GLOBAL UNIQUENESS AND LIPSCHITZ-STABILITY FOR THE INVERSE ROBIN TRANSMISSION PROBLEM∗

B. HARRACH† AND H. MEFTAHI‡

Abstract. In this paper, we consider the inverse problem of detecting a corrosion coefficient between two layers of a conducting medium from the Neumann-to-Dirichlet map. This inverse problem is motivated by the description of the index of corrosion in non-destructive testing. We show a monotonicity estimates between the Robin coefficient and the Neumann-to-Dirichlet operator. We prove a global uniqueness result and Lipschitz stability estimate. Our arguments rely on a Runge approximation property, the monotonicity result and the method of localized potentials.

To solve the problem numerically, we reformulate the inverse problem into a minimization problem using least square functional. The reformulation of the minimization problem as a suitable saddle point problem allows us to obtain the optimality conditions by using differentiability properties of the min-sup formulation. The reconstruction is then performed by means of BFGS algorithm. Finally, numerical results are presented to illustrate the efficiency of the proposed algorithm.

1. Introduction. This paper is concerned with the inverse problem of detecting a corrosion contamination between two layers of a non-homogenous electric conductor. This problem can be encountered in several area of engineering such as diffusion of chemical substances in a given medium, delamination in certain elastic materials [5, 47].

The corrosion may occur in many different forms and several models are considered in the literature [10, 59, 57, 21, 23, 17, 52]. Identifying the Robin parameter from boundary measurements turns out to be a way to locate the corroded part in a given medium and possibly evaluate the damage level by electrical impedance tomography process.

In this work, we consider the mathematical model problem where the corrosion takes place between two layers of a non-homogenous medium [10, 59, 57]. The geometry of the corrosion boundary is assumed to be known in advance, but the coefficient of corrosion is unknown and is subject to be reconstructed from the Neumann-to-Dirichlet map. This problem shares similarities with the inverse problem with Robin condition on the external boundary [21, 23, 17, 52, 24].

The two major questions for the inverse problem are the uniqueness and stability of a solution. For the classical mathematical model problem, Chaabane and Jaoua [20] proved a uniqueness result and local and monotone Lipschitz stability estimate from boundary measurements, provided that the Robin coefficient is a continuous function with some negative lower bound. The proof rely on the study of the behavior of the solution of the forward problem with respect to the Robin coefficient. In [63] Sincich establish a Lipschitz stability estimate from electrostatic boundary measurements under a further prior assumptions of a piecewise constant Robin coefficient. The

Lipschitz constant behaves exponentially with respect to the portions considered.

For the model problem considered here, a particular uniqueness result for simultaneous reconstruction of the conductivity and the Robin coefficient is proven in [10]. The proof is based on integrals representation of the solution of the forward problem and decomposition on the basis of spherical harmonics.

Several numerical methods have been proposed for the inverse Robin problem in the context of external boundary corrosion detection [51, 29, 19, 17, 18, 65]. Some methods are based on the variational approach, such as the Kohn-Vogelius functional [17, 18], the least square functional [65]. $L^1$-tracking functional is considered in [19], where the authors prove differentiability using complex analysis techniques. The proof is strongly related to the positivity and monotonicity of the derivative of the state. This kind of functional is robust with respect to data outliers but it has not been tested numerically. Some numerical results restricted to the case of thin plate are based on the asymptotic expansion of the solution [51, 29].

In this paper we prove a global uniqueness and Lipschitz stability estimate for the Robin transmission inverse problem. The proof is based on a monotonicity estimates combined with the method of localized potentials [33] that we derive from a Runge approximation result. Note that monotonicity estimates and localized potentials techniques have been used in different ways for the study of inverse problems [35, 43, 36, 6, 44, 8, 46, 16, 34, 42, 38, 39] and several recent works build practical reconstruction methods on monotonicity properties [66, 37, 45, 40, 58, 67, 30, 31, 32, 64, 68, 41, 71]. But this is the first work proving a Lipschitz stability result with the relatively simple technique of monotonicity and localized potentials. Previous works on Lipschitz stability for inverse coefficient problems usually required technically more challenging approaches involving Carleman estimates or quantitative unique continuation, cf. [54, 1, 49, 50, 22, 4, 7, 11, 56, 12, 56, 55, 63, 69, 70, 15, 14, 60, 3, 13, 9, 2, 62].

To solve numerically the optimization problem, we use a quasi-Newton method which employs the analytic gradient of the cost function and the approximation of the inverse Hessian is updated by the Broyden, Fletcher, Goldfarb, Shanno (BFGS) scheme [61].

The paper is organized as follows. In section 2, we introduce the forward and inverse problem, the Neumann-to-Dirichlet operator and formulate our main theoretical results: a global uniqueness result and a Lipschitz stability estimate. Section 3 and 4 contain the main theoretical tools for this work. In section 3, we prove a Runge approximation result and based on this result, we prove the global uniqueness theorem. In section 4, we show a monotonicity result between the Robin coefficient and the Neumann-to-Dirichlet operator and deduce the existence of localized potential from the Runge approximation result. Then, we prove the Lipschitz stability estimate. In section 5, we introduce the minimization problem, we prove the existence of optimal solution and we compute the first order optimality condition using the framework of the min-sup differentiability. In the last section, satisfactory numerical results for two-dimensional problem are presented to illustrate the efficiency of the method.

2. Problem statement. Let $\Omega \subset \mathbb{R}^d \, (d \geq 2)$, be a bounded domain with Lipschitz boundary $\partial \Omega$ and let $\Omega_1$ be an open subset of $\Omega$ such that $\Omega_1 \Subset \Omega$, $\Gamma := \partial \Omega_1$ is Lipschitz, and $\Omega_2 := \Omega \setminus \overline{\Omega_1}$ is connected. Thus, we have $\partial \Omega_2 = \Gamma \cup \partial \Omega$; see Figure 1 for a description of the geometry. For a piecewise-constant conductivity $\sigma = \sigma_1 \chi_{\Omega_1} + \sigma_2 \chi_{\Omega_2}$, with given $\sigma_1, \sigma_2 > 0$, and a Robin parameter $\gamma \in L^\infty_+ (\Gamma)$, where $L^\infty_+$ denotes the subset of $L^\infty$-functions with positive essential infima, we consider the
The domain $\Omega = \Omega_1 \cup \Gamma \cup \Omega_2$.

