A GENERALIZED SCHEME FOR BSDES BASED ON DERIVATIVE APPROXIMATION AND ITS ERROR ESTIMATES

CHOL-KYU PAK*, MUN-CHOL KIM*, AND HUN O*

Abstract. In this paper we propose a generalized numerical scheme for backward stochastic differential equations (BSDEs). The scheme is based on approximation of derivatives via Lagrange interpolation. By changing the distribution of sample points used for interpolation, one can get various numerical schemes with different stability and convergence order. We present a condition for the distribution of sample points to guarantee the convergence of the scheme.

Key words. backward stochastic differential equations, numerical scheme, nonequidistant difference scheme

AMS subject classifications. 60H35, 65C20, 60H10

1. Introduction. Let \((\Omega, \mathcal{F}, \mathbb{P})\) be a probability space, \(T > 0\) a finite time and \(\{\mathcal{F}_t\}_{0 \leq t \leq T}\) a filtration satisfying the usual conditions. Let \((\Omega, \mathcal{F}, \mathbb{P}, \{\mathcal{F}_t\}_{0 \leq t \leq T})\) be a complete filtered probability space on which a standard \(d\)-dimensional Brownian motion \(W = (W_1, W_2, \ldots, W_d)^T\) is defined and \(\mathcal{F}_0\) contain all the \(\mathbb{P}\)-null sets of \(\mathcal{F}\).

The standard form of backward stochastic differential equation (BSDE) is

\[
y_t = \xi + \int_t^T f(s, y_s, z_s)ds - \int_t^T z_s dW_s, \quad t \in [0, T]
\]

where the generator \(f : [0, T] \times \mathbb{R}^m \times \mathbb{R}^{m \times d} \to \mathbb{R}^m\) is \(\mathcal{F}_t\)-adapted for each \((y, z)\) and the terminal variable \(\xi\) is a \(\mathcal{F}_T\)-measurable and square integrable random variable. A process \((y_t, z_t) : [0, T] \times \Omega \to \mathbb{R}^m \times \mathbb{R}^{m \times d}\) is called an \(L^2\)-solution of the BSDE (1.1) if it satisfies the equation (1.1) while it is \(\mathcal{F}_t\)-adapted and square integrable.

In 1990, Pardoux and Peng proved in [11] the existence and uniqueness of the solution of general nonlinear BSDEs and afterwards there has been active works in this field. BSDEs and their extensions are very important in mathematical finance([6]), stochastic control([1, 5]) and partial differential equations ([12, 10]).

In this paper we assume that the terminal condition is a function of \(W_T\), i.e., \(\xi = \varphi(W_T)\) and the BSDE (1.1) has a unique solution \((y_t, z_t)\). It was shown in [12] that the solution \((y_t, z_t)\) of (1.1) can be represented as

\[
y_t = u(t, W_t), \quad z_t = \nabla_x u(t, W_t), \quad \forall t \in [0, T]
\]

where \(u(t, x)\) is the solution of the parabolic partial differential equation

\[
\frac{\partial u}{\partial t} + \frac{1}{2} \sum_{i=1}^d \frac{\partial^2 u}{\partial x_i^2} + f(t, u, \nabla_x u) = 0
\]

with the terminal condition \(u(T, x) = \varphi(x)\), and \(\nabla_x u\) is the gradient of \(u\) with respect to the spatial variable \(x\). The smoothness of \(u\) depends on \(f\) and \(\varphi\).

