COHOMOLOGY OF LINE BUNDLES ON HOROSPHERICAL VARIETIES

NARASIMHA CHARY BONALA AND BENOÎT DEJONCHEERE

Abstract. A horospherical variety is a normal algebraic variety where a connected reductive algebraic group acts with an open orbit isomorphic to a torus bundle over a flag variety. In this article we study the cohomology of line bundles on complete horospherical varieties.

1. Introduction

Let $G$ be a connected reductive algebraic group over the field of complex numbers $\mathbb{C}$ and let $H$ be a closed subgroup of $G$. A homogeneous space $G/H$ is said to be horospherical if $H$ contains the unipotent radical of a Borel subgroup of $G$, or equivalently, $G/H$ is isomorphic to a torus bundle over a rational homogeneous variety $G/P$. A normal $G$-variety is called horospherical if it contains an open dense $G$-orbit isomorphic to a horospherical homogeneous space $G/H$. Toric varieties and flag varieties are horospherical varieties (see [Pas08] for more details). Horospherical varieties are a special class of spherical varieties. A spherical variety is a normal $G$-variety $X$ such that there exists $x \in X$ and a Borel subgroup $B$ of $G$ satisfying that the $B$-orbit of $x$ is open in $X$.

Let $\mathcal{L}$ be a $G$-line bundle on $X$. Assume that $X$ is projective, then the cohomology groups $H^i(X, \mathcal{L})$ are finite dimensional representations of $G$. If $X$ is a flag variety, then Borel-Weil-Bott theorem describe these cohomology groups. If $X$ is a toric variety, then the cohomology groups can be described using combinatorics of its associated fan (see [CLS11]). For spherical varieties, in [Bri94], Brion has given a bound on the multiplicities...
of these modules. In [Bri90], if \( X \) is complete spherical and \( L \) is generated by global sections, Brion proved that the cohomology groups \( H^i(X, L) \) for \( i > 0 \) vanish. In [Tch02], [Tch04], [Tch07] and [Tch10], Tchoudjem studied these cohomology groups in the case of \( X \) is a compactification of adjoint semisimple group, a wonderful compactification of a reductive group, a wonderful variety of minimal rank and a complete symmetric variety respectively. In this article we consider the cohomology of line bundles on complete horospherical varieties. We prove that the cohomology groups splits into cohomology of line bundles on flag varieties and toric varieties. Our main tool in this article is the machinery of Grothendieck-Cousin complexes (see [Kem78] for more details), and we also prove a Künneth-like formula for local cohomology.

To describe our results we need some notation: let \( X \) and \( Y \) be affine schemes. Let \( Z_1 \subseteq X \) and \( Z_2 \subseteq Y \) be two locally complete intersections subschemes, of respective codimensions \( l_1 \) and \( l_2 \). Let \( L_1 \) and \( L_2 \) be two invertible sheaves respectively on \( X \) and \( Y \). Let \( p_1 : X \times Y \to X \) and \( p_2 : X \times Y \to Y \) be the projections, and let \( L_i := p_i^* L_i \). Assume \( X \) and \( Y \) are irreducible and Cohen-Macaulay. Then we have the following isomorphism (See Theorem 3.5):

**Theorem.**

\[
H^{l_1 + l_2}_{Z_1 \times Z_2}(X \times Y, L_1 \otimes L_2) \cong H^{l_1}_{Z_1}(X, L_1) \otimes_k H^{l_2}_{Z_2}(Y, L_2).
\]

Let \( X \) be a complete horospherical variety. Then any Weil divisor \( D \) of \( X \) is linearly equivalent to a \( B \)-stable divisor, that is of the form

\[
D \approx \sum_{i=1}^{k} d_i X_i + \sum_{\alpha \in S} d_\alpha D_\alpha,
\]

where \( X_i \)’s are \( G \)-stable divisors, \( D_\alpha \)’s are \( B \)-stable divisors and \( S \) is the set of simple roots for \( G \) (for more details see Section 2). If further, assume that \( X \) toroidal, then \( D \approx L_1 \otimes L_2 \) where \( L_2 \) is the line bundle on \( X \) correspond to \( G \)-stable divisor (associated to toric fibre \( Y \)) and \( L_1 \) is the line bundle correspond to the \( B \)-stable divisor (associated to the base space \( G/P \)). Let \( T \) be a maximal torus of a Borel subgroup \( B \) and \( T' \) be the torus correspond the toric fibre (see Section 2 for more details). Let \( \mathfrak{g} \) be the Lie algebra of \( G \). Then we prove the following (See Corollary 6.2):

**Corollary.** There is an isomorphism of \( T \times T' \)-modules (hence of \( B \times T' \)-modules) and of \( \mathfrak{g} \)-modules

\[
H^n(X, L_1 \otimes L_2) = \bigoplus_{p+q=n} H^p(G/P, L_1) \otimes H^q(Y, L_2)
\]

The case of other projective horospherical varieties is straightforward: they all admit a \( G \)-equivariant resolution by a smooth projective toroidal horospherical variety.