The following problem with Neumann boundary data $g \in L^2(\partial \Omega)$:

\[
\begin{align*}
&- \text{div}(\sigma \nabla u) = 0 \quad \text{in} \ \Omega, \\
&\sigma_2 \partial_\nu u = g \quad \text{on} \ \partial \Omega, \\
&\|u\| = 0 \quad \text{on} \ \Gamma, \\
&\|\sigma \partial_\nu u\| = \gamma u \quad \text{on} \ \Gamma,
\end{align*}
\]

where $\nu$ is the unit normal vector to the interface $\Gamma$ or $\partial \Omega$ pointing outward of $\Omega_1$ or $\Omega$, respectively, and

\[
\|u\| := u^+ - u^-, \quad \text{with} \quad u^+ = \beta_0|_{\Omega_2}(u), \quad u^- = \beta_0|_{\Omega_1}(u),
\]

\[
\|\sigma \partial_\nu u\| := \sigma_2 \partial_\nu u^+ - \sigma_1 \partial_\nu u^-, \quad \text{with} \quad \partial_\nu u^+ = \beta_1|_{\Omega_2}(u), \quad \partial_\nu u^- = \beta_1|_{\Omega_1}(u).
\]

Here $\beta_0|_{\Omega_i} : H^1(\Omega_i) \to L^2(\Gamma)$, $\beta_1|_{\Omega_i} : H(\Omega_i) \to L^2(\Gamma)$ are the Dirichlet and Neumann trace operators and $H(\Omega_i)$ is a subspace of $H^1(\Omega_i)$ defined by

\[
H(\Omega_i) := \{u \in H^1(\Omega_i) : \Delta u \in L^2(\Omega_i)\}.
\]

In (2.1), $u$ represents the electric potential, $g$ the prescribed current density on the external boundary $\partial \Omega$, while $\gamma$ is called the corrosion coefficient and describe the presence of corrosion damage on $\Gamma$.

The Neumann problem (2.1) is equivalent to the variational formulation of finding $u \in H^1(\Omega)$ such that

\[
\int_\Omega \sigma \nabla u \cdot \nabla w \, dx + \int_\Gamma \gamma uw \, ds = \int_{\partial \Omega} gw \, ds \quad \text{for all} \quad w \in H^1(\Omega).
\]

Using the Riesz representation theorem (or the Lax-Milgram Theorem), it is easily seen that (2.2) is uniquely solvable and that the solution depends continuously on $g \in L^2(\partial \Omega)$ and $\gamma \in L^\infty(\Omega)$. When dealing with different Robin coefficients or Neumann data, we also denote the solution by $u_{(g)}$.

We denote by $\Lambda(\gamma)$ the so-called Neumann-to-Dirichlet map:

\[
\Lambda(\gamma) : L^2(\partial \Omega) \rightarrow L^2(\partial \Omega)
\]

\[
g \mapsto u_{|_{\partial \Omega}}.
\]
where \( u \) is solution to (2.1). The physical interpretation of the Neumann-to-Dirichlet (ND) map \( \Lambda(\gamma) \) is knowledge of the resulting voltages distributions on the boundary of \( \Omega \) corresponding to all possible current distributions on the boundary. Thus the inverse problem we are concerned with is the following:

\[
\text{(2.3) Find the parameter } \gamma \text{ from the knowledge of the map } \Lambda(\gamma).
\]

There are several aspects of this inverse problem which are interesting both for mathematical theory and practical applications.

- **Uniqueness.** If \( \Lambda(\gamma_1) = \Lambda(\gamma_2) \) show that \( \gamma_1 = \gamma_2 \).
- **Stability.** If \( \Lambda(\gamma_1) \) is close to \( \Lambda(\gamma_2) \), show that \( \gamma_1 \) and \( \gamma_2 \) are close (in a suitable sense).
- **Reconstruction.** Given the boundary measurements \( \Lambda_\gamma \), find a procedure to reconstruct the Robin parameter \( \gamma \).
- **Partial data.** If \( S \) is a subset of \( \partial \Omega \) and if \( \Lambda(\gamma_1)g|_S = \Lambda(\gamma_2)g|_S \) for all boundary currents \( g \), show that \( \gamma_1 = \gamma_2 \).

In this work, we will concentrate on the first three aspects. Note however that our theoretical results on uniqueness and stability also hold with the same proofs when currents are applied on an arbitrarily small open subset \( S \subseteq \partial \Omega \) (with \( \partial \Omega \setminus S \) kept insulated) and voltages are measured on the same subset \( S \).

We will show a monotonicity result:

\[ \gamma_1 \leq \gamma_2 \implies \Lambda(\gamma_1) \geq \Lambda(\gamma_2) \text{ in the sense of quadratic forms,} \]

and using Runge approximation and localized potentials, we deduce the following uniqueness and stability results for determining \( \gamma \) from \( \Lambda(\gamma) \).

**Theorem 2.1 (Uniqueness).** For \( \gamma_1, \gamma_2 \in L^\infty(\Gamma) \),

\[ \Lambda(\gamma_1) = \Lambda(\gamma_2) \text{ if and only if } \gamma_1 = \gamma_2. \]

**Theorem 2.2 (Lipschitz stability).** Let \( \mathcal{A} \) be a finite dimensional subspace of \( L^\infty(\Gamma) \). Given constants \( b > a > 0 \), we define

\[ \mathcal{A}_{[a,b]} := \{ \gamma \in \mathcal{A} : a \leq \gamma(x) \leq b \text{ for } x \in \Gamma \text{ (a.e.)} \}. \]

Then there exists a constant \( C > 0 \) such that for all \( \gamma_1, \gamma_2 \in \mathcal{A}_{[a,b]} \), we have

\[ \|\gamma_1 - \gamma_2\|_{L^\infty(\Gamma)} \leq C\|\Lambda(\gamma_1) - \Lambda(\gamma_2)\|_*, \]

where \( \| . \|_* \) is the natural operator norm in \( \mathcal{L}(L^2(\partial \Omega)) \).

Theorem 2.1 and 2.2 will be proven in the following two sections. Note that Theorem 2.2 obviously implies Theorem 2.1, but we give an independent proof since it is short and simple.

**3. Runge approximation and uniqueness.** We will deduce the uniqueness theorem 2.1 from the following Runge approximation result:

**Theorem 3.1 (Runge approximation).** Let \( \gamma \in L^\infty(\Gamma) \). For all \( f \in L^2(\Gamma) \) there exists a sequence \( (g_n)_{n \in \mathbb{N}} \subset L^2(\partial \Omega) \) such that the corresponding solutions \( u^{(g_n)} \) of (2.1) with boundary data \( g_n \), \( n \in \mathbb{N} \), fulfill

\[ u^{(g_n)}|_\Gamma \to f \text{ in } L^2(\Gamma). \]
Proof. We introduce the operator

\[ A : L^2(\Gamma) \to L^2(\partial \Omega), \quad f \mapsto Af := v|_{\partial \Omega}, \]

where \( v \in H^1(\Omega) \) solves

\[ \int_{\Omega} \sigma \nabla v \cdot \nabla w \, dx + \int_{\Gamma} \gamma v w \, ds = \int_{\Gamma} f w \, ds \quad \text{for all } w \in H^1(\Omega). \]  

(3.1)

Let \( g \in L^2(\partial \Omega) \) and \( u \in H^1(\Omega) \) be the corresponding solution of problem (2.1). Then the adjoint operator of \( A \) is characterized by

\[ \int_{\Gamma} (A^* g) f \, ds = \int_{\partial \Omega} (Af) g \, ds = \int_{\partial \Omega} v g \, ds = \int_{\Omega} \nabla u \cdot \nabla v \, dx + \int_{\Gamma} \gamma u v \, ds \]

\[ = \int_{\Gamma} f u \, ds, \quad \text{for all } f \in L^2(\Gamma), \]

which shows that \( A^* : L^2(\partial \Omega) \to L^2(\Gamma) \) fulfills \( A^* g = u|_{\Gamma} \). The assertion follows if we can show that \( A^* \) has dense range, which is equivalent to \( A \) being injective.

