Abstract

Integrating adaptive learning rate and momentum techniques into SGD leads to a large class of efficiently accelerated adaptive stochastic algorithms, such as Nadam, AccAdaGrad, etc. In spite of their effectiveness in practice, there is still a large gap in their theories of convergences, especially in the difficult non-convex stochastic setting. To fill this gap, we propose weighted AdaGrad with unified momentum, dubbed AdaUSM, which has the main characteristics that (1) it incorporates a unified momentum scheme which covers both the heavy ball momentum and the Nesterov accelerated gradient momentum; (2) it adopts a novel weighted adaptive learning rate that can unify the learning rates of AdaGrad, AccAdaGrad, Adam, and RMSProp. Moreover, when we take polynomially growing weights in AdaUSM, we obtain its $O(\log(T)/\sqrt{T})$ convergence rate in the non-convex stochastic setting. We also show that the adaptive learning rates of Adam and RMSProp correspond to taking exponentially growing weights in AdaUSM, which thereby provides a new perspective for understanding Adam and RMSProp. Lastly, comparative experiments of AdaUSM against SGD with momentum, AdaGrad, AdaEMA, Adam, and AMSGrad on various deep learning models and datasets are also provided.

1 Introduction

In this work we consider the following general non-convex stochastic optimization problem:

$$\min_{x \in \mathbb{R}^d} f(x) := \mathbb{E}_z [F(x, z)],$$  

where $\mathbb{E}_z[\cdot]$ denotes the expectation with respect to the random variable $z$. We assume that $f$ is bounded from below, i.e., $f^* = \inf_{x \in \mathbb{R}^d} f(x) > \infty$, and its gradient $\nabla f(\cdot)$ is $L$-Lipschitz continuous. Problem (1) arises from many statistical learning (e.g., logistic regression, AUC maximization) and deep learning models [10, 18]. In general, one only has access to noisy estimates of $\nabla f$, as the expectation in problem (1) often can only be approximated as a finite sum. Hence, one of the most popular algorithms to solve problem (1) is Stochastic Gradient Decent (SGD) [30, 2]:

$$x_{t+1} := x_t - \eta_t g_t,$$  

where $\eta_t$ is the learning rate and $g_t$ is the noisy gradient estimate of $\nabla f(x)$ in the $t$-th iteration. Its convergence rates for both convex and non-convex settings have been established [1, 8].

*Equal Contribution

Preprint. Under review.
However, vanilla SGD suffers from slow convergence, and its performance is sensitive to the learning rate—which is tricky to tune. Many techniques have been introduced to improve the convergence speed and robustness of SGD, such as variance reduction [4, 14, 27], adaptive learning rate [6, 15], and momentum acceleration [28, 26, 21]. Among them, adaptive learning rate and momentum acceleration techniques are most economic, since they merely require slightly more computation per iteration. SGD with adaptive learning rate was first proposed as AdaGrad [23, 6] and the learning rate is adjusted by cumulative gradient magnitudes:

$$\eta_t = \frac{\eta}{\sqrt{\sum_{i=1}^{t} g_i^2 + \epsilon}},$$

where $\epsilon, \eta > 0$ are fixed parameters. On the other hand, Heavy Ball (HB) [28, 7] and Nesterov Accelerated Gradient (NAG) [26, 25] are two most popular momentum acceleration techniques, which have been extensively studied for stochastic optimization problems [9, 35, 21]:

$$\text{(SHB):} \quad \left\{ \begin{array}{l} m_t = \mu m_{t-1} - \eta_t g_t \\ x_{t+1} = x_t + m_t \end{array} \right., \quad \text{(SNAG):} \quad \left\{ \begin{array}{l} y_{t+1} = x_t - \eta_t g_t \\ x_{t+1} = y_{t+1} + \mu (y_{t+1} - y_t) \end{array} \right.,$$

where $x_1 = y_1 \in \mathbb{R}^d$, $m_0 = 0 \in \mathbb{R}^d$, and $\mu \in (0, 1)$ is the momentum factor.

