Abstract

We study twisted products $H = \alpha^r H_r$ of natural autonomous Hamiltonians $H_r$, each one depending on a separate set, called here separate $r$-block, of variables. We show that, when the twist functions $\alpha^r$ are a row of the inverse of a block-Stäckel matrix, the dynamics of $H$ reduces to the dynamics of the $H_r$, altered by a scalar potential depending only on variables of the corresponding $r$-block. We characterize this block-separation in an invariant way by writing in block-form classical results of Stäckel separation of variables. We classify the block-separable coordinates of $E^3$.

1 Introduction

Paul Stäckel opened in [23] the theory of complete separation of variables for the Hamilton-Jacobi equation of natural Hamiltonians $H$ with $N$ degrees of freedom, written in orthogonal coordinates. The characterization, both coordinate dependent, involving $N \times N$ Stäckel matrices (invertible matrices with each row depending on one different variable) and invariant, involving $N$ quadratic first integrals of the Hamiltonian. Remark that complete separation implies the completeness of the separated integral of the Hamilton-Jacobi equation, thanks to the existence of then $N$ constants of motion in involution. The theory greatly developed in the following years, thanks to the works of Levi-Civita [16], Eisenhart [11, 12] and many others (see [15, 21] for more complete references).

Stäckel himself considered in [24] the case of partial separation of variables and obtained a sufficient characterization of it in terms of Stäckel matrices of reduced dimension and of a corresponding number of quadratic first integrals of $H$. Differently from complete separation, partial separation of variables gained much less interest, certainly due to its scarce utility for finding solutions of the Hamilton-Jacobi equation. Moreover, partial separation does not guarantee the existence of complete integrals of the partially separated Hamilton-Jacobi equation. However, as pointed out by [17], in this case the Jacobi method of inversion
can, sometimes, produce additional first integrals of $H$. Recent articles developing partial separation theory for Hamilton-Jacobi and Schrödinger equations develop somehow the results of Stäckel, giving a more detailed characterization of the metric coefficients in partially separable coordinates and further conditions for the separation of the quantum systems \cite{[18],[14]}. Another approach to non-complete additive separation is represented by non-regular separation which relies on the existence of a complete additively separated solution on proper submanifolds only \cite{[5],[3]}

In our study, we shift for the first time the interest from the Hamilton-Jacobi equation to the dynamics of the system. We observe that the partial separation introduced by Stäckel, as well as the complete separation, establishes a dynamical relationship between $H$ and the (partially) separated equations when these are considered as Hamiltonians on submanifolds of the original phase space. Namely, we find that the projection of the orbits of $H$ on these submanifolds, spanned by the separated blocks of coordinates, coincides with the orbits of the separated Hamiltonians on the same submanifolds. The only difference is a position-dependent rescaling of the corresponding Hamiltonian parameters. As a consequence, the dynamics of $H$ can be decomposed into a number of lower-dimensional Hamiltonian systems, allowing a simpler analysis of the original system. The separated blocks of coordinates, considered together as a $N$ dimensional coordinate system on the base manifold of $H$, correspond to a block-diagonal form of the $N$-dimensional metric tensor, from this the name we choose for this kind of separation. We prefer do not use the expression partial separation since it is already associated with Hamilton-Jacobi theory, which we do not consider here. Indeed, by shifting the focus from Hamilton-Jacobi theory to the dynamics, we remove the discontinuity represented by the completeness of the integral of the Hamilton-Jacobi equation, which is strictly connected with Stäckel theory of complete separation of variables. Partial separation does not imply the existence of a complete integral, so that the Jacobi method (the construction of a canonical transformation to a trivially integrable Hamiltonian) is not in general applicable. On the contrary, our dynamical interpretation of block separation is basically insensitive to complete or partial separation, the only difference being the dimension of the separated blocks of coordinates. We find useful and natural to relate block-separation with the structure of twisted product that the Hamiltonian assumes when the separation is possible. This allows us to state our results in a form very close to analogous results in classical Stäckel separation, analogy missing in all the other studies about partial separation. Namely, we can characterize block-separation by introducing "block" versions of celebrated Levi-Civita, Eisenhart and more recent theorems about complete separation.

In Section 2 we recall the basic theorems about Stäckel complete separation of variables which we restate in block-separable form. In Section 3 we define twisted products of Hamiltonians and state some relevant properties of them. In Section 4 we give a dynamical interpretation of Stäckel separation, providing examples of the related properties of time-scaling. In Section 5 we introduce block-separation and our main results about its characterization, with the blocklike formulations of Levi-Civita, Eisenhart and other theorems, and we provide an invariant characterization of block separation. As example we consider the four-body Calogero system. In Section 6, we characterize, at least with necessary conditions, all the possible block-separable coordinates of $E^3$. Section 7 contains
2 Outline of Stäckel separation

We recall shortly the principal theorems regarding complete separation of the Hamilton-Jacobi equation see [15] and [1] for further details. The theory of complete additive separation of the Hamilton-Jacobi equation begins with the work of Stäckel [23, 24]

Theorem 1. The necessary and sufficient conditions such that the Hamilton-Jacobi equation

\[ H = \frac{1}{2} \left( g^{ii} \left( \frac{\partial W}{\partial q^i} \right)^2 + V(q) \right) = c_1, \quad i = 1, \ldots, N, \quad (1) \]

admits a complete integral via separation of variables,

\[ W = \sum_{i=1}^N W_i(q^i, c_a), \quad a = 1, \ldots, N, \quad \det \left( \frac{\partial^2 W}{\partial q^i \partial c_a} \right) \neq 0, \]

are

i) there exists a \( N \times N \) matrix \( S \) which is invertible and each row \( j \) depends on \( q^i \) only, the Stäckel matrix, such that the \( (g^{ii}) \) are a row of \( S^{-1} \).

ii) \( V \) is a Stäckel multiplier, i.e. there exist \( N \) functions \( v_i(q^i) \) such that

\[ V = v_i(q^i)g^{ii}. \]

As a consequence of i and ii, there exist \( N - 1 \) independent quadratic first integrals \((K_a)\) of \( H \) such that \((c_a)\) are the constant values of \((H, K_a)\).

A complete integral of the \( (1) \) is then determined by the \( N \) separated equations

\[ \left( \frac{dW_r}{dq^r} \right)^2 + v_r = 2S_i^ic_i, \quad (2) \]

Remark that completeness for the integral \( W \) of the Hamilton-Jacobi equation means that it depends from \( N \) parameters \((c_a)\), constants of motion, such that

\[ \det \left( \frac{\partial W}{\partial q^i \partial c_a} \right) \neq 0. \]

Therefore, the \((c_a)\) can be part of a new set of canonical coordinates in which the Hamiltonian flow becomes trivially integrable.

Later, Levi-Civita [16] obtained necessary and sufficient conditions for the complete separability of given coordinate systems. For natural Hamiltonians and orthogonal coordinates, \( H = \frac{1}{2} g^{ii} p^i_2 + V(q) \), the Levi-Civita equations split into

\[ g^{ii}g^{jj}\partial_{ij}g^{ll} - g^{ii}\partial_{i}g^{jj}\partial_{j}g^{ll} - g^{jj}\partial_{j}g^{ii}\partial_{i}g^{ll} = 0, \quad (3) \]

with \( i \neq j \) not summed, \( i, j, l = 1, \ldots, N \), for the components of the metric tensor, and

\[ g^{ii}g^{jj}\partial_{ij}V - g^{ii}\partial_{i}g^{jj}\partial_{j}V - g^{jj}\partial_{j}g^{ii}\partial_{i}V = 0, \]
with \(i \neq j\) not summed, \(i, j = 1, \ldots, N\), called Bertrand-Darboux equations and whose solution is \(V\) in the form of a Stäckel multiplier.

