THE PERSISTENT HOMOLOGY OF
RANDOM GEOMETRIC COMPLEXES ON FRACTALS

BENJAMIN SCHWEINHART

Abstract. We study the asymptotic behavior of the persistent homology of i.i.d.
samples from a \( d \)-Ahlfors regular measure on a metric space — one that satisfies
uniform bounds of the form

\[
\frac{1}{c} r^d \leq \mu(B_r(x)) \leq c r^d
\]

for some \( c > 0 \), all \( x \) in the support of \( \mu \), and all sufficiently small \( r \). Our main
result is that if \( x_1, \ldots, x_n \) are sampled from a \( d \)-Ahlfors regular measure on a metric
space and \( E_\alpha(x_1, \ldots, x_n) \) denotes the \( \alpha \)-weight of the minimal spanning tree on
\( x_1, \ldots, x_n \) :

\[
E_\alpha(x_1, \ldots, x_n) = \sum_{e \in T(x_1, \ldots, x_n)} |e|^\alpha
\]

then

\[
E_\alpha(x_1, \ldots, x_n) \approx n^{\frac{d-\alpha}{d}}
\]

with high probability as \( n \to \infty \). We also prove theorems about the asymptotic
behavior of weighted sums defined in terms of the higher-dimensional persistent
homology of subsets of Euclidean space. As an application, we exhibit hypotheses
under which the fractal dimension of a measure can be computed from the per-
sistent homology of i.i.d. samples from that space, in a manner similar to that
proposed in the experimental work of Adams et al. [1].

1. Introduction

The properties of minimal spanning trees on points sampled independently from an
absolutely continuous measure on Euclidean space are the subject of an expansive
literature. More recently, researchers in the field of stochastic topology have studied
higher dimensional analogues of these results for the persistent homology of random
geometric complexes. In contrast, very little is known about the topology of random
geometric complexes built on points sampled from sets of fractional dimension. This
is despite the prevalence of such sets in nature — in the words of Mandelbrot, “Clouds

Date: September 2018.
are not spheres, mountains are not cones, coastlines are not circles, and bark is not smooth, nor does lightning travel in a straight line.”[20] Here, we initiate the rigorous study of the persistent homology of random geometric complexes on fractals.

We study the asymptotic behavior of random variables of the form

\[ E_\alpha^i (x_1,\ldots,x_n) = \sum_{I \in PH_i(x_1,\ldots,x_n)} |I|^\alpha \]

where \( \{x_j\}_{j \in \mathbb{N}} \) are i.i.d. samples from a probability measure \( \mu \) on a metric space, and \( PH_i(x_1,\ldots,x_n) \) denotes the \( i \)-dimensional reduced persistent homology of the Čech or Vietoris—Rips complex of \( \{x_1,\ldots,x_n\} \). Unless otherwise specified, our results apply to the persistent homology of either the Čech or Vietoris—Rips complex, though the constants may differ.

The case where \( i = 0 \) and \( \mu \) is absolutely continuous is already well-studied, under a different guise: if

\[ E_\alpha (x_1,\ldots,x_n) = \sum_{e \in T(x_1,\ldots,x_n)} |e|^\alpha \]

where \( T \) is a minimal spanning tree on \( x_1,\ldots,x_n \) then

\[ E_\alpha (x_1,\ldots,x_n) = E_0^\alpha (x_1,\ldots,x_n) \]

if persistent homology is taken with respect to the Vietoris—Rips complex. In 1988, Steele [26] proved the following celebrated result:

**Theorem 1 (Steele).** Let \( \mu \) is a compactly supported probability measure on \( \mathbb{R}^m \), and let \( \{x_n\}_{n \in \mathbb{N}} \) be i.i.d. samples from \( \mu \). If \( \alpha < m \),

\[ \lim_{n \to \infty} n^{-\frac{m-\alpha}{m}} E_0^\alpha (x_1,\ldots,x_n) \to c(\alpha,m) \int_{\mathbb{R}^d} f(x)^{(m-\alpha)/m} \]

with probability one, where \( f(x) \) is the probability density of the absolutely continuous part of \( \mu \), and \( c(\alpha,m) \) is a positive constant that depends only on \( \alpha \) and \( m \).

Following the publication of this result, several other papers established sharper results about the asymptotics of \( \alpha \)-weighted sums of minimal spanning trees, including those by Aldous and Steele [2], Kesten and Lee [15], and Yukich [28].

More recently, as the field of stochastic topology has matured, several studies have examined the properties of the higher dimensional persistent homology of random geometric complexes [6, 11, 3]. In 2018, we [24] proved results about the asymptotics of \( E_\alpha^i (x_1,\ldots,x_n) \) of i.i.d. samples from a from a locally bounded probability
density on the bi-Lipschitz image of a compact \( m \)-dimensional simplicial complex. Independently and concurrently, Divol and Polonik [10] showed a sharper analogue of Steele’s theorem for the persistent homology of points sampled from bounded, absolutely continuous probability densities on \([0,1]^m\).

In contrast to the absolutely continuous case, little is known about the behavior of random variables defined in terms of the persistent homology of points sampled from a set of fractional dimension, even for \( i = 0 \). As far as we know, the only rigorous result in the literature toward this end is that of Kozma, Lotker and Stupp [16], who proved that if \( \mu \) is \( d \)-Ahlfors regular measure with connected support, then the length of the longest edge of a minimal spanning tree (or, equivalently, the longest \( PH_0 \) interval) on \( n \) i.i.d. points sampled from \( \mu \) is \( \approx (\log(n)/n)^{1/d} \), where the symbol \( \approx \) denotes that the ratio between the two quantities is bounded between two positive constants that do not depend on \( n \). In the extremal setting, the same authors [17] defined a minimal spanning tree dimension for a metric space \( M \) in terms of the behavior of \( E_0^0(Y) \) as \( Y \) ranges over all subsets of \( M \), and proved that it equals the upper box dimension. Earlier this year, we generalized this concept to higher dimensional homology by defining a notion of a \( PH_i \) dimension of a metric space, and establishing hypotheses under which it agrees with the upper box dimension [23].

Despite the paucity of rigorous results, a relationship between persistent homology and fractal dimension has been observed in several experimental studies. In 1991, Weygaert, Jones, and Martinez [27] proposed using the asymptotics of \( E_0^0(x_1,\ldots,x_n) \) for negative \( \alpha \) to estimate the generalized Hausdorff dimensions. The PhD thesis of Robins, which was perhaps the first publication in the field of topological data analysis, studied the scaling of Betti numbers of fractals, and proved results for the 0-dimensional persistent homology of disconnected sets [22]. In joint work with Robert MacPherson, we proposed a dimension for probability distributions of geometric objects based on persistent homology in 2012 [19]. Note that the quantities studied in that paper and in the thesis of Robins measure the complexity of a shape rather than the fractional dimension. Most recently, Adams et al. [1] proposed a persistent homology dimension for measures in terms of the asymptotics of \( E_1^1(x_1,\ldots,x_n) \). We study a slightly modified version of their dimension here, and find hypotheses under which it agrees with the Ahlfors dimension.

1.1. Our Results. We prove analogues of the theorem of Steele [26] for probability measures defined on sets of fractional dimension that satisfy a certain regularity condition:
Definition 1. A probability measure \( \mu \) supported on a metric space \( X \) is \( d \)-Ahlfors regular if there exist positive real numbers \( c \) and \( r_0 \) so that
\[
\frac{1}{c} r^d \leq \mu(B_r(x)) \leq c r^d
\]
for all \( x \in X \) and \( r < r_0 \), where \( B_r(x) \) denotes the ball of radius \( r \) centered at \( x \).

Ahlfors regularity is a common hypothesis when studying analysis on fractals [9, 11, 18]. Example of Ahlfors regular measures include the natural measures on the Sierpinski triangle and Cantor set, and, more generally, on any self-similar subset of Euclidean space defined by an iterated function system satisfying the open-set condition. If \( \mu \) is \( d \)-Ahlfors regular on \( X \) then it is comparable to the \( d \)-dimensional Hausdorff measure on \( X \). In particular, \( d \) equals the Hausdorff dimension of \( X \). Ahlfors regularity also implies that a host of other fractional dimensions, including the upper and lower box dimensions, coincide and equal \( d \).