To prove this, let \( v|_{\partial \Omega} = Af = 0 \) with \( v \in H^1(\Omega) \) solving (3.1). Since (3.1) also implies that \( \sigma \partial_{\nu} v|_{\partial \Omega} = 0 \), and \( \Omega \) is connected, it follows by unique continuation that \( v|_{\Omega_2} = 0 \) and thus \( v^+|_{\Gamma} = 0 \). Since \( v \in H^1(\Omega) \) this also implies that \( v^-|_{\Gamma} = 0 \), and together with (3.1) we obtain that \( v|_{\Omega_1} \in H^1(\Omega_1) \) solves

\[ \nabla \cdot (\sigma_1 \nabla v) = 0 \quad \text{in } \Omega_1 \]

with homogeneous Dirichlet boundary data \( v|_{\partial \Omega_1} = 0 \). Hence, \( v|_{\Omega_1} = 0 \), so that \( v = 0 \) almost everywhere in \( \Omega \). From (3.1) it then follows that \( \int_{\Gamma} f w \, ds = 0 \) for all \( w \in H^1(\Omega) \) and thus \( f = 0 \).

**Proof of Theorem 2.1.** For Robin parameters \( \gamma_1, \gamma_2 \in L^\infty_+(\Gamma) \) and Neumann data \( g, h \in L^2(\partial \Omega) \) we denote the corresponding solutions of (2.1) by \( u_1^g, u_1^h, u_2^g, \) and \( u_2^h \) respectively.

The variational formulation (2.2) yields the Alessandrini-type equality

\[ \int_{\partial \Omega} h (\Lambda(\gamma_2) - \Lambda(\gamma_1)) g \, ds \]

\[ = \int_{\partial \Omega} h \Lambda(\gamma_2) g \, ds - \int_{\partial \Omega} g \Lambda(\gamma_1) h \, ds = \int_{\partial \Omega} h u_2^g \, ds - \int_{\partial \Omega} g u_1^h \, ds \]

\[ = \int_{\Omega} \sigma \nabla u_1^h \cdot \nabla u_2^g \, dx + \int_{\Gamma} \gamma_1 u_1^h u_2^g \, ds - \left( \int_{\Omega} \sigma \nabla u_2^h \cdot \nabla u_1^h \, dx + \int_{\Gamma} \gamma_2 u_2^h u_1^h \, ds \right) \]

\[ = \int_{\Gamma} (\gamma_1 - \gamma_2) u_1^h u_2^g \, ds. \]

This shows that \( \Lambda(\gamma_1) = \Lambda(\gamma_2) \) implies that

\[ \int_{\Gamma} (\gamma_1 - \gamma_2) u_1^h u_2^g \, ds = 0, \quad \text{for all } g, h \in L^2(\partial \Omega). \]

Using the Runge approximation result in theorem 3.1, this yields that \( (\gamma_1 - \gamma_2) u_1^h = 0 \) (a.e.) in \( \Gamma \) for all \( h \in L^2(\partial \Omega) \), and using theorem 3.1 again, this implies \( \gamma_1 = \gamma_2 \).
4. Monotonicity, localized potentials and Lipschitz stability. To prove the Lipschitz stability result in Theorem 2.2, we first show a monotonicity estimate between the Robin coefficient and the Neumann-to-Dirichlet operator, and deduce the existence of localized potentials from the Runge approximation result in the last section. The idea of the following monotonicity estimate stems from the works of Ikehata, Kang, Seo, and Sheen [48, 53], and the proof is analogue to [43, Lemma 2.1], cf. also the other references to monotonicity-based methods in the introduction.

**Lemma 4.1 (Monotonicity estimate).** Let \( \gamma_1, \gamma_2 \in L^\infty_+(\Gamma) \) be two Robin parameters, let \( g \in L^2(\partial\Omega) \) be an applied boundary current, and let \( u_2 := u^g_{\gamma_2} \in H^1(\Omega) \) solve (2.1) for the boundary current \( g \) and the Robin parameter \( \gamma_2 \). Then

\[
(4.1) \quad \int_\Gamma (\gamma_1 - \gamma_2) u_2^2 \, ds \geq \int_{\partial\Omega} g (\Lambda(\gamma_2) - \Lambda(\gamma_1)) \, g \, ds \geq \int_{\Gamma} \left( \gamma_2 - \frac{\gamma_2^2}{\gamma_1} \right) u_2^2 \, ds.
\]

**Proof.** Let \( u_1 := u^g_{\gamma_1} \in H^1(\Omega) \). From the variational equation, we deduce

\[
\int \sigma \nabla u_1 \cdot \nabla u_2 \, dx + \int_{\Gamma} \gamma_1 u_1 u_2 \, ds = \int_{\partial\Omega} g \Lambda(\gamma_2) g \, ds = \int_\Omega \sigma |\nabla u_2|^2 \, dx + \int_{\Gamma} \gamma_2 u_2^2 \, ds.
\]

Thus

\[
\int_\Omega \sigma |\nabla (u_1 - u_2)|^2 \, dx + \int_{\Gamma} \gamma_1 (u_1 - u_2)^2 \, ds
= \int_\Omega \sigma |\nabla u_1|^2 \, dx + \int_{\Gamma} \gamma_1 u_1^2 \, ds + \int_\Omega \sigma |\nabla u_2|^2 \, dx + \int_{\Gamma} \gamma_1 u_2^2 \, ds
- 2 \int_\Omega \sigma |\nabla u_2|^2 \, dx - 2 \int_{\Gamma} \gamma_2 u_2^2 \, ds
= \int_{\partial\Omega} g \Lambda(\gamma_1) g \, ds - \int_{\partial\Omega} g \Lambda(\gamma_2) g \, ds + \int_{\Gamma} (\gamma_1 - \gamma_2) u_2^2 \, ds.
\]

Since the left-hand side is nonnegative, the first asserted inequality follows.