Both the adaptive learning rate and momentum techniques have been individually investigated and have displayed to be effective in practice, so are independently and widely applied in tasks such as training deep networks [17, 31, 15, 29]. It is natural to consider: Can we effectively incorporate both techniques at the same time so as to inherit their dual advantages and moreover develop convergence theory for this scenario, especially in the more difficult non-convex stochastic setting? To the best of our knowledge, Levy et al. [21] firstly attempted to combine the adaptive learning rate with NAG momentum, which yields the AccAdaGrad algorithm. However, its convergence is limited to the stochastic convex setting. Yan et al. [35] unified SHB and SNAG to a three-step iterate without considering the adaptive learning rate in Eq. (3).

In this work, we revisit the momentum acceleration technique [28, 26] and adaptive learning rate [6, 15], and propose weighted AdaGrad with unified stochastic momentum, dubbed as AdaUSM, to solve the general non-convex stochastic optimization problem (1). Specifically, the proposed AdaUSM has two main features: it develops a novel Unified Stochastic Momentum (USM) scheme to cover SHB and SNAG, entirely different from the three-step scheme in [35], and it generalizes the adaptive learning rate in Eq. (3) to a more general weighted adaptive learning rate (see Section 3) that can unify the adaptive learning rates of AdaGrad, AccAdaGrad, and Adam into a succinct framework. In contrast to those in AdaGrad [6], the weighted adaptive learning rate in AdaUSM is estimated via a novel weighted gradient accumulation technique, which puts more weights on the most recent stochastic gradient estimates. Moreover, to make AdaUSM more practical for large-scale problems, a coordinate-wise weighted adaptive learning rate with a low computational cost is used.

We also characterize the $O(\log(T)/\sqrt{T})$ convergence rate of AdaUSM in the non-convex stochastic setting, when we take polynomially growing weights in AdaUSM. When momentum is NAG and weights are set as the same as those in [21], AdaUSM reduces to AccAdaGrad [21]. In consequence, the convergence rate of AccAdaGrad in the non-convex setting is derived directly as byproduct. Thus, our work generalizes AccAdaGrad [21] in three aspects: (i) more general weights in estimating the adaptive learning rate; (ii) new unified momentum including both NAG and HB; (iii) the convergence rate in the more difficult non-convex stochastic setting. To the best of our knowledge, our work is the first to explore the convergence rates of adaptive stochastic algorithms with momentum acceleration in the non-convex stochastic setting. Our contributions are three-fold:

- We develop a new weighted gradient accumulation technique to estimate the adaptive learning rate, and propose a novel unified stochastic momentum scheme to cover SHB and SNAG. We then integrate the weighted coordinate-wise AdaGrad with a unified momentum mechanism, yielding a novel adaptive stochastic momentum algorithm, dubbed as AdaUSM.
- We establish the $O(\log(T)/\sqrt{T})$ non-asymptotic convergence rate of AdaUSM under the general non-convex stochastic setting. Our assumptions are natural and mild.
- We show that the adaptive learning rates of Adam and RMSProp correspond to taking exponentially growing weights in AdaUSM, which thereby provides a new perspective for understanding Adam and RMSProp.
Related Works. There exist several works to study the convergence rates of adaptive SGD in the non-convex stochastic setting. For example, Li and Orabona [22] first proved the global convergence of perturbed AdaGrad\footnote{In [22], the convergence rate of AdaGrad was established with perturbed adaptive learning rate: $\eta_t = \eta/(\epsilon + \sum_{i=1}^t g_i^2)^{\frac{1}{2}+\beta}$. The perturbation factor $\beta > 0$ is unavoidable for its convergence argument.}; Ward et al. [33] established $O(\log(T)/\sqrt{T})$ convergence rates for the original AdaGrad [6] and WNgrad [34]; the convergence rates of Adam/RMSProp [36] and AMSGrad [3] were also established in the non-convex stochastic setting, respectively.

2 Preliminaries

Notations. $T$ denotes the maximum number of iterations. The noisy gradient of $f$ at the $t$-th iteration is denoted by $g_t$ for all $t = 1, 2, \ldots, T$. We use $\mathbb{E}[]$ to denote expectation as usual, and $\mathbb{E}_t[.]$ as the conditional expectation with respect to $g_t$ conditioned on the random variables $\{g_1, g_2, \ldots, g_{t-1}\}$.