Our main result is:

Theorem 2. If \( \mu \) is a \( d \)-Ahlfors regular measure on a metric space and \( 0 < \alpha < d \), then
\[
E_{\alpha}^0 (x_1, \ldots, x_n) \approx n^{\frac{d-\alpha}{d}}
\]
with high probability as \( n \to \infty \), where the symbol \( \approx \) denotes that the ratio of the two quantities is bounded between positive constants that do not depend on \( n \).

We provide a proof of this result using the language of minimal spanning trees (rather than persistent homology) in Section 3. The special case where \( \mu \) is a measure on Euclidean space is also a consequence of Theorem 3 below.

As we noted in our earlier paper [23], proving results for higher dimensional persistent homology is challenging due to extremal questions about the number of persistent homology intervals of a finite point set. While a minimal spanning tree on \( n \) points always has \( n - 1 \) edges, a set of \( n \) points may have no \( PH_i \), for any \( i > 0 \), and there exist families of point sets for which \(|PH_i(x_1, \ldots, x_n)|\) grows faster than \( n \).

To prove upper bounds for the asymptotics of \( E_{\alpha}^i \) for \( i > 0 \), we require either extremal or probabilistic control of the number of persistent homology intervals of a set of \( n \) points. Families of point sets in Euclidean space with more than a linear number of persistent homology intervals exist [23, 12], but are considered somewhat pathological. As far as we know, the Upper Bound Theorem [25] on the number
of faces of a neighborly polytope provides the best upper bound for the number of persistent homology intervals of the Čech complex of a finite subset of $\mathbb{R}^m$:

$$|PH_i(x_1, \ldots, x_n)| = \begin{cases} 
  i + 1 & i < \left\lfloor \frac{m}{2} \right\rfloor \\
  \left\lfloor \frac{m+1}{2} \right\rfloor & i \geq \left\lfloor \frac{m}{2} \right\rfloor
\end{cases}$$

For the Vietoris—Rips complex of points in Euclidean space, we [23] showed that

$$|PH_1(x_1, \ldots, x_n)| \in O(n)$$

by modifying an argument of Goff [12].

A different extremal question arises in the process of proving lower bounds for $E_{\alpha}^i$. In particular, a subset $\mathbb{R}^m$ must have dimension above a certain non-triviality constant $\gamma_i^m$ (defined in Section 6.1) to guarantee the existence of subsets with non-trivial $i$-dimensional persistent homology. We showed that $\gamma_i^m < m - 1/2$ in our previous paper [23].

The proofs of the upper bounds in the next two theorems work for Ahlfors regular measures on arbitrary triangulable metric spaces, but the lower bound requires that the measure is defined on a subset of Euclidean space:

**Theorem 3.** Let $\mu$ be a $d-$Ahlfors regular measure supported on $X \subset \mathbb{R}^m$. If $d > \gamma_i^m$,

$$|PH_i(x_1, \ldots, x_n)| < Dn^a$$

for some positive real numbers $a$ and $D$ and all finite subsets of $X$, and $0 < \alpha < ad$, then there are real numbers $0 < \zeta < Z$ so that

$$\zeta n^{\frac{d-a}{d}} \leq E_{\alpha}^i(x_1, \ldots, x_n) \leq Z n^{\frac{ad-a}{d}}$$

with high probability, as $n \to \infty$. In fact, the upper bound holds with probability one.

The upper bound is shown in Proposition 3 and the lower bound in Proposition 6. The following is a corollary:

**Corollary 1.** Let $\mu$ be a $d$-Ahlfors regular measure on $\mathbb{R}^2$ with $d > 1.5$. If $0 < \alpha < d$ and persistent homology is taken of the Čech complex,

$$E_{\alpha}^i(x_1, \ldots, x_n) \approx n^{\frac{d-a}{d}}$$

in probability, as $n \to \infty$. In fact, the upper bound holds with probability one.
For large $i$ or $m$, we show better upper bounds for $d$-Ahlfors regular measures for which the expectation and variance of $|PH_i(x_1,\ldots,x_n)|$ scale linearly and subquadratically, respectively. These quantities can be measured in practice, allowing one to determine whether higher dimensional persistent homology would be suitable for dimension estimation in applications.

**Theorem 4.** Let $\mu$ be a $d$–Ahlfors regular measure supported on $\mathbb{R}^m$ so that $d > \gamma_i^m$, and let $0 < \alpha < d$. If

$$\mathbb{E}(|PH_i(x_1,\ldots,x_n)|) = O(n) \quad \text{and} \quad \text{Var}(|PH_i(x_1,\ldots,x_n)|)/n^2 \to 0$$

there are real numbers $0 < \lambda < \Lambda$ so that

$$\lambda n^{\frac{d-\alpha}{\alpha}} \leq E_\alpha^i(x_1,\ldots,x_n) \leq \Lambda n^{\frac{d-\alpha}{\alpha}} \log(n)^{\frac{\alpha}{d}}$$

with high probability, as $n \to \infty$.

The upper and lower bounds are shown in Propositions 5 and 6, respectively.

1.2. Dimension Estimation. As we noted earlier in the introduction, several authors have proposed to use persistent homology for dimension estimation. Here, we provide the first proof that these methods recover the fractal dimension, under certain hypotheses. Toward that end, we define a family of $PH_i$ dimensions of a measure, one for each real number $\alpha > 0$ and $i \in \mathbb{N}$:

**Definition 2.**

$$\dim_{PH_i}(\mu) = \frac{\alpha}{1 - \beta}$$

where

$$\beta = \limsup_{n \to \infty} \frac{\log(\mathbb{E}(E_\alpha^i(x_1,\ldots,x_n)))}{\log(n)}$$

That is, $\dim_{PH_i}(\mu)$ is the unique real number $d$ so that

$$\limsup_{n \to \infty} \mathbb{E}(E_\alpha^i(x_1,\ldots,x_n)) n^{-\frac{k-\alpha}{\alpha}}$$

equals $\infty$ for all $k < d$, and is bounded for $k > d$. The case $\alpha = 1$ is very closely related to the dimension studied by Adams et al. [1], and agrees with it if defined.

The following is a corollary of our theorems on the asymptotic behavior of $E_\alpha^i$. 

Theorem 5. If $\mu$ is a $d$-Ahlfors regular measure on a metric space and $0 < \alpha < d$ then
\[ \dim_{PH_{\alpha}} = d \]
Furthermore, if $\mu$ is defined on $\mathbb{R}^m$, $d > \gamma^m$, and
\[ \mathbb{E}(|PH_{\alpha}(x_1, \ldots, x_n)|) = O(n) \quad \text{and} \quad \operatorname{Var}(|PH_{\alpha}(x_1, \ldots, x_n)|)/n^2 \to 0 \]
then
\[ \dim_{PH_{\alpha}} = d \]

2. Preliminaries

We will use the following two lemmas in our proofs for both minimal spanning trees and higher dimensional persistent homology.

Let $X$ be a metric space, and let $M_{\delta}(X)$ be the maximal number of disjoint balls of radius $\delta$ centered at points of $X$. (The upper and lower box dimensions are defined in terms of the asymptotic properties of $M_{\delta}(X)$). If $X$ admits a $d$-Ahlfors regular measure, we can control the behavior of $M_{\delta}(X)$:

Lemma 1 (Ball-counting Lemma). If $\mu$ is a $d$-Ahlfors regular measure supported on a metric space $X$ then
\[ \frac{1}{c} 2^{-d} \delta^{-d} \leq M_{\delta}(X) \leq c \delta^{-d} \]
for all $\delta < \delta_0$.

