0 is in an infinite cluster of $\mathcal{V}^\alpha$ is left-continuous for all $\alpha$, since it can be expressed as a decreasing limit of non-increasing continuous functions, and it is right-continuous for all $\alpha < \alpha^*$, by the uniqueness of the infinite cluster of $\mathcal{V}^\alpha$, see also [34, Corollary 1.2], where the argument of van den Berg and Keane is adapted to the vacant set of random interlacements. (Although the infinite cluster of $\mathcal{V}^\alpha$ is unique for all $\alpha < \alpha^*$ by an adaptation of the classical Burton-Keane argument, see Remark 3.5, the uniqueness is immediate for $\alpha$ that satisfy $S_1$ by the Borel-Cantelli lemma.) Thus, the conclusions of Corollary 6.3 hold for $\mathcal{V}^\alpha$, which is the statement of Theorem 1.3.

### 6.2 Proof of Theorem 6.2

The proofs of (a) and (b) are essentially the same, we only prove (a).

Let $\mathcal{G}_x, x \in \mathcal{G}_0$ be increasing events and the family $\mathbb{P}^u$ satisfy $D(a)$. We assume further that for some $u' \in (a, b)$,

$$
\lim_{L_0 \to \infty} \sup_{x \in \mathcal{G}_0} \mathbb{P}^{u'}[\mathcal{G}_x] = 0 \quad (6.8)
$$
and prove that for any \( u \in (a, u') \), there exist \( C = C(u, u') \) and \( C' = C'(u, u', l_0, \mathcal{G}) \), such that (6.7) holds for all \( l_0 \geq 1 \), \( r_0 \geq C(1 + \log l_0)^\delta \) and \( L_0 \geq C' \). It will be seen from the proof how (a) follows if (6.8) is replaced by (6.6), see the note below (6.13).

Let \( u \in (a, u') \). Fix \( \chi, \beta, \gamma \) for which \( D(a) \) holds and recall that \( \xi = \gamma - \beta \chi > 0 \). By the choice of \( r_k \) in (6.5), there exists \( C_1 = C_1(u, u') \) such that for all \( r_0 \geq C_1 \),

\[
\sum_{k=0}^{\infty} r_k^{-\chi} u_1 \leq u' - u. \tag{6.9}
\]

Let

\[
u_0 = u', \quad \nu_{k+1} = \nu_k - r_k^{-\chi}, \quad k \geq 0. \tag{6.10}
\]

By (6.9), \( \nu_k \geq u \) for all \( k \geq 0 \).

Consider the sequence

\[
\Delta_0 = 1 + \sum_{i=0}^{\infty} \frac{\log_2(2t^{2d}_{i+k})}{2^{i+1}}, \quad \Delta_{k+1} = \Delta_k - \frac{\log_2(2t^{2d}_{k+1})}{2^{k+1}}, \quad k \geq 0. \tag{6.11}
\]

Note that \( \Delta_k \geq 1 \) for all \( k \geq 0 \). Since the events \( \overline{G}_{x, k}, x \in \mathcal{G}_k, \) are increasing, the events \( \overline{G}_{x,k}, x \in \mathcal{G}_k, \) are also increasing for all \( k \geq 0 \). Thus, to prove (6.7) it suffices to show that

\[
\sup_{x \in \mathcal{G}_k} \mathbb{P}^{\nu_k}[\overline{G}_{x,k}] \leq 2^{-\Delta_k 2^k}, \quad k \geq 0. \tag{6.12}
\]

We prove (6.12) by induction on \( k \).

*Base of induction:* By the definition of \( l_k \) in (6.5), \( \Delta_0 = \Delta_0(l_0) \). Thus, if (6.8) holds, then for any \( l_0 \), there exists \( C_1' = C_1'(u, u', l_0, \mathcal{G}) \) such that

\[
\sup_{x \in \mathcal{G}_0} \mathbb{P}^{\nu_0}[\overline{G}_{x,0}] \leq 2^{-\Delta_0} \tag{6.13}
\]

holds for all \( L_0 \geq C_1' \). (If only the weaker (6.6) is assumed, then the existence of (arbitrarily large) \( L_0 \) for which (6.13) holds follows.)