Although BSDEs and their extensions such as FBSDEs have very important applications in many fields, it is well known that it is difficult to obtain the analytic solutions except some special cases and there have been many works on numerical methods. ([2, 4, 7, 8, 9, 14, 13, 15, 17])

*Faculty of Mathematics, Kim Il Sung University, Pyongyang, Democratic People’s Republic of Korea (pck2016217@gmail.com).
By making use of the relations between the BSDEs and the partial differential equations, a four step scheme was proposed in [8, 7] and a layer method for PDEs was applied to the BSDEs to the random time horizon in [9]. On the other hand several kinds of probabilistic approaches have also been developed and they generally need approximation of conditional expectations. Bouchard and Touzi[2] developed a backward simulation scheme and Gobet[4] proposed a method based on regression on function bases. Ruijter and Oosterlee[13] developed a Fourier cosine method and Zhao and his co-authors have developed several schemes for various types of BSDEs and FBSDEs using Gauss-Hermite quadrature rule for approximation of conditional expectations. [14, 16, 15, 17]

Among all the previous works, our work is closely related to [15] where a kind of multi-step scheme for FBSDEs was proposed and Gauss-Hermite quadrature rule was used for approximation of conditional expectations. They derived a new kind of reference scheme which was much simpler than the previous ones. They demonstrated experimentally that their scheme is of up to 6th order and stated that their scheme does not seem to converge for higher order because the coefficients fail to satisfy root condition.

Our scheme is based on the same reference equation with [15] but use general form of derivative approximation. We got an inspiration of nonequidistant difference scheme while trying to avoid spatial interpolation for the approximation of conditional expectation using Gauss-Hermite quadrature rule. In the previous works spatial interpolation has been inevitable because it was impossible to set up a fully nested time-space grid and it contributed much to complexity. But through some investigation, we showed that if we derive a scheme using quadratically distant derivative approximation we can set up a fully nested time-space grid for second or third order and avoid spatial interpolation. ([3])

In this paper we generalized a numerical scheme based on derivative approximation which varies according to the distribution of sample points used for derivative approximation. We present a condition for the "parameters" under which the resulting scheme converges. The result on error estimates supports the previous works [15, 3].

We note that our scheme is limited to the case of Brownian setting, Markovian terminal condition and deterministic time horizon. One can refer to [9] for numerical solution of random terminal time problems.

The rest of the paper is organized as follows. In Section 2, we introduce a generalized discrete scheme for BSDEs. In Section 3, we present the error estimates of the scheme for semidiscrete version for certain types of generator function. In Section 4, we discuss some specific resulting schemes. Finally some conclusions are given in Section 5.

2. A generalized numerical scheme for BSDEs based on derivative approximation.

2.1. The reference equations. We firstly note that the major content of this subsection is from [15] where decoupled FBSDEs were discussed.

Let us consider the following backward stochastic differential equation:

$$y_t = \varphi(W_T) + \int_t^T f(s, y_s, z_s)ds - \int_t^T z_s dW_s, \quad t \in [0, T]$$

where the generator $f : [0, T] \times \Omega \times \mathbb{R}^m \times \mathbb{R}^{m \times d} \to \mathbb{R}^m$ is a stochastic process that is $\mathcal{F}_t$-adapted for all $(y, z)$ and $\varphi : \mathbb{R}^d \to \mathbb{R}^m$ is a measurable function.
Throughout the paper, we make assumptions on the parameters as follows.

**Assumption 1.** The generator function \( f \) and \( \varphi \) are smooth enough and their derivatives as well as themselves are all bounded.

Let \( 0 = t_0 < \cdots < t_N = T \) be an equidistant partition of \([0, T]\) and \( t_{n+1} - t_n = h = T/N \). As in \([14, 16]\), we define \( \mathcal{F}_{s,t}^x \) for \( t \leq s \leq T \) to be a \( \sigma \)-field generated by the Brownian motion \( \{x + W_r - W_t, t \leq r \leq s\} \) starting from the time-space point \((t, x)\) and \( E^x_t[\cdot] := E[\cdot|\mathcal{F}_t^x] \).