Proof. Let $\{x_j\}_{j=1}^{M_{\delta}(X)}$ be the centers of a maximal set of disjoint balls of radius $\delta$ centered at points of $X$.
\[
1 = \mu(X) \\
\geq \sum_{j=1}^{M_{\delta}(\mu)} \mu(B_\delta(x_j)) \\
\geq \frac{1}{c} \delta^d M_{\delta}(\mu) \\
\implies M_{\delta}(\mu) \leq c \delta^{-d}
\]
The maximality of \( \{ B_\delta(x_i) \}_{i=1}^{M_\delta(\mu)} \) implies that the balls of radius 2\( \delta \) centered at the points \( \{ x_i \} \) cover \( X \). It follows that

\[
1 = \mu(X) \\
\leq \sum_{j=1}^{M_\delta(X)} \mu(B_{2\delta}(x_j)) \\
\leq c2^d\delta^d M_\delta(X) \\
\implies M_\delta(X) \geq \frac{1}{c}2^{-d}\delta^{-d}
\]
as desired. \( \Box \)

We also require the following lemma of Cohen-Steiner et al. \([8]\):

**Lemma 2.** Let \( J \subset \mathbb{R}^+ \) be a set of positive real numbers and let \( J_\epsilon = \{ j \in J : j > \epsilon \} \).
If \( |J_\epsilon| \leq f(\epsilon) < \infty \) for all \( \epsilon > 0 \) then

\[
\sum_{j \in J_\epsilon} j^\alpha \leq \epsilon^\alpha f(\epsilon) + \alpha \int_{\delta=\epsilon}^{\max J} f(\delta) \delta^{\alpha-1} d\delta
\]

Furthermore, if \( |J| \leq f(0) < \infty \) then

\[
\sum_{j \in J} j^\alpha \leq \alpha \int_{\delta=0}^{\max J} f(\delta) \delta^{\alpha-1} d\delta
\]

For completeness, we reproduce the proof in \([8]\). \( \sum_{j \in J_\epsilon} j^\alpha \) can be expressed as an integral involving the distributional derivative of \( |J_\epsilon| \). Applying integration by parts yields:

\[
\sum_{j \in J_\epsilon} j^\alpha = \int_{\delta=\epsilon}^{\infty} -\frac{\partial |J_\delta|}{\partial \delta} \delta^\alpha d\delta \\
= \left[ -|J_\delta| \delta^\alpha \right]_{\delta=\epsilon}^{\infty} + \alpha \int_{\delta=\epsilon}^{\max J} |J_\delta| \delta^{\alpha-1} d\delta \\
= \epsilon^\alpha |J_\epsilon| + \alpha \int_{\delta=\epsilon}^{\max J} |J_\delta| \delta^{\alpha-1} d\delta \\
\leq \epsilon^\alpha f(\epsilon) + \alpha \int_{\delta=\epsilon}^{\max J} f(\delta) \delta^{\alpha-1} d\delta
\]
2.1. **Occupancy Events.** Our strategy for proving lower bounds will be to define certain “occupancy events” that imply the existence of a persistent homology interval of a certain length.

If $A$ and $B$ are sets define

$$\delta(A, B) = \begin{cases} 0 & A \cap B = \emptyset \\ 1 & A \cap B \neq \emptyset \end{cases}$$

Also, If $A$ is a set and $\mathcal{B}$ is a collection of sets define the occupancy event

$$\Xi(x, A, \mathcal{B}) = \begin{cases} 1 & \delta(A, x) = 0 \text{ and } \delta(B, x) = 1 \forall B \in \mathcal{B} \\ 0 & \text{otherwise} \end{cases}$$

**Definition 3.** A $n, p, q, r$-occupancy event is a random variable of the form

$$\Xi(x_1, \ldots, x_n, A, \{B_1, \ldots, B_r\})$$

where $A$ and $B_1, \ldots, B_r$ are pairwise disjoint sets and $x_1, \ldots, x_n$ are independent random variables with common distribution $\nu$ satisfying

$$\nu(A) = q/n \text{ and } \nu(B_j) = p/n \text{ for } j = 1, \ldots, r$$

Two occupancy events $\Xi(x_1, \ldots, x_n, A_1, \mathcal{B})$ and $\Xi(x_1, \ldots, x_n, A_1, \mathcal{C})$ are disjoint if

$$\left( A_1 \cup \bigcup_{B \in \mathcal{B}} B \right) \cap \left( A_1 \cup \bigcup_{C \in \mathcal{C}} C \right) = \emptyset$$

Disjoint $n, p, q, r$-occupancy events satisfy something akin to a weak law of large numbers as $n \to \infty$:

**Lemma 3.** Let $r, a > 0$, and $0 < p, q < 1$. Also, let $X_1^n, \ldots, X_{an}$ be disjoint $n, p, q, r$-occupancy events for each $n \in \mathbb{N}$. If $Y_n = \frac{1}{n} \sum_{j=1}^{\lfloor an \rfloor} X_j^n$,

$$\lim_{n \to \infty} Y_n = \gamma$$

in probability, where $\gamma = ae^{-q} (1 - e^{-p})^r$.

**Proof.** First, we compute the limiting expectation of the events $X_j^n$ as $n \to \infty$:

$$\mathbb{E}(X_j^n) = \mathbb{P}(X_j^n = 1) = \left( 1 - \frac{q}{n} \right)^n \sum_{j=0}^{r} (-1)^j \binom{r}{j} \left( 1 - \frac{jp}{n} \right)^n$$
by inclusion-exclusion. Therefore
\[
\lim_{n \to \infty} E \left( X_j^n \right) = e^{-q} \sum_{j=0}^{r} (-1)^j \binom{r}{j} e^{-jp} = e^{-q} \left( 1 - e^{-p} \right)^r
\]
by the binomial theorem, and \( \lim_{n \to \infty} E (Y_n) = \gamma \) by linearity of expectation.
A similar computation shows that if \( j \neq k \),
\[
\lim_{n \to \infty} E \left( X_j^n X_k^n \right) = e^{-2q} \left( 1 - e^{-p} \right)^{2r}
\]
It follows that
\[
\lim_{n \to \infty} \text{Cov} \left( X_j^n, X_k^n \right) = \lim_{n \to \infty} \left( E \left( X_j^n X_k^n \right) - E \left( X_j^n \right) E \left( X_k^n \right) \right) = 0
\]
Therefore
\[
\text{Var} \left( Y_n \right) = \frac{1}{n^2} \left( \sum_{j=1}^{\lfloor an \rfloor} \text{Var} \left( X_j \right) + 2 \sum_{j=1}^{\lfloor an \rfloor} \sum_{i=1}^{j-1} \text{Cov} \left( X_j^n, X_k^n \right) \right)
\sim \frac{a}{n} \text{Var} \left( X_1^n \right) + a \frac{n^2 - n}{n^2} \text{Cov} \left( X_1^n, X_2^n \right)
\leq \frac{1}{n} + a \left( 1 - \frac{1}{n} \right) \text{Cov} \left( X_1^n, X_2^n \right)
\]
also converges to 0 as \( n \) goes to \( \infty \).
Let \( \epsilon > 0 \) and \( 0 < \rho < 1 \). Choose \( N \) sufficiently large so that
\[ |E \left( Y_n \right) - \gamma| < \epsilon/2 \quad \text{and} \quad \text{Var} \left( Y_n \right) < \frac{\epsilon^2 \rho}{4} \]
for all \( n > N \). If \( n > N \),
\[ \mathbb{P} \left( |Y_n - \gamma| > \epsilon \right) \leq \mathbb{P} \left( |Y_n - E \left( Y_n \right)| > \epsilon/2 \right) \]
\[ \leq \mathbb{P} \left( \left| Y_n - E \left( Y_n \right) \right| > \frac{1}{\sqrt{\rho}} \sqrt{\text{Var} \left( Y_n \right)} \right) \]
\[ \leq \rho \]
by Chebyshev’s Inequality. \( \square \)
2.2. **Notation.** If the measure $\mu$ is obvious from the context, $\{x_j\}_{j \in \mathbb{N}}$ will denote a collection of independent random variables with common distribution $\mu$. Also, $x_n$ will be shorthand for $\{x_1, \ldots, x_n\}$ and $x$ will denote a finite point set.

3. **The Proof for Minimal Spanning Trees**

If $x$ is a finite metric space, let $p(x, \epsilon)$ be the number of edges of $T(x)$ of length greater than $\epsilon$. Also, let $G_{x,\epsilon}$ be graph the with vertex set $x$ so that $x_1$ and $x_2$ are connected by an edge if and only if $d(x_1, x_2) < \epsilon$ (this is the one-skeleton of the Vietoris-Rips complex). The following is a corollary of Kruskal’s algorithm:

**Lemma 4.**

$$p(x, \epsilon) = \beta_0(G_{x,\epsilon}) - 1$$

where $\beta_0(G_{x,\epsilon})$ is the number of connected components of $G_{x,\epsilon}$.

