EXPLICIT EXAMPLE OF COLLAPSING $\kappa^+$ IN ITERATION OF $\kappa$–PROPER FORCINGS

ANDRZEJ ROSLANOWSKI

Abstract. We give an example of iteration of length $\omega$ of ($<\kappa$)–complete $\kappa^+$–cc forcing notions with the limit collapsing $\kappa^+$. The construction is decoded from the proof of Shelah [11, Appendix, Theorem 3.6(1)].

1. Introduction

Since 1980s it has been known that there is no straightforward generalization of properness to the context of iterations with uncountable supports. The canonical reason for that situation was the failure of club uniformization for colorings on ladder systems given by Shelah in [10, Appendix], [11, Appendix, Theorem 3.6(2)].

In a series of papers [3, 4, 5, 6, 7, 8, 9], Roslanowski and Shelah presented several properties of ($<\kappa$)--strategically complete forcing notions implying that their $\kappa$–support iterations do not collapse $\kappa^+$. Those properties were carefully crafted to “cover” nice forcing notions without colliding with the bad example of a uniformization forcing. The need for the careful work was typically justified by saying that some iteration of uniformization forcings must fail properness without actually spelling out any detailed example.

Martin Goldstern [1] asked me if I know a simple example of an $\omega$–step iteration of ($<\kappa$)–complete $\kappa^+$–cc forcing notions with the limit collapsing $\kappa^+$. My answer then was that there cannot be any very simple example, because of the works mentioned above. I was not correct. The purpose of this note is to give such an explicit, relatively simple, example. The argument given here is actually included in some form in the proof of Shelah [11, Appendix, Theorem 3.6(1)]. But the advantage of writing it down explicitly is that, unlike [11, Appendix, Theorem 3.6(2)], the argument applies to inaccessible $\kappa$ as well. So, while for inaccessible $\kappa$ the theory of $\kappa$–support iterations appear to be much richer (and easier), we still have to work hard to ensure properness of the limit.

Notation: Our notation is rather standard and compatible with that of classical textbooks (like Jech [2]). However, in forcing we keep the older convention that a stronger condition is the larger one.

(1) Ordinal numbers will be denoted be the lower case initial letters of the Greek alphabet $\alpha, \beta, \gamma, \delta$. Finite ordinals (non-negative integers) will be denoted by $k, n$.

(2) The letter $\kappa$ will denote a regular uncountable cardinal such that $\kappa = \kappa^{<\kappa}$.

(3) For a set $\mathcal{A}$, the family of all subsets of $\mathcal{A}$ of size $\kappa$ is denoted $[\mathcal{A}]^\kappa$ and the family of all sequences of length $<\kappa$ with values in $\mathcal{A}$ is called $^{<\kappa}\mathcal{A}$.

1991 Mathematics Subject Classification. Primary 03E40; Secondary: 03E05.
(4) For a forcing notion $\mathbb{P}$, all $\mathbb{P}$–names for objects in the extension via $\mathbb{P}$ will be denoted with a tilde below (e.g., $\tau$, $X$), and $G_\mathbb{P}$ will stand for the canonical $\mathbb{P}$–name for the generic filter in $\mathbb{P}$.

2. The Example

For the rest of this note we keep the following assumptions.

**Hypothesis 2.1.** We assume that:

1. $\kappa$ is an uncountable cardinal satisfying $\kappa^\kappa = \kappa$, and
2. $\mathcal{F} \subseteq \kappa^+$ is a family of size $\kappa^+$.

**Definition 2.2.** (1) An $\mathcal{F}$–coloring is a sequence $\bar{H} = (H_f : f \in \mathcal{F})$ such that $H_f : \kappa \to \kappa^\kappa$ (for $f \in \mathcal{F}$).

(2) For an $\mathcal{F}$–coloring $\bar{H}$ we define a forcing notion $\mathbb{Q}(\bar{H})$ as follows.

A **condition in** $\mathbb{Q}(\bar{H})$ is a tuple $p = (\gamma^p, e^p, v^p, u^p, h^p)$ such that

(a) $\gamma^p < \kappa$, $e^p \subseteq \gamma^p + 1$ is a closed set with $\max(e^p) = \gamma^p$,

(b) $v^p \in [\mathcal{F}]^{<\kappa}$, $u^p = \{ f[\alpha : \alpha \in e^p \land f \in v^p] \}$,

(c) if $f, g \in v$ are distinct, then $f[\gamma^p] \neq g[\gamma^p]$,

(d) $h^p : u^p \to \kappa^\kappa$.