Taking the conditional expectation \( E^x_t[y] \) on both sides of (2.1), we get

\[
E^x_{t_n}[y_t] = E^x_{t_n}[\varphi(W_T)] + \int_t^T E^x_{t_n}[f(s, y_s, z_s)]ds
\]

By differentiating the both sides of (2.2) with respect to \( t \), we obtain the following ODE (see \([15]\) for differentiability)

\[
\frac{dE^x_{t_n}[y_t]}{dt} = -E^x_{t_n}[f(s, y_s, z_s)]
\]

Next, for \( t \in [t_n, T] \) we have

\[
y_{t_n} = y_t + \int_t^{t_n} f(s, y_s, z_s)ds - \int_{t_n}^{t} z_s dW_s.
\]

Multiplying \( \Delta W_{t_n,t} := W_T - W_{t_n} \) to the both sides of (2.4) and taking \( E^x_{t_n}[\cdot] \), we obtain

\[
0 = E^x_{t_n}[y_t \Delta W_{t_n,t}] + \int_{t_n}^{t} E^x_{t_n}[f(s, y_s, z_s) \Delta W_{t_n,t}]ds - \int_{t_n}^{t} E^x_{t_n}[z_s]ds
\]

where \((\cdot)^T\) means transpose of \((\cdot)\).

Taking derivatives of the both sides of (2.5) with respect to \( t \), we obtain the following ODE.

\[
E^x_{t_n}[z_t] = \frac{dE^x_{t_n}[y_t \Delta W_{t_n,t}]}{dt} + E^x_{t_n}[f(t, y_t, z_t) \Delta W_{t_n,t}] - E^x_{t_n}[z_t]
\]

The two ODEs (2.3) and (2.6) are called the reference equations for the BSDE (2.1).

From these reference equations we have

\[
\frac{dE^x_{t_n}[y_t]}{dt} |_{t=t_n} = -f(t_n, y_{t_n}, z_{t_n})
\]

\[
z_{t_n} = \frac{dE^x_{t_n}[y_t \Delta W_{t_n,t}]}{dt} |_{t=t_n}.
\]

**2.2. Derivative approximation and semi-discrete scheme for BSDE.**

Now by approximating the derivatives in (2.7) and (2.8) we get discrete scheme for BSDE (2.1). Among many methods for numerical differentiation, we will use the one based on Lagrange interpolation. In \([15]\) the approximation formula was derived by solving linear system obtained by Taylor’s expansion and it coincides with the one from Lagrange interpolation based on equidistant points.
Let \( u(t) : \mathbb{R} \to \mathbb{R} \) be \( k + 1 \) times differentiable and \( a_0 = 0 < a_1 < a_2 < \cdots < a_k < N \) be \( k + 1 \) integers, then the Lagrange interpolation polynomial based on values \( \{ u_0, u_1, \cdots, u_k \} \) on sample points \( \{ t_0, t_0 + a_1 h, \cdots, t_0 + a_k h \} \) can be written as

\[
L(t) = \sum_{i=0}^{k} \prod_{j \neq i} (t - t_0 - a_j h) h^{-k} u_i \tag{2.9}
\]
and the deviation is given by

\[
L(t) - u(t) = \frac{f^{(k+1)}(\xi) \prod_{i=0}^{n} (t - t_0 - a_i h)}{(k+1)!}, \quad t_0 \leq \xi \leq t_0 + a_k h. \tag{2.10}
\]

Hereafter we will call \( a_1, \cdots, a_k \) the "parameters of the scheme". By differentiating (2.9), we get

\[
\frac{dL}{dt}(t) = \sum_{i=0}^{k} \prod_{j \neq i} (a_i - a_j) \prod_{j \neq i, l \neq j} (t - t_0 - a_l h) h^{-k} u_i \tag{2.11}
\]
and furthermore,

\[
\frac{du}{dt}(t_0) = \frac{\sum_{i=0}^{k} \gamma_i^k u_i}{h} + \frac{(-1)^k f^{(k+1)}(\xi)}{h^k}, \quad t_0 \leq \xi \leq t_0 + a_k h. \tag{2.12}
\]
where

\[
\gamma_0^k = -\sum_{j \neq 0}^{1} \frac{1}{a_j}, \quad \gamma_i^k = \frac{(-1)^{k-1} a_1 a_2 \cdots a_k}{a_i \prod_{j \neq i} (a_i - a_j)}, \quad (1 \leq i \leq k). \tag{2.13}
\]

So under the assumption that \( u^{(k+1)} \) is bounded we have

\[
\frac{du}{dt}(t_0) = \frac{\sum_{i=0}^{k} \gamma_i^k u_i}{h} + O(h^k) \tag{2.14}
\]
About the coefficients, the following proposition holds.