This paper is organized as followed. Section 2 will be a remainder on horospherical varieties. Section 3 is devoted to proving Theorem 3.5. In Section 4, we shall introduce the Cousin complexes and show how to compute, under nice assumptions, the cohomology of line bundles on some locally trivial fibrations. The behaviour of the obtained isomorphisms with respect to actions of algebraic groups will be investigated in Section 5, and we shall prove Corollary 6.2 in Section 6. It should be noted that results of Sections 3 to 5 are characteristic free.
2. Preliminaries on horospherical varieties

In this section we recall some basic definition and properties of projective horospherical varieties. For more details we refer to [Pas08] and [Per14].

Let $G$ be a reductive algebraic group over the field of complex numbers. A $G$-variety is a reduced scheme of finite type over the field of complex numbers, with an algebraic action of $G$. Let $B$ be a Borel subgroup of $G$.

**Definition 2.1.** A spherical variety is a $G$-variety $X$ such that it has a dense open $B$-orbit.

These varieties have many interesting properties, for example, there are only finitely many $B$-orbits (see [Bri86]). We consider a special class of spherical varieties, called horospherical varieties.

**Definition 2.2.** Let $H$ be a closed subgroup of $G$. Then $H$ is said to be horospherical if it contains the unipotent radical of a Borel subgroup of $G$.

We also say that the homogeneous space $G/H$ is horospherical if $H$ is horospherical. Up to conjugation, we can assume that $H$ contains $U$, the maximal unipotent subgroup of $G$ contained in the Borel subgroup $B$. Let $P$ be the normalizer $N_G(H)$ of $H$ in $G$. It is a parabolic subgroup of $G$, and $T' := P/H$ is a torus. Then it is clear that $G/H$ is a torus bundle over the flag variety $G/P$ with fibers $P/H$.

**Definition 2.3.** Let $X$ be a $G$-spherical variety and let $H$ be the stabilizer of a point in the dense $G$-orbit in $X$. Then we say $X$ is horospherical if $H$ is horospherical subgroup of $G$.

A geometric equivalent definition can be given as follows (see for example, [Pas08]): Let $X$ be a $G$-variety. Then $X$ is horospherical if there exists a parabolic subgroup $P$ of $G$, and a toric $T'$-variety $Y$ such that there is a diagram of $G$-equivariant morphisms

$$
\begin{array}{ccc}
G \times^P Y & \longrightarrow & X \\
\downarrow^p & & \\
G/P & & 
\end{array}
$$

where $G \times^P Y := (G \times Y)/P$, the action of $P$ is given by $p \cdot (g, y) = (gp, p^{-1} \cdot y)$, $\pi$ is birational, and $p$ is a locally trivial fibration with fibers isomorphic to $Y$. The classification of horospherical varieties can be given by using colored fans, see [Pas08] for precise details.

2.1. Divisors of horospherical varieties. In this subsection we recall some properties of divisors of a spherical variety $X$. We start by the following result from [Bri89]:

**Proposition 2.4.** Any divisor of $X$ is linearly equivalent to a $B$ stable divisor.

Let $X$ be a horospherical variety. Now we consider the $B$-stable prime divisors of $X$. We denote by $X_1, X_2, \ldots, X_r$ the $G$-stable divisors of $X$. The other $B$-stable divisors (i.e. those are not $G$-stable) are the closures of $B$-stable divisors of $G/H$, which are called the colours of $G/H$. These are the inverse images of the torus fibration $G/H \longrightarrow G/P$ of
the Schubert divisors of the flag variety $G/P$. Now we recall what the Schubert divisors of $G/P$ are. Fix a maximal torus $T$ of $B$. Then we denote by $S$ the set of simple roots of $G$ with respect to $B$ and $T$. Also denote by $R$ the subset of $S$ of simple roots of $P$, that is simple roots of the Levi factor $L_P$ of $P$. Then the Schubert divisors of $G/P$ are indexed by the subset of simple roots $S \setminus R$ and are of the form $Bw_0s_\alpha P/P$, where $w_0$ denotes the longest element of the Weyl group of $G$ and $s_\alpha$ denotes the simple reflection associated to the simple root $\alpha$. Hence the $B$-stable irreducible divisors of $G/H$ are of the form $Bw_0s_\alpha P/H$, which we denote by $D_\alpha$ for $\alpha \in S \setminus R$. Then the following holds:

**Lemma 2.5.** Any divisor $D$ of $X$ equivalent to a linear combination of $X_i$'s and $D_\alpha$ for $\alpha \in S \setminus R$. That is,

$$D \approx \sum_{i=1}^{r} d_i X_i + \sum_{\alpha \in S \setminus R} d_\alpha D_\alpha.$$ 

A horospherical variety is called toroidal if it has no color containing a $G$-orbit. It is of the form $G \times^P Y$, where $Y$ is as above. Also note that any $G$-stable divisor of $G \times^P Y$ is of the form $G \times^P D'$, where $D'$ is a $T'$-stable divisor of $Y$.

3. A Künneth-like formula for local cohomology

We start by recalling a few results on local cohomology functors. We refer the reader to [Gro68] and [Kem78] for more details. In Sections 3 to 5, for simplicity and unless noted otherwise, all schemes will be supposed to be Noetherian over an algebraically closed field $k$.

Let $X = \text{Spec}(A)$ be an affine scheme, let $\text{QCoh}(X)$ be the category of quasi-coherent $\mathcal{O}_X$-modules, and let $Z \subset X$ be a closed subscheme.