3.1. **Proof of the Upper Bound.** Our strategy to prove an upper bound for the asymptotics of $E(x_n)$ is to control the number of edges in $T(x_n)$ of length greater than $\epsilon$ in terms of the maximal number of disjoint balls of radius $\epsilon/2$ centered at points of $x_n$. The approach is similar to that in our earlier papers [23, 24].

**Lemma 5.** Let $X$ be a metric space and suppose there are positive real numbers $D$ and $d$ so that

$$M_\epsilon(X) \leq D \epsilon^{-d}$$

for all $\delta > 0$. Then

$$p(x, \epsilon) < 2^{-d} D \epsilon^{-d}$$

for all finite subsets $x$ of $X$ and all $\epsilon > 0$.

**Proof.** Let $x \subset X$, $\epsilon > 0$, and let $y$ be the centers of a maximal set of disjoint balls of radius $\epsilon/2$ centered at points of $x$. The maximality of $y$ implies that for every $x \in x$ there exists a $y \in y$ so that $d(x, y) < \epsilon$. In particular, every connected component of $G_{x,\epsilon}$ has a vertex that is an element of $y$. Therefore

$$p(x, \epsilon) = b_0(G_{x,\epsilon}) - 1$$

$$\leq |y| - 1$$

$$\leq D (\epsilon/2)^{-d}$$

$$= 2^{-d} D \epsilon^{-d}$$
We prove an extremal bound on $E_\alpha (x_n)$ that implies the upper bound for our main theorem on minimal spanning trees:

**Proposition 1.** Let $X$ be a metric space and suppose there are positive real numbers $D$ and $d$ so that

$$M_\delta (X) \leq D \delta^{-d}$$

for all $\delta > 0$. For all $0 < \alpha < d$, there exists a $D_\alpha > 0$ so that

$$E_\alpha (x_1, \ldots, x_n) \leq D_\alpha n^{d-\alpha}$$

for all $n$ and all $x_1, \ldots, x_n \subset X$. Furthermore, there exist a $D_d > 0$ so that

$$E_d (x_1, \ldots, x_n) \leq D_d \log (n)$$

for all $n$ and all $x_1, \ldots, x_n \subset X$.

**Proof.** Rescale $X$ if necessary so that its diameter is less than 1, and let

$$\kappa = \frac{1}{2} \left( \frac{D}{n-1} \right)^{1/d}$$

The previous lemma together with the fact that a minimal spanning tree on $n$ points has $n-1$ lemma implies that

$$p(\{x_n\}, \epsilon) \leq \min \left( n-1, 2^{-d}D\epsilon^{-d} \right)$$

In fact, diam $X < 1$ so $p(\{x_n\}, \epsilon) \leq f(\epsilon)$ where

$$f(\epsilon) = \begin{cases} n-1 & \epsilon \leq \kappa \\ 2^{-d}D\epsilon^{-d} & \kappa \leq \epsilon < 1 \\ 0 & \epsilon \geq 1 \end{cases}$$
Applying Lemma 2 to the set of edge lengths of the minimal spanning tree on \( x_n \) yields

\[
E_\alpha (x_n) = \sum_{e \in T(x_n)} |e|^\alpha
\leq \alpha \int_{\delta=0}^{1} f(\delta) \delta^{\alpha-1} d\delta \\
= (n-1) \int_{\delta=0}^{\kappa} \alpha \delta^{\alpha-1} d\delta + \alpha 2^{-d} D \int_{\delta=\kappa}^{1} \delta^{\alpha-d-1} d\delta \\
= (n-1) [\delta^{\alpha}]_{\delta=0}^{\kappa} - \frac{\alpha}{d-\alpha} 2^{-d} D \left[ \delta^{\alpha-d} \right]_{\delta=\kappa}^{1} \\
= (n-1) \kappa^{\alpha} + \frac{\alpha}{d-\alpha} 2^{-d} D \left( \kappa^{\alpha-d} \right) \\
= 2^{\alpha} D^{\frac{\alpha}{d}} \left( 1 + D \frac{\alpha}{d-\alpha} \right) (n-1)^{\frac{d-\alpha}{d}} \\
\leq D_\alpha n^{\frac{d-\alpha}{d}}
\]

where

\[
D_\alpha = 2^{\alpha} D^{\frac{\alpha}{d}} \left( 1 + D \frac{\alpha}{d-\alpha} \right)
\]

The result for \( \alpha = d \) follows from a similar computation.

3.2. **Proof of the Lower Bound.** Our strategy to prove a lower bound for the asymptotics of \( E_\alpha (x_n) \) is to define a random variable based on occupancy patterns of disjoint balls of radius \( 2r \) that imply the existence of minimal spanning tree edges of length at least \( r \). Let \( M \) be a metric space, \( \mu \) be a \( d \)-Ahlfors regular measure with support \( M \). If \( B \) is a ball of radius \( 2r \) centered at a point \( x \in M \) and \( x \) is a finite subset of \( M \), define

\[
\omega(B, x) = \Xi (B_{2r} (x) \setminus B_r (x), \{B_r (x)\})
\]

That is, \( \omega(B, x) = 1 \) if \( x \) intersects \( B_r (x) \) but not the annulus centered at \( x \) with radii \( r \) and \( 2r \).

**Lemma 6.** Let \( \mathcal{B} \) be a set of disjoint balls of radius \( 2r \) centered at points of \( M \), and let \( x \) be a finite subset of \( M \).

\[
p(x, r) \geq \sum_{B \in \mathcal{B}} \omega(B, x) - 1
\]
Figure 1. The red balls on the right all satisfy $\omega(B, x) = 1$, which guarantees that the minimal spanning tree on the left has at least three edges whose length exceeds $r$.

Proof. This is an immediate consequence of Lemma 4. See Figure 1. □

Fix $n \in \mathbb{N}$ and let $\epsilon = n^{-1/d}$. Let $B^n_1, \ldots, B^n_{s_n}$ be a maximal collection of disjoint balls of radius $2\epsilon$ centered at points of $X$, and let $y^n_j$ be the center of $B^n_j$ for $j = 1, \ldots, s_n$. We require one more lemma before proving the lower bound:

Lemma 7. There is a positive real number $\gamma > 0$ so that

$$\lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{s_n} \omega\left(B^n_j, x^n\right) \geq \gamma$$

in probability as $n \to \infty$.

Proof. Let

$$p = \frac{1}{c} \quad \text{and} \quad q = 2^d c - \frac{1}{c}$$

By the definition of Ahlfors regularity

$$\mu\left(B_{\epsilon}\left(y^n_j\right)\right) \geq p c^d = \frac{p}{n}$$
and
\[ \mu \left( B^n_j \setminus B^n_{y^*} \right) \leq c(2\epsilon)^d - \frac{1}{c} \epsilon^d = \frac{q}{n} \]

Also, Lemma 1 implies that
\[ s_n \geq \frac{1}{c} 2^{-d} 2\epsilon^{-d} = \frac{1}{c} 2^{-2d} n \]

It follows that \( \frac{1}{n} \sum_{j=1}^{s_n} \omega \left( B^n_j, x_n \right) \) stochastically dominates the sum \( \frac{1}{n} \sum_{j=1}^{\lfloor an \rfloor} X^n_j \), where \( a = 2^{-2d}/c \), and \( X^n_1, \ldots, X^n_{\lfloor an \rfloor} \) are disjoint \( n, p, q \)-2-occupancy events. By Lemma 3
\[ \lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{\lfloor an \rfloor} X^n_j = \gamma \]
in probability as \( n \to \infty \), where
\[ \gamma = ae^{-q} \left( 1 - e^{-p} \right)^r \]
therefore
\[ \lim_{n \to \infty} \sum_{j=1}^{s_n} \frac{1}{n} \omega \left( B^n_j, x_n \right) \geq \gamma \]
in probability, as desired.

The lower bound in our main theorem on minimal spanning trees follows quickly:

**Proposition 2.** Let \( \mu \) be a \( d \)-Ahlfors regular measure on a metric space \( M \). If \( \{ x_j \}_{j \in \mathbb{N}} \) are i.i.d. samples from \( \mu \), and \( \gamma \) is as given in the previous lemma,
\[ \lim_{n \to \infty} n^{-\frac{d}{d-\alpha}} E_\alpha (x_n) \geq \gamma \]
in probability.