In [11], Eisenhart provided a geometrical characterization of complete separation of variables in orthogonal coordinates introducing Killing tensors and, later, determined all the possible orthogonal separable coordinate systems of \(E^3\). The systems are 11 and they are described, for example, in [21]. In Eisenhart’s characterization are fundamental the Eisenhart equations

\[
\partial_i \lambda_j = (\lambda_i - \lambda_j) \partial_i \ln |g^{ij}|, \quad i, j = 1, \ldots, N,
\]

expressing necessary and sufficient conditions for the 2-tensor tensor \(k\) of simple eigenvalues \((\lambda_i)\) and \((\partial_i)\) as base of its eigenvectors is a Killing tensor. The integrability conditions of Eisenhart equations coincide with the Levi-Civita equations [3].

After Eisenhart, the coordinate systems can be geometrically understood as foliations of hypersurfaces called coordinate webs. The geodesic separability of a coordinate web can be characterized by a single characteristic Killing tensor, i.e. a symmetric Killing 2-tensor with pointwise simple eigenvalues and normally integrable eigenvectors which determine in each point of the space (apart possible singular sets of zero measure) the basis of coordinate vectors [1]. Recall that a symmetric Killing 2-tensor \(k\) is defined by the equivalent equations

\[
[g, k] = 0, \quad \nabla(k_{ij}l^k) = 0,
\]

where \([,]\) are the Schouten brackets and \(\nabla\) is the covariant derivative with respect to the metric \(g\).

**Theorem 2.** The geodesic Hamilton Jacobi equation is completely separable in an orthogonal coordinate web if and only if there exists a characteristic Killing 2-tensor whose eigenvectors are normal to the foliations of the web.

Necessary and sufficient conditions for a Killing tensor to be characteristic are given in [8].

**Theorem 3.** Tonolo-Schouten-Nijenhuis. A 2-tensor \(K\) with real distinct eigenvalues has normal eigenvectors iff the following conditions are satisfied

\[
N_{ij}^{k}g_{kl} = 0, \quad N_{ij}^{k}K_{kl} = 0, \quad N_{ij}^{l}K_{lm} = 0,
\]

where \(N_{jk}^{i}\) are the components of the Nijenhuis tensor of \(K_{j}^{i}\) defined by

\[
N_{jk}^{i} = K_{j}^{i}K_{[j,k]} + K_{[j}^{i}K_{k]}^{l}l.
\]

An equivalent formulation of Theorem 2 involves \(N\) independent quadratic first integrals, therefore \(N\) Killing 2-tensors, instead of a single characteristic Killing tensor [1].

**Theorem 4.** The natural Hamiltonian \(H\), is separable in orthogonal coordinates \((q^i)\) if and only if
i) there exist other $N-1$ independent quadratic in the momenta functions $K_a$ such that

$$\{H, K_a\} = 0,$$

ii) the Killing two-tensors $(k_a)$ associated with $(K_a)$ are simultaneously diagonalized with pointwise simple eigenvalues and have common normally integrable eigenvectors.

It follows that $\{K_a, K_b\} = 0$.

The original formulation of the Theorem requires reality of the eigenvalues, however, this request is non necessary if one allows complex separable coordinates [9].

3 Twisted products of Hamiltonians

Let

$$M = \times_{r=1}^n M_r,$$

be the product of $n$ Riemannian or pseudo-Riemannian manifolds $(M_r, g_r)$ of dimension $n_r$, so that $\dim(M) = n_1 + \ldots + n_n = N$, and let $\alpha^r$ be $n$ non zero functions on $M$. The manifold $M$ with metric tensor

$$G = \alpha^1 g_1 + \ldots + \alpha^n g_n,$$

is a Riemannian or pseudo-Riemannian manifold called twisted product manifold of the $(M_r)$ with twist functions $(\alpha^r)$ [19]. In the case when $\alpha^1 = 1$ and $\alpha^2, \ldots, \alpha^n$ are functions on $M_1$, the manifold $M$ is called warped product. We extend to functions on $T^*M$ and $T^*M_r$ the concept of twisted and warped products in a natural way. In particular, for each $r$ we consider natural Hamiltonians

$$H_r = \frac{1}{2} \left( g_r^{ij} p_r i p_r j + V_r(q^r) \right),$$

where $(q^r_i, p_r i), i = 1, \ldots, n_r$, are canonical coordinates on $T^*M_r$, we construct twisted product

$$H = \alpha^r H_r = \alpha^1 H_1 + \ldots + \alpha^n H_n,$$

of the $H_r$ with twist functions $\alpha^r \in F(M)$.

Then, $H$ is a natural Hamiltonian on $T^*M$ with metric $G$ and potential $V = \alpha^r V_r$.

The manifold $M$ is naturally endowed with block-diagonal coordinates $(q^r_i)$ such that the components of $G$ are in the form

$$G^{r,rs} = \alpha^r g_r^{rs}, \quad G^{r,s} = 0, \quad s \neq r,$$

we call these coordinates twisted coordinates.

We have now $n+1$ Hamiltonians, each one with its own Hamiltonian parameter. We call $t$ the Hamiltonian parameter of $H$ and $\tau_r$ the Hamiltonian parameter of $H_r$. From Hamilton’s equations we get

$$\frac{dq^r_i}{dt} = \frac{\partial H}{\partial p_r i} = \alpha^r \frac{\partial H_r}{\partial p_r i} = \alpha^r \frac{dq^r_i}{d\tau_r},$$
\[ \frac{dp_{r}}{dt} = -\frac{\partial H}{\partial q_{r}^{i}} = -\alpha^{r} \frac{\partial H}{\partial q_{r}^{i}} - H_{s} \frac{\partial \alpha^{s}}{\partial q_{r}^{i}} = \alpha^{r} \frac{dp_{r}}{d\tau_{r}} - H_{s} \frac{\partial \alpha^{s}}{\partial q_{r}^{i}}. \]

Therefore, the relation between the Hamiltonian vector fields \( X_{H} \) of \( H \) and \( X_{r} \) of \( H_{r} \) is

\[ X_{H} = \bar{X}_{1} + \ldots + \bar{X}_{N} - H_{s} \frac{\partial \alpha^{s}}{\partial q_{r}^{i}} \frac{\partial}{\partial p_{r}}, \]

where

\[ \bar{X}_{r} = \alpha^{r} X_{r}, \quad r \text{ not summed}, \]

is the rescaled Hamiltonian vector field of \( H_{r} \).

4 \ Stäckel systems as twisted Hamiltonians

In this section we study Stäckel systems in their nature of twisted Hamiltonians. Our aim is to enlighten the relations among the dynamics of the \( N \)-dimensional Hamiltonian system determined by \( H \) and the dynamics of the \( N \) one-dimensional Hamiltonians \( H_{r} \), determined by the separated equations of \( H \). Separation of variables for the Hamilton-Jacobi equation of \( H \) will not be of primary interest in what follows. See the Appendix for definitions of Stäckel matrix, Stäckel multiplier and separated equations.

Let be \( H_{r} = \frac{1}{2}(p_{r}^{2} + V_{r}) \) and assume that \( \alpha^{r} \) are a row (say the first one) of the inverse of a Stäckel matrix \( S \) for given coordinates \( (q_{r}^{i}) \). Then, the twisted product \( H = \alpha^{r} H_{r} \) admits separation of variables and we have the separated equations

\[ H_{r} = S_{r}^{i} c_{i}, \quad (4) \]

where \( c_{i} \) are \( N \) constants, corresponding to the \( N \) constants of motion \( K_{i} \) of \( H = K_{1} \) and

\[ K_{a} = (S^{-1})_{a}^{r} H_{r}, \quad a = 2, \ldots, N. \]

The Hamilton-Jacobi complete separated integral \( W = W_{1}(q^{1}, c_{1}) + \ldots + W_{N}(q^{N}, c_{i}) \) is given by integration of

\[ \left( \frac{dW_{r}}{dq^{r}} \right)^{2} + V_{r} = 2S_{r}^{i} c_{i}. \quad (5) \]