**Proposition 3.1.** Let $\mathcal{F} \in \text{QCoh}(X)$, and $p \geq 0$. The functor $H^p_Z(\mathcal{F} \otimes \bullet) : \text{QCoh}(X) \to \text{QCoh}(X)$ is additive and commutes with direct limits.

**Proof.** Since we assume $X$ to be Noetherian, all open $U \subset X$ are quasi-compact. Then to prove the proposition, one can use the same arguments as in [Kem80] Section 2, where this is done for $H^p(X, \bullet)$. One should recall that, as for ordinary sheaf cohomology, one can compute $H^p_Z(X, \bullet)$ using a flabby resolution. \qed

We can now follow the previous useful lemma.

**Lemma 3.2.** Let $\mathcal{F}, \mathcal{G} \in \text{QCoh}(X)$. Let $t^p_{\mathcal{F}, \mathcal{G}} : H^p_Z(\mathcal{G} \otimes \mathcal{O}_X \mathcal{F}) \to H^p_Z(\mathcal{G} \otimes \mathcal{O}_X \mathcal{F})$ be the natural map, and let $l$ be the codimension of $Z$ in $X$.

(i) If $\mathcal{F}$ is a flat $\mathcal{O}_X$-module, $t^p_{\mathcal{F}, \mathcal{G}}$ is an isomorphism for all $p \geq 0$.

(ii) Assume that $X$ is Cohen-Macaulay. If $\mathcal{G}$ is a flat $\mathcal{O}_X$-module, and if $Z$ is a locally complete intersection, $t^p_{\mathcal{F}, \mathcal{G}}$ is an isomorphism.

**Proof.** Proof of (i): We first recall the following facts:

(1) If $T : \{\text{left } A - \text{Mod}\} \to \text{Ab}$ is an additive functor, and if $L$ is a free $A$-module, then $T(A) \otimes_A L \to T(L)$
is an isomorphism (see [Gro63, Lemma 7.2.4])

(2) (Lazard’s theorem) Let \( M \) be a \( A \)-module. Then \( M \) is flat if and only if it is the colimit of a directed system of free finite \( A \)-modules.

Then by flatness of \( F \), \( F(X) \) is flat over \( A \), hence \( F(X) \) is a directed colimit of free \( A \)-modules of finite rank, and \( F \) is a directed colimit of free \( O_X \)-modules of finite rank. Now since both \( \mathcal{H}^i_Z(G \otimes \bullet) \) and global sections commute with direct limits, it is enough to show the isomorphism for global sections of free \( O_X \)-modules, which is exactly (1).

Proof of (ii): We start by proving that the functor \( \mathcal{H}^l_Z(G \otimes \bullet) \) is right exact. Let

\[
0 \to F_1 \to F_2 \to F_3 \to 0
\]

be an exact sequence of quasi-coherent \( O_X \)-modules. Since \( G \) is flat, this gives a long exact sequence of local cohomology sheaves

\[
\ldots \to \mathcal{H}^i_Z(G \otimes F_1) \to \mathcal{H}^i_Z(G \otimes F_2) \to \mathcal{H}^i_Z(G \otimes F_3) \to \mathcal{H}^{i+1}_Z(G \otimes F_1)
\]

But the conditions on \( Z \) ensure the vanishing of \( \mathcal{H}^{i+1}_Z(G \otimes F_1) \) (see [Gro68, Lemma 3.12, III]), hence the right-exactness. Now pick an exact sequence \( L' \to L \to F \to 0 \) with \( L \) and \( L' \) being free \( O_X \)-modules. We have a commutative diagram

\[
\begin{array}{cccc}
\mathcal{H}^i_Z(G) \otimes L' & \longrightarrow & \mathcal{H}^i_Z(G) \otimes L & \longrightarrow & \mathcal{H}^i_Z(G) \otimes F & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \\
\mathcal{H}^i_Z(G \otimes L') & \longrightarrow & \mathcal{H}^i_Z(G \otimes L) & \longrightarrow & \mathcal{H}^i_Z(G \otimes F) & \longrightarrow & 0
\end{array}
\]

Since \( L \) and \( L' \) are free, the two first vertical maps are isomorphisms, so is the third one. \( \Box \)

**Remark 3.3.** An invertible sheaf \( L \) on \( X = \text{Spec}(A) \) is automatically flat.

Before stating our Künneth-like formula for local cohomology, let us recall a few known results on local cohomology (which hold in much more generality).

**Lemma 3.4.** Let \( F \in QCoh(X) \).

(i) If \( Z_2 \subset Z_1 \) are two closed subschemes of \( X \) such that \( Z_1 \setminus Z_2 \) is affine, then

\[
\mathcal{H}^i_{Z_1/Z_2}(X, F) \simeq H^0(X, \mathcal{H}^i_{Z_1/Z_2}(F))
\]

(ii) Let \( Z_2 \subset Z_1, W_2 \subset W_1 \) be closed subschemes, and let \( S_1 = W_1 \cap Z_1, S_2 = (W_1 \cap Z_2) \cup (W_2 \cap Z_1) \). Then we have a spectral sequence

\[
E_2^{p,q} = \mathcal{H}^q_{W_1/W_2}(\mathcal{H}^p_{Z_1/Z_2}(F)) \Rightarrow \mathcal{H}^{p+q}_{S_1/S_2}(F)
\]