**Proof.** We have that
\[ \lim_{n \to \infty} n^{-\frac{d-\alpha}{d}} E_\alpha^i (x_n) \geq \lim_{n \to \infty} n^{-\frac{d-\alpha}{d}} n^{-\alpha/d} p \left( x_n, n^{-1/d} \right) \]
\[ \geq \lim_{n \to \infty} \frac{1}{n} \left( \sum_{j=1}^{s_n} \omega \left( B^n_j, x_n \right) - 1 \right) \]
by Lemma 6
\[ \geq \gamma \]
by Lemma 7
in probability, as \( n \to \infty \).
4. Persistent Homology

We provide a brief introduction to the persistent homology of the $\epsilon$-neighborhood filtration of a subset $X$ of a metric space. If $X$ is finite, this is equivalent to the persistent homology of the $\check{C}$ech complex. As noted earlier, all of our results also apply to the Vietoris—Rips complex.

If $X$ is a bounded subset of a triangulable metric space $M$, let $X_\epsilon$ denote the $\epsilon$-neighborhood of $X$:

$$X_\epsilon = \{ x \in M : d(x, X) < \epsilon \}$$

Also, let $H_i(X)$ be the reduced homology of $X$, with coefficients in a field $k$. The persistent homology of $X$ is the product $\prod_{\epsilon > 0} H_i(X_\epsilon)$, together with the inclusion maps $i_{\epsilon_0, \epsilon_1} : H_i(X_{\epsilon_0}) \to H_i(X_{\epsilon_1})$ for $\epsilon_0 < \epsilon_1$. The structure of persistent homology is captured by a set of intervals, which we refer to as $PH_i(X)$ [29]. These intervals represent how the topology of $X_\epsilon$ changes as $\epsilon$ increases. Under certain finiteness hypotheses — which are satisfied if $X$ is a finite point set — $PH_i(X)$ is the unique set of intervals so that the rank of $i_{\epsilon_0, \epsilon_1}$ equals the number of intervals containing $(\epsilon_0, \epsilon_1)$ [7].

4.1. More Properties of Persistent Homology. Let $M$ be a triangulable metric space. If $X \subset M$ and $\epsilon > 0$ let $PH_i^\epsilon(X)$ denote the set of intervals of $PH_i(X)$ of length greater than $\epsilon$:

$$PH_i^\epsilon(X) = \{ I \in PH_i(X) : |I| > \epsilon \}$$

Also, define

$$p_i(X, \epsilon) = |PH_i^\epsilon(X)|$$

If $X, Y \subset M$, let $d_H(X, Y)$ will denote the Hausdorff distance between $X$ and $Y$:

$$d_H(X, Y) = \inf_{\epsilon \geq 0} Y \subseteq X_\epsilon \quad \text{and} \quad X \subset Y_\epsilon$$

and $d(X, Y)$ denote infimal distance between pairs of points, one in each set:

$$d(X, Y) = \inf_{x \in X, y \in Y} d(x, y)$$

We use the following properties of persistent homology in our proofs:

(1) **Stability:** If $d_H(X, Y) < \epsilon$, there is an injection

$$\eta : PH_i^{2\epsilon}(X) \to PH_i(Y)$$
so that if $\eta(b_0, d_0) = (b_1, d_1)$ then
$$\max(|b_0 - b_1|, |d_0 - d_1|) < \epsilon$$

In particular,
$$p_i(X, 2\epsilon + \delta) \leq p_i(Y, \delta)$$
for all $\delta \geq 0$. [7]

(2) **Additivity for well-separated sets**: If $X_j \subset M$ for $j = 1, \ldots, n$ and

$$d(X_j, X_k) > \max \left(\text{diam } X_j, \text{diam } X_k\right) \left(1 - \delta_{j,k}\right) \quad \forall j, k$$

then
$$p_i(\bigcup_j X_j, \epsilon) \geq \sum_j p_i(X_j, \epsilon)$$

(3) **Translation invariance**: $PH_i(X) = PH_i(X + t)$ for all $t \in \mathbb{R}^n$.

(4) **Scaling**: For all $\rho > 0$,
$$PH_i(\rho X) = \{(\rho b, \rho d) : (b, d) \in PH_i(X)\}$$

We use property (1) in our proofs of both the upper and lower bounds, and property (2) for our proof of the lower bound. For these results, we also require a non-triviality property (as in Definition 4) and an upper bound on $PH_i(x_1, \ldots, x_n)$ in terms of $n$.

4.2. **A Lemma**. If $X$ is a subset of a metric space let

$$F_\alpha^i(X, \epsilon) = \sum_{I \in PH_i(X)} |I|^\alpha$$

We will use the following lemma in the next section:

**Lemma 8**. If $d_H(X, Y) < \epsilon/4$ then
$$F_\alpha^i(X, \epsilon) < 2^\alpha F_\alpha^i(Y, \epsilon/2)$$

**Proof.** By stability, there is an injection
$$\eta : PH_i^\epsilon(X) \to PH_i^{\epsilon/2}(Y)$$

satisfying
$$|I| < |\eta(I)| + \epsilon/2 \leq 2|\eta(I)|$$
for all $I \in PH_i^\epsilon(X)$.
It follows that
\[
F_{i\alpha}(X, \epsilon) = \sum_{I \in PH_i(X)} |I|^\alpha < \sum_{I \in PH_i(X)} 2^\alpha |\eta(I)|^\alpha \\
\leq 2^\alpha \sum_{J \in PH_i/2(Y)} |J|^\alpha \\
= 2^\alpha F_{i\alpha}(Y, \epsilon/2)
\]

\[\square\]

5. Upper Bounds

Our strategy to prove an upper bound for the asymptotics of $E_{i\alpha}(x_n)$ is similar to that in Section 3.1: we control to control the number of persistence intervals of length greater than $\epsilon$ by approximating $x_n$ by a set consisting of the centers of disjoint balls of radius $\epsilon/2$ centered at points of $x_n$.

5.1. Extremal Hypotheses. First, we prove the upper bound in Theorem 3, which implies the upper bound for our theorem on minimal spanning trees:

Lemma 9 (Interval Counting Lemma). If $X$ is a triangulable metric space so that $|PH_i(x_1, \ldots, x_n)| < Dn^a$ for some positive real numbers $a$ and $D$ and all finite subsets $\{x_1, \ldots, x_n\}$ of $X$ then
\[p_i(Y, \epsilon) < D'\epsilon^{-ad}\]
for some $D' > 0$, all $Y \subseteq X$, and all $\epsilon > 0$.

Proof. Let $Y \subseteq X$, $\epsilon > 0$, and $\{y_j\}$ be the centers of a maximal set of disjoint balls of radius $\epsilon/4$ centered at points of $Y$. The balls of radius $\epsilon/2$ centered at the points $\{y_j\}$ cover $Y$ so
\[d_H(\{y_i\}, Y) < \epsilon/2\]
It follows that

\[
p_i(Y, \epsilon) \leq p_i(\{y_i\}, 0) \leq D |y_i|^a \leq DM_{\epsilon/4}(X)^a \leq De^a4^{-a/d}e^{-ad}
\]

as desired. \[\square\]

**Proposition 3.** If \(X\) satisfies the hypotheses of the previous lemma and \(\alpha < ad\) there exist a \(D_\alpha > 0\) so that

\[
E_\alpha^i(x_1, \ldots, x_n) \leq D_\alpha \left( \frac{ad-\alpha}{d} \right)
\]

for all finite subsets \(\{x_1, \ldots, x_n\} \subset X\) and all \(n \in \mathbb{N}\). Furthermore there exists a \(D_d > 0\) so that

\[
E_d^ad(x_1, \ldots, x_n) \leq D_d \log(n)
\]

for all finite subsets \(\{x_1, \ldots, x_n\} \subset X\) and all \(n \in \mathbb{N}\).