The Hamilton's equations of \( H \), in time \( t \), are

\[ \dot{q}^{r} = \alpha^{r} p_{r}, \quad (6) \]

\[ \dot{p}_{r} = -\partial_{r} \alpha^{i} H_{i} - \alpha^{i} \partial_{r} H_{i} = -\partial_{r} \alpha^{i} S_{r}^{j} c_{j} - \frac{1}{2} \alpha^{r} \frac{d}{dq^{r}} V_{r}, \]

where we use the separated equations (4) to replace \( H_{r} \) along the integral curves. Since \( \alpha^{r} = (S^{-1})_{1}^{r} \) is a row of the inverse of \( S \), we have

\[ \partial_{r} \alpha^{r} S_{r}^{i} = \partial_{r}(\alpha^{i} S_{r}^{j}) - \alpha^{i} \partial_{r} S_{r}^{j} = \partial_{r}(\delta_{r}^{i}) - \alpha^{r} \frac{d}{dq^{r}} S_{r}^{j} = -\alpha^{r} \frac{dS_{r}^{j}}{dq^{r}}, \quad (7) \]

and the same for all other elements of the rows of \( S^{-1} \). Then, we can write

\[ \dot{p}_{r} = \alpha^{r} \frac{d}{dq^{r}} \left( c_{j} S_{r}^{j} - \frac{1}{2} V_{r} \right). \quad (8) \]
Let be $\gamma_P$ the integral curve of $X_H$ based in any point $P \in T^* M$. We consider the values $c_i = K_i(P)$ and we introduce the Hamiltonians
\[
\tilde{H}_r = H_r - c_j S^j_r,
\]
with Hamiltonian parameters $\tilde{\tau}_r$, we can write the equations of Hamilton for $\tilde{H}_r$ as
\[
\frac{d}{d\tilde{\tau}_r} q^r = p_r = \partial q^r \tilde{H}_r, \quad \frac{d}{d\tilde{\tau}_r} p_r = \frac{d}{dq^r} \left( c_j S^j_r - \frac{1}{2} V_r \right) = -\partial p_r \tilde{H}_r. \tag{9}
\]
Therefore,

**Proposition 5.** For each orbit of $H$, the $N$ Hamiltonian vector fields $X_{\tilde{H}_r}$ of the $\tilde{H}_r$ are proportional to the components with respect to $(\partial q^r, \partial p_r)$ of the Hamiltonian vector field $X_H$ of $H$, where $\alpha^r$ are the proportionality functions.

**Proof.** Let be
\[
X_{\tilde{H}_r} = \frac{\partial \tilde{H}_r}{\partial p_r} \partial_q - \frac{\partial \tilde{H}_r}{\partial q^r} \partial p_r,
\]
and
\[
(X_H)_r = \ddot{q}^r \partial_q + \ddot{p}_r \partial p_r.
\]
Due to (9) and (10) we can write (6) and (8) as
\[
\dot{q}^r = \alpha^r \partial q^r \tilde{H}_r, \quad \dot{p}_r = -\alpha^r \partial p_r \tilde{H}_r, \tag{11}
\]
and it follows immediately
\[
(X_H)_r = \alpha^r X_{\tilde{H}_r}. \tag{12}
\]

**Remark 1.** After Proposition 5 we can put
\[
\alpha^r = \frac{d\tilde{\tau}_r}{dt}, \tag{13}
\]
and consider the twist functions as determining position-dependent time-scalings between the Hamiltonian parameters $t$ and $\tilde{\tau}_r$.

From Proposition 5 follows the important result

**Proposition 6.** The projection of each orbit of $H$ on the coordinate manifolds $(q^r, p_r)$ coincides with the orbit of $\tilde{H}_r = H_r - c_j S^j_r$.

**Remark 2.** The Lagrange equation of the dynamics of $\tilde{H}_r$, expressed in times $\tilde{\tau}_r$ is
\[
\frac{d^2 q^r}{d\tilde{\tau}_r^2} = \frac{d}{dq^r} \left( c_j S^j_r - \frac{1}{2} V_r \right). \tag{14}
\]
Remark 3. The equations \( \frac{d\mathcal{q}}{dt} = 2 \left( c_j S_j^3 - \frac{1}{2} V_r \right) \) are associated with the Weierstrass equations (14).

Remark 4. Observe that \( \tilde{H} = \alpha^r \tilde{H}_r = H - c_1, \quad \tilde{K}_j = (S^{-1})_j^r \tilde{H}_r = K_j - c_j, \quad j \neq 1, \) i.e. the St"ackel systems associated with \( H \) and \( \tilde{H} \) coincide up to additive constants. To the constants \((c_i)\) for \((H, K_a)\) correspond the constants \((\tilde{c}_i = 0)\) for \((\tilde{H}, \tilde{K}_a)\).

Example 1. Twisted product of pendula. In order to show the effect of the time-scaling described above, we consider the twisted product of the following three one-dimensional Hamiltonians

\[
H_i = \frac{1}{2}(p_i^2 - \cos q_i), \quad i = 1, 2, \\
H_3 = \frac{1}{2}p_3^2.
\]

corresponding to two pendula and a purely inertial term, coupled together by the first row of the inverse of the \(3 \times 3\) matrix

\[
S = \begin{pmatrix}
2 & 1 + q^1 & 2(q^1)^2 + 2 \\
3 & q^2 & (q^2)^3 + 2 \\
4 & q^3 & (q^3)^2 + 1
\end{pmatrix},
\]

which is a St"ackel matrix in a neighborhood of the origin, since the Taylor expansion up to the second order terms of its determinant \(\Delta\) around \((0, 0, 0)\) is \(\Delta = 5 + 5q^1 - 6q^2 + 2q^3\). The elements of the matrix \(S^{-1}\) are therefore quite complicated rational functions that we do not need to explicit but make the coupling of the \(H_r\) suitable to enhance the effect of the time-scaling. We take as \((\alpha^r)\) the first row of \(S^{-1}\) and consider

\[
H = \alpha^r H_r = c_1.
\]

The quadratic first integrals of \(H\) are simply determined by the remaining rows of \((S^{-1})\)

\[
K_a = (S^{-1})_a^r H_r = c_a, \quad a = 2, 3.
\]

We already know from the previous section, that, despite the complicated expression of the coupling terms \((\alpha^r)\), the relation among the dynamics of \(H\) and of the separated Hamiltonians \(\tilde{H}_r = H_r - c_a S_r^a\) reduces to a simple position-dependent time scaling.

We plot the numerical evaluation of the systems of Hamiltonian \(H\) and

\[
\tilde{H}_1 = H_1 - 2c_1 - (1 + q^1)c_2 - 2((q^1)^2 + 1)c_3
\]

respectively, and project the orbits on \((q^1, p_1)\), obtaining, for the initial conditions \(p_1 = 0, p_2 = 0, p_3 = 0, q^1 = 0.2, q^2 = -0.2, q^3 = 0\) and consequently \(c_1 = H = 0.09494666248, c_2 = 0.0916913483, c_3 = -0.3797866499\), the graphs in Fig. 1.
where we see that the orbits on \((q^1, p_1)\) of the two systems coincide. But, if we include the dependence from the different Hamiltonian parameters (denoted in both graphs as \(t\)), we get Fig. 2. and we can see how the dependence from the Hamiltonian parameters can be extremely variate in the two cases.

**Example 2.** Twisted product with constant coefficients of harmonic oscillators. Taking twisted products of Hamiltonians seems an interesting way to establish an interaction among Hamiltonian systems. An example, even if somehow trivial, is provided by the twisted product with constant coefficients of harmonic oscillators. Let

\[ H_i = \frac{1}{2} (p_i^2 + \omega_i^2 (q_i)^2), \quad i = 1, \ldots, n \]

be a finite set of harmonic oscillators. Let

\[ H = \alpha^i H_i, \quad \alpha^i \in \mathbb{R}^+, \]

be their twisted product with constant twist functions. The \(H_i\) are all constants of motion of \(H\) and there is actually no interaction among them. However, some effect of the twisted product is nevertheless evident. The Hamilton equations of \(H\) are

\[ \frac{dq^i}{dt} = \alpha^i \frac{dq^i}{d\tau^i} = \alpha^i p_i, \]
\[ \frac{dp_i}{dt} = -\alpha^i \frac{dp_i}{d\tau_i} = -\alpha^i \omega_i^2 q^i. \]

The general solution of these equations is

\[ q^i(t) = c^i_1 \sin(\alpha^i \omega^i t) + c^i_2 \cos(\alpha^i \omega^i t), \quad c^i_j \in \mathbb{R}. \]

We see that, for example, the choice \( \alpha^i = k/\omega_i \) for any real positive \( k \), determines a time-scaling that gives to all the oscillators the same frequency \( k \) with respect to \( t \) (as well as any other different real positive frequency for different choices of \( k \) for each \( i \)). Namely, the rescaling is in this case

\[ t = \sum_{i=1}^n \frac{1}{\alpha^i} \tau_i + t_0, \quad \text{or} \quad \tau_i = \alpha^i t + \tau_i^0. \]

The frequency of each oscillator \( H_i \) with respect to its own Hamiltonian parameter \( \tau_i \) remains clearly \( \omega_i \).