In particular, when \( Z_2 = W_2 = \emptyset \), we have

\[
E_2^{p,q} = \mathcal{H}^p_{W_1}(\mathcal{H}^q_{Z_1}(F)) \Rightarrow \mathcal{H}^{p+q}_{W_1 \cap Z_1}(F)
\]
(iii) Let $Z_2 \subset Z_1$ be two close subschemes of $X$. Let $Y$ be scheme, and $p : X \times Y \to X$ be the first projection. There is an isomorphism
\[ p^* \mathcal{H}^i_{Z_1/Z_2}(\mathcal{F}) \simeq \mathcal{H}^i_{Z_1 \times Y/Z_2 \times Y}(p^* \mathcal{F}) \]

\textbf{Proof.} For proof of (i) see [Kem78, Theorem 9.5 (d)]. For proof of (ii) see [Kem78, Lemma 8.5 (d)]. For proof of (iii) see [Kem78, Proposition 11.5]. \hfill \square

Let $Y$ be an affine scheme. Let $Z_1 \subset X$ and $Z_2 \subset Y$ be two locally complete intersections, of respective codimensions $l_1$ and $l_2$. Let $L_1$ and $L_2$ be two invertible sheaves respectively on $X$ and $Y$. Let $p_1 : X \times Y \to X$ and $p_2 : X \times Y \to Y$ be the projections, and let $L_i := p_i^* L_i$. We are now ready to state our result.

\textbf{Theorem 3.5.} Assume $X$ and $Y$ are irreducible and Cohen-Macaulay. Then
\[ H^{1+l_2}_{Z_1 \times Z_2}(X \times Y, \mathcal{L}_1 \otimes \mathcal{L}_2) \simeq H^{l_2}_{Z_1}(X, L_1) \otimes_k H^{l_2}_{Z_2}(Y, L_2) \]

\textbf{Proof.} First let us notice that
\[ H^n_{Z_1 \times Z_2}(X \times Y, \mathcal{L}_1 \otimes \mathcal{L}_2) = H^0(X \times Y, \mathcal{H}^n_{Z_1 \times Z_2}(\mathcal{L}_1 \otimes \mathcal{L}_2)) \]

Since $\mathcal{L}_1$ and $\mathcal{L}_2$ are locally free, and by the conditions on the $Z_i$, the spectral sequence
\[ E_2^{pq} = \mathcal{H}^p_{Z_1 \times Y}(\mathcal{H}^q_{X \times Z_2}(\mathcal{L}_1 \otimes \mathcal{L}_2)) \Rightarrow \mathcal{H}^{p+q}_{Z_1 \times Z_2}(\mathcal{L}_1 \otimes \mathcal{L}_2) \]
collapses, and it may only be nonzero for $p = l_1$ and $q = l_2$. Here we are using that $\mathcal{L}_1 \otimes \mathcal{L}_2$ is also locally free, and that $\mathcal{I}_{Z_1 \times Z_2}$ is locally generated by $l_1 + l_2$ elements.

Using Lemma 3.2, we compute
\[ \mathcal{H}^p_{Z_1 \times Y}(\mathcal{H}^{l_2}_{X \times Z_2}(\mathcal{L}_1 \otimes \mathcal{L}_2)) \simeq \mathcal{H}^p_{Z_1 \times Y}(\mathcal{L}_1 \otimes \mathcal{H}^{l_2}_{X \times Z_2}(\mathcal{L}_2)) \simeq \mathcal{H}^p_{Z_1 \times Y}(\mathcal{L}_1) \otimes \mathcal{H}^{l_2}_{X \times Z_2}(\mathcal{L}_2) \]

Taking global sections yield the wanted isomorphism. \hfill \square

4. Locally trivial fibrations and Cousin complexes

Let $B$ and $F$ be smooth complete connected schemes, and let $E \to B$ be a (Zariski) locally trivial fibration, with fiber $F$. Moreover, assume that the Picard group $\text{Pic}(F)$ of $F$ is a projective $\mathbb{Z}$-module, and that $F$ is rational. We start with the following useful description of Picard group $\text{Pic}(E)$ of $E$.

\textbf{Proposition 4.1.} We have an isomorphism $\text{Pic}(E) \simeq \text{Pic}(B) \oplus \text{Pic}(F)$

\textbf{Proof.} Using [F173, Proposition 2.3], we have an exact sequence
\[ H^0(F, \mathcal{O}_F^*)/k^* \to \text{Pic}(B) \to \text{Pic}(E) \to \text{Pic}(F) \to 0 \]

By the hypotheses on $F$, $H^0(F, \mathcal{O}_F^*) = k^*$. Since $\text{Pic}(F)$ is projective, we get the required splitting. This completes the proof of the proposition. \hfill \square

Let $\mathcal{L}_1$ and $\mathcal{L}_2$ be line bundles on $B$ and $F$ respectively. The aim of this section is to compute the cohomology groups $H^n(E, \mathcal{L}_1 \otimes \mathcal{L}_2)$. To do that, we shall need the formalism of Cousin complexes.