The **order** $\leq$ of $\mathbb{Q}(\bar{H})$ is such that $p \leq q$ if and only if

(i) $\gamma^p \leq \gamma^q$ and $e^p = e^q \cap (\gamma^p + 1)$, and

(ii) $v^p \subseteq v^q$ (so also $u^p \subseteq u^q$) and $h^p \subseteq h^q$, and

(iii) if $f \in v^p$ and $\alpha \in e^q \setminus e^p$, then $h^q(f[\alpha]) = H_f(\alpha)$.

**Proposition 2.3.** Assume $\kappa = \kappa^{\kappa^\kappa}$ is an uncountable cardinal and let $\bar{H}$ be an $\mathcal{F}$–coloring.

1. $(\mathbb{Q}(\bar{H}), \leq)$ is indeed a partial order.
2. The forcing notion $\mathbb{Q}(\bar{H})$ is ($<\kappa$)–complete and $|\mathbb{Q}(\bar{H})| = \kappa^+$.
3. The forcing notion $\mathbb{Q}(\bar{H})$ satisfies the $\kappa^+$–chain condition (as a matter of fact, it has the $\kappa^+$–Knaster property), so it is also $\kappa$–proper (in the standard sense).

**Proof.** (2) To show the completeness of $\mathbb{Q}(\bar{H})$, suppose that $\bar{p} = \langle p_\alpha : \alpha < \delta \rangle \subseteq \mathbb{Q}(\bar{H})$ is increasing, $\delta < \kappa$ is limit.

If $\gamma^{p_\alpha}$ are eventually constant, say $\gamma^{p_\alpha} = \gamma^{p_\alpha^*}$ for $\alpha^* \leq \alpha < \delta$, then also $e^{p_\alpha} = e^{p_\alpha^*}$ for $\alpha^* \leq \alpha < \delta$. Set $\gamma = \gamma^{p_\alpha^*}$, $e = e^{p_\alpha^*}$, $v = \bigcup\{ v^{p_\alpha} : \alpha < \delta \}$, $u = \bigcup\{ u^{p_\alpha} : \alpha < \delta \}$ and $h = \bigcup\{ h^{p_\alpha} : \alpha < \delta \}$. Easily, $(\gamma, e, v, u, h) \in \mathbb{Q}(\bar{H})$ is an upper bound to $\bar{p}$.

Otherwise we may assume without loss of generality that the sequence $(\gamma^{p_\alpha} : \alpha < \delta)$ is strictly increasing. Let $\gamma = \sup(\gamma^{p_\alpha} : \alpha < \delta)$, $e = \bigcup\{ e^{p_\alpha} : \alpha < \delta \}$, $v = \bigcup\{ v^{p_\alpha} : \alpha < \delta \}$, $u = \bigcup\{ u^{p_\alpha} : \alpha < \delta \}$, and note that these objects satisfy demands 2.2(2)(a–c). Thus, in particular, for distinct $f, g \in v$ we have $f[\gamma] \neq g[\gamma]$. Hence may define $h : u \to \kappa^\kappa$ so that $h^{p_\alpha} \subseteq h$ for all $\alpha < \delta$ and $h(f[\gamma]) = H_f(\gamma)$ for $f \in v$. Easily, $(\gamma, e, v, u, h) \in \mathbb{Q}(\bar{H})$ is an upper bound to $\bar{p}$.

(3) Suppose that $\langle p_\alpha : \alpha < \kappa^+ \rangle$ is a sequence of distinct conditions from $\mathbb{Q}(\bar{H})$.

Since $\kappa^{\kappa^\kappa} = \kappa$ we may pick $\mathcal{A} \subseteq \kappa^+$ of size $\kappa^+$ and $\gamma, e, u, h$ such that for each $\alpha \in \mathcal{A}$:

$$
\gamma^{p_\alpha} = \gamma, \quad e^{p_\alpha} = e, \quad u^{p_\alpha} = u \quad \text{and} \quad h^{p_\alpha} = h.
$$
Suppose now $\alpha < \beta$ are from $A$. Set $v_0 = v^{P_\alpha} \cup v^{P_\beta}$ and choose $\gamma_0$ such that $\gamma < \gamma_0 < \kappa$ and $$\forall f, g \in v_0)(f \neq g \Rightarrow f\upharpoonright \gamma_0 \neq g\upharpoonright \gamma_0).$$ Then put $e_0 = e \cup \{\gamma_0\}$ and $u_0 = u \cup \{f\upharpoonright \gamma_0 : f \in v\}$. Plainly, we may now define $h_0 : u_0 \to (\kappa^{+} \kappa)$ so that $h^{P_\alpha} = h^{P_\beta} \subseteq h_0$ and $h_0(f\upharpoonright \gamma_0) = H_f(\gamma_0)$ for $f \in v_0$.