## 5 Block-separation

The results of the previous section can be generalized as follows, leading to a kind of partial separation of variables that we call block-separation.

Let \( M \) be a \( N \)-dimensional manifold. Let us consider a partition of a coordinate system on \( M \) organized as follows. For \( n \leq N \), consider for each integer \( r = 1, \ldots, n \) the integers \( n^r \) such that \( N = n^1 + \ldots + n^n \). The coordinate system is therefore composed of \( n \) blocks, and for each \( r \leq n \) we have an \( r \)-block of coordinates that we denote as \( (q^r_1, \ldots, q^r_{n^r}) \). We call \( M_r \) the manifold spanned by the \( r \)-block of coordinates. Consider \( T^*M \) with the conjugate \( r \)-block momenta \( (p^r_1, \ldots, p^r_{n^r}) \).

Let us consider

\[ H_r = \frac{1}{2} g_r^{rs} p_r p_s + V_r(q^r_s), \tag{15} \]

and the \( n \) block-separated equations

\[ H_r = S^a_r c_a, \quad a = 1, \ldots, n, \tag{16} \]

where we assume that \( g_r^{rs}, S^a_r \) and \( V_r \) are functions of coordinates of the \( r \)-block only and \( c_a \) are constants. If we assume that the \( n \times n \) matrix \( (S^a_r) \) is invertible, and we call it \textit{block-St"ackel matrix}, then we can write the \( n \) equations

\[ (S^{-1})^a_r H_r = c_a. \tag{17} \]

We denote \( \alpha^r = (S^{-1})^1_r \) and call

\[ H = \alpha^r H_r, \quad K_a = (S^{-1})^a_r H_r, \quad a = 2, \ldots, n. \tag{18} \]

Hence, \( H \) is in the form of twisted product and it is a natural Hamiltonian whose metric tensor \( G \) is block-diagonalized, with components

\[ G^{r,s} = \alpha^r g_r^{rs}, \quad G^{s,j} = 0, \quad s \neq r. \]
and whose scalar potential has the form

\[ V = \alpha^r V_r, \]

while the scalar potentials in \( K_a \) are

\[ W_a = (S^{-1})^r_a V_r. \]  \hspace{1cm} (19)

A necessary condition for the above procedure is that the \( (\ref{eq:17}) \) are indeed constants of motion of \( H \).

**Proposition 7.** The \( n \) functions \((H, K_a)\) are all independent, quadratic in the momenta and pairwise in Poisson involution.

**Proof.** We have, since \( S \) is a block-Stäckel matrix, the analogous of (7)

\[ \partial_r \alpha^s S^l_s = \partial_r (\alpha^s S^l_s) - \alpha^s \partial_r S^l_s = \delta^l_s \partial_r \alpha^s = -\alpha^r \partial_r S^l_r, \]  \hspace{1cm} (20)

where \( r \) is not summed, and the same for the other elements \( \alpha^a_r = (S^{-1})^a_r \) of \( S^{-1} \). Then, from the definition of Poisson bracket and of block-separated coordinates, we get the statement. \( \square \)

For the dynamics of \( H \), holds an analogous of Proposition 6

**Proposition 8.** The dynamics of \( H \) coincides in each \( r \)-block with the dynamics of

\[ \tilde{H}_r = H_r - c_a S^a_r, \]

up to a reparametrization of the Hamiltonian parameter given by \( \alpha^r = d\tilde{\tau}_r/dt \).

The projections of the orbits of \( H \) on each \( T^*M_r \) coincide with the orbits of \( \tilde{H}_r \).

**Proof.** The proof follows the same reasoning of the proof of Proposition 6. It follows that, denoting with \((X_H)_r\), the \( r \)-block component of the Hamiltonian vector field \( X_H \) of \( H \),

\[ (X_H)_r = \dot{q}^r \partial_r + \dot{p}_r \partial^r, \]

we have

\[ (X_H)_r = \alpha^r X_{\tilde{H}_r}, \]  \hspace{1cm} (21)

where \( X_{\tilde{H}_r} \) is the Hamiltonian vector field of \( \tilde{H}_r \). Therefore, if \((X_H)_r\), is tangent to any submanifold \( f \subseteq T^*M \), then also \( X_{\tilde{H}_r} \) is, and vice-versa. Hence, just as for the Stäckel systems, the dynamics of \( H \) is determined in each \( r \)-block, up to reparametrizations of the Hamiltonian parameter, by the dynamics of the \( \tilde{H}_r \), with the difference that the \( \tilde{H}_r \) are no longer one-dimensional. \( \square \)

In this way, the time-independent dynamics of \( H \) can be exactly decomposed into the \( n \) lower-dimensional separated dynamics of Hamiltonians \( \tilde{H}_r \). The \( \tilde{H}_r \) share with the \( H_r \), factors of the twisted product \( H \), the same inertial terms, while the scalar potential is modified by the addition of the term \(-c_a S^a_r\).

Partial separation of Hamilton-Jacobi equation was introduced by di Pirro in [10] and generalized by Stäckel in [24]. He introduced the \( n \times n \) matrix \( S \) and his results are analogous to our Proposition 7. Stäckel obtained sufficient conditions for partial separation of the H-J equation of natural Hamiltonians. His work has been continued more recently in [14] and [18], including the study
of partial separation of the Schrödinger equation, obtaining again sufficient conditions for partial separation, and a more detailed form of the components of the metric tensor in partially separable coordinates. We remark that, by introducing twisted products, our characterization of block-separation provides necessary and sufficient conditions for it, in analogy with Stäckel theory of complete separation. We do not make here a strict comparison between our results and those of [24] and [14], since these last are strictly related to Hamilton-Jacobi theory and there is no consideration of the dynamical relations among the N-dimensional Hamiltonian and the separated Hamiltonians, which is our main interest. The detailed characterization of the partially separable metric’s components in [14] should eventually coincide with a similar characterization of block-separable metrics, we do not consider here the distinction between linear and quadratic in the momenta first integrals (from linear first integrals one can always obtain quadratic ones). It is remarkable that in the last century very few works have been devoted to partial separation of H-J equation. This is understandable when one considers that Hamilton-Jacobi theory is of not easy application, apart the simplest cases, already when completely separated integrals of the H-J equations do exist. Some applications of partially separated integrals of the H-J equation, in order to generate new possible first integrals of the Hamiltonian, are presented in [17] and [22]. Our approach based upon the block-separated dynamics, instead of the partially separated Hamilton-Jacobi equation, appears to be completely new and can be more suitable for applications of the theory, particularly in the analysis of systems with many degrees of freedom.