Let $X$ be a Noetherian scheme, let $\mathcal{F}$ be an $\mathcal{O}_X$-module, and let $\{Z\} := \emptyset = Z_{n+1} \subset Z_n \subset \ldots \subset Z_1 \subset Z_0 = X$ be a filtration by closed subschemes. For simplicity, let us
assume moreover that \( X \) is irreducible. Then one can construct (see [Kem78 Lemma 7.8]) the Cousin complex of \( \mathcal{F} \) relatively to the filtration \( \{ Z \} \)

\[
\text{Cousin}_{(Z)}(\mathcal{F}) := 0 \to H^0(X, \mathcal{F}) \to H^0_{Z_0/Z_1}(X, \mathcal{F}) \to H^1_{Z_1/Z_2}(X, \mathcal{F}) \to H^0_{Z_2/Z_3}(X, \mathcal{F}) \to \ldots
\]

and its sheaf analogue, denoted by \( \text{Cousin}_{(Z)}(\mathcal{F}) \). Kempf showed in [Kem78 Theorem 9.6, 10.3 and 10.5] that under some conditions, these Cousin complexes can be used to compute the cohomology groups \( H^i(X, \mathcal{F}) \):

**Proposition 4.2.** Assume that the \( Z_i \setminus Z_{i+1} \) are all affine, that \( Z_i \) is of codimension \( i \) for all \( i \geq 0 \), and that \( \mathcal{F} \) is locally free. Then we have an isomorphism of complexes

\[
\text{Cousin}_{(Z)}(\mathcal{F}) \simeq H^0(X, \text{Cousin}_{(Z)}(\mathcal{F}))
\]

and \( H^i(X, \mathcal{F}) \) is the \( i \)-th homology group of \( \text{Cousin}_{(Z)}(\mathcal{F}) \)

We shall now state our main result.

**Theorem 4.3.** Assume that \( B \) is stratified by locally closed affine irreducible schemes \( \{ Z_i^1 \}_{i \in I} \), and that \( F \) is stratified by locally closed affine irreducible schemes \( \{ Z_j^2 \}_{j \in J} \) such that:

(i) there are affine open \( U_i^1 \subset B \) and \( U_j^2 \subset F \) containing respectively \( Z_i^1 \) and \( Z_j^2 \), in which they are locally complete intersections;

(ii) \( E \) is stratified by the \( \{ Z_i^1 \times Z_j^2 \} \), and there are open embeddings \( U_i^1 \times U_j^2 \to E \).

Then we can compute \( H^n(E, \mathcal{L}_1 \otimes \mathcal{L}_2) \) with the following converging spectral sequence

\[
E_2^{p,q} = H^p(B, \mathcal{L}_1) \otimes H^q(F, \mathcal{L}_2) \Rightarrow H^n(E, \mathcal{L}_1 \otimes \mathcal{L}_2)
\]

If further, either \( \mathcal{L}_1 \) or \( \mathcal{L}_2 \) has its cohomology concentrated in a single degree, this spectral sequence collapses, and we get

\[
H^n(E, \mathcal{L}_1 \otimes \mathcal{L}_2) = \bigoplus_{p+q=n} H^p(B, \mathcal{L}_1) \otimes H^q(F, \mathcal{L}_2)
\]

Proof. Let us start by fixing some notations. Let

\[
\overline{B}_l := \bigcup_{\text{codim}(Z_i^1) \geq l} Z_i^1, \quad \overline{F}_l := \bigcup_{\text{codim}(Z_j^2) \geq l} Z_j^2, \quad \text{and} \quad \overline{E}_l := \bigcup_{\text{codim}(Z_i^1 \times Z_j^2) \geq l} Z_i^1 \times Z_j^2
\]

and let \( B_l = \overline{B}_l \setminus \overline{B}_{l+1}, F_l = \overline{F}_l \setminus \overline{F}_{l+1}, \) and \( E_l = \overline{E}_l \setminus \overline{E}_{l+1} \).

By using twice the excision formula, we can rewrite the cohomology groups occurring in the Cousin complex of \( \mathcal{L}_1 \otimes \mathcal{L}_2 \) the following way:

\[
H^l_{\overline{E}_l/\overline{E}_{l+1}}(E, \mathcal{L}_1 \otimes \mathcal{L}_2) \simeq H^l_{E_l}(E \setminus \overline{E}_{l+1}, \mathcal{L}_1 \otimes \mathcal{L}_2)
\]

\[
\simeq \bigoplus_{p+q=l, \text{codim}(Z_i^1) = p, \text{codim}(Z_j^2) = q} H^{Z_i^1 \times Z_j^2}(E \setminus \overline{E}_{l+1}, \mathcal{L}_1 \otimes \mathcal{L}_2)
\]

\[
\simeq \bigoplus_{p+q=l, \text{codim}(Z_i^1) = p, \text{codim}(Z_j^2) = q} H^l_{Z_i^1 \times Z_j^2}(U_i^1 \times U_j^2, \mathcal{L}_1 \otimes \mathcal{L}_2)
\]

\[
\simeq \bigoplus_{p+q=l, \text{codim}(Z_i^1) = p, \text{codim}(Z_j^2) = q} H^l_{Z_i^1 \times Z_j^2/\partial(Z_i^1 \times Z_j^2)}(E, \mathcal{L}_1 \otimes \mathcal{L}_2)
\]

