FRESH EXAMPLES OF HYponormal Terraced Matrices With TRANSCENDENTAL Entries

H. C. RHALY JR.

Abstract. This note calls attention to an alternative version of the main result from [4], which can be used together with Maclaurin series expansions and trigonometric identities to show that the terraced matrices generated by the sequences \( \{\ln(1 + 1/(n + 1)) : n \geq 0\} \), \( \{\tan(1/(n + 2)) : n \geq 0\} \), and \( \{\sinh(1/(n + 2)) : n \geq 0\} \) are hyponormal operators on \( \ell^2 \). Along the way it is also shown that the matrix generated by \( \{\tan(1/(n + 1)) : n \geq 0\} \) is not a hyponormal operator on \( \ell^2 \).

1. Introduction

Assume that \( a = \{a_n\} \) is a sequence of complex numbers such that the terraced matrix \( M = M(a) \), a lower triangular infinite matrix with constant row segments, acts through multiplication to give a bounded linear operator on \( \ell^2 \), the Hilbert space of square-summable sequences.

\[
M = M(a) = \begin{pmatrix}
a_0 & 0 & 0 & \ldots \\
a_1 & a_0 & 0 & \ldots \\
a_2 & a_1 & a_0 & \ldots \\
\vdots & \vdots & \vdots & \ddots
\end{pmatrix}.
\]

(see [2, 3]). A hyponormal operator \( M \) satisfies

\[
\langle (M^*M - MM^*)f, f \rangle \geq 0
\]

for all \( f \) in \( \ell^2 \). Recall that the Cesàro matrix \( C \) is the terraced matrix that arises when \( a_n = \frac{1}{n+1} \) for all \( n \geq 0 \). In [1] it is shown that \( C \) is bounded, noncompact, and hyponormal; its norm is \( ||C|| = 2 \), and its spectrum is

\[
\sigma(C) = \{\lambda : |\lambda - 1| \leq 1\}.
\]

Since scalar multiples of hyponormal operators are hyponormal, \( \pi C \) is an example of a hyponormal operator with transcendental entries. However, much more interesting examples are possible, as we see in the next section.

2010 Mathematics Subject Classification. Primary 47B20.

Key words and phrases. Cesàro operator, hyponormal operator, terraced matrix.
2. Main Results

Our primary tool is the main (and only) theorem in [4], where the proof can be found.

**Theorem 1.** Assume that $M : \equiv M(a)$ is a bounded linear operator on $\ell^2$ with $a_n > 0$ for all $n$, and $\{a_n\}$ is strictly decreasing to 0. If $0 < a_0 \leq 1$ and

$$a_n(1 - a_n) \leq a_{n+1} \leq \frac{a_n}{1 + a_n}$$

for each nonnegative integer $n$, then $M$ is hyponormal.

The displayed inequality string from the theorem can be rearranged to obtain the following corollary, whose proof is obvious and will be omitted.

**Corollary 1.** Assume that $M : \equiv M(a)$ is a bounded linear operator on $\ell^2$ with $a_n > 0$ for all $n$, and $\{a_n\}$ is strictly decreasing to 0. If $0 < a_0 \leq 1$ and

$$\frac{a_n - a_{n+1}}{a_n^2} \leq 1 \leq \frac{a_n - a_{n+1}}{a_n a_{n+1}}$$

for each nonnegative integer $n$, then $M$ is hyponormal.  

**Proposition 1.** The terraced matrix generated by

$$a_n = \ln(1 + \frac{1}{n + 1})$$

is a hyponormal operator on $\ell^2$.

**Proof.** We show that the inequality string (1) in Corollary 1 is satisfied by looking at the upper inequality and the lower inequality separately and using the Maclaurin series expansion for $\ln(1 + x)$. Software such as [8] may be used to facilitate the computations.