In this paper we allow differential learning rates across coordinates, so the learning rate $\eta_t$ is a vector in $\mathbb{R}^d$. Given a vector $v \in \mathbb{R}^d$ we denote its $k$-th coordinate by $v_k$. The $k$-th coordinate of the gradient $\nabla f(x)$ is denoted by $\nabla_k f(x)$. Given two vectors $v_t, w_t \in \mathbb{R}^d$, the inner product between them is denoted by $(v_t, w_t) := \sum_{k=1}^d v_{tk} w_{tk}$. We also heavily use the coordinate-wise product between $v$ and $w$, denoted as $vw \in \mathbb{R}^d$, with $(vw)_k = v_k w_k$. Division by a vector is defined similarly. Given a vector $v \in \mathbb{R}^d$, we define the weighted norm: $\|\nabla f(x)\|^2 := \sum_{k=1}^d v_k \|\nabla_k f(x)\|^2$. Norm $\|\cdot\|$ without any subscript is the Euclidean norm, and $\|\cdot\|_1$ is defined as $\|v\|_1 = \sum_{k=1}^d |v_k|$. Let $0 = (0, 0, \ldots, 0)^T \in \mathbb{R}^d$ and $\epsilon = (\epsilon, \ldots, \epsilon)^T \in \mathbb{R}^d$.

Assumptions. We assume that $g_t$, $t = 1, 2, \ldots, T$ are independent of each other. Moreover,

(A1) $\mathbb{E}_t [g_t] = \nabla f(x_t)$, i.e., stochastic gradient $g_t$ is an unbiased estimator;

(A2) $\mathbb{E}_t \|g_t\|^2 \leq \sigma^2$, i.e., the second-order moment of $g_t$ is bounded.

Notice that the condition (A2) is slightly weaker than that in [3] which assumes that stochastic gradient estimate $g_t$ is uniformly bounded, i.e., $\|g_t\| \leq \sigma$.

3 Weighted AdaGrad with Unified Momentum

We describe the two main ingredients of AdaUSM: the unified stochastic momentum formulation of SHB and SNAG (see Subsection 3.1), and the weighted adaptive learning rate (see Subsection 3.2).

3.1Unified Stochastic Momentum (USM)

By introducing $m_t = y_{t+1} - y_t$ with $m_0 = 0$, the iterate of SNAG can be equivalently written as

\[ \text{SNAG}: m_t = \mu m_{t-1} - \eta y_t, \quad x_{t+1} = x_t + m_t + \mu (m_t - m_{t-1}). \]

Comparing SHB and above SNAG, the difference lies in that SNAG has more weight on the current momentum $m_t$. Hence, we can rewrite SHB and SNAG in the following unified form:

\[ \text{USM}: \begin{cases} m_t = \mu m_{t-1} - \eta y_t, \\ x_{t+1} = x_t + m_t + \lambda \mu (m_t - m_{t-1}), \end{cases} \]

where $\lambda \geq 0$ is a constant. When $\lambda = 0$, it is SHB; when $\lambda = 1$, it is SNAG. We call $\lambda$ the interpolation factor. For any $\mu \in (0, 1)$, $\lambda$ can be chosen from the range $[0, 1/(1 - \mu)]$.

Remark 1. Yan et al. [35] unified SHB and SNAG as a three-step iterate scheme as follows:

\[ y_{t+1} = x_t - \eta y_t, \quad y_t^s = x_t - s \eta y_t, \quad x_{t+1} = y_{t+1} + \mu (y_t^s - y_t^s), \]

where $y_t^s = x_0$. Its convergence rate has been established for $\eta_t = O(1/\sqrt{T})$. Notably, USM is slightly simpler than Eq. (6) and the learning rate $\eta_t$ in USM is adaptively determined.
3.2 Weighted Adaptive Learning Rate

We generalize the learning rate in Eq. (3) by assigning different weights to the past stochastic gradients accumulated. It is defined as follows:

$$\eta_{t,k} = \frac{\eta}{\sqrt{\sum_{i=1}^{t} a_i g_{t,k}^2/a_t + \epsilon}} = \frac{\eta/\sqrt{t}}{\sqrt{\sum_{i=1}^{t} a_i g_{t,k}^2/(\sum_{i=1}^{t} a_i) + \epsilon/\sqrt{t}}},$$