**Proof.** The proof is nearly identical to that of Proposition\[1\] and we omit it here. \[\square\]

### 5.2. Probabilistic Hypotheses.

While the extremal hypotheses of the previous section allow us to prove the desired upper bound for \(PH_0\), they are inadequate to show a similar upper bound for \(i > 0\). Here, we show that hypotheses on the asymptotics of the expectation and variance of the number of \(PH_i\) intervals of \(n\) imply that the \(PH_i(x_n) \in O\left(\frac{d-a}{d}\right)\). The idea of the proof is that if the expected number of intervals of \(n\) points sampled from \(X\) scales linearly with \(n\), we can use that to control the behavior of the intervals of \(PH_i(X)\). With that, we write \(PH_i(x_n)\) a sum of two terms, one which approximates \(PH_i(X)\) and one which corresponds to “\(d\)-dimensional noise” at a certain scale.

First, we require the following lemma, which follows from a standard argument using the union bound; see [21] for a proof:

**Lemma 10.** If \(\mu\) is a probability measure on \(X\) and \(\{B_j\}_{j=1}^l \subset X\) have the property that \(\mu(B_j) \geq a\) for all \(j\). Then

\[
\mathbb{P}\left(\{x_n\} \cap B_j \neq \emptyset, j = 1, \ldots, l\right) \geq 1 - le^{-an}
\]
Lemma 11. If $\mu$ is a $d$-Ahlfors regular measure with support $X$ then
\[ \mathbb{P}(d_H(\{x_n\}, X) < \epsilon) \geq 1 - c\epsilon^{-d}e^{-A_0\epsilon^d n} \]
for a positive real number $A_0$ depending only on the constants $c$ and $d$ appearing in the definition of Ahlfors regularity.

Proof. Let $\{y_1, \ldots, y_{M\epsilon/3(X)}\}$ be the centers of a maximal set of disjoint balls of radius $\epsilon/3$ centered at points of $X$. By the definition of Ahlfors regularity,
\[ \mu(B_{\epsilon/3}(y_j)) \geq A_0 \epsilon^d \]
for all $j$, where $A_0 = 3^{-d+1}c$.

The balls of radius $2\epsilon/3$ centered at the points $\{y_j\}$ cover $X$ so
\[ d_H(\{y_i\}, X) < 2\epsilon/3 \]
Therefore, if $\{x_n\} \cap B_{\epsilon/3}(y_j) \neq \emptyset$ for $j = 1, \ldots, M\epsilon/3(X)$
\[ d_H(\{x_n\}, X) < \epsilon/3 + 2\epsilon/3 = \epsilon \]
It follows that
\[ \mathbb{P}(d_H(\{x_n\}, X) < \epsilon) \geq \mathbb{P}(\{x_n\} \cap B_{\epsilon/3}(y_j) \neq \emptyset \text{ for } j = 1, \ldots, M\epsilon/3(X)) \]
\[ \geq 1 - M\epsilon/3(X) e^{-A_0\epsilon^d n} \] \hspace{1cm} \text{by Lemma 10}
\[ \geq 1 - c\epsilon^{-d}e^{-A_0\epsilon^d n} \] \hspace{1cm} \text{by Lemma 1}

Lemma 12. Let $X$ be a metric space that admits a $d$-Ahlfors regular measure $\mu$ satisfying
\[ \mathbb{E}(|PH_i(x_n)|) = O(n) \]
There are real numbers $A_1, \epsilon_0 > 0$ so that
\[ p_i(X, \epsilon) \leq A_1 \epsilon^{-d} \log(1/\epsilon) \]
for all $\epsilon < \epsilon_0$. 

□
Proof. Find positive real numbers $D_1$ and $N_1$ so that 
\[ \mathbb{E}( |PH_i(x_n)| ) \leq D_1 n \]
for all $n > N_1$. By Markov’s inequality,
\[ \mathbb{P}( |PH_i(x_n)| > 2D_1 n ) < 1/2 \]
Manipulating the inequality in the previous lemma gives that
\[ \mathbb{P} \left( d_H \left( \{ x_1, \ldots, x_{m(\epsilon)} \} , X \right) < \epsilon/2 \right) \geq 1/2 \]
where
\[ m(\epsilon) = \left\lceil \frac{2^d}{A_0} \epsilon^{-d} \log \left( 2^{d+1} c \epsilon^{-d} \right) \right\rceil \]
Let $\epsilon$ be sufficiently small so that $m(\epsilon) > N_1$. We have that
\[ |PH_i(x_1, \ldots, x_{m(\epsilon)})| \leq 2D_1 n \quad \text{and} \quad d_H \left( \{ x_1, \ldots, x_{m(\epsilon)} \} , X \right) < \epsilon \]
for some $\{ x_1, \ldots, x_{m(\epsilon)} \} \subset X$. Therefore, by stability
\[
\begin{align*}
p_i (X, \epsilon) &\leq p_i \left( \{ x_1, \ldots, x_{m(\epsilon)} \} , 0 \right) \\
&\leq 2D_1 m(\epsilon) \\
&= \left\lceil \frac{2^d}{A_0} \epsilon^{-d} \log \left( 2^{d+1} c \epsilon^{-d} \right) \right\rceil \\
&= O \left( \epsilon^{-d} \log \left( \frac{1}{\epsilon} \right) \right)
\end{align*}
\]
as $\epsilon \to 0$. □

Proposition 4. If $X$ satisfies the hypotheses of the previous lemma and $0 < \alpha < d$, then there exist positive real numbers $A_2$ and $\epsilon_1$ so that
\[ F_{\alpha}^i (X, \epsilon) \leq A_2 \epsilon^{\alpha-d} \log (1/\epsilon) \]
for all $\epsilon < \epsilon_1$.

Proof. By the previous lemma
\[ p_i (X, \epsilon) \leq f(\epsilon) := A_1 (\epsilon)^{-d} \log \left( \frac{1}{\epsilon} \right) \]
For all $\epsilon < \epsilon_0$. Applying Lemma 2 yields

$$F^i_\alpha (Y, \epsilon ) \leq \epsilon \alpha f (\epsilon ) + \alpha \int_{t=\epsilon}^1 f (t) t^{\alpha - 1} \, dt + F^i_\alpha (Y, \epsilon_0)$$

The first term equals

$$A_1 \epsilon^{\alpha - d} \left( \log \left( 1/\epsilon \right) \right)$$

which has the desired asymptotics as $\epsilon \to 0$. Evaluating the second term yields

$$\alpha \int_{t=\epsilon}^1 A_1 t^{\alpha - d - 1} \log \left( 1/t \right) \, dt =$$

$$= \left[ - \frac{1}{d - \alpha} t^{\alpha - d} \log \left( 1/t \right) - \frac{1}{(d - \alpha)^2} t^{\alpha - d} \right]_{\epsilon}^1$$

$$= A_1 \left( \frac{1}{d - \alpha} \epsilon^{\alpha - d} \log \left( 1/\epsilon \right) + \frac{1}{(d - \alpha)^2} \epsilon^{\alpha - d} - \frac{1}{(d - \alpha)^2} \right)$$

$$= O \left( \epsilon^{\alpha - d} \log \left( 1/\epsilon \right) \right)$$

□

**Proposition 5.** Let $\mu$ be a $d$–Ahlfors regular measure on $\mathbb{R}^m$. If

$$\mathbb{E} \left( \left| PH_i (x_n) \right| \right) = O \left( n \right)$$

and

$$\text{Var} \left( \left| PH_i (x_n) \right| \right) / n^2 \to 0$$

then there is a $\Lambda > 0$ so that

$$\lim_{n \to \infty} E^\alpha_i (x_n) \leq \Lambda n^{d - \alpha} \log \left( n \right)^{\frac{\alpha}{d}}$$

in probability.

**Proof.** Let

$$G^i_\alpha (x, \epsilon) = \sum_{I \in PH_i (x) \setminus PH^i (x)} |I|^\alpha$$

our strategy is to write

$$E^\alpha_i (x_n) = G^i_\alpha (x_n, \epsilon) + F^i_\alpha (x_n, \epsilon)$$

for a well-chosen $\epsilon$. The former term can be interpreted as “noise” and the latter approximates the persistent homology of the support of $\mu$. 
Let \(0 < p < 1\), and let \(D\) be a positive real number so that

\[ \mathbb{E} (|PH_i (x_n)|) \leq (D/2) n \]

for all sufficiently large \(n\). Then

\[ \mathbb{P} (|PH_i (x_n)| > Dn) \leq \mathbb{P} \left( \left| |PH_i (x_n)| - \mathbb{E} (|PH_i (x_n)|) \right| > Dn/2 \right) \leq \text{Var} (|PH_i (x_n)|) \frac{4}{D^2 n^2} \]

which converges to 0 as \(n \to \infty\). Therefore, there is a \(M\) so that

\[ \mathbb{P} (|PH_i (x_n)| > Dn) < p/2 \]

for all \(n > M\).