**Proposition 2.1.** The coefficients \( \gamma_i^k \) satisfy \( \sum_{i=0}^{k} \gamma_i^k = 0 \)

Now we apply this approximation formula to the reference equations (2.7) and (2.8) to get

\[
-\gamma_0^k y_{t_n} = \sum_{i=1}^{k} \gamma_i^k E_{t_n}^x [y_{t_{n+a_i}}] + h f(t_n, y_{t_n}) + h R_{y,n}^k \tag{2.15}
\]

\[
h z_{t_n} = \sum_{i=1}^{k} \gamma_i^k E_{t_n}^x [y_{t_{n+a_i}}] \Delta W_{t_{n+a_i}}^t + h R_{z,n}^k \tag{2.16}
\]
where \( R_{y,n}^k, R_{z,n}^k \) are the truncation errors as follows.

\[
R_{y,n}^k = \left. \frac{dE_{t_n}^x[y_t]}{dt} \right|_{t=t_n} - \sum_{i=0}^{k} \frac{\gamma_i^k}{h} E_{t_n}^x [y_{t_{n+a_i}}] \tag{2.17}
\]
\[ R_{z,n}^k = \frac{dE_{t_n}^x [y_t \Delta W_{t_n,t}]}{dt} \bigg|_{t_n} - \sum_{i=0}^{k} \gamma_k^i E_{t_n}^x [y_{t_n+a_i} \Delta W_{t_n,t}] \].

Note that we denote \( W_{t_n+a_i} - W_{t_n} \) by \( \Delta W_{t_n,a_i} \) for the simplicity in notion. From (2.14) one can easily prove the following lemma.

**Lemma 2.2.** Under the assumption Assumption 1, the truncation errors satisfy

\[ |R_{y,n}^k| \leq C h^k, |R_{z,n}^k| \leq C h^k \]

where \( C \) is a constant that depends only on bounds of \( f, \varphi \) and their derivatives.

Now we present a semi-discrete scheme for BSDE (2.1).

**Scheme 1.** Assume that \( y^{N-i}, z^{N-i} (i = 0, \ldots, a_k - 1) \) are known. For \( n = N - a_k, \ldots, 0 \) solve \( y^n = y^n(x), z^n = z^n(x) \) at time-space point \( (t_n, x) \) by

\[ -\gamma_k^0 y^n = \sum_{j=1}^{k} \gamma_k^j E_{t_n}^x [y^{n+a_j}] + h \cdot f(t_n, y^n, z^n) \]

\[ z^n = \frac{\sum_{j=1}^{k} \gamma_k^j E_{t_n}^x [y^{n+a_j} \Delta W_{t_n,a_j}]}{h} \]

This is called a semi-discrete scheme because it is discretized only in time domain and one needs a spatial grid to get the fully discrete scheme. We will discuss about the full discrete scheme later in Section 4.

Note that the scheme is explicit for \( z \) but implicit for \( y \). At every step we calculate \( z \) component first and then get \( y \) through Picard’s iteration.

Note that one can make various schemes by selecting \( a_1, \ldots, a_k \) variously. For the case where \( a_j = j (j = 1, \ldots, k) \) the scheme is exactly the same with the one discussed in [15]. If we select \( a_j = j^2 (j = 1, \ldots, k) \) we get a one based on quadratically distant sample points which is considered

**3. Error estimates.** In this section we prove the error estimates of the semidiscrete Scheme 1 for the case where the generator is independent on control variable \( z \). We assume \( m = d = 1 \) for the sake of simplicity.

\[ y_t = \varphi(W_T) + \int_t^T f(s, y_s) ds - \int_t^T z_s dW_s, t \in [0, T] \]

Let \( y_t, z_t \) be the solutions of the BSDE (3.1) and \( y^n, z^n \) be the solutions of the Scheme 1. We define error terms like \( e_y^n := y_y^n - y^n, e_z^n := z_t^n - z^n \).