*Induction step:* Assume that (6.12) holds for some \( k \geq 0 \) and prove that it also holds for \( k + 1 \). Here we will use the definition of events \( \overline{G}_{x,k+1} \) and the assumption \( D(a) \). Recall that for all \( x \in \mathcal{G}_0, \overline{G}_x \in \sigma(\Psi_y, y \in x + [-L_0, 3L_0]^d) \). Thus, by (6.4), for all \( x \in \mathcal{G}_k, \overline{G}_{x,k} \in \sigma(\Psi_y, y \in x + [-L_0, L_k + 2L_0]^d) \); furthermore, events \( \overline{G}_{x,k} \) are increasing. Hence, for each \( x \in \mathcal{G}_{k+1}, \)

\[
\mathbb{P}^{\nu_{k+1}}[\overline{G}_{x,k+1}] \leq \sum_{x_1, x_2 \in \Lambda_{x,k+1} \setminus \{x_1 - x_2\}} \mathbb{P}^{\nu_{k+1}}[\overline{G}_{x_1,k} \cap \overline{G}_{x_2,k}] \tag{6.14}
\]

\[
\leq |\Lambda_{x,k+1}|^2 \left( \sup_{x \in \mathcal{G}_k} \mathbb{P}^{\nu_k}[\overline{G}_{x,k}] \right)^2 + C \exp \left( -c \min \left\{ r_k^{-\chi \beta} r_k^{\gamma}, e^{(\log L_k)^\delta} \right\} \right) \tag{6.15}
\]

\[
\leq r_k^{2d} \left( 2^{-\Delta_k 2^{k+1}} + C \exp \left( -c \min \left\{ r_k^{\xi}, e^{(\log L_k)^\delta} \right\} \right) \right). \tag{6.16}
\]
To bound (6.14) from above, note that for some $C$, if
\[
\min \left\{ r^\xi_k, e^{(\log L_k)^\zeta} \right\} \geq C \Delta_0 2^{k+1} \quad \left( \geq C \Delta_k 2^{k+1} \right),
\]
then (6.14) is bounded from above by
\[
2 l \Delta_k 2^{-\Delta_k 2^{k+1}} \overset{(6.11)}{=} 2^{-\Delta_{k+1} 2^{k+1}}.
\]

By the definition of $r_k$ in (6.5) and $\Delta_0$ in (6.11) and using that $\theta > 1$, the inequality $r^\xi_k \geq C \Delta_0 2^{k+1}$ holds for all $k \geq 0$ if for some $C_2$, $r_0^\xi \geq C_2 (1 + \log l_0)$. Also, by the definition of $L_k$ in (6.5) and this time using that $(\theta + 1) \zeta > 1$, the inequality $e^{(\log L_k)^\zeta} \geq C \Delta_0 2^{k+1}$ holds for all $k \geq 0$ if $L_0 \geq C'_2$ for some $C'_2 = C'_2(l_0)$.

Thus, we proved that there exist constants $C = C(u, u')$ and $C' = C'(u, u', l_0, G)$, such that (6.12) holds for all $l_0 \geq 1$, $r_0 \geq C(1 + \log l_0)^{\frac{1}{2}}$ and $L_0 \geq C'$. (If (6.6) is assumed instead of (6.8), then (6.12) holds for all $l_0 \geq 1$, $r_0 \geq C(1 + \log l_0)^{\frac{1}{2}}$ and any $L_0 \geq C'_2$ for which (6.13) holds.)

**Remark 6.5.** If $\zeta > \frac{1}{2}$, we can choose $\theta > 1$ in the statement of Theorem 6.2 such that $(\theta + 1)\zeta > \theta$. In this case, for any given $\rho > 0$, the inequality $r^\rho_k e^{(\log L_k)^\zeta} \geq C \Delta_0 2^{k+1}$ holds for all $k \geq 0$ if $r_0 \geq C$ and $L_0 \geq C'(l_0)$. From the estimate (6.15) it follows that for such choice of $\zeta$, $\theta$ and $\rho$, Theorem 6.2 holds even if the error terms in $D$ are replaced by
\[
C \exp \left( -c \min \left\{ (u' - u)^{s\gamma}, (u' - u)^{\rho} e^{(\log L_k)^\zeta} \right\} \right).
\]