(7)

for \( k = 1, 2, \ldots, d \), where \( a_1, a_2, \ldots, a_t > 0 \) and \( a_t = \sum_{i=1}^{t} a_i/t \). Here, \( \eta/\sqrt{t} \) can be understood as the base learning rate. The classical AdaGrad corresponds to taking \( a_t = 1 \) for all \( t \) in Eq. (7), i.e., uniform weights. However, recent gradients tend to carry more information of local geometries than remote ones. Hence, it is natural to assign the recent gradients more weights. A typical choice for such weights is to choose \( a_t = t^\alpha \) for \( \alpha > 0 \), which grows in a polynomial rate. For instance, in AccAdaGrad [21] weights are chosen to be \( a_t = [(1 + t)/4]^2 \) for \( t \geq 3 \) and \( a_t = 1 \) for \( 0 \leq t \leq 2 \).

3.3 AdaUSM: Weighted AdaGrad with USM

In this subsection, we present the AdaUSM algorithm, which effectively integrates the weighted adaptive learning rate in Eq. (7) with the USM technique in Eq. (5), and establish its convergence rate.

**Algorithm 1** AdaUSM: Weighted AdaGrad with USM

1: **Parameters:** Choose \( x_1 \in \mathbb{R}^d \), fixed parameter \( \eta \geq 0 \), momentum factor \( \mu \), and initial accumulator factor \( \epsilon > 0 \). Set \( m_0 = 0 \), \( v_0 = 0 \), \( A_0 = 0 \), \( 0 \leq \mu < 1 \), \( 0 \leq \lambda \leq 1/(1-\mu) \), and weights \( \{a_t\} \).
2: **for** \( t = 1, 2, \ldots, T \) **do**
3:   **Sample** a stochastic gradient \( g_t \);
4:   **for** \( k = 1, 2, \ldots, d \) **do**
5:     \( v_{t,k} = v_{t-1,k} + a_t g_{t,k}^2 \);  
6:     \( A_t = A_{t-1} + a_t \);  
7:     \( \bar{a}_t = A_t/t \);  
8:     \( m_{t,k} = \mu m_{t-1,k} - \eta g_{t,k}/(\sqrt{v_{t,k}/\bar{a}_t + \epsilon}) \);  
9:     \( x_{t+1,k} = x_{t,k} + m_{t,k} + \lambda \mu (m_{t,k} - m_{t-1,k}) \);  
10: **end for**
11: **end for**

Note that AdaUSM extends the AccAdaGrad in [21] by using more general weighted parameters \( a_t \) and momentum accelerated mechanisms in the non-convex stochastic setting. In addition, when \( \lambda = 0 \), AdaUSM reduces to the weighted AdaGrad with a heavy ball momentum, which we denote by AdaHB for short. When \( \lambda = 1 \), AdaUSM reduces to the weighted AdaGrad with Nesterov accelerated gradient momentum, which we denote by AdaNAG for short. The detailed iterate schemes of AdaHB and AdaNAG are placed in the supplementary material due to the space limit.

**Theorem 1.** Let \( \{x_t\} \) be a sequence generated by AdaUSM. Assume that the noisy gradient \( g_t \) satisfies assumptions (A1)- (A2), and the sequence of weights \( \{a_t\} \) is non-decreasing in \( t \). Let \( \tau \) be uniformly randomly drawn from \( \{1, 2, \ldots, T\} \). Then

$$\mathbb{E}[\|\nabla f(x_\tau)\|^{4/3}]^{2/3} \leq \text{Bound}(T) = \mathcal{O}(\log (\sum_{t=1}^{T} a_t)/\sqrt{T}),$$

(8)

where \( \text{Bound}(T) = \frac{\sqrt{2\eta^2 + 2\eta^3 T}}{\eta^2} \left[ C_1 + C_2 \log \left( 1 + \frac{\eta^2}{\mu} \sum_{t=1}^{T} a_t \right) \right] \), and constants \( C_1 \) and \( C_2 \) are defined as \( C_1 = \frac{2(\|x_1\| - f^*)}{(1 + \lambda \mu \eta)^2} \) and \( C_2 = \frac{2\eta(1 + 2\lambda)^2 Ld}{(1 + \lambda \mu)^2(1 - \mu)^2} \), respectively.