Solving for \(\epsilon\) in the expression in Lemma 11 gives that

\[ \mathbb{P} (d_H (\{x_n\} , X) > \epsilon (n) /4) < p/2 \]

if

\[ \epsilon (n) = 4A_0^{-1/d} n^{-1/d} W \left( \frac{2cA_0 n}{p} \right)^{1/d} \]

where \(W\) is the Lambert W function. \(W (m) \sim \log (m)\) as \(m \to \infty\), and \(W (m) \leq \log (m)\) for \(m \geq e\). Therefore, there is an \(N_1 > 1/p\) and real number \(A_3 > 0\) so that

\[ (1) \quad (1/2) A_3 n^{-1/d} \log (n)^{1/d} \leq \epsilon (n) \leq A_3 n^{-1/d} \log (n)^{1/d} \]

for all \(n > N_1\).

Choose \(N_2 > N_1\) to be sufficiently large so that \(\epsilon (n) < \epsilon_1\) for all \(n > N\), where \(\epsilon_1\) is given in Proposition 4. Let \(n > N_2\) and suppose that \(x_n = \{x_1, \ldots, x_n\}\) satisfies \(|x| < Dn\) and \(d_H (x, X) < \epsilon (n) /4\) — an event which occurs with probability greater than \(1 - p\). Write

\[ E^i_\alpha (x_n) = F^i_\alpha (x_n, \epsilon (n)) + G^i_\alpha (x_n, \epsilon (n)) \]

We consider the two terms separately:
\[ G^i_n(x_n, \epsilon(n)) \leq |x| \epsilon(n)^{\alpha} \]
\[ \leq 2^\alpha DA^3_n \frac{\alpha}{d} \log(n)^{\frac{\alpha}{d}} \]
\[ = O \left( \frac{\alpha}{n^{\frac{d}{d}}} \log(n)^{\frac{\alpha}{d}} \right) \]

To bound the second term, we apply Lemma 8 to find
\[ F^i_n(x, \epsilon(n)) \leq 2^\alpha F^i_n(X, \epsilon(n)/2) \]
\[ \leq A_2 \epsilon(n)^{\alpha-d} \log(1/\epsilon(n)) \] by Proposition 4
\[ \leq A_2 A_3^{d} n^{-\frac{\alpha}{d}} \log(n)^{-\frac{d}{d}} \log \left( \frac{1}{2A_3n^{-1/d}} \log(n)^{1/d} \right) \] by Equation 1
\[ = O \left( n^{-\frac{d}{d}} \log(n)^{\frac{2}{d}} \right) \]

\[ \square \]

6. The Lower Bound

While our proof of the upper bounds works for Ahlfors regular measures on arbitrary metric spaces, here we restrict to the case of an Ahlfors regular measure on Euclidean space. This will allow us to use the additional structure of the cubical grid on \( \mathbb{R}^m \).

To prove the lower bound, we combine the approach of our paper on extremal \( PH \)-dimension \[23\] with the probabilistic approach in \[24\]. If \( \mu \) is a \( d \)-Ahlfors regular measure on \( \mathbb{R}^m \) and \( \delta > 0 \), let \( C_\delta(\mu) \) be the cubes in the grid of mesh \( \delta \) that intersect the support of \( \mu \). The basic idea is to sub-divide the grid of mesh \( \delta \) so each cube contains \( k^m \) sub-cubes. If \( k \) is chosen carefully, we can find a positive fraction of cubes of \( C_\delta \) that contain enough cubes of \( C_{\delta/k}(\mu) \) whose measure exceeds some threshold to guarantee a stable \( PH_i \) class. We then control the number of stable \( PH_i \) classes realized by a random sample \( \{x_1, \ldots, x_n\} \) with Lemma 3.

First, we define the non-triviality constants \( \gamma_i^m \):

6.1. Non-triviality. In previous work \[23\], we raised the question of how large a subset of the integer lattice can be without having a subset with “stable” \( i \)-dimensional persistent homology:
Figure 2. The $PH_1$ class of the lattice points corresponding to the gray cubes in (a) and (b) is stable — any choice of one point in each cube will result in a set with non-trivial $PH_1$. The one in (c) and (d) is not. [23]

Definition 4. For $x \in \mathbb{Z}^m$, let the cube corresponding to $x - C(x)$ be the Voronoi cell of $x$ in $\mathbb{Z}^m \subset \mathbb{R}^m$. A subset $X$ of $\mathbb{Z}^m$ has a **stable** $i$-dimensional persistent homology class if any $Y \subset \bigcup_{x \in X} C(x)$ satisfying

$$Y \cap C(x) \neq \emptyset \quad \forall x \in X$$

has a $PH_i$ interval $I$ so that $|I| > c$ for some constant $c > 0$ (see Figure 2). The supremal such $c$ is called the **size** of the stable persistence class.

Definition 5. Let $\xi_i^m(N)$ be the size of the largest $X$ of $[N]^m \subset \mathbb{Z}^m$ so that no subset $Y$ of $X$ has a stable $PH_i$-class. Define

$$\gamma_i^m = \liminf_{N \to \infty} \frac{\log (\xi_i^m(N))}{\log (N)}$$

$\gamma_i^m = 0$ for all $m \in \mathbb{N}$: any subset of $\mathbb{Z}^m$ with more than $3^m$ points has a stable $PH_0$ class. In [23], we proved that $\gamma_1^m \leq m - \frac{1}{2}$ for the Čech complex and conjectured that $\gamma_i^m < m$ for all $0 \leq i < m$ and $m \in \mathbb{N}$. Note that we do not include the same restriction on the size as in that paper.

6.2. Ahlfors Regular Measures and Box Counting. Before proceeding to the proof of the lower bound, we prove a lemma about the asymptotics of the number of cubes that intersect the support of a $d$-Ahlfors regular measure. Let $C_{\delta,a}(\mu)$ be the set of closed cubes $C$ in the cubic grid of mesh $\delta$ in $\mathbb{R}^m$ centered at the origin that intersect $X$ and satisfy

$$\mu(C) \geq a\delta^d$$

and let $N_{\delta,a}(\mu) = |C_{\delta,a}(\mu)|$. (The upper and lower box dimensions of a subset of Euclidean space can be defined in terms of the asymptotic properties of $N_{\delta,0}(X)$).
Lemma 13. If $\mu$ is a $d$-Ahlfors regular measure with support $X \subset \mathbb{R}^m$, then there exit real numbers $0 < c_0 \leq c_1 < \infty$ depending on $c$, $d$, and $m$ so that
\[ c_0 \delta^{-d} \leq N_{\delta,\hat{c}}(\mu) \leq c_1 \delta^{-d} \]
where $\hat{c} = \frac{1}{c_2 m}$ for all $\delta < \delta_0$. Similarly, there exist real numbers $0 < c'_0 \leq c'_1 < \infty$ depending on $c$, $d$, and $m$
\[ c'_0 \delta^{-d} \leq N_{\delta,0}(\mu) \leq c'_1 \delta^{-d} \]
for all $\delta < \delta_0$.