(*)

\[
H^l_{\overline{E}_l/\overline{E}_{l+1}}(E, \mathcal{L}_1 \otimes \mathcal{L}_2) \simeq \bigoplus_{p+q=l} H^p(B_l, \mathcal{L}_1) \otimes H^q(F_l, \mathcal{L}_2)
\]
where \( \partial(Z_i^1 \times Z_j^2) \) denotes \( \overline{Z_i^1 \times Z_j^2} \setminus Z_i^1 \times Z_j^2 \). The boundary maps
\[
\partial_E : H^1_{Z_i^1 \times Z_j^2 / \partial(Z_i^1 \times Z_j^2)}(E, \mathcal{L}_1 \otimes \mathcal{L}_2) \rightarrow H^1_{Z_i^1 \times Z_j^2 / \partial(Z_i^1 \times Z_j^2)}(E, \mathcal{L}_1 \otimes \mathcal{L}_2)
\]
are zero whenever \( Z_i^1 \times Z_j^2 \not\subset \partial(Z_i^1 \times Z_j^2) \). But a stratum \( Z_i^1 \times Z_j^2 \) of codimension \( l + 1 \) lies \( \partial(Z_i^1 \times Z_j^2) \) exactly when it is of the form \( Z_i^1 \times Z_j^2 \) or \( Z_i^1 \times Z_j^2 \), with either \( Z_i^1 \subset \partial Z_i^1 \)
of codimension \( \text{codim}(Z_i^1) + 1 \) or \( Z_j^2 \subset \partial Z_j^2 \) of codimension \( \text{codim}(Z_j^2) + 1 \).

We shall now introduce the following bicomplex:
\[
K^{p,q} := \bigoplus_{\text{codim}(Z_i^1) = p} H^{p+q}_{Z_i^1}(U_i^1, \mathcal{L}_1) \otimes H^q_{Z_j^2}(U_j^2, \mathcal{L}_2) \quad \text{by Theorem 3.5}
\]
Notice that with the same kind of arguments than for \((*)\), \( \bigoplus_{\text{codim}(Z_i^1) = p} H^{p+q}_{Z_i^1}(U_i^1, \mathcal{L}_1) \) is the \( p + 1 \)-th term of the Cousin\(_{(B_i)}(\mathcal{L}_1)\), and denote by \( \partial_{B,i} \) the induced map on \( H^{p+q}_{Z_i^1}(U_i^1, \mathcal{L}_1) \).

For the same reasons, \( \bigoplus_{\text{codim}(Z_j^2) = q} H^q_{Z_j^2}(U_j^2, \mathcal{L}_2) \) is the \( q + 1 \)-th term of the Cousin\(_{(E_j)}(\mathcal{L}_2)\), and denote by \( \partial_{E,j} \) the induced map on \( H^q_{Z_j^2}(U_j^2, \mathcal{L}_2) \). Define boundary maps on \( K^{p,q} \) by:

\[
\begin{array}{c}
\vdots \\
\cdots \\
K^{p,q+1} \xrightarrow{\partial_{h,i}} K^{p+1,q+1} \xrightarrow{\partial_{E,i}^{p+1,q+1}} \\
\vdots \\
\vdots \\
\end{array}
\]

- the horizontal boundary maps \( \partial_{h,i}^{p,q} : K^{p,q} \rightarrow K^{p+1,q+1} \) are given by \( \bigoplus_{\text{codim}(Z_i^1) = p} (\partial_{B,i}^p \otimes 1) \);
- the vertical boundary maps \( \partial_{E,j}^{p,q} : K^{p,q} \rightarrow K^{p,q+1} \) are given by \( \bigoplus_{\text{codim}(Z_j^2) = q} (1 \otimes \partial_{E,j}^q) \).

The previous argument on the boundary maps \( \partial_E \) of Cousin\(_{(E_j)}(\mathcal{L}_1 \otimes \mathcal{L}_2)\) shows that
\[
\text{Tot}(K) = \text{Cousin}_{(E_j)}(\mathcal{L}_1 \otimes \mathcal{L}_2)
\]
where \( \text{Tot}(K) \) denotes the total complex of \( K \). Since \( K^{p,q} \) vanishes for \( p < 0 \) or \( q < 0 \), the bicomplex \( \text{C}H_{*,*}(K) \) obtained from \( K \) by taking homology of columns gives rise to a spectral sequence whose \( E^2 \)-page is given by
\[
E^2_{p,q} = H_p(\text{C}H_{q,*}(K))
\]
converging to \( H_*(\text{Tot}(K)) \). But by Proposition 4.2, we have
\[
H_n(\text{Tot}(K)) = H_n(\text{Cousin}_{(E_j)}(\mathcal{L}_1 \otimes \mathcal{L}_2)) = H^n(E, \mathcal{L}_1 \otimes \mathcal{L}_2)
\]
and
\[ H_p(cH_q)(K) = H_p(CO \bigoplus_{\text{codim}(Z'_1) = *} H^*_Z(U^1_i \otimes L_1) \otimes H^q(F, L_2)) \]
\[ = H^p(B, L_1) \otimes H^q(F, L_2) \]
If either \(L_1\) or \(L_2\) has its cohomology concentrated in a single degree, the last claim is obvious. \(\square\)

5. Equivariance

Let \(G_1\) and \(G_2\) be two affine algebraic groups. In this section, we shall take into account actions of \(G_1 \times G_2\) in the previous results. The key point will come from lemma 11.6 of [Kem78].

We start to show the following lemma:

**Lemma 5.1.** With notations and settings of Lemma 3.2, if \(G_1\) acts in \(X\) in such a way that \(Z\) is \(G_1\)-stable, and that both \(F\) and \(G\) are \(G_1\)-linearized, the isomorphisms \(t^p_{F,G}\) given by Lemma 3.2 are \(G_1\)-equivariant.