5.1 Block-Eisenhart and block-Levi-Civita equations

We can see, with some surprise, that the characterisation of block-separation includes tools developed for Stäckel complete separation. Indeed, we can formulate classical results by Eisenhart and Levi-Civita in block form. If we assume that \((q')\) are twisted coordinates \((q'^r)\), then for \(G\) we have
\[
G_{r,r} = \frac{1}{\alpha^r} g_{r,r}, \quad r \text{ not summed},
\]
so that
\[
G_{r,a} G^{a,s}_r = \delta^{s}_r.
\]
Moreover, assuming \((q'^r)\) are block-separated
\[
k_a^{r,r} = (S^{-1})_a^{r} g_{r,r},
\]
where \(k_a^{bc}\) are the components of the 2-tensor associated with \(K_a\). Then,
\[
(k_a)_{r,r}^{r} = \frac{1}{\alpha^r} (S^{-1})_a^{r} \delta^{r}_r,
\]
and we can consider the functions
\[
\lambda^r_a = \frac{1}{\alpha^r} (S^{-1})_a^r, \quad r \text{ not summed},
\]
as the analogous of eigenvalues of Killing Tensors \(k_a\) in Stäckel theory. They are indeed the eigenvalues with respect to \(G\) of the Killing tensors \((k_a)\) associated with the first integrals \((K_a)\).
Proposition 9. In block-separated coordinates, we have that
\[ \{ H, K_a \} = 0, \]
if and only if the block-Eisenhart equations
\[ \partial_{r_k} \lambda^s_a = (\lambda^r_a - \lambda^s_a) \partial_{r_k} \ln |\alpha^s|, \tag{22} \]
hold, with \( r, s = 1, \ldots, n \), for all \( r_i, s_j \) in the respective separated blocks, and \( \{ K_a \} = 0 \) hold.

Proof. By expanding
\[ \{ H, K_a \} = 0, \]
in block-separable coordinates and collecting homogeneous terms in the momenta, dividing by \( \alpha^r \alpha^s \), from the higher order terms in the momenta, we have,
\[ (\lambda^s_a - \lambda^r_a) \partial_{r_k} g^{r_is_j} + g^{r_is_j} [\partial_{r_k} \lambda^s_a - (\lambda^r_a - \lambda^s_a) \partial_{r_k} \ln |\alpha^s|] = 0, \tag{23} \]
for all \( r, s, r_k, s_i, s_j \) in the respective blocks. If \( r = s \) the equations become
\[ g^{r_is_j} \partial_{r_k} \lambda^s_a = 0, \]
and, if \( r \neq s \), then \( \partial_{r_k} g^{r_is_j} = 0 \). Hence, \( \{ H, K_a \} = 0 \), is equivalent to
\[ g^{r_is_j} [\partial_{r_k} \lambda^s_a - (\lambda^r_a - \lambda^s_a) \partial_{r_k} \ln |\alpha^s|] = 0. \]
If \( g^{r_is_j} = 0 \), the equations are identically satisfied, otherwise, we have the \( \{ H, K_a \} = 0 \). Since not all the \( g^{r_is_j} \) are zero, we have the statement. The first-order terms in the momenta vanish if and only if \( \{ K_a \} = 0 \) hold.

By definition of the \( \lambda^s_a \) and of the \( \alpha^s \), we have the equations
\[ S^*_r \alpha^r = \delta^r_1, \quad S^*_r \lambda^s_a = \delta^s_a. \]
We observe that, after putting \( \alpha^r = g^{rr} \), the previous equations are identical to the relations typical of Stäckel systems. In the same way, the block-Eisenhart equations become the standard Eisenhart equations.

Proposition 10. The block-Eisenhart equations \( \{ H, K_a \} = 0 \) hold if and only if \( (S^*_r) \) is a block-Stäckel matrix.

As for the Stäckel systems, the block-Levi-Civita equations can be interpreted as the integrability conditions of the block-Eisenhart equations. The derivations is essentially the same as in \([1]\).

It is therefore straightforward to see that the block-diagonalized coordinates \((q^1, \ldots, q^N)\) are block-separated for the Hamiltonian \( H \) if and only if the block-Levi-Civita equations
\[ \alpha^r \alpha^s \partial_{r_is_j} \alpha^m - \alpha^r \partial_{r_is_j} \alpha^m - \alpha^s \partial_{r_is_j} \alpha^r \alpha^m = 0, \tag{24} \]
are satisfied, where the coordinates \( r_i, s_j \) are in different blocks and \( m = 1, \ldots, n \). The scalar potential \( V \) is already in the form of a block-Stäckel multiplier thanks to the form of \( H \) and satisfies
\[ \alpha^r \alpha^s \partial_{r_is_j} V - \alpha^r \partial_{r_is_j} \alpha^s \partial_{r_is_j} V - \alpha^s \partial_{r_is_j} \alpha^r \partial_{r_is_j} V = 0. \tag{25} \]
See \([3]\) for a comparison.
5.2 Invariant characterization

As in Stäckel theory, we can use the previous results for an invariant characterization of block-separation. Therefore, we have the analogous of the Eisenhart-Kalnins-Miller-Benenti theorem [1],

**Proposition 11.** The twisted Hamiltonian $H = \alpha^r H_r$, $r = 1, \ldots, n$, is block-separated in twisted coordinates $(q^r)$ if and only if

i) there exist other $n - 1$ independent quadratic in the momenta functions $K_a = \alpha^r H_r$ such that

$$\{H, K_a\} = 0,$$

ii) the Killing two-tensors $(k_a)$ are simultaneously block-diagonalized and have common normally integrable eigenspaces

Moreover, it follows that $\{K_a, K_b\} = 0$.

**Remark 5.** The proof of the previous statement relies on the assumption that each $H_r$ depends only from coordinates in $T^*M_r$. Otherwise, if the metric tensor of $H$ is only block-diagonal in $(q^r)$, conditions i and ii are only necessary.

Consequently, the strategy for finding block-separated coordinates of a given $N$-dimensional natural Hamiltonian $H$ is the following

• Find a number $n \leq N$ of independent quadratic first integrals $(K_a)$ of $H$ in involution among themselves, whose associated Killing tensors $(k_a)$ admit common block-diagonalized normally integrable eigenspaces. The number $n$ corresponds to the number of blocks. The dimension of the common eigenspaces equals the dimension of each block.

• At this point, we have block-diagonalized coordinates and we can write $H = \alpha^r H_r$ for some functions $H_r$, the $\alpha^r$ being determined by the block-Stäckel matrix determined by the $(k_a)$.

• The last step consists in checking that each $H_r$ depends only from coordinates in $T^*M_r$.

This is indeed the procedure applied in Example 3.

The algebraic multiplicity of each $\lambda^r_a$ is $n_r$ at least (for some $a$, we can have $\lambda_a^r = \lambda_a^s$, and the algebraic multiplicity is in this case $n_r + n_s$).

Proposition 11 provides an invariant characterization of block-separable coordinates in terms of what we can call block- Killing-Stäckel algebras generated by the $(k_a)$. See [1, 2] for a definition of Killing-Stäckel algebras.

If we assume that for $N$-dimensional 2-tensors $T^a_\lambda$ to each eigenvalue of algebraic multiplicity $n_r$ it corresponds a space of $n_r$ linearly independent covariant eigenvectors $\{X_a\}$, we can consider the $(N - n_r)$-dimensional space of vectors $E_{N-n_r}$ such that $<X_a, E^b> = 0$, $\forall E^b \in E_{N-n_r}$. We assume that $E_{N-n_r}$ is a regular distribution of constant rank $N - n_r$.

The necessary and sufficient condition for the integrability of the distributions $E_{N-n_r}$ is given by the Haantjes theorem [3].
Theorem 12. Let $T^\lambda_\kappa$ be a tensor such that to each root with multiplicity $n_r$ of the characteristic equation belongs a set of $n_r$ linearly independent covariant eigenvectors. Then the $E_{N-n_r}$ determined by these vectors are integrable if and only if

$$H^\kappa_\mu T^\mu_\lambda T^\sigma_\lambda - 2H^\sigma_\nu T^\nu_\mu T^\kappa_\sigma + H^\nu_\mu T^\kappa_\sigma T^\sigma_\nu = 0,$$

where

$$H^\kappa_\mu = 2T^\nu_\mu \partial_\nu T^\kappa_\lambda - 2T^\kappa_\nu \partial_\nu T^\mu_\lambda,$$

is the so-called Haantjes tensor of $T$.

Therefore, in analogy with the characterization of the Stäckel separable coordinate systems, we have

Proposition 13. A natural Hamiltonian admits block-separable coordinates only if its metric tensor admits a symmetric Killing 2-tensor $T$ satisfying the Haantjes theorem and its scalar potential $V$ satisfies $dTdV = 0$. We call $T$ the characteristic tensor of the block-separable coordinates.