**Sketch of proof.** Our starting point is the following inequality which follows from the Lipschitz continuity of \( \nabla f \) and the descent lemma in [25]:

$$f(x_{t+1}) \leq f(x_t) + \langle \nabla f(x_t), m_t + \lambda \mu (m_t - m_{t-1}) \rangle + \frac{L}{2} \|m_t + \lambda \mu (m_t - m_{t-1})\|^2.$$
The key point is to estimate the term $\langle \nabla f(x_t), m_t \rangle$, which involves the momentum. However, $m_t$ is far from an unbiased estimate of the true gradient. This difficulty is resolved in Lemma 3, where we establish an estimate for the term $\langle \nabla f(x_t), m_t \rangle$ via iteration

$$\langle \nabla f(x_t), m_t \rangle \leq (1 + 2\lambda)L \sum_{i=1}^{t-1} \|m_i\|^2 \mu^{t-i} - \sum_{i=1}^{t} \langle \nabla f(x_i), \eta_i g_i \rangle \mu^{t-i}.$$ 

Furthermore, we can derive an estimate on each $\|m_i\|^2$ in terms of $\sum_{j=1}^{t} \|\eta_j g_j\|^2$ (by Lemma 2). For the term $\langle \nabla f(x_t), \eta_i g_i \rangle$, taking expectation of $\eta_i g_i$ is tricky as $\eta_i$ is correlated with $g_i$. We follow the idea of [33] and consider the term $\langle \nabla f(x_i), \hat{\eta}_i g_i \rangle$, where $\hat{\eta}_i$ is an approximation of $\eta_i$ independent of $g_i$. Hence its expectation gives rise to the desired term $\|\nabla f(x_i)\|^2_{\hat{\eta}_i}$. With a suitable choice of $\hat{\eta}_i$, in Lemma 4 we establish the following estimate

$$-E_t \langle \nabla f(x_t), \eta_i g_i \rangle \leq -\frac{1}{2} \|\nabla f(x_t)\|^2_{\hat{\eta}_i} + 2\frac{2}{\eta_i} E_t \left[ \sqrt{\langle a_t / \hat{a}_i \rangle \|\eta_i g_i\|^2} \right].$$

Summarizing the estimates above leads to the estimate in Lemma 7:

$$E \left[ \sum_{t=1}^{T} \|\nabla f(x_t)\|^2_{\hat{\eta}_i} \right] \leq C_1 + C_2 E \left[ \sum_{t=1}^{T} (a_t / \hat{a}_i) \|\eta_i g_i\|^2 \right].$$

With the specific adaptive learning rate $\eta_t$ as Eq. (7), we can further show that the principal term $E \left[ \sum_{t=1}^{T} (a_t / \hat{a}_i) \|\eta_i g_i\|^2 \right]$ is bounded by $\log(1 + \sigma^2 \sum_{t=1}^{T} a_t)$ (by Lemma 5), while the term $E \left[ \sum_{t=1}^{T} \|\nabla f(x_t)\|^2_{\hat{\eta}_i} \right] \geq \frac{\sqrt{T} + \sigma^2 T}{\eta T} \left( E \left[ \|\nabla f(x_T)\|^4 \right] \right)^{1/3}$ via Hölder inequality (by Lemma 6). This immediately gives rise to our theorem.

**Remark 2.** When we take $a_t = t^\alpha$ for some constant power $\alpha \geq 0$, then $\sum_{t=1}^{T} a_t = O(T^{\alpha+1})$ and conditions (i)-(ii) are satisfied. Hence, AdaUSM with such weights has the $O(\log(T) / \sqrt{T})$ convergence rate. In fact, AdaUSM is convergent as long as $\log \left( \sum_{t=1}^{T} a_t \right) = o(\sqrt{T})$.