Interchanging \( \gamma_1 \) and \( \gamma_2 \), we get

\[
\int_{\partial\Omega} g \Lambda(\gamma_2) g \, ds - \int_{\partial\Omega} g \Lambda(\gamma_1) g \, ds
= \int_\Omega \sigma |\nabla (u_2 - u_1)|^2 \, dx + \int_{\Gamma} \gamma_2 (u_2 - u_1)^2 \, ds - \int_{\Gamma} (\gamma_2 - \gamma_1) u_1^2 \, ds
= \int_\Omega \sigma |\nabla (u_2 - u_1)|^2 \, dx + \int_{\Gamma} (\gamma_2 u_2^2 - 2\gamma_2 u_1 u_2 + \gamma_1 u_1^2) \, ds
= \int_\Omega \sigma |\nabla (u_2 - u_1)|^2 \, dx + \int_{\Gamma} \gamma_1 \left( u_1 - \frac{\gamma_2}{\gamma_1} u_2 \right)^2 \, ds + \int_{\Gamma} \left( \gamma_2 - \frac{\gamma_2^2}{\gamma_1} \right) u_2^2 \, ds.
\]

Since the first two integrals on the right-hand side are non negative, the second asserted inequality follows. \( \square \)

Note that we call Lemma 4.1 a monotonicity estimate because of the following corollary:

**Corollary 4.2 (Monotonicity).** For two Robin parameters \( \gamma_1, \gamma_2 \in L^\infty_+(\Gamma) \)

\[
(4.2) \quad \gamma_1 \leq \gamma_2 \implies \Lambda(\gamma_1) \geq \Lambda(\gamma_2) \quad \text{in the sense of quadratic forms.}
\]
The existence of localized potentials [33] follows from the Runge approximation property as in [38, Corollary 3.5]:

**Lemma 4.3 (Localized potentials).** Let \( \gamma \in L^\infty_+(\Gamma) \), and let \( M \subseteq \Gamma \) be a subset with positive boundary measure. Then there exists a sequence \((g_n)_{n \in \mathbb{N}} \subseteq L^2(\partial \Omega)\) such that the corresponding solutions \( u^{(g_n)} \) of (2.1) fulfill

\[
\lim_{n \to \infty} \int_M |u^{(g_n)}|^2\,ds = \infty \quad \text{and} \quad \lim_{n \to \infty} \int_{\Gamma \setminus M} |u^{(g_n)}|^2\,ds = 0.
\]

**Proof.** Using the Runge approximation property in Theorem 3.1 we find a sequence \( \tilde{g}_n \in L^2(\partial \Omega) \) so that the corresponding solutions \( u^{(\tilde{g}_n)} \) fulfill

\[
u^{(\tilde{g}_n)}|_\Gamma \to \chi_M \frac{\chi_M}{\int_M} \quad \text{in} \quad L^2(\Gamma).
\]

Hence

\[
\lim_{n \to \infty} \int_M |u^{(\tilde{g}_n)}|^2\,ds = 1 \quad \text{and} \quad \lim_{n \to \infty} \int_{\Gamma \setminus M} |u^{(\tilde{g}_n)}|^2\,ds = 0,
\]

so that

\[
g_n := \frac{\tilde{g}_n}{\left(\int_{\Gamma \setminus M} \tilde{u}_n^2\,ds\right)^{1/4}},
\]

has the desired property

\[
\lim_{n \to \infty} \int_M |u^{(g_n)}|^2\,ds = \lim_{n \to \infty} \frac{\int_M |u^{(\tilde{g}_n)}|^2\,ds}{\left(\int_{\Gamma \setminus M} |u^{(\tilde{g}_n)}|^2\,ds\right)^{1/2}} = \infty,
\]

\[
\lim_{n \to \infty} \int_{\Gamma \setminus M} |u^{(g_n)}|^2\,ds = \lim_{n \to \infty} \left(\int_{\Gamma \setminus M} |u^{(\tilde{g}_n)}|^2\,ds\right)^{1/2} = 0.
\]

Now, we are ready to proof Theorem 2.2.

**Proof of Theorem 2.2.** Let \( \mathcal{A} \) be a finite dimensional subspace of \( L^\infty(\Gamma) \), \( b > a > 0 \), and

\[
\gamma_1, \gamma_2 \in \mathcal{A}_{[a,b]} = \{ \gamma \in \mathcal{A} : \ a \leq \gamma(x) \leq b \ \text{for} \ x \in \Gamma \ \text{(a.e.)}\}.
\]

For the ease of notation, we write in the following

\[
\|\gamma_1 - \gamma_2\| := \|\gamma_1 - \gamma_2\|_{L^\infty(\Gamma)} \quad \text{and} \quad \|g\| := \|g\|_{L^2(\partial \Omega)}.
\]

Since \( \Lambda(\gamma_1) \) and \( \Lambda(\gamma_2) \) are self-adjoint, we have that

\[
\|\Lambda(\gamma_2) - \Lambda(\gamma_1)\|_* = \sup_{\|g\| = 1} \left| \int_{\partial \Omega} g (\Lambda(\gamma_2) - \Lambda(\gamma_1)) g \,ds \right|
\]

\[
= \sup_{\|g\| = 1} \max \left\{ \int_{\partial \Omega} g (\Lambda(\gamma_2) - \Lambda(\gamma_1)) g \,ds, \int_{\partial \Omega} g (\Lambda(\gamma_1) - \Lambda(\gamma_2)) g \,ds \right\}.
\]
Using the first inequality in the monotonicity relation (4.1) in Lemma 4.1 in its original form, and with \( \gamma_1 \) and \( \gamma_2 \) interchanged, we obtain for all \( g \in L^2(\partial \Omega) \)

\[
\int_{\partial \Omega} g (\Lambda(\gamma_2) - \Lambda(\gamma_1)) \, g \, ds \geq \int_{\Gamma} (\gamma_1 - \gamma_2) |u^{(g)}_{\gamma_1}|^2, \\
\int_{\partial \Omega} g (\Lambda(\gamma_1) - \Lambda(\gamma_2)) \, g \, ds \geq \int_{\Gamma} (\gamma_2 - \gamma_1) |u^{(g)}_{\gamma_2}|^2,
\]

where \( u^{(g)}_{\gamma_1}, u^{(g)}_{\gamma_2} \in H^1(\Omega) \) denote the solutions of (2.1) with Neumann data \( g \) and Robin parameter \( \gamma_1 \) and \( \gamma_2 \), resp. Hence, for \( \gamma_1 \neq \gamma_2 \), we have

\[
\frac{\|\Lambda(\gamma_2) - \Lambda(\gamma_1)\|}{\|\gamma_1 - \gamma_2\|} \geq \sup_{\|g\|=1} \Psi \left( g, \frac{\gamma_1 - \gamma_2}{\|\gamma_1 - \gamma_2\|_{L^\infty(\Gamma)}}, \gamma_1, \gamma_2 \right),
\]

where (for \( g \in L^2(\partial \Omega) \), \( \zeta \in A \), and \( \kappa_1, \kappa_2 \in A_{[a,b]} \))

\[
\Psi(g, \zeta, \kappa_1, \kappa_2) := \max \left( \int_{\Gamma} \zeta |u^{(g)}_{\kappa_1}|^2 \, ds, \int_{\Gamma} (-\zeta) |u^{(g)}_{\kappa_2}|^2 \, ds \right).
\]