The coordinates are therefore divided into $n$ blocks, where $n$ is the number of the pointwise different eigenvalues of $T$, the dimension of each block equals the multiplicity of the corresponding eigenspace.

An analogous result about characteristic Killing tensors of Stäckel systems is given in [3] making use of theorems due to Tonolo, Schouten and Nijenhuis (see Section 2). The main difference is due to the fact that, in that case, the eigenvalues of the tensors are simple.

The characterization of block-separation via Killing 2-tensors is extremely powerful in view of applications. For example, in any Riemannian manifold of constant curvature, all Killing tensors, of any order, are linear combinations with constant coefficients of symmetric products of Killing vectors, i.e. isometries [15]. Many common computer-algebra softwares include specific commands for the determination of Killing tensors of Riemannian manifolds.

Example 3. The four-body Calogero system. The $N$-body Calogero system is the Hamiltonian system of $N$ points of unitary mass on a line, subject to the interaction

$$V = \sum_{i=1}^{N-1} \sum_{j=i+1}^{N} (x_i - x_j)^{-2}.$$ 

The Hamiltonian is therefore

$$H_{(N)} = \frac{1}{2} \sum_{i=1}^{N} p_i^2 + V,$$

in Cartesian coordinates $(x^i)$ and it is known to be maximally superintegrable for any $N$ and multiseparable for $N < 4$ [25][2]. Indeed, $H_{(4)}$ admits, other than the Hamiltonian, only two quadratic independent first integrals in involution, and not the three necessary for standard Stäckel separation. The two quadratic first integrals of $H_{(4)}$ can be chosen as follows

$$K_a = \frac{1}{2} K^{ij}_a p_ip_j + W_a,$$
where $W_a$ are suitable functions that we will make explicit later on, and

$$K_{1}^{i} = \sum_{j,k} x^j x^k, \quad j,k = 1 \ldots 4, \quad j < k, \quad j,k \neq i,$$

$$K_{1}^{ij} = \frac{1}{2} \left( (x^j)^2 + (x^m)^2 + x^r x^s - \sum_{j<k} x^j x^k \right),$$

where $j,k = 1 \ldots 4$, $l,m,r,s$ all different,

$$K_{2}^{i} = \sum_{j \neq i} (x^j)^2,$$

$$K_{2}^{ij} = -x^i x^j, \quad i \neq j.$$

The eigenvalues of $K_1$ are

$$\{0, (x^1)^2 + (x^2)^2 + (x^3)^2 + (x^4)^2\}$$

of multiplicity 1, and

$$\sum_{i,j} x^i x^j - \frac{1}{2}(x^1)^2 + (x^2)^2 + (x^3)^2 + (x^4)^2, \quad i,j = 1 \ldots 4, \quad i < j,$$

of multiplicity 2.

The eigenvalues of $K_2$ are

$$0$$

of multiplicity 1 and

$$(x^1)^2 + (x^2)^2 + (x^3)^2 + (x^4)^2,$$

of multiplicity 3. Since the tensors of components $K_{1}^{ij}$ and $K_{2}^{ij}$ commute as linear operators and the metric is definite positive, they can be diagonalized simultaneously in some coordinate system.

By using some properties of the eigenvalues of Killing tensors [4], one finds that these coordinates $(r, \phi_1, \phi_2, \phi_3)$ are spherical and determined by the consecutive transformations [6]

$$z^1 = 2^{-1/2}(x^1 - x^2),$$
$$z^2 = 6^{-1/2}(x^1 + x^2 - 2x^3),$$
$$z^3 = 12^{-1/2}(x^1 + x^2 + x^3 - 3x^4),$$
$$z^4 = 2^{-1}(x^1 + x^2 + x^3 + x^4),$$

$$z^4 = r \cos \phi_1,$$
$$z^3 = r \sin \phi_1 \cos \phi_2,$$
$$z^2 = r \sin \phi_1 \sin \phi_2 \cos \phi_3,$$
$$z^1 = r \sin \phi_1 \sin \phi_2 \sin \phi_3.$$

The scalar potential $V$ of $H_{(4)}$ becomes in these coordinates
\[ V = \frac{1}{r^2 \sin^2 \phi_1} f(\phi_2, \phi_3), \]

with

\[
\begin{align*}
  f(\phi_2, \phi_3) &= \frac{81}{2} \left[ \sin(\phi_2)^2 \sin(\phi_3)^4 + 2 \sin(\phi_2)^2 \sin(\phi_3)^2 \cos(\phi_3)^2 + \sin(\phi_2)^2 \cos(\phi_3)^4 \\
  &- 12 \sin(\phi_2) \sin(\phi_3)^2 \cos(\phi_3) \cos(\phi_3)^{1/2} + 4 \sin(\phi_2) \cos(\phi_3)^3 \cos(\phi_3)^{1/2} \\
  &+ 8 \cos(\phi_3)^2 \sin(\phi_3)^2 + 8 \cos(\phi_3)^2 \cos(\phi_3)^2 \sin(\phi_3)^2 \sin(\phi_3)^6 \\
  &- 9 \sin(\phi_2)^4 \sin(\phi_3)^2 \cos(\phi_3)^2 + 21 \sin(\phi_2)^4 \sin(\phi_3)^2 \cos(\phi_3)^2 + \sin(\phi_2)^4 \cos(\phi_3)^6 \\
  &+ 6 \sin(\phi_2)^4 \sin(\phi_3)^4 \cos(\phi_3) \cos(\phi_3)^{1/2} - 4 \sin(\phi_2)^3 \sin(\phi_3)^2 \cos(\phi_3)^3 \cos(\phi_3)^{1/2} \\
  &+ 2 \sin(\phi_2)^3 \sin(\phi_3)^4 \cos(\phi_3)^{1/2} - 6 \sin(\phi_2)^3 \sin(\phi_3)^4 \cos(\phi_3)^2 \\
  &- 12 \sin(\phi_2)^2 \sin(\phi_3)^2 \cos(\phi_3)^2 \cos(\phi_3)^2 \\
  &+ 6 \sin(\phi_2)^2 \sin(\phi_3)^2 \cos(\phi_3)^2 + 24 \sin(\phi_2) \sin(\phi_3)^2 \cos(\phi_3) \cos(\phi_3)^{1/2} \\
  &- 8 \sin(\phi_2) \cos(\phi_3)^3 \cos(\phi_3)^{2/2} \\
  &+ 16 \sin(\phi_3)^2 \cos(\phi_3)^4 + 16 \cos(\phi_3)^2 \cos(\phi_3)^4 \right] / \left[ -3^{1/2} \sin(\phi_2) \cos(\phi_3) \\
  &+ 22^{1/2} \cos(\phi_2) + 3 \sin(\phi_2) \sin(\phi_3)^2 \cos(\phi_3) \cos(\phi_3)^{1/2} + 2 \sin(\phi_2) \cos(\phi_3)^3 \cos(\phi_3)^{1/2} \\
  &+ 3 \sin(\phi_2) \sin(\phi_3)^3 \sin(\phi_3)^2 \cos(\phi_3) - 2^{1/2} \cos(\phi_2)^2 \cos(\phi_3)^2 - 3^{1/2} \cos(\phi_3)^2 + 3 \sin(\phi_2) \sin(\phi_3)^2 \cos(\phi_3)^2 \right].
\end{align*}
\]

Therefore, the Hamiltonian becomes

\[ H_{(4)} = \alpha^1 H_1 + \alpha^2 H_2 + \alpha^3 H_3, \]

with

\[
\begin{align*}
  \alpha^1 &= 1, \quad \alpha^2 = \frac{1}{r^2}, \quad \alpha^3 = \frac{1}{r^2 \sin^2 \phi_1},
\end{align*}
\]

\[ H_1 = \frac{1}{2} p_{\phi_1}^2 + V_1, \quad H_2 = \frac{1}{2} p_{\phi_2}^2 + V_2, \quad H_3 = \frac{1}{2} \left( p_{\phi_2}^2 + \frac{1}{\sin^2 \phi_2} p_{\phi_3}^2 \right) + V_3, \]

where

\[ V = \alpha^4 V_1, \]

with \( V_1 = 0, V_2 = 0, V_3 = f(\phi_2, \phi_3). \) Moreover,

\[ K_1 = H_2 + \frac{1 - 2 \sin^2 \phi_1}{\sin^2 \phi_1} H_3, \]

\[ K_2 = H_2 + \frac{1}{\sin^2 \phi_1} H_3. \]