We also define \( c_j, \alpha_j (j = 0, 1, \ldots, a_k) \) for the statement of the estimates as follows.

\[ c_j := \begin{cases} 
\gamma_k^l, & 30 \leq l \leq k, j = a_l \\
0, & \text{otherwise}
\end{cases}, \quad \alpha_j := \sum_{l=j}^{a_k} c_l \]

The following theorem gives the error estimates for \( y \).
Theorem 3.1. Suppose that Assumption 1 holds and the initial values satisfy $\max_{N-a_k+1 \leq n \leq N} E||e_y^n|| = O(h^k)$. Furthermore suppose that the numbers $\alpha_1, \cdots, \alpha_{a_k}$ that are defined as (3.2) satisfy the following inequality.

\begin{equation}
\frac{\sum_{j=2}^{a_k} |\alpha_j|}{|\alpha_1|} < 1
\end{equation}

Then for sufficiently small time step $\Delta t$ we have

\begin{equation}
\max_{0 \leq n \leq N-a_k} E||e_y^n|| \leq Ch^k
\end{equation}

where $C > 0$ is a constant depending only on $\{\gamma_j\}, T,$ the upper bounds of functions $\varphi$ and $f$, and their derivatives.

Proof. We prove the theorem in two steps.

STEP 1. We assume that the time horizon $T$ is small, say more accurately

\begin{equation}
T < \frac{|\alpha_1| - \sum_{j=2}^{a_k} |\alpha_j|}{2L}
\end{equation}

where $L$ is a Lipschitz constant of the generator function $f$.

From the reference equation (2.7) and the scheme, we can write

\[-\gamma_0 e_y^n = \sum_{j=1}^{k} \gamma_j E_{t_n}^x [e_y^{n+a_j}] + h\Delta f_n + O(h^{k+1})\]

where

\[\Delta f_n = f(t_n, y_{t_n}) - f(t_n, y^n)\]

From the Proposition 2.1, $\sum_{j=0}^{k} \gamma_j = 0$ and we have

\begin{equation}
\sum_{j=1}^{k} \gamma_j e_y^n = \sum_{j=1}^{k} \gamma_j E_{t_n}^x [e_y^{n+a_j}] + h\Delta f_n + O(h^{k+1})
\end{equation}

which leads to

\[\sum_{j=1}^{k} \gamma_j (e_y^n - E_{t_n}^x [e_y^{n+a_j}]) = h\Delta f_n + O(h^{k+1}).\]

Using $c_j$ we can rewrite the above equation as follows.

\begin{equation}
\sum_{j=1}^{a_k} c_j (e_y^n - E_{t_n}^x [e_y^{n+a_j}]) = h\Delta f_n + O(h^{k+1}).
\end{equation}

Similarly we can get the following equations.

\begin{align*}
\sum_{j=1}^{a_k} c_j (E_{t_n}^x [e_y^{n+1}] - E_{t_n}^x [e_y^{n+1+j}]) &= h\Delta f_{n+1} + O(h^{k+1}) \\
&\vdots \\
\sum_{j=1}^{a_k} c_j (E_{t_n}^x [e_y^{N-a_k}] - E_{t_n}^x [e_y^{N-a_k+j}]) &= h\Delta f_{N-a_k} + O(h^{k+1})
\end{align*}
Summing up all the above equations including (3.6) we have
\[
\alpha_1 e_y^n + \sum_{j=2}^{a_k} E_{t_n}^r [e_y^{n+j-1}] - \sum_{j=1}^{a_k} \alpha_i E_{t_n}^r [e_y^{N-i-a_k}] = \\
h \Delta f_n + h \sum_{j=n+1}^{N-a_k} E_{t_n}^r [\Delta f_j] + (N - a_k - n + 1)O(h^{k+1})
\]
where \(\alpha_1, \ldots, \alpha_{a_k}\) that are defined as (3.2).