Introduce the compact set

\[
C = \{ \zeta \in A : \|\zeta\|_{L^\infty(\Gamma)} = 1 \}.
\]

Then, we have

\[
\frac{\|\Lambda(\gamma_2) - \Lambda(\gamma_1)\|}{\|\gamma_1 - \gamma_2\|} \geq \inf_{\kappa_1, \kappa_2} \sup_{\|g\|=1} \Psi(g, \zeta, \kappa_1, \kappa_2).
\]

The assertion of Theorem 2.2 follows if we can show that the right hand side of (4.3) is positive. Since \( \Psi \) is continuous, the function

\[
(\zeta, \kappa_1, \kappa_2) \mapsto \sup_{\|g\|=1} \Psi(g, \zeta, \kappa_1, \kappa_2)
\]

is semi-lower continuous, so that it attains its minimum on the compact set \( C \times A_{[a,b]} \times A_{[a,b]} \). Hence, to prove Theorem 2.2, it suffices to show that

\[
\sup_{\|g\|=1} \Psi(g, \zeta, \kappa_1, \kappa_2) > 0 \quad \text{for all } (\zeta, \kappa_1, \kappa_2) \in C \times A_{[a,b]} \times A_{[a,b]}.
\]

To show this, let \( (\zeta, \kappa_1, \kappa_2) \in C \times A_{[a,b]} \times A_{[a,b]} \). Since \( \|\zeta\|_{L^\infty(\Gamma)} = 1 \), there exists a subset \( M \subseteq \Gamma \) with positive boundary measure such that either

\[
\text{(a) } \zeta(x) \geq \frac{1}{2} \text{ for all } x \in M, \quad \text{or } \quad \text{(b) } -\zeta(x) \geq \frac{1}{2} \text{ for all } x \in M.
\]

In case (a), we use the localized potentials sequence in lemma 4.3 to obtain a boundary current \( \tilde{g} \in L^2(\partial \Omega) \) with

\[
\int_M |u^{(g)}_{\kappa_1}|^2 \, ds \geq 2 \quad \text{and} \quad \int_{\Gamma \setminus M} |u^{(g)}_{\kappa_1}|^2 \, ds \leq \frac{1}{2},
\]

so that (using again \( \|\zeta\|_{L^\infty(\Gamma)} = 1 \))

\[
\Psi(\tilde{g}, \zeta, \kappa_1, \kappa_2) \geq \int_{\Gamma} \zeta |u^{(g)}_{\kappa_1}|^2 \, ds \geq \frac{1}{2} \int_M |u^{(g)}_{\kappa_1}|^2 \, ds - \int_{\Gamma \setminus M} |u^{(g)}_{\kappa_1}|^2 \, ds \geq \frac{1}{2}.
\]
In case (b), we can analogously use a localized potentials sequence for \( \kappa_2 \), and find \( \hat{g} \in L^2(\partial \Omega) \) with

\[
\Psi(\hat{g}, \zeta, \kappa_1, \kappa_2) \geq \int_{\Gamma} (\zeta) |u(\hat{g})|_2^2 \, ds \geq \frac{1}{2} \int_{\partial \Omega_\kappa_2} |u(\hat{g})|_2^2 \, ds - \int_{\Gamma \setminus \partial \Omega_\kappa_2} |u(\hat{g})|_2^2 \, ds \geq \frac{1}{2}.
\]

Hence, in both cases,

\[
\sup_{\|g\|=1} \Psi(g, \zeta, \kappa_1, \kappa_2) \geq \Psi(\hat{g}, \zeta, \kappa_1, \kappa_2) = \frac{1}{\|\hat{g}\|_2^2} \Psi(\hat{g}, \zeta, \kappa_1, \kappa_2) > 0,
\]

so that Theorem 2.2 is proven.

5. The minimization problem. In order to solve numerically the inverse problem (2.3), we consider only Robin coefficients in the admissible set

\[
P_{\text{ad}} := \{ \gamma \in C(\Gamma) : 0 < c_0 \leq \gamma(x) \leq c_1 \text{ for } x \in \Gamma, \text{ where } c_0, c_1 \text{ are constants} \},
\]

and study the following minimization problem:

\[
(5.1) \quad \min_{\gamma \in P_{\text{ad}}} J(\gamma) = \frac{1}{2} \int_{\partial \Omega} (u(\gamma) - u_a)^2 \, ds + \frac{\lambda}{2} \int_{\Gamma} \gamma^2 \, ds,
\]

where \( u(\gamma) \) solves the variational equation (2.2), \( u_a \) is the measured data and \( \lambda \) is a regularization parameter that must be chosen by the user. It is obvious that the optimization problem (5.1) is equivalent to the inverse problem (2.3) when the data \( u_a \) are exact and the regularization parameter \( \lambda = 0 \). When the data \( u_a \) are contaminated with measurement errors, the inverse problem (2.3) may not have a solution. However, the optimization problem (5.1) has always a solution, and it may not be equivalent to the solution of the inverse problem.

**Theorem 5.1.** The minimization problem (5.1) has at least one solution.

**Proof.** It is clear that \( \inf J(\gamma) \) is finite over the admissible set \( P_{\text{ad}} \). Therefore there exists a minimizing sequence \( \gamma_n \) such that

\[
\lim_{n \to +\infty} J(\gamma_n) = \inf_{\gamma \in P_{\text{ad}}} J(\gamma).
\]

The sequence \( \gamma_n \) is bounded, by the Banach-Alaoglu theorem, there exists a subsequence still denoted \( \gamma_n \) such that

\[
\lim_{n \to \infty} \gamma_n = \gamma^* \text{ weak-* in } L^\infty(\Gamma).
\]

By definition \( u(\gamma_n) \) satisfies

\[
(5.2) \quad \int_{\Omega} \sigma \nabla u(\gamma_n) \cdot \nabla v \, dx + \int_{\Gamma} \gamma_n u(\gamma_n)v \, ds = \int_{\partial \Omega} gv \, ds \quad \forall v \in H^1(\Omega).
\]