When interpolation factor $\lambda = 1$, and $a_t = [(1+t)/4]^2$ for $t \geq 3$ and $a_t = 1$ for $0 \leq t \leq 2$, AdaUSM reduces to coordinate-wise AccAdaGrad [20]. In this case, $\sum_{t=1}^{T} a_t = O(T^3)$. Thus, we have the following corollary for the convergence rate of AccAdaGrad in the non-convex stochastic setting.

**Corollary 1.** Assume the same setting as Theorem 1. Let $\tau$ be randomly selected from $\{1, 2, \ldots, T\}$ with equal probability $P(\tau = t) = 1/T$. Then

$$\left( E \left[ \|\nabla f(x_\tau)\|^4 \right] \right)^{1/3} \leq Bound(T) = O \left( \log T / \sqrt{T} \right),$$

where $Bound(T) = \frac{\sqrt{T} + \sigma^2 T}{\eta T} \left[ C_1 + C_2 \log \left( \frac{1 + \sigma^2 T^3}{\epsilon} \right) \right]$, and constants $C_1$ and $C_2$ are defined as $C_1 = \frac{2}{1+\mu} \left( f(x_1) - f^* \right)$ and $C_2 = \frac{18\lambda L d}{(1+\mu)(1-\mu)^2} + \frac{4\sigma d}{1-\mu}$, respectively.

**Remark 3.** The $O(\log(T) / T)$ non-asymptotic convergence rate measured by the objective for AccAdaGrad has already been established in [21] in the convex stochastic setting. Corollary 1 provides the convergence rate of coordinate-wise AccAdaGrad measured by gradient residual, which also supplements the results in [21] in the non-convex stochastic setting.

## 4 Relationships with Adam and RMSProp

In this section, we show that the exponential moving average (EMA) technique in estimating adaptive learning rates in Adam [15] and RMSProp [12] is a special case of the weighted adaptive learning rate in Eq. (7), i.e., their adaptive learning rates correspond to taking exponentially growing weights in AdaUSM, which thereby provides a new angle for understanding Adam and RMSProp.
4.1 Adam

For better comparison, we first represent the $t$-th iterate scheme of Adam [15] as follows:

$$\begin{align*}
\bar{m}_{t,k} &= \beta_1 \bar{m}_{t-1,k} + (1 - \beta_1) g_{t,k}, \quad m_{t,k} = \bar{m}_{t,k}/(1 - \beta_1^t), \\
\bar{v}_{t,k} &= \beta_2 \bar{v}_{t-1,k} + (1 - \beta_2) g_{t,k}^2, \quad v_{t,k} = \bar{v}_{t,k}/(1 - \beta_2^t), \\
x_{t,k} &= x_{t-1,k} - \eta m_{t,k}/(\sqrt{v_{t,k}} + \epsilon),
\end{align*}$$

for $k = 1, \ldots, d$, where $\beta_1, \beta_2 \in [0, 1)$ and $\eta > 0$ are constants, and $\epsilon$ is a sufficiently small constant.

Denoting $\eta_{t,k} = \eta/(\sqrt{v_{t,k}} + \epsilon)$, we can simplify the iterations of Adam as

$$\begin{align*}
\bar{m}_{t,k} &= \beta_1 \bar{m}_{t-1,k} + (1 - \beta_1) g_{t,k}, \quad m_{t,k} = \bar{m}_{t,k}/(1 - \beta_1^t), \\
\bar{v}_{t,k} &= \beta_2 \bar{v}_{t-1,k} + (1 - \beta_2) g_{t,k}^2, \quad v_{t,k} = \bar{v}_{t,k}/(1 - \beta_2^t), \\
x_{t,k} &= x_{t-1,k} - \eta_{t,k} m_{t,k}.
\end{align*}$$

(EMA step)

Below, we show that AdaUSM and Adam differ in two aspects: momentum estimation $m_{t,k}$ and coordinate-wise adaptive learning rate $\eta_{t,k}$.