Taking expectation to the both sides of the above equation, we have
\[
|\alpha_1| E[|e_y^n|] \leq \sum_{i=2}^{a_k} |\alpha_i| E[|e_y^{n+i-1}|] + \sum_{i=1}^{k} |\alpha_i| E[|e_y^{N+i-a_k}|] + h \sum_{j=n}^{N-a_k} E[|\Delta f_j|] + NO(h^{k+1}).
\]

Then from the Lipschitz continuity of the generator function and the assumption on the initial approximation, there exists a constant \(C\) such that
\[
|\alpha_1| E[|e_y^n|] \leq \sum_{i=2}^{a_k} |\alpha_i| E[|e_y^{n+i-1}|] + Lh \sum_{j=n}^{N-a_k} E[|e_y^j|] + Ch^k.
\]

We used the fact that \(N = T/h\).

Rearranging the terms leads to
\[
(1 - \frac{Lh}{|\alpha_1|}) E[|e_y^n|] \leq \sum_{i=2}^{a_k} \frac{|\alpha_i|}{|\alpha_1|} E[|e_y^{n+i-1}|] + \frac{Lh}{|\alpha_1|} \sum_{j=n+1}^{N-a_k} E[|e_y^j|] + Ch^k.
\]

Let \(p := \arg \max_{0 \leq a \leq N-a_k} E[|e_y|^a]\) then
\[
(1 - \frac{Lh}{|\alpha_1|}) E[|e_y^n|] \leq \sum_{i=2}^{a_k} \frac{|\alpha_i|}{|\alpha_1|} E[|e_y^{p+i-1}|] + \frac{Lh}{|\alpha_1|} \sum_{j=p+1}^{N-a_k} E[|e_y^j|] + Ch^k
\]
\[
\leq E[|e_y^p|] \sum_{i=2}^{a_k} \frac{|\alpha_i|}{|\alpha_1|} + \frac{Lh}{|\alpha_1|} E[|e_y^p|](N - a_k - p) + Ch^k
\]
\[
\leq E[|e_y^p|] \left( \sum_{i=2}^{a_k} \frac{|\alpha_i|}{|\alpha_1|} + \frac{LT}{|\alpha_1|} \right) + Ch^k
\]

So we get
\[
\left(1 - \sum_{i=2}^{a_k} \frac{|\alpha_i|}{|\alpha_1|} - \frac{LT}{|\alpha_1|} \left(1 + \frac{1}{N}\right)\right) E[|e_y^p|] \leq Ch^k.
\]

From (3.3) and (3.5) we finally get
\[
E[|e_y^p|] \leq Ch^k
\]
where \(C\) is a generic constant which only depends on \(\{\gamma_j\}, T\), the upper bounds of functions \(\varphi\) and \(f\), and their derivatives.

**STEP 2.** Now let us consider the case \(T\) is big. In this case we can divide the time interval \([0, T]\) into several subintervals that satisfy (3.5). Then we can get the result through typical procedure.
Now we discuss the error for \( z \). We introduce the variational equation of (3.1) as follows.

\[
\nabla y_t = \varphi_x(W_T) + \int_t^T f_y(s, y_s) \nabla y_s \, ds - \int_t^T \nabla z_s \, dW_s
\]

where \( \varphi, f \) are the partial derivatives of \( \varphi, f \) with respect to \( x, y \) and \( \nabla y_s, \nabla z_s \) are the variations of \( y_s, z_s \) with respect to spatial variable \( x \). (See [16]) From the relationship (1.2), \( z_t = \nabla y_t \).