Taking \( v = u(\gamma_n) \) in (5.2), we obtain

\[
\int_{\Omega} \sigma |\nabla u(\gamma_n)|^2 \, dx + \int_{\Gamma} \gamma_n u(\gamma_n)^2 \, ds = \int_{\partial \Omega} gu(\gamma_n) \, ds.
\]

Using the fact that \( \|u\|^2 := \|\nabla u\|^2_{L^2(\Omega)} + \|u\|^2_{L^2(\Gamma)} \) is a norm on \( H^1(\Omega) \) equivalent to the natural norm (cf. [59]) and from the trace theorem, we deduce the existence of a constant \( c > 0 \) such that

\[
\|u(\gamma_n)\|_{H^1(\Omega)} \leq c\|g\|_{L^2(\partial \Omega)}.
\]
This implies that \( u(\gamma_n) \) is uniformly bounded independent of \( n \). Therefore there exists a subsequence of \( u(\gamma_n) \) still denoted \( u(\gamma_n) \) such that
\[
\lim_{n \to \infty} u(\gamma_n) = u^* \text{ weakly in } H^1(\Omega).
\]
As the embedding of \( H^1(\Omega) \) into \( L^2(\Omega) \) is compact, we also have
\[
\lim_{n \to \infty} u(\gamma_n) = u^* \text{ strongly in } L^2(\Omega).
\]
Now the strong convergence of \( u(\gamma_n) \) in \( L^2(\Gamma) \) and the weak-* convergence of \( \gamma_n \) in \( L^\infty(\Gamma) \) yield that
\[
\lim_{n \to \infty} \int_{\Gamma} \gamma_n u(\gamma_n)v ds = \int_{\Gamma} \gamma^* u^* v ds,
\]
Letting \( n \) goes to infinity in equation (5.2), we conclude that \( u^* \) satisfies
\[
\int_{\Omega} \sigma \nabla u^*_n \cdot \nabla v dx + \int_{\Gamma} \gamma^* u^* v ds = \int_{\partial \Omega} g v ds, \quad \forall v \in H^1(\Omega).
\]
Due to the uniqueness of the weak limit, we get \( u(\gamma^*) = u^* \). This means that
\[
\lim_{n \to \infty} u(\gamma_n) = u(\gamma^*) \text{ weakly in } H^1(\Omega) \text{ and strongly in } L^2(\Omega).
\]
Using the lower semi-continuity of the \( L^2 \)-norm yields
\[
J(\gamma^*) \leq \liminf_{n \to \infty} J(\gamma_n) = J(\gamma),
\]
which concludes the proof.

In what follows we focus on the computation of the derivative of the function \( J \).

**5.1. Derivative by the min-sup differentiability.** We introduce the Lagrangian functional
\[
G(\gamma, \varphi, \psi) = J(\gamma, \varphi) + \int_{\Omega} \sigma \nabla \varphi \cdot \nabla \psi dx + \int_{\Gamma} \gamma \varphi \psi ds - \int_{\partial \Omega} g \psi ds, \quad \forall \varphi, \psi \in H^1(\Omega).
\]
Then, it is easy to check that
\[
J(\gamma, u(\Gamma)) = \min_{\varphi \in H^1(\Omega)} \sup_{\psi \in H^1(\Omega)} G(\gamma, \varphi, \psi),
\]
since
\[
\sup_{\psi \in H^1(\Omega)} G(\Gamma, \varphi, \psi) = \begin{cases} J(\gamma, u(\gamma)) & \text{if } \varphi = u(\gamma), \\ +\infty & \text{otherwise}. \end{cases}
\]
It is easily shown that the functional \( G \) is convex continuous with respect to \( \varphi \) and concave continuous with respect to \( \psi \). Therefore, according to Ekeland and Temam [28], the functional \( G \) has a saddle point \((u, v)\) if and only if \((u, v)\) solves the following system:
\[
\begin{align*}
\partial_{u} G(\gamma, u; \psi) &= 0, \\
\partial_{\psi} G(\gamma, u; \varphi) &= 0,
\end{align*}
\]
for all \( \psi \in H^1(\Omega) \) and \( \varphi \in H^1(\Omega) \). This yields that \( G \) has a saddle point \((u, v)\), where the state \( u \) is the unique solution of (2.2) and the adjoint state \( v = v(\gamma) \) is the solution of the following adjoint problem:
\[
(5.3) \quad \int_{\Omega} \sigma \nabla v \cdot \nabla \hat{v} dx + \int_{\Gamma} \gamma \hat{v} ds + \int_{\partial \Omega} (u - u_a) \hat{v} ds = 0 \quad \text{for all } \hat{v} \in H^1(\Omega).
\]
Summarizing the above, we have obtained
Theorem 5.2. The functionals $J(\gamma, u(\gamma))$ is given as

$$J(\gamma, u(\gamma)) = \min_{\varphi \in H^1(\Omega)} \sup_{\psi \in H^1(\Omega)} G(\gamma, \varphi, \psi),$$

The unique saddle point for $G$ is given by $(u, v)$.

Theorem 5.3. The functional $J$ is Gateaux differentiable, and its Gateaux derivative at $\gamma \in C(\Gamma)$ in the direction $\hat{\gamma}$ is given by

$$D_\gamma J(\gamma, u(\gamma); \hat{\gamma}) = \int_\Gamma \hat{\gamma} (uv + \lambda \gamma) \, ds.$$

Proof. Let $\gamma_t = \gamma + t \hat{\gamma}$, where $\hat{\gamma} \in C(\Gamma)$ and $t \in \mathbb{R}$ is sufficiently small parameter. Under hypotheses of Theorem 8.1, we have

$$D_\gamma J(\gamma, u(\gamma); \hat{\gamma}) = \partial_t G(\gamma_t, u(\gamma_t), v(\gamma_t)) \bigg|_{t=0},$$

where

$$G(\gamma_t, \varphi, \psi) = J(\gamma, \varphi) + \int_\Omega \sigma \nabla \varphi \cdot \nabla \psi \, dx + \int_\Gamma \gamma_t \varphi \psi \, ds - \int_{\partial \Omega} g \psi \, ds,$$

and

$$\partial_t G(\gamma_t, u, v) \bigg|_{t=0} = \int_\Gamma \hat{\gamma} (uv + \lambda \gamma) \, ds.$$

From the above equation yields (5.5). To end the proof, we should verify the four assumptions ($H_1$) – ($H_4$) of Theorem 8.1 given in the appendix. As in Theorem 8.1, introduce the sets

$$X(t) := \left\{ x^t \in H^1(\Omega) : \sup_{y \in H^1(\Omega)} G(t, x^t, y) = \inf_{x \in H^1(\Omega)} \sup_{y \in H^1(\Omega)} G(t, x, y) \right\},$$

$$Y(t) := \left\{ y^t \in H^1(\Omega) : \inf_{x \in H^1(\Omega)} G(t, x, y^t) = \sup_{y \in H^1(\Omega)} \inf_{x \in H^1(\Omega)} G(t, x, y) \right\},$$

we obtain

$$\forall \ t \in [0, \varepsilon] \quad S(t) = X(t) \times Y(t) = \{u(\gamma_t), v(\gamma_t)\} \neq \emptyset,$$

and assumption ($H_1$) is satisfied.