(a) The upper inequality in (1) is satisfied when

$$\frac{\ln \frac{(n+2)^2}{(n+1)(n+3)}}{\ln \frac{n+2}{n+1} \ln \frac{n+3}{n+2}} \geq 1.$$  \hspace{1cm} (2)

for all $n$. For $N \geq 1$ take

$$p_N(x) = \sum_{k=1}^{N} (-1)^{k+1} \frac{x^k}{k}.$$  

The inequality (2) above follows from the fact that

$$\frac{p_4(\frac{1}{(n+1)(n+3)})}{p_5(\frac{1}{n+1}) \cdot p_5(\frac{1}{n+2})} \geq 1$$

for all $n \geq 1$. Inequality (2) can be verified separately for $n = 0$.

\[1\text{cf. [7, Theorem 6].}\]
(b) The lower inequality in (1) is satisfied when

$$\frac{\ln \frac{(n+2)^2}{(n+1)(n+3)}}{(\ln \frac{e^2}{n+1})^2} \leq 1$$  

for all \( n \). Inequality (3) follows from the fact that

$$\frac{p^3 \left( \frac{1}{(n+1)(n+3)} \right)}{(p^2 \left( \frac{1}{n+1} \right))^2} \leq 1$$

for all \( n \geq 1 \). Inequality (3) can be verified separately for \( n = 0 \).

**Corollary 2.** The terraced matrix \( M \) generated by

$$a_n = \ln(1 + \frac{1}{n+k})$$

is a hyponormal operator on \( \ell^2 \) for all positive integers \( k \geq 1 \).

**Proof.** This follows from [5].

Does the approach of Proposition 1 work when \( a_n = \sin(\frac{1}{n+1}) \) or \( a_n = \tan^{-1}(\frac{1}{n+1}) \)? It seems natural to ask this question since, in all three cases, \( \{(n+1)a_n\} \) is strictly increasing to 1 – and all three operators are normaloid (the norm equals the spectral radius; see [6]), as required for hyponormality. However, in these last two cases, the answer is – No, since the upper inequality in Corollary 1 is not satisfied, so the hyponormality question remains open for these two cases.

Note that \( \{(n+1)a_n\} \) is strictly increasing in the three cases above, whereas \( \{(n+1)a_n\} \) is strictly decreasing when \( a_n = \tan(\frac{1}{n+1}) \).

**Proposition 2.** The terraced matrix \( M \) generated by

$$a_n = \tan(\frac{1}{n+1})$$

is not a hyponormal operator on \( \ell^2 \).

**Proof.** Since \( \lim_{n \to \infty} (n+1)a_n = 1 \) and \( 0 < a_0 < 2 \), it follows from [3] that \( \sigma(M) = \{ \lambda : |\lambda - 1| \leq 1 \} \). If \( \{e_n\} \) is the standard orthonormal basis for \( \ell^2 \), then

\[
|| (M - I)e_0 ||^2 \geq (\tan(1) - 1)^2 + \sum_{n=1}^{\infty} \left( \frac{1}{n+1} + \frac{3}{9} \left( \frac{1}{n+1} \right)^3 \right)^2 \geq \\
(\tan(1) - 1)^2 + 2 \zeta(2) - 1 + \frac{2}{3} (\zeta(4) - 1) + \frac{1}{9} (\zeta(6) - 1) > 1.01,
\]

so \( ||M - I|| > 1 \), so \( M - I \) is not normaloid and \( M \) is not hyponormal.

As we see below, the result is quite different for the terraced matrix generated by \( a_n = \tan(\frac{1}{n+2}) \), and it should be noted that \( \{(n+1)a_n\} \) is not strictly decreasing in this case.
Proposition 3. The terraced matrix $M$ generated by

$$a_n = \tan\left(\frac{1}{n+2}\right)$$

is a hyponormal operator on $\ell^2$.

Proof. (a) The upper inequality in Corollary 1 is satisfied when

$$\frac{\sin \frac{1}{n+2} \cdot \sin \frac{1}{n+3}}{\sin \frac{1}{n+2} \cdot \sin \frac{1}{n+3}} \geq 1,$$

for all $n$. For $N \geq 0$ take

$$r_N(x) = \sum_{k=0}^{N} (-1)^k \frac{x^{2k+1}}{(2k+1)!},$$

and

$$s_N(x) = \sum_{k=0}^{N} (-1)^k \frac{x^{2k}}{(2k)!}.$$ 

Inequality (4) follows from the fact that

$$\frac{r_1(\frac{1}{(n+2)(n+3)})}{r_2(\frac{1}{n+2}) \cdot r_2(\frac{1}{n+3})} \geq 1$$

for all $n$.