Easily, $(\gamma, e, u, h) \in \mathcal{Q}(\tilde{H})$ is a condition stronger than both $p_\beta$ and $p_\alpha$. \hfill $\square$

**Definition 2.4.** Let $\tilde{H}$ be an $\mathcal{F}$-coloring. We define $\mathcal{Q}(\tilde{H})$-names $E$ and $h$ by $$\overset{\mathcal{Q}(\tilde{H})}{\models} "E = \bigcup \{e^p : p \in G_{\mathcal{Q}(\tilde{H})}\} \land h = \bigcup \{h^p : p \in G_{\mathcal{Q}(\tilde{H})}\}".$$ \hfill $\square$

**Proposition 2.5.**

(1) $\overset{\mathcal{Q}(\tilde{H})}{\models} "E \subseteq \kappa$ is a club of $\kappa\)."

(2) $\overset{\mathcal{Q}(\tilde{H})}{\models} "h$ is a function with domain $\bigcup \{u^p : p \in G_{\mathcal{Q}(\tilde{H})}\}$ and values in $\kappa^{+}$ and such that for each $f \in \mathcal{F}$, for some $\alpha^f < \kappa$, if $\alpha \in E \setminus \alpha^f$, then $f\upharpoonright \alpha \in \text{dom}(h)$ and $h(f\upharpoonright \alpha) = H_f(\alpha)\)."

**Proof.** First note that for every $f \in \mathcal{F}$ and $\alpha < \kappa$ the set $$\mathcal{Z}_\alpha^f = \{p \in \mathcal{Q}(\tilde{H}) : f \in v^p \land \alpha < \gamma^p\}$$ is open dense in $\mathcal{Q}(\tilde{H})$. Then the assertions easily follow by the definition of the forcing (particularly, by the definition of the order). \hfill $\square$

**Theorem 2.6.** Assume $\kappa, \mathcal{F}$ are as in Hypothesis 2.1. Then there is an iteration $$\langle \mathbb{P}_n, \mathcal{Q}_n : n < \omega \rangle$$ such that

(1) for each $n < \omega$, for some $\mathbb{P}_n$-name $\tilde{H}_n$ we have

$$\overset{\mathbb{P}_n}{\models} "\tilde{H}_n$ is an $\mathcal{F}$-coloring and $\mathcal{Q}_n = \mathcal{Q}(\tilde{H}_n)"\),

so also

$$\overset{\mathbb{P}_n}{\models} "\mathcal{Q}_n$ satisfies $\kappa^{+}$-cc \)."

(2) the full support limit $\mathbb{P}_\omega$ collapses $\kappa^{+}$ while preserving all cardinals and cofinalities $\leq \kappa$.

**Proof.** We define $\mathcal{Q}_n$ and $\tilde{H}_n$ by induction on $n < \omega$.

We start with letting $H_0^f(\alpha) = \langle \rangle$ (for $f \in \mathcal{F}$ and $\alpha < \kappa$). Then put $\tilde{H}_0 = (H_f^0 : f \in \mathcal{F})$ and $\mathcal{Q}_0 = \mathcal{Q}(H_0)$. Suppose we have defined $\mathbb{P}_k, \mathcal{Q}_k, \tilde{H}_k$ for $k < n$ and $\overset{\mathbb{P}_k}{\models} \mathcal{Q}_k = \mathcal{Q}(\tilde{H}_k)$. Let $\mathbb{P}_n = \mathbb{P}_{n-1} \ast \mathcal{Q}_{n-1}^{-1}$. It should be clear that the forcing notion $\mathbb{P}_n$ preserves cofinalities and cardinals and forces $\kappa^{<\kappa} = \kappa$. By our choice of $\mathcal{Q}_k$ for each $k < n$ and we may choose $\mathcal{P}_n$-name $E^k$ such that

$$\overset{\mathbb{P}_n}{\models} " E^k \subseteq \kappa$ is the club added by the $k$-th coordinate forcing (cf. 2.3, 2.5\)."$$

Now suppose that $f \in \mathcal{F}$. Let $H_f^f$ be a $\mathbb{P}_n$-name for a function from $\kappa$ to $^\kappa \kappa$ such that

$$\overset{\mathbb{P}_n}{\models} H_f^f(\alpha) = f\upharpoonright \min (\bigcap_{k < n} E^k \setminus (\alpha + 1)) \text{ for each } \alpha < \kappa.$$ (Remember, $E^k$ are names for clubs of $\kappa$). Then we let $\tilde{H}_n = (H_f^0 : f \in \mathcal{F})$ and $\mathcal{Q}_n = \mathcal{Q}(\tilde{H}_n)$.