So that the inverse of the block-Stäckel matrix is

\[ S^{-1} = \begin{pmatrix}
  1 & \frac{1}{r^2} & \frac{r^2 \sin^2 \phi_1}{1 - 2 \sin^2 \phi_1} \\
  0 & 1 & \frac{1 - 2 \sin^2 \phi_1}{\sin^2 \phi_1} \\
  0 & 0 & \frac{2 \sin^2 \phi_1 - 1}{2}
\end{pmatrix}, \]

and the block-Stäckel matrix

\[ S = \begin{pmatrix}
  1 & 0 & -\frac{1}{2} \\
  0 & \frac{1}{2 \sin^2 \phi_1} & \frac{2 \sin^2 \phi_1 - 1}{2} \\
  0 & \frac{1}{2} & \frac{1}{2}
\end{pmatrix}. \]

17
Therefore, the block-separated Hamiltonians are

\[
\tilde{H}_1 = H_1 - c_1 + \frac{1}{r^2} c_3,
\]
\[
\tilde{H}_2 = H_2 - \frac{1}{2 \sin^2 \phi_1} c_2 - \frac{2 \sin^2 \phi_1 - 1}{2 \sin^2 \phi_1} c_3,
\]
\[
\tilde{H}_3 = H_3 + \frac{1}{2} c_2 - \frac{1}{2} c_3.
\]

The dynamics of the original Hamiltonian \( H \) is therefore decomposed into three separated blocks, corresponding to the two dynamics of Hamiltonians \( \tilde{H}_1 \), \( \tilde{H}_2 \), with one degree of freedom, and the two-degrees of freedom dynamics generated by \( \tilde{H}_3 \).

**Example 4.** Killing tensor with an eigenvalue of multiplicity \( N - 1 \). If \( H \) admits a single quadratic first integral, this one determines block-separable coordinates if it has exactly one eigenvalue of multiplicity one and another one of multiplicity \( N - 1 \), so that we have a \( 2 \times 2 \) Stäckel matrix. Indeed, from block-Eisenhart equations we have

\[
X_1 \lambda_1 = 0, \quad X_i \lambda_2 = 0, \quad i = 1, \ldots, N - 1,
\]

where \( X_1 \) is the eigenvector corresponding to the eigenvalue \( \lambda_1 \) of multiplicity one and \( X_2, \lambda_2 \) the eigenvectors of \( \lambda_2 \) of multiplicity \( N - 1 \). Hence, provided \( \lambda_1 \) is not a constant, we have that the submanifolds \( \lambda_1 = \text{const.} \) are orthogonal to the eigenvector \( X_1 \), which is therefore normally integrable. We can put in this case \( X_1 = \partial_1 \) and the block separation is essentially determined by the equations

\[
\lambda_1(q^2, \ldots, q^N) = \text{const.}
\]

moreover \( \lambda_2(q^1) \).

We find in this way another (partial) analogy with Stäckel separation, since in that case, the existence of a single Killing 2-tensor with distinct eigenvalues in dimension two is enough to determine Stäckel separable coordinates and the eigenvalues themselves, if not constants, generate the separable coordinates.

In [4] we show that Stäckel coordinates can be completely determined from the eigenvalues of the associated Killing two-tensors. Part of those results can be easily extended to block-separable systems. However, we leave the analysis of these questions for future researches.

6 Block-separable coordinates of \( \mathbb{E}^3 \)

In dimension three, only two types of block-separable coordinates can exist, apart the trivial case of a single three-dimensional block. Either each block is one-dimensional, and the coordinates are standard separable orthogonal coordinates, or one block is one-dimensional an the other is two-dimensional. In this last case, denoting the separable coordinates as \( (u, v, w) \), the geodesic Hamiltonian is

\[
H = \alpha^1 H_1 + \alpha^2 H_2,
\]

with

\[
H_1 = g_1(u)p_u^2,
\]

\[
H_2 = H_2(u,v,w),
\]

\[
H_3 = H_3(u,v,w),
\]

where \( g_1(u) \) is a metric function, \( H_2(u,v,w) \) a quadratic first integral, and \( H_3(u,v,w) \) a polynomial of degree \( N - 1 \).

The block separation is then essentially determined by the equations

\[
\lambda_1(q^2, \ldots, q^N) = \text{const.}
\]

moreover \( \lambda_2(q^1) \).

We find in this way another (partial) analogy with Stäckel separation, since in that case, the existence of a single Killing 2-tensor with distinct eigenvalues in dimension two is enough to determine Stäckel separable coordinates and the eigenvalues themselves, if not constants, generate the separable coordinates.
and, since any 2-dimensional Riemannian manifold is locally conformally flat,
\[ H_2 = g_2(v, w)(p_u^2 + p_v^2), \]
where the choice of local Cartesian coordinates on the manifolds \( u = \text{const.} \) is not restrictive. Since \( g_1 \) can always be set equal to 1 by a rescaling of \( u \), we can assume \( g_1 = 1 \) and call \( g_2 \) simply \( g \).

The corresponding general block-Stäckel matrix has the form
\[
S = \begin{pmatrix} S_1^1(u) & S_2^1(u) \\ S_1^2(v, w) & S_2^2(v, w) \end{pmatrix}. 
\]

Since
\[
\alpha^1 = (S^{-1})_1^1, \quad \alpha^2 = (S^{-1})_2^2,
\]
the contravariant metric \( G \) associated with \( H \) has components
\[
G_{uu} = \frac{S_2^2(v, w)}{\Delta}, \quad G_{vv} = G_{ww} = -\frac{S_1^1(u)g}{\Delta},
\]
with \( \Delta = S_1^1(u)S_2^2(v, w) - S_2^1(u)S_1^2(v, w) \).

We restrict ourselves to the space \( E^3 \) by imposing that the Riemann tensor of the metric \( G \) is identically zero. We have
\[
R_{2132} = -\frac{3(\partial_u S_2^2 S_1^1 - \partial_v S_1^1 S_2^1)(\partial_u S_2^2 S_1^2 - \partial_v S_2^1 S_2^2)}{4\Delta S_1^1 g},
\]
and
\[
R_{4123} = -\frac{3(\partial_u S_2^2 S_1^1 - \partial_v S_1^1 S_2^1)(\partial_u S_2^2 S_1^2 - \partial_v S_2^1 S_2^2)}{4\Delta S_1^1 g}.
\]

Hence, two cases are possible
i) \( (\partial_u S_2^2 S_1^1 - \partial_v S_1^1 S_2^1) = 0 \),
ii) \( (\partial_u S_2^2 S_1^2 - \partial_v S_2^1 S_2^2) = 0 \) and \( (\partial_u S_2^2 S_1^1 - \partial_v S_2^1 S_2^2) = 0 \).

**Case i**

We have
\[ S_1^1 = aS_2^1, \]
where \( a \) is a constant. We observe that the components of \( G \) become
\[
G_{uu} = \frac{S_2^2}{S_1^1(aS_2^2 - S_2^1)}, \quad G_{vv} = G_{ww} = -\frac{g}{aS_2^2 - S_2^1},
\]
that is, we can write without restrictions
\[
G_{uu} = h(u)^{-2}f(v, w)^{-2}, \quad G_{vv} = G_{ww} = l(v, w)^{-2},
\]
with the obvious definitions of \( h, f \) and \( l \).