**Proof.** The \(G_1\)-linearization of \(H^p_Z(F)\) is constructed thanks to [Kem78, Lemma 11.3]. Let us give a few detail of the construction here. Let \(\rho: G_1 \times X \to X\) be the action map, and let \(\pi\) denote the second projection. The \(G_1\)-linearization of \(F\) gives an isomorphism \(\rho^*F \to \pi^*F\). Since \(Z\) is \(G_1\)-stable, we get a map \(\rho^*(H^p_Z(F)) \to H^p_{G_1 \times Z}(\pi^*F)\), and composing it with the isomorphism \(H^p_{G_1 \times Z}(\pi^*F) \to \pi^*(H^p_Z(F))\) gives the required natural \(G_1\)-linearization on \(H^p_Z(F)\). The commutativity of the diagram (whose horizontal arrows are isomorphisms thanks to the linearizations, and all vertical arrows are isomorphisms by flatness)

\[ \begin{array}{ccc}
\rho^*H^p_Z(F \otimes G) & \longrightarrow & H^p_Z(\pi^*(F \otimes G)) \\
\Uparrow & & \Upward Arrow \\
\rho^*(H^p_Z(F)) \otimes G & \longrightarrow & H^p_Z(\pi^*F) \otimes \pi^*G \\
\end{array} \]

is enough to conclude the lemma. \(\square\)

Lemma 5.1 is enough to prove equivariant analogues of theorems 3.5 and 4.3. Let us keep the notations and settings of Theorem 3.5. Assume that \(G_1\) acts on \(X\) and that \(Z_1\) is \(G_1\)-stable, that \(G_2\) acts on \(Y\) and that \(Z_2\) is \(G_2\)-stable, and that the \(L_i\) are \(G_i\)-linearized. Equip \(L_1 \otimes L_2\) with the induced \(G_1 \times G_2\)-linearization. Then we have:

**Proposition 5.2.** The isomorphism given in Theorem 3.5 is an isomorphism of \(G_1 \times G_2\)-modules.

**Proof.** By Lemma 5.1, the isomorphism
\[ H^p_{Z_1 \times Z_2}(L_1 \otimes L_2) \simeq H^p_{Z_1 \times Y}(L_1) \otimes H^q_{X \times Z_2}(L_2) \]
obtained in the proof is an isomorphism of \(G_1 \times G_2\)-equivariant sheaves, hence taking global sections, we get an isomorphism of \(G_1 \times G_2\)-modules. \(\square\)
Now take the notations and settings of Theorem \ref{theorem}. Assume that $G_1$ acts on $B$ and that the $Z_i^1$ and $U_j^1$ are $G_1$-stable, that $G_2$ acts on $F$ and that the $Z_i^2$ and $U_j^2$ are $G_2$-stable, and that the $L_i$ are $G_i$-linearized. If further, we equip $L_1 \otimes L_2$ with the induced $G_1 \times G_2$-linearization, we get:

**Proposition 5.3.** The isomorphism given in Theorem \ref{theorem} is an isomorphism of $G_1 \times G_2$-modules.

**Proof.** This is a direct consequence of \cite[Theorem 11.6 (e)]{Kem78}.

Now assume that $k$ is of characteristic 0. Then we can lower the hypotheses to obtain a weaker result. Namely, we do not need to assume that the closed subschemes occurring in the filtration are stable: in the setting of Theorem \ref{theorem}, assume we equip $L_1 \otimes L_2$ with the induced $G_1 \times G_2$-linearization, we get:

**Proposition 5.4.** The isomorphism given in Theorem \ref{theorem} is an isomorphism of $g_1 \times g_2$-modules.

**Proof.** For an affine algebraic group $G$, let $\widehat{G}$ denote the formal completion of $G$ at the identity. The $G_1 \times G_2$-linearization of $L_1 \otimes L_2$ gives rise to a $\widehat{G_1} \times \widehat{G_2}$-linearization on $L_1 \otimes L_2$. Then by using the natural map $\widehat{G_1} \times \widehat{G_2} \rightarrow G_1 \times G_2$, we get $\widehat{G_1} \times \widehat{G_2}$-linearization. Hence by \cite[Lemma 11.1(a)]{Kem78}, the cohomology groups $H^{i_1 + i_2}_{Z_1^1 \times Z_2^1}(U_j^1 \times U_j^2, L_1 \otimes L_2)$, $H^{i_1}_{Z_1^1}(U_j^1, L_1)$ and $H^{i_2}_{Z_2^2}(U_j^2, L_2)$ have respectively a natural structure of $\widehat{G_1} \times \widehat{G_2}$-module, that we explicitly describe here.

A $\widehat{G}$-linearization of a sheaf $F$ of $O_X$-modules on a scheme $X$ is given by an inverse system of morphisms $F \rightarrow k[G]/m^i \otimes F$ (where $m$ denotes the ideal of regular functions vanishing at the identity). Since the $k[G]/m^i$ are finite dimensional vector spaces, and since the local cohomology functor commutes with direct sums, this gives, for any closed $Z_2 \subset Z_1 \subset X$, there is an inverse system $H^p_{Z_1/Z_2}(X, F) \rightarrow k[G]/m^i \otimes H^p_{Z_1/Z_2}(X, F)$, which is precisely the required linearization.