Assumption ($H_2$): The partial derivative $\partial_t G(t, \varphi, \psi)$ exists everywhere in $[0, \varepsilon)$ and the condition ($H_2$) is satisfied.

Assumptions ($H_3$) and ($H_4$): We show first the boundedness of $(u(\gamma_t), v(\gamma_t))$. Let $w = u(\gamma_t)$ in the variational equation

$$\int_\Omega \sigma \nabla u(\gamma_t) \cdot \nabla w \, dx + \int_\Gamma \gamma_t u(\gamma_t) w \, ds = \int_{\partial \Omega} g v \, ds \text{ for all } w \in H^1(\Omega).$$

We get

$$\min(\sigma_1, \sigma_2) \|\nabla u(\gamma_t)\|_{L^2(\Omega)}^2 + c_0 \|u(\gamma_t)\|_{L^2(\Gamma)}^2 \leq \|g\|_{L^2(\partial \Omega)} \|u(\gamma_t)\|_{L^2(\partial \Omega)}.$$
Using the fact that \( \|u\|^2 := \|\nabla u\|_{L^2(\Omega)}^2 + \|u\|_{L^2(\Gamma)}^2 \) is a norm on \( H^1(\Omega) \) equivalent to the natural norm and from the trace theorem, there exists \( c > 0 \), depending only on \( \Omega \) such that

\[
\|u(\gamma_t)\|_{H^1(\Omega)} \leq c\|g\|_{L^2(\partial\Omega)},
\]

which yields

\[
\sup_{t \in [0,\varepsilon]} \|u(\gamma_t)\|_{H^1(\Omega)} \leq c\|g\|_{L^2(\partial\Omega)}.
\]

We apply the same technique to the variational equation

\[
(5.7) \quad \int_{\Omega} \sigma \nabla v(\gamma_t) : \nabla \hat{v} \, dx + \int_{\Gamma} \gamma t v(\gamma_t) \hat{v} \, ds + \int_{\partial\Omega} (u(\gamma_t) - u_a) \, ds = 0,
\]

for all \( \hat{v} \in H^1(\Omega) \), and we are able to show that the function \( v(\gamma_t) \) is bounded.

The next step is to show the continuity with respect to \( t \) of the vector \( (u(\gamma_t), v(\gamma_t)) \). Subtracting (5.6) at \( t > 0 \) and \( t = 0 \) and choosing \( w = u(\gamma) - u(\gamma_t) \) yields

\[
\int_{\Omega} \sigma |\nabla (u(\gamma) - u(\gamma_t))|^2 \, dx + \int_{\Gamma} \gamma t (u(\gamma) - u(\gamma_t))^2 \, ds = \int_{\Gamma} (\gamma_t - \gamma) u(\gamma_t)(u(\gamma) - u(\gamma_t)) \leq \|\gamma_t - \gamma\|_{L^\infty(\Gamma)} \|u(\gamma_t)\|_{L^2(\Gamma)} \|u(\gamma) - u(\gamma_t)\|_{L^2(\Gamma)}.
\]

Furthermore due to the boundedness of \( u(\gamma_t) \), we obtain

\[
\|u(\gamma_t) - u(\gamma)\|_{H^1(\Omega)} \leq c\|\gamma_t - \gamma\|_{L^\infty(\Gamma)}.
\]

Due to the strong continuity of \( \gamma_t \) as a function of \( t \), one deduces that \( u(\gamma_t) \rightarrow u(\gamma) \) in \( H^1(\Omega) \) as \( t \rightarrow 0 \). Concerning the continuity of \( v(\gamma_t) \), one may show from (5.7) that \( v(\gamma_t) \rightarrow v(\gamma) \) in \( H^1(\Omega) \). Finally in view of the strong continuity of

\[
(t, \varphi) \rightarrow \partial_t G(\gamma_t, \varphi, \psi), \quad (t, \psi) \rightarrow \partial_t G(\gamma_t, \varphi, \psi),
\]

assumptions (H3) and (H4) are verified. \( \square \)

6. Implementation details and numerical examples. In the following numerical examples, the domain \( \Omega \) under consideration is the unit disk centered at the origin and the boundary \( \Gamma \) is given by:

\[
\Gamma = \{(x_1, x_2) \in \mathbb{R}^2 : \ x_1^2 + x_2^2 = 0.5^2\}.
\]

The domain \( \Omega \) is discretized using a Delaunay triangular mesh. A standard finite element method with piecewise finite elements is applied to compute numerically the state and the adjoint state for our problem. The exact data \( u_a \) are computed synthetically by solving the direct problem (2.1). In the real-world, the data \( u_a \) are experimentally acquired and thus always contaminated by errors. In our numerical examples the simulated noise data are generated using the following formula:

\[
\tilde{u}_a(x_1, x_2) = u_a(x_1, x_2) (1 + \varepsilon \delta) \quad \text{on} \partial\Omega,
\]

where \( \delta \) is a normal distributed random variable and \( \varepsilon \) indicates the level of noise. For our examples, the random variable \( \delta \) is realized using the matlab function randn(). The conductivity \( \sigma \) is taken to be

\[
\sigma = 2\chi_{\Omega_1} + \chi_{\Omega_2}.
\]

We use the BFGS algorithm to solve the minimization problem (5.1). This quasi-Newton method is well adapted to such problem.
6.1. Numerical examples. For the following numerical examples, we include both reconstruction from a noiseless and noisy data. The regularization parameter $\lambda$ is set to zero because it does not seem to play an indispensable role in our numerical experiments.

Figure 2, shows the monotonicity relation between the Robin coefficient $\gamma$ and the Neumann-to-Dirichlet operator $\Lambda(\gamma)$.

6.1.1. Example 1. In this example, we use three measurements corresponding to the following fluxes:

$$g_1(\theta) = \cos(\theta), \quad g_2(\theta) = \sin(\theta) \quad \text{and} \quad g_3(\theta) = \cos^2(\theta) - \sin^2(\theta) \text{ on } \partial \Omega.$$  

In this case the cost function $J$ takes the form:

$$J(\gamma) = \frac{1}{2} \sum_{k=1}^{3} \int_{\partial \Omega} (u_{\gamma}^{g_k} - u_{a_k}^{g_k})^2 \, ds + \frac{\lambda}{2} \int_{\Gamma} \gamma^2 \, ds,$$

where $u_{\gamma}^{g_k}$ is the solution to problem (2.1) with respect to the flux $g_k$ and $u_{a_k}^{g_k}$ is the corresponding measurement data.