For the variational equation we can derive the following equation similarly as in (2.15) and (2.16).

\[
- \gamma_0^k \nabla y_{tn} = \sum_{i=0}^k \gamma_i^k E_t^n [\nabla y_{n+a_i}] + hf_y(t_n, y_{tn}) \nabla y_{tn} + hR_{\nabla y,n}^k
\]

where

\[
R_{\nabla y,n}^k = \frac{dE_t^n [\varphi]}{dt}_{t=t^n} - \sum_{i=0}^k \gamma_i^k E_t^n [\nabla y_{n+a_i}].
\]

And from (2.17), we also have the following equation for the variation of \( y^n \).

\[
- \gamma_0^k \nabla y_{n} = \sum_{i=0}^k \gamma_i^k E_t^n [\nabla y_{n+a_i}] + hf_y(t_n, y_{n}) \nabla y_{n}.
\]

The following lemma is about the bound of \( y_t \) and \( \nabla y_t \). (See Lemma 4 in [16] and references therein for details.)

**Lemma 3.2.** Suppose that Assumption 1 holds, and let \( y_t \) and \( \nabla y_t \) be the solutions of (3.1) and (3.10), respectively. Then it holds that

\[
\sup_{t \in [0,T]} E[|y_t|] + \sup_{t \in [0,T]} E[|\nabla y_t|] \leq C,
\]

where \( C > 0 \) is a generic constant depending only on \( T \), the upper bounds of functions \( \varphi \) and \( f \), and their derivatives.

We define \( e_{\nabla y}^n := \nabla y_{tn} - y^n \). Then through the similar procedure as in the Theorem 3.1 we can prove the following lemma about \( e_{\nabla y}^n \).

**Lemma 3.3.** Suppose that Assumption 1 holds and the initial approximations satisfy

\[
\max_{N-a_k+1 \leq n \leq N} E[|e_{\nabla y}^n|] = O(h^k).
\]

Furthermore suppose that the following inequality holds.

\[
\frac{\sum_{j=2}^{a_k} |\alpha_j|}{|\alpha_1|} < 1
\]

Then for sufficiently small time step \( \Delta t \) we have

\[
\max_{0 \leq n \leq N-a_k} E[|e_{\nabla y}^n|] \leq C h^k
\]

where \( C > 0 \) is a constant depending only on \( \{\gamma_j\}, T \), the upper bounds of functions \( \varphi \) and \( f \), and their derivatives.
Now we present a theorem which gives the error estimates for $z$.

**Theorem 3.4.** Suppose that Assumption 1 holds and the initial approximations satisfy
\[
\max_{N-a_k+1 \leq n \leq N} E[|e^n_y|] = O(h^k) \quad \text{and} \quad \max_{N-a_k+1 \leq n \leq N} E[|e^n_z|] = O(h^k).
\]
Furthermore suppose that the numbers $\alpha_1, \cdots, \alpha_{a_k}$ that are defined as (3.2) satisfy the following inequality.

\[
\sum_{j=2}^{a_k} |\alpha_j| \quad < \quad 1
\]

(3.16)

Then for sufficiently small time step $\Delta t$ we have

\[
\max_{0 \leq n \leq N-a_k} E[|e^n_z|] \leq C h^k
\]

(3.17)

where $C > 0$ is a constant depending only on $\{\gamma_j\}, T$, the upper bounds of functions $\varphi$ and $f$, and their derivatives.

**Proof.** From (2.16) and (2.18) we have

\[
he^n_z = \sum_{j=1}^{a_k} \gamma_j^k a_j E^n_{t_n}[e^{n+a_j} \Delta W_{n,a_j}] + O(h^{k+1}).
\]

(3.18)

We can derive

\[
E^n_{t_n}[e^{n+a_j} \Delta W_{n,a_j}] = E[e^{n+a_j} (x + \Delta W_{n,a_j}) \Delta W_{n,a_j}] =
\]

\[
= \int_\mathbb{R} \frac{1}{\sqrt{2\pi a_j h}} \exp\left(-\frac{y^2}{2a_j h}\right) dy =
\]

\[
= a_j h E[e^{n+a_j} (x + \Delta W_{n,a_j}) \Delta W_{n,a_j}] =
\]

\[
= a_j h E^n_{t_n}[e^{n+a_j}].
\]