Now, the limit $\mathbb{P}_\omega$ is ( ($\kappa^{<\kappa}$)-complete, so it preserves cardinals and cofinalities $\leq \kappa$. Also $\overset{\mathbb{P}_\omega}{\models} \kappa^{<\kappa} = \kappa$. We will argue that $\mathbb{P}_\omega$ collapses $\kappa^{+}$ by showing that $\overset{\mathbb{P}_\omega}{\models} |\mathcal{F}| = \kappa$.}
For \( n < \omega \) let \( E^n \) be a \( \mathbb{P}_{n+1} \)-name for a club of \( \kappa \) as above and let \( h_n \) be a \( \mathbb{P}_{n+1} \)-name for a \( \kappa \)-partial function from \( \kappa \) to \( n \)-th coordinate (cf. 2.4).

Assume \( G \subseteq \mathbb{P}_\omega \) is generic over \( V \) and let us work in \( V[G] \).

Suppose towards contradiction that \( |\mathcal{F}| = \kappa^+ \). For each \( n < \omega \), the set \( (E^n)^G \) is a club of \( \kappa \), and therefore the intersection \( E = \bigcap_{n<\omega} (E^n)^G \) is also a club of \( \kappa \). By 2.5, for every \( f \in \mathcal{F} \) and \( n \in \omega \) we may fix \( \alpha^n_f \in E \) such that
\[
(\forall \alpha \in (E^n)^G \setminus \alpha^n_f) \left( f|\alpha \in \text{dom}((h_n)^G) \land (h_n)^G(f|\alpha) = (H^n_f)^G(\alpha) \right),
\]
and we let \( \alpha^n_f = \sup(\alpha^n_f : n < \omega) \in E \). Since \( |\mathcal{F}| = \kappa^+ \), we may find distinct \( f, g \in \mathcal{F} \) such that
\[
\alpha^n_f = \alpha^n_g = \alpha^* \quad \text{and} \quad f|\alpha^* = g|\alpha^*.
\]
The set \( C \) defined \( \{ \alpha \in E : f|\alpha = g|\alpha \} \) is nonempty (as \( \alpha^* \in C \)), closed and bounded. Let \( \alpha^+ = \max(C) \) and for \( n < \omega \) let \( \beta_n = \min \left( \bigcap_{k<n} (E^k)^G(\alpha^+ + 1) \right) \). By the definition of \( H^n_f, H^n_g \) and (\( \forall \)) we know that for each \( n \):
\[
f|\beta_n = (H^n_f)^G(\alpha^+) = (h_n)^G(f|\alpha^+) = (h_n)^G(g|\alpha^+) = (H^n_g)^G(\alpha^+) = g|\beta_n.
\]
Let \( \beta = \sup(\beta_n : n < \omega) \). Then \( \beta \in E, \beta > \alpha^+ \) and \( f|\beta = g|\beta \), a contradiction. \( \Box \)

Assuming \( \kappa, \mathcal{F} \) as in Hypothesis 2.1 we may use the proof of Theorem 2.6 to argue that the following statement is not true:

**Consequentely** for every \( \mathcal{F} \)-coloring \( \bar{H} \) there is a club \( E \subseteq \kappa \) and a function \( h : \kappa \to \kappa \) such that:
\[
(\forall f \in \mathcal{F}) (\exists \alpha_f < \kappa)(\forall \alpha \in E \setminus \alpha_f) \left( h(f|\alpha) = H_f(\alpha) \right).
\]

Consequently, if \( K \) is a class of forcing notions including all forcings of the form \( \mathbb{Q}(H) \) (for an \( \mathcal{F} \)-coloring \( \bar{H} \)), then the Forcing Axiom \( \text{FA}_\kappa(K) \) fails. This is yet another example of limitations on possible extensions of Martin Axiom.