The exact Robin coefficient to be reconstructed is given by

$$\gamma(\theta) = \exp \left( -\frac{1}{2} \cos(\theta) \right), \quad \theta \in [0, 2\pi].$$

The accuracy of the reconstruction of the Robin coefficients depend on the initial guess $\gamma_0$ as depicted in figure 3. The numerical solution represents reasonable approximation and it is stable with respect to a small amount of noise as shown in figures 6, 9. Figures 4, 5, 7, 8, 10, 11, shown the decrease of cost function $J$ and the $L^\infty$-norm of $DJ(\gamma)$ in the course of the optimization process.

![Fig. 2. Monotonicity of the Neumann-to-Dirichlet operator $g_i \rightarrow \Lambda(\gamma)g_i$. In figure (a) $\gamma_1 = \exp(-\cos(\theta)) \leq \gamma_2 = \exp(-\cos(\theta)) + 1, \theta \in [0, 2\pi]$. In figure (b), $(\Lambda(\gamma_1)g_i, g_i) \geq (\Lambda(\gamma_2)g_i, g_i)$ with $g_i = \sin(i\theta), i = 1, \ldots, 10$.](image)

6.1.2. Example 2. In the second example, we consider the following three fluxes

$$g_1(\theta) = 5 + \cos(\theta), \quad g_2(\theta) = 1 + \sin(\theta) \quad \text{and} \quad g_3(\theta) = 3 + \cos^2(\theta) - \sin^2(\theta) \text{ on } \partial \Omega.$$
Fig. 3. Reconstruction of the Robin coefficient for two different initialization $\gamma_i(\theta) = \exp(-0.2 \cos(\theta))$ and $\gamma_i = 1$, with level noise $\varepsilon = 0$.

Fig. 4. History of the cost function $J(\gamma)$ and the $L^\infty$-norm of $D J(\gamma)$ in the case of the initialization $\gamma_i = \exp(-0.2 \cos(\theta))$ and the level noise $\varepsilon = 0$.

The exact Robin coefficient to be reconstructed is given by

$$\gamma(\theta) = 1 + \cos(\theta)^2, \quad \theta \in [0, 2\pi].$$

A reasonable reconstruction of the Robin coefficient with noiseless and noisy data can be seen in figure 12. Figures 13, 14, shown the decrease of cost function $J$ and the $L^\infty$-norm of $D J(\gamma)$ in the course of the optimization process.

7. Conclusion. We have studied theoretically and numerically the inverse Robin transmission problem from boundary measurements. More precisely, we proved global uniqueness and Lipschitz stability. Our proofs rely on monotonicity and localized potentials arguments and seem simpler than the commonly used technique of Carleman estimates or complex geometrical optics (CGO). Notably this is the first work to prove Lipschitz stability using monotonicity and localized potentials arguments.

The inverse problem is recast into a minimization of an output least-square formulation and a technique based on the differentiability of the min-sup is suggested to
drive the first order optimality condition without the derivative of the state solution. The BFGS method is employed to solve the minimization problem, and numerical results for two-dimensional problem in the case of noiseless and noisy data are presented to illustrate the efficiency of the proposed algorithm.

8. Appendix.

8.1. An abstract differentiability result. In this section we give an abstract result for differentiating Lagrangian functionals with respect to a parameter. This result is used to prove Theorem 5.5. We first introduce some notations. Consider the functional

$$G : [0, \varepsilon] \times X \times Y \to \mathbb{R}$$

for some $\varepsilon > 0$ and the Banach spaces $X$ and $Y$. For each $t \in [0, \varepsilon]$, define

$$g(t) = \inf_{x \in X} \sup_{y \in Y} G(t, x, y), \quad h(t) = \sup_{y \in Y} \inf_{x \in X} G(t, x, y),$$

$$\text{(8.1)} \quad \text{(8.2)}$$
and the associated sets

\[ X(t) = \left\{ x^t \in X : \sup_{y \in Y} G(t, x^t, y) = g(t) \right\}, \tag{8.3} \]

\[ Y(t) = \left\{ y^t \in Y : \inf_{x \in X} G(t, x, y^t) = h(t) \right\}. \tag{8.4} \]

Note that inequality \( h(t) \leq g(t) \) holds. If \( h(t) = g(t) \) the set of saddle points is given by

\[ S(t) := X(t) \times Y(t). \tag{8.5} \]

We state now a simplified version of a result from [26] derived from [25] which gives realistic conditions that allows to differentiate \( g(t) \) at \( t = 0 \). The main difficulty is to obtain conditions which allow to exchange the derivative with respect to \( t \) and the inf-sup in (8.2).
Reconstruction of the Robin coefficient (e) with level noise $\varepsilon = 0.05$, (f) with level noise $\varepsilon = 0.1$

Theorem 8.1 (Correa and Seeger[27]). Let $X, Y, G$ and $\varepsilon$ be given as above. Assume that the following conditions hold:

(H1) $S(t) \neq \emptyset$ for $0 \leq t \leq \varepsilon$.

(H2) The partial derivative $\partial_t G(t, x, y)$ exists for all $(t, x, y) \in [0, \varepsilon] \times X \times Y$.

(H3) For any sequence $\{t_n\}_{n \in \mathbb{N}}$ with $t_n \to 0$, there exist a subsequence $\{t_{n_k}\}_{k \in \mathbb{N}}$ and $x^0 \in X(0)$, $x_{n_k} \in X(t_{n_k})$ such that for all $y \in Y(0)$,

$$\lim_{t \searrow 0, k \to \infty} \partial_t G(t, x_{n_k}, y) = \partial_t G(0, x^0, y),$$

(H4) For any sequence $\{t_n\}_{n \in \mathbb{N}}$ with $t_n \to 0$, there exist a subsequence $\{t_{n_k}\}_{k \in \mathbb{N}}$ and $y^0 \in Y(0)$, $y_{n_k} \in Y(t_{n_k})$ such that for all $x \in X(0)$,

$$\lim_{t \searrow 0, k \to \infty} \partial_t G(t, x, y_{n_k}) = \partial_t G(0, x, y^0).$$
Fig. 11. History of the objective function $J(\gamma)$ and the $L^\infty$-norm of $DJ(\gamma)$ in the case of the initialization $\gamma_i = 1$ and level noise $\varepsilon = 0.1$.

Fig. 12. Reconstruction of the Robin coefficient (g) with level noise $\varepsilon = 0.00$, (h) with level noise $\varepsilon = 0.05$.

Then there exists $(x^0, y^0) \in X(0) \times Y(0)$ such that

$$\frac{dg}{dt}(0) = \partial_t G(0, x^0, y^0).$$