A further rescaling of \( u \) allows to set \( h = 1 \) and \( u \) can always be considered an ignorable coordinate, therefore, associated with a Killing vector \( \partial_u \).
The unknown functions are now reduced to two, and we can consider the remaining components of the Riemann tensor. The resulting equations are

\[ l (\partial_{vv}l + \partial_{ww}l) - (\partial_v l)^2 - (\partial_w l)^2 = 0, \]
\[ l \partial_{vv}f - \partial_v l \partial_v f + \partial_w l \partial_w f = 0, \]
\[ l \partial_{ww}f + \partial_v l \partial_v f - \partial_w l \partial_w f = 0, \]
\[ l \partial_{vw}f - \partial_v l \partial_w f - \partial_w l \partial_v f = 0. \]

(27) (28) (29) (30)

Proposition 14. The coordinate leaves \( u = \text{const.} \) are planes and \( \partial_u \) is proportional to a Killing vector.

Proof. Equation (27) means that the Riemann tensor of the coordinate leaves \( u = \text{const} \) is zero.

The block-Stäckel matrix is in this case

\[ S = \begin{pmatrix} \frac{\alpha}{(1 - \frac{\alpha}{\beta})g} & \frac{1}{\beta} \\ \frac{1}{\beta} & -\frac{\beta}{\alpha} \end{pmatrix}, \]

(31)

and the Hamiltonian \( H = \alpha_1^1 H_1 + \alpha_2^2 H_2 \) and first integral \( K = \alpha_1^2 H_1 + \alpha_2^2 H_2 \) are

\[ H = \frac{1}{f^2} p_u^2 + \frac{1}{f^2} (p_v^2 + p_w^2), \]
\[ K = (1 - \frac{\alpha}{f^2}) p_u^2 - \frac{\alpha}{f^2} (p_v^2 + p_w^2), \]

since \( K = p_u^2 - \alpha H \), we have that the first integral associated with this kind of block-separation is simply \( p_u^2 \).

An expected result, because the variable \( u \) is ignorable.

We observe that the solution of the equation (27) is

\[ l = c_2 e^{\frac{\alpha}{\beta} (w^2 - v^2) - c_1 v - c_3 w}, \]

(32)

where \( (c_i) \) are real constants. The substitution of such \( l \) in the remaining equations yields

\[ \partial_{vv}f + (c_1 - c_0 v) \partial_v f - (c_3 + c_0 w) \partial_w f = 0, \]
\[ \partial_{ww}f - (c_1 - c_0 v) \partial_v f + (c_3 + c_0 w) \partial_w f = 0, \]
\[ \partial_{vw}f + (c_3 + c_0 w) \partial_v f + (c_1 - c_0 v) \partial_w f = 0. \]

(33) (34) (35)

The sum of the first two equations implies that \( f \) is a solution of the Laplace equation. Then,

\[ f = f_1(v + i w) + f_2(v - i w). \]

The substitution of this equation into (33) gives, after few manipulations, the equivalent system

\[ f_1'' + (c_1 - ic_3 - c_0 (v + i w)) f_1' = 0, \]
\[ f_2'' + (c_1 + ic_3 - c_0 (v - i w)) f_2' = 0. \]

(36) (37)
Example 5. Rotational and cylindrical coordinates. Given in an Euclidean plane any coordinate system with a symmetry axis, the coordinates of $E^3$ obtained by rotating the plane around the symmetry axis and taking as third coordinate the angle of rotation are of this form. If $f$ is constant and $l^{-2}$ represents a metric in the Euclidean plane $(v, w)$, then the cylindrical coordinate system with the plane $(v, w)$ as base is of this form.

Case ii

A similar analysis for the case ii gives the equivalent condition

$$S_2^1 = a S_2^2.$$ 

We have

$$G^{uu} = \frac{1}{S_1^1 - a S_2^1}, \quad G^{ww} = - \frac{S_2^2 g}{S_2^2(S_1^1 - a S_2^1)},$$

and we can write without restrictions

$$G^{uu} = h(u)^2, \quad G^{vv} = G^{ww} = l(u)^2 f(v, w)^2,$$

with the obvious definitions of $h$, $f$ and $l$.

Again, a rescaling of $u$ allows to set $h = 1$, in this case, $u$ is not necessarily ignorable, but the metric has the structure of a warped metric. Therefore, $\partial_u$ must be parallel to a conformal Killing vector [7].

The equations arising from imposing Riemann tensor equal to zero are now

$$l'' l - 2(l')^2 = 0, \quad l^4 (f(\partial_{uu} f + \partial_{ww} f) - (\partial_v f)^2 - (\partial_w f)^2) - (l')^2 = 0.$$ 

The block-Stäckel matrix is in this case

$$S = \begin{pmatrix} 1 - a l^2 & -l^2^{\frac{a}{2}} \\ a l^2 & a l^2 \end{pmatrix}, \quad (40)$$

and the Hamiltonian $H = \alpha_1^1 H_1 + \alpha_2^2 H_2$ and first integral $K = \alpha_1^1 H_1 + \alpha_2^2 H_2$ are

$$H = p_v^2 + l^2 f^2 (p_v^c + p_w^c), \quad K = -\alpha p_v^2 + (1 - a l^2) f^2 (p_v^c + p_w^c),$$

since $K = f^2 (p_v^c + p_w^c) - a H$, we have that the first integral associated with this kind of block-separation is

$$f^2 (p_v^c + p_w^c),$$

as expected due to the warped form of the metric.

The solutions of (38) are

$$l = -(c_1 u + c_2)^{-1}, \quad (41)$$

that, substituted in the second equation, give

$$f(\partial_{uv} f + \partial_{ww} f) - (\partial_v f)^2 - (\partial_w f)^2 - c_1^2 = 0. \quad (42)$$
We remark that (42) means that the Ricci scalar of the submanifolds $u = \text{const.}$ is

$$R = 2l^2(u)c_1^2,$$

and its Riemann tensor has non null components

$$R_{yzyz} = \frac{c_1^2}{l^2}.$$

Therefore,

**Proposition 15.** In case ii, all the coordinate leaves orthogonal to $\partial_u$ are planes $(c_1 = 0)$ or spheres. The vector $\partial_u$ is proportional to a conformal Killing vector.

**Example 6.** Spherical and cylindrical coordinates. An example of type ii of block separation is given by spherical-type coordinates, where $u$ is the radius of the spheres and $(v, w)$ are any coordinates on the sphere. If $c_1 = 0, c_2 \neq 0$, the coordinates are cylindrical with base the plane $(v, w)$.

**Remark 6.** From the previous remarks it follows that, if a coordinate system is block-separable in $n > m$ blocks, then, not necessarily it is block separable in $m$ blocks too. Indeed, if we consider the ellipsoidal coordinates in $E^3$, they are Stäckel-separable, then block-separable in three blocks, but they cannot be block-separable in 2 blocks, since these coordinates do not include planes or spheres. This fact is not surprising, since it is known that Stäckel separation in ellipsoidal coordinates cannot be achieved by successive separation of the single variables, and block-separation into two blocks in dimension three means exactly that one of the variables can be separated from the others.

7 Conclusions and future directions

By introducing the idea of twisted product of natural Hamiltonians and the analysis of the consequent relations among the Hamiltonian flows of the product and of its factors, we find a new, dynamical, interpretation of classical partial separation of variables of Hamilton-Jacobi equation, as well as of complete separation. We find that our block-separation, when possible, allows the reconstruction of the orbits of the product Hamiltonian from the orbits of the several lower-dimensional block-separated Hamiltonians. We characterize in an invariant way block-separation, by adapting classical results of complete separation theory for the Hamilton-Jacobi equation. We extend Eisenhart’s classification of completely separable coordinate systems, the Stäckel systems, in $E^3$ to block-separable coordinate systems, finding essentially coordinate-blocks of rotational, cylindrical, and spherical type. We are confident that the possibility of reducing the analysis of the dynamics of Hamiltonians with many degrees of freedom to the dynamics of its block-separated Hamiltonians can find many applications, even in the field of numerical computations. We do not consider here the block-separation of Schrödinger’s and other related equations of mathematical physics. Studies on partial separation of these equations are somehow more developed than those on partial separation of Hamilton-Jacobi equation, probably because the absence of completeness in partial separation and the consequent impossibility of application of the Jacobi’s canonical transformation do not seem to be an obstacle in this case. We will study block-separation of Schrödinger and related equations in next papers.