By simple substitution we have

\[
e^n_z = \sum_{j=1}^{a_k} \gamma_j^k a_j E^n_{t_n}[e^{n+a_j}] + O(h^k)
\]

and this leads to

\[
E[|e^n_z|] \leq \sum_{j=1}^{a_k} |\gamma_j^k| a_j E[|e^{n+a_j}|] + C h^k.
\]

where $C > 0$ is a constant. So from Lemma 3.3 we obtain

\[
\max_{N-a_k+1 \leq n \leq N} E[|e^n_z|] \leq C h^k,
\]

where $C > 0$ is a constant depending only on $\{\gamma_j\}; T$, the upper bounds of functions $\varphi$ and $f$, and their derivatives.
4. Discussions. In [16, 15] the authors stated that the stability of Scheme 1 is closely related to its corresponding characteristics polynomial defined as follows.

\[ P_k^{\gamma}(\lambda) := \sum_{i=0}^{k} \gamma_i^k \lambda^{a_k - a_i} \]

The roots \( \{ \lambda_i^k \}_{i=1}^{k} \) of this polynomial are said to satisfy the root conditions if \( |\lambda_i^k| \leq 1 \) and \( |\lambda_i^k| = 1 \implies P_k^{\gamma}(\lambda_i^k)' \neq 0 \). In [15], they showed that the roots of \( P_k^{\gamma}(\lambda) \) satisfy the root conditions for only \( 1 \leq k \leq 6 \) when the sample points are equally distant, i.e. \( a_i = i \). In [3] they proposed a scheme based on quadratically distant sample points (i.e. \( a_i = i^2 \)) and it was effective in decrease of the computational complexity.

Now Theorem 3.1 and Theorem 3.4 show that the convergence of the Scheme 1 is also decided by the parameters \( a_1, \ldots, a_k \). Let us test if the parameters satisfy the condition (3.3) for two kinds of selection of parameters. The first one will be the case where \( a_i = i \) and the second one will be the case where \( a_i = i^2 \). In Table 4.1 we present two kinds of test values for several schemes changing the value of \( k \) from 2 to 7. The first value is the maximum absolute values of the roots except 1 and it represents the stability of the scheme. The second value is \( \sum_{i=2}^{a_k} |\alpha_i|/|\alpha_1| \) which represents the convergence of the scheme. As one can see the equidistant scheme (\( a_i = i \)) fails to satisfy the condition for convergence from \( k = 4 \) while the nonequidistant scheme satisfy all conditions for all test cases. This shows that although one would need more initial approximations to use nonequidistant difference scheme, it could have a better convergence and stability.

5. Conclusions. In this paper we proposed a generalized numerical scheme for BSDEs. The scheme is based on approximation of derivatives via Lagrange interpolation on generally distributed sample points. By changing the distribution of sample points used for interpolation, one can get various numerical schemes with different stability and convergence order. We presented a condition for the distribution of sample points to guarantee the convergence of the scheme. Through discussion we showed that a scheme based on quadratically distant sample points is both stable and convergent.

<table>
  <tr><th>Param</th><th>k = 2</th><th>k = 3</th><th>k = 4</th><th>k = 5</th><th>k = 6</th><th>k = 7</th></tr>
  <tr><td>\( a_i = i \)</td><td>0.33</td><td>0.33</td><td>0.81</td><td>0.42</td><td>1.56</td><td>0.56</td><td>2.73</td><td>0.70</td><td>4.65</td><td>0.86</td><td>7.87</td><td>1.02</td></tr>
  <tr><td>\( a_i = i^2 \)</td><td>0.06</td><td>0.48</td><td>0.20</td><td>0.63</td><td>0.37</td><td>0.73</td><td>0.44</td><td>0.80</td><td>0.50</td><td>0.83</td><td>0.57</td><td>0.85</td></tr>
</table>

satisfy the condition for convergence from \( k = 4 \) while the nonequidistant scheme satisfy all conditions for all test cases. This shows that although one would need more initial approximations to use nonequidistant difference scheme, it could have a better convergence and stability.