(b) The lower inequality in Corollary 1 is satisfied when

$$\frac{\sin \frac{1}{n+2} \cdot \cos \frac{1}{n+2}}{\sin^2 \frac{1}{n+2} \cdot \cos \frac{1}{n+3}} \leq 1,$$

for all $n$. Inequality (5) follows from the fact that

$$\frac{r_0(\frac{1}{(n+2)(n+3)}) \cdot s_0(\frac{1}{n+2})}{(r_1(\frac{1}{n+2}))^2 \cdot s_1(\frac{1}{n+3})} \leq 1,$$

for all $n$. \qed

Next we consider $a_n = \sinh(\frac{1}{n+1})$. Since $a_0 > 1$, the hypothesis of Corollary 1 is not satisfied, so hyponormality when $a_n = \sinh(\frac{1}{n+1})$ remains an open question. But the issue for $a_n = \sinh(\frac{1}{n+2})$ will be settled now.

Proposition 4. The terraced matrix $M$ generated by

$$a_n = \sinh\left(\frac{1}{n+2}\right)$$

is a hyponormal operator on $\ell^2$. 
Proof. (a) The upper inequality in Corollary 1 is satisfied when
\[
2 \cosh\left(\frac{2n+5}{2(n+2)(n+3)}\right) \sinh\left(\frac{1}{2(n+2)(n+3)}\right) \geq 1
\]
for all \(n\). For \(N \geq 0\) take
\[
r_N(x) = \sum_{k=0}^{N} \frac{x^{2k+1}}{(2k+1)!},
\]
and
\[
s_N(x) = \sum_{k=0}^{N} \frac{x^{2k}}{(2k)!}.
\]
Inequality (6) follows from the fact that
\[
\frac{2s_1\left(\frac{2n+5}{2(n+2)(n+3)}\right) \cdot r_1\left(\frac{1}{2(n+2)(n+3)}\right)}{(r_1\left(\frac{1}{n+2}\right)^2 + 2 \cdot \frac{1}{4}\left(\frac{1}{n+2}\right)^4) \cdot (r_1\left(\frac{1}{n+3}\right) + 2 \cdot \frac{1}{4}\left(\frac{1}{n+3}\right)^4)} \geq 1
\]
for all \(n\).
(b) The lower inequality in Corollary 1 is satisfied when
\[
2 \cosh\left(\frac{2n+5}{2(n+2)(n+3)}\right) \sinh\left(\frac{1}{2(n+2)(n+3)}\right) \leq 1
\]
for all \(n\). Inequality (7) follows from the fact that
\[
\frac{2(s_1\left(\frac{2n+5}{2(n+2)(n+3)}\right) + \frac{2n+5}{2(n+2)(n+3))}^3(r_1\left(\frac{1}{2(n+2)(n+3)}\right) + \frac{2}{3}\left(\frac{2n+5}{2(n+2)(n+3)}\right)^4)}{(r_1\left(\frac{1}{n+2}\right))^2} \leq 1
\]
for all \(n\). □

Corollary 3. The terraced matrices \(M\) generated by
\[
a_n = \tan\left(\frac{1}{n+k}\right) \quad \text{and} \quad a_n = \sinh\left(\frac{1}{n+k}\right)
\]
are hyponormal operators on \(\ell^2\) for all positive integers \(k \geq 2\).

3. Conclusion

In closing, we note the following questions, which have not been settled here.

(1) Are the terraced matrices generated by the following sequences \(\{a_n\}\) hyponormal operators on \(\ell^2\)?
   (a) \(a_n = \sin\left(\frac{1}{n+1}\right)\)
   (b) \(a_n = \tan^{-1}\left(\frac{1}{n+1}\right)\)
   (c) \(a_n = \sinh\left(\frac{1}{n+1}\right)\)
   (d) \(a_n = \sin^{-1}\left(\frac{1}{n+2}\right)\)

(2) Does there exist a hyponormal terraced matrix generated by a positive sequence \(\{a_n\}\) such that \((n+1)a_n\) is strictly decreasing?