Proof. Let $C$ be a cube in the grid of mesh $\delta$ that intersects $X$, and $x \in C \cap X$. $\mu(B_\delta(x)) > 1/c_3 \delta^d$ and $B_\delta(x)$ intersects at most $2^m$ cubes in the grid of mesh $\delta$, so at least one one cube adjacent to $C$ has measure exceeding $\hat{c} \delta^d$ (where two cubes are adjacent if they share at least one point). Also, each cube of $C_{\delta,a}(\mu)$ is adjacent to at most $3^m$ cubes of $C_{\delta}(\mu)$. It follows that
\[ \frac{1}{3^m} N_{\delta,0}(\mu) \leq N_{\delta,\hat{c}}(\mu) \leq N_{\delta,0}(\mu) \]
so the existence of bounds for $N_{\delta,0}(\mu)$ implies bounds for $N_{\delta,\hat{c}}(\mu)$, and visa versa. We have that
\[ 1 = \mu(X) \leq \sum_{C \in C_{\delta}} \mu(C) \leq c_3 \delta^d m^{d/2} N_{\delta,0}(\mu) \leq 3^m c_3 \delta^d m^{d/2} N_{\delta,\hat{c}}(\mu) \implies N_{\delta,\hat{c}}(\mu) \geq 3^{-m} m^{-d/2} \delta^{-d} \]
For the upper bound, note that the intersection of two cubes may have positive measure, but a cube can share measure with only $3^m - 1$ adjacent cubes. It follows that
\[ 1 = \mu(X) \geq \frac{1}{3^m} \hat{c} \delta^d N_{\delta,\hat{c}}(\mu) \implies N_{\delta,\hat{c}}(\mu) \leq c_6^m \delta^{-d} \]
\[ \square \]
For each $k \in \mathbb{N}$, $\delta > 0$, and $C \in C_\delta (\mu)$, let $\mathcal{D}_k (C)$ be the set of cubes in $C_{\delta/k, \delta}$ that are contained in $C$, and let $D_k (C) = |\mathcal{D}_k (C)|$. See Figure 3.

**Lemma 14.** Let $0 < \beta < d$ and let

$$C_\delta^{k, \beta} = \left\{ C \in C_\delta : D_k (C) > k^{-\beta} \right\}$$

and

$$M (\delta, k, \beta) = \left| C_\delta^{k, \beta} \right|$$

There exists a $K > 0$ so that for all $k > K$ there exist $\delta_1, c_2 > 0$ so that

$$M (\delta, k_0, \beta) > c_2 \delta^{-d}$$

for all $\delta < \delta_1$.

**Proof.** Let $c_0, c_1'$, and $\delta$ be the constants from the previous lemma so $N_\delta (n \mu) \leq c_1' \delta^{-d}$ and $N_{\delta, \mu} (\mu) \geq c_0 \delta^{-d}$ for all $\delta < \delta_1$.

$D_k (C) \leq k^m$ for all $C \in C_\delta^{k, \beta}$ so $N (\delta, k, \beta)$ is bounded below by the smallest integer $a (k, \delta)$ satisfying

$$a (k, \delta) k^m + \left( c_1' \delta^{-d} - a (k, \delta) \right) k^\beta \geq c_0 k^m \delta^{-d}$$

Rearranging terms, we have that

$$a (k, \delta) = \left[ \frac{\delta^{-d} \left( c_0 k^{m-\beta} - c_1' \right)}{k^{m-\beta} - 1} \right]$$

Let

$$K = \left( \frac{c_1'}{c_0} \right)^{\frac{1}{m-\beta}}$$
so both the numerator and the denominator of the previous expression are positive for $k > K$. Let $k > K$ and set
\[
c_2 = \frac{1}{2} \left( c_0 k^{m-\beta} - c_1' \right)
\]
so
\[
a(k, \delta) \sim 2c_2\delta^{-d}
\]
as $\delta \to 0$. It follows that
\[
N(\delta, k, \beta) \geq a(k, \delta) > c_2\delta^{-d}
\]
for all sufficiently small $\delta$, as desired. $\square$

6.3. Proof of the Lower Bound. We require one more lemma before proving the lower bound. The idea is similar to that of Lemma 7.

**Lemma 15.** Let $\mu$ be a $d$-Ahlfors regular measure on $\mathbb{R}^m$ with $d > \gamma_i^m$. There exist positive real numbers $\epsilon_0$ and $\Omega_0$ so that
\[
\lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{r} p_1(\mathbf{x}_n, \epsilon_0 n^{-1/d}) \geq \Omega_0
\]
in probability.

**Proof.** Let $\gamma_i^m < \beta < d$. By the definition of $\gamma_i^m$ we can find a $K_0$ so that $k^\beta > \xi_i^m(k)$ for all $k > K_0$. Let $k_0 > \min(K, K_0)$, where $K$ is given in the previous lemma, and let $\delta_1$ and $c_2$ also be as in the previous lemma. There are only finitely many collections of sub-cubes of $[k_0]^m$, so there are only finitely many stable $PH_i$ classes of subsets of $[k_0]^m$. Let $\epsilon_0$ be the minimum of the sizes of these stable classes.

Let $\delta = n^{-1/d}$ and choose $n$ large enough so that $\delta < \delta_1$. Also, let $\{D_1, \ldots, D_r\}$ be a maximal collection of cubes in $C_{k_0}^{\delta} \subset C_{k_0}$ so that $d(D_j, D_k) > \delta \sqrt{m}$ for all $j, k \in \{1, \ldots, r\}$ so that $j \neq k$. See Figure 4. There is a constant $0 < \kappa < 1$ that depends only on $d$ so that
\[
r \geq \kappa N(\delta, k, \beta) > \kappa c_2\delta^{-d} = \kappa c_2 n
\]
Let $l \in \{1, \ldots, r\}$. By the definition of $\gamma_i^m$, there is a collection of sub-cubes $B_l \subset D_{k_0}(D_l)$ with a stable $PH_i$ class. Let
\[
A_l = \hat{B}_{\delta \sqrt{m}}(C) \setminus \cup_{B \in B_l} B
\]
where $\tilde{B}_{\delta \sqrt{m}}(D_j)$ is the union of all cubes in the grid of mesh $\delta/k$ within distance $\delta \sqrt{m}$ of $D_j$. It follows from property (2) in Section 4.1 that

$$p_i \left( x_n, \epsilon_0 n^{-1/d} \right) \geq \frac{1}{n} \sum_{j=1}^{r} \Xi \left( x_n, A_l, B_l \right)$$

To finish the proof, we will control the sum in the previous equation in terms of the uniform occupancy events of Definition 3. There is a $q > 0$ depending only on $k_0$, $c$, $d$, and $m$ so that

$$\mu \left( A_l \right) \leq q \delta^d = \frac{q}{n}$$

for $l = 1, \ldots, r$. Also, if $B \in B_l$, then $B$ is a cube in the grid of mesh $\delta/k_0$ on $\mathbb{R}^m$ so

$$\mu \left( B \right) \geq \frac{1}{c} \left( \frac{\delta \sqrt{m}}{k_0} \right)^d = \frac{p}{n}$$

where $p = k_0^{-d} m^{d/2}/c$. It follows that $\frac{1}{n} \sum_{l=1}^{r} \Xi \left( x_n, A_l, B_l \right)$ stochastically dominates the sum $\frac{1}{n} \sum_{l=1}^{n} X_l^n$, where $a = \kappa c_2$ and $X_1^n, \ldots, X_n^n$ are disjoint $n, p, q, k^n$-occupancy events. By Lemma 3

$$\lim_{n \to \infty} \frac{1}{n} \sum_{l=1}^{n} X_l^n = \Omega_0$$

in probability as $n \to \infty$, where

$$\Omega_0 = ae^{-q} \left( 1 - e^{-p} \right)^r$$
Combining equations 2 and 3 gives that
\[ p_i \left( x_n, \epsilon_0 n^{-1/d} \right) \geq \Omega_0 \]
in probability, as desired. \( \square \)

The proof of the lower bound is now straightforward:

**Proposition 6.** Let \( \mu \) be a \( d \)-Ahlfors regular measure on \( \mathbb{R}^m \) with \( d > \gamma_i^m \). There is an \( \Omega > 0 \) so that

\[ \lim_{n \to \infty} n^{-\frac{d-\alpha}{d}} E^\mu_\alpha (x_1, \ldots, x_n) \geq \Omega \]
in probability.

**Proof.** It follows immediately from the previous lemma that

\[ 
\lim_{n \to \infty} n^{-\frac{d-\alpha}{d}} E^\mu_\alpha (x_n) \geq \\
\lim_{n \to \infty} n^{-\frac{d-\alpha}{d}} p_i \left( x_n, \epsilon_0 n^{-1/d} \right) \left( \epsilon_0 n^{-1/d} \right)^{\alpha} \\
= \epsilon_0^{\alpha} \lim_{n \to \infty} \frac{1}{n} p_i \left( x_n, \epsilon_0 n^{-1/d} \right) \\
\geq \epsilon_0^{\alpha} \Omega_0 \]

by Lemma 15

\[ := \Omega \]
in probability. \( \square \)