Now since the linearization construction is detailed, it is immediate that the isomorphism

$$H^{i_1 + i_2}_{Z_1^1 \times Z_2^1}(U_j^1 \times U_j^2, L_1 \otimes L_2) \rightarrow H^{i_1}_{Z_1^1}(U_j^1, L_1) \otimes H^{i_2}_{Z_2^2}(U_j^2, L_2)$$

is an isomorphism of $\widehat{G_1} \times \widehat{G_2}$-modules. Notice that for example we can rewrite the $H^{j_1}_{Z_1^1}(U_j^1, L_1) = H^{j_1}_{Z_1^1/\partial Z_1^1}(B, L)$, hence these modules are exactly the direct summands of the modules occurring in the Cousin complexes. Using \cite[Lemma 11.1(d)]{Kem78}, the Cousin complex of $L_1 \otimes L_2$ relatively to $\{E_i\}$ is a complex of $\widehat{G_1} \times \widehat{G_2}$-modules. Hence the isomorphism given in Theorem \ref{theorem} is an isomorphism of $\widehat{G_1} \times \widehat{G_2}$-modules. Since we are in characteristic 0, this gives us an isomorphism of Lie algebra $g_1 \times g_2$-modules. \hfill \Box

6. **APPLICATION TO HOROSPHERICAL VARIETIES**

Let $G$ be a complex connected reductive group. Let $X$ be a smooth toroidal horospherical variety. We recall the following fact from Section 2, and we refer to \cite{Pas08} (prop. 2.2 and ex. 2.3) for its proof.
Proposition 6.1.

(i) There is a parabolic subgroup $P$ containing $B$ such that

$$H = \bigcap_{\lambda \in \mathcal{X}(P)} \ker(\lambda)$$

where $\mathcal{X}(P)$ denotes the characters of $P$. Moreover, $P = N_G(H)$, and $T' := P/H$ is a torus.

(ii) There is a smooth $T'$-toric variety $Y$ such that $X = G \times^P Y$, and the natural map $X = G \times^P Y \to G/P$ is a locally trivial fibration.

Let $T \subset B$ be a maximal torus of $G$. The next step is to stratify $X$ in such a way that we can apply Theorem 4.3. This is done by looking at the stratification of $X$ by $B \times T'$-orbits. The $B \times T'$-orbits are exactly the $BwP \times^P P$-orbits, where $w \in W^P$ ($W^P$ is the Weyl group of the Levi factor $L_P$ of $P$) and $C_\sigma$ is the $T'$-orbit of $Y$ associated by the cone $\sigma$ (living in the fan defining $Y$).

$X$ being spherical and toroidal, the local structure theorem tells us that these orbits are isomorphic to $BwP/P \times C_\sigma$, and they are closed in an open of $X$ of the form $U_w \times U_\sigma$, where $U_w = w(w_0^P)^{-1}Bw_0^P P/P \subset G/P$ and $U_\sigma = \text{Spec}(k[M \cap \sigma^\vee]) \subset Y$ (again, this locally trivial fibration is actually a product by local structure theorem, see for example [Tim11, Theorem 29.1]). Remark that $U_w$ is $T$-stable, and that $U_\sigma$ is $T'$-stable. Both $BwP/P$ and $C_\sigma$ are locally complete intersections, of respective dimensions $l(w)$ and $\dim(\sigma)$. Notice that since $Y$ is a toric variety, $\text{Pic}(Y)$ is a free $\mathbb{Z}$-module. By Borel-Weil-Bott theorem, the cohomology of line bundles on $G/P$ is concentrated in at most one degree. Hence we can apply Theorem 4.3 and get:

Corollary 6.2. Assume that $X$ is complete. Let $\mathcal{L}_1$ be a $G$-linearized line bundle on $G/P$ and let $\mathcal{L}_2$ is a $T'$-linearized line bundle on $Y$. Then we have an isomorphism of $T \times T'$-modules (hence of $B \times T'$-modules) and of $\mathfrak{g}$-modules

$$H^p(X, \mathcal{L}_1 \otimes \mathcal{L}_2) = \bigoplus_{p+q=n} H^p(G/P, \mathcal{L}_1) \otimes H^q(Y, \mathcal{L}_2)$$

Now let $X$ be a complete horospherical variety. Then it admits a $G$-equivariant complete toroidal resolution of singularities $\pi : \check{X} \to X$. By equivariance, $\check{X}$ is also horospherical. Then we can compute with Corollary 6.2 the cohomology groups of invertible sheaves on $X$ as well.

Proposition 6.3. Let $\mathcal{L}$ be a $G$-linearized line bundle on $X$ and let $\mathfrak{g}$ be the Lie algebra of $G$. Then we have $H^i(X, \mathcal{L}) = H^i(\check{X}, \pi^* \mathcal{L})$.

Proof. $X$ being a spherical variety, it has rational singularities. Hence the Leray spectral sequence

$$H^p(X, R^q \pi_* \pi^* \mathcal{L}) \Rightarrow H^*(\check{X}, \pi^* \mathcal{L})$$

degenerates, since $R^q \pi_* \pi^* \mathcal{L} = 0$ for $q > 0$ by the projection formula. \qed

Acknowledgments: We would like to thank Michel Brion for valuable discussions and many critical comments.