**Momentum estimation.** EMA technique is widely used in the momentum estimation step in Adam [15] and AMSGrad [29]. Without loss of generality, we consider the simplified EMA step

$$\begin{align*}
&\text{AdaUSM: } x_{t+1,k} = x_t - \sum_{i=1}^{t} \eta_{t,k} g_{i,k} \beta_1^{t-i}, \\
&\text{EMA: } x_{t+1,k} = x_t - (1 - \beta_1) \eta_{t,k} \sum_{i=1}^{t} g_{i,k} \beta_1^{t-i}.
\end{align*}$$

One can see that AdaUSM uses the past step-sizes but EMA uses only the current one in exponential moving averaging. Moreover, when momentum factor $\beta_1$ is very close to 1, the update of $x_t$ via EMA could stagnate since $\|x_{t+1} - x_t\| = O(1 - \beta_1)$. This dilemma will not appear in AdaUSM.

**Adaptive learning rate.** Note that $\bar{v}_{t,k} = \beta_2 \bar{v}_{t-1,k} + (1 - \beta_2) g_{t,k}^2$. We have $\bar{v}_{t,k} = \beta_2^t \bar{v}_{0,k}$ and $\sum_{i=1}^{t} (1 - \beta_2) \beta_2^{t-i} g_{i,k}^2$. Without loss of generality, we set $\bar{v}_{0,k} = 0$. Hence, it holds that

$$v_{t,k} = \bar{v}_{t,k}/(1 - \beta_2^t) = \sum_{i=1}^{t} (1 - \beta_2^t) \beta_2^{t-i} g_{i,k}^2.$$

Then, the adaptive learning rate $\eta_{t,k}$ in Adam can be rewritten as

$$\eta_{t,k} = \frac{\eta}{\sqrt{v_{t,k}} + \epsilon} = \frac{\eta}{\sqrt{t \sum_{i=1}^{t} \frac{(1-\beta_2^t) \beta_2^{t-i} g_{i,k}^2}{t \sum_{i=1}^{t} \frac{(1-\beta_2^t) \beta_2^{t-i} g_{i,k}^2}{t \sum_{i=1}^{t-1} \frac{1-\beta_2^t} {1-\beta_2^t} g_{i,k}^2}} + t \epsilon}}. \quad (11)$$

Let $a_i = \beta_2^{-i}$. Note that $\sum_{i=1}^{t} a_i = 1/(1-\beta_2^t)$. Hence, Eq. (11) can be further reformulated as

$$\eta_{t,k} = \frac{\eta}{t \sum_{i=1}^{t} \sum_{i=1}^{t} a_i g_{i,k}^2 + \sqrt{t \epsilon}}. \quad (12)$$

For comparison, the adaptive learning rates of Adam and AdaUSM are summarized as follows:

$$\begin{align*}
\eta_{t,k}^{\text{Adam}} &= \eta / \left[ \sqrt{t \sum_{i=1}^{t} \sum_{i=1}^{t} a_i g_{i,k}^2 + \sqrt{t \epsilon}} \right], \\
\eta_{t,k}^{\text{AdaUSM}} &= \eta / \left[ \sqrt{t \sum_{i=1}^{t} \sum_{i=1}^{t} a_i g_{i,k}^2 + \epsilon} \right].
\end{align*}$$

\(^3\)Since the learning rates $\eta_{t,k}$ in AdaUSM and Adam are determined adaptively, we do not have $\eta_{t,k} = \eta_{t-1,k}$. 

6
Hence, the adaptive learning rate in Adam is actually equivalent to that in AdaUSM by specifying $a_i = \beta_2^{-i}$ if $\epsilon$ is sufficiently small. For the parameter setting in Adam, it holds that $\log \left( \sum_{i=1}^{T} a_i \right) = \log \left( \frac{1-\beta_2^{-T}}{1-\beta_2^{-1}} \right) \geq \log \left( \frac{\beta_2^{-T+1}}{\beta_2^{-1}} \right) \geq (T-1) \log \left( \frac{1}{1-\beta_2} \right) = O(T) > o(T)$. Thus, we gain an insight on understanding the convergence of Adam from the convergence results of AdaUSM in Theorem 1.

Remark 4. Recently, Chen et al. [3] have also proposed AdaGrad with exponential moving average (AdaEMA) by setting $\beta_2$ as $(\beta_2)_i = 1 - 1/t$ and removing the bias-correction steps in Adam. Its $O(\log(T)/T)$ convergence rate in the non-convex stochastic setting has been established under a slightly stronger assumption that the stochastic gradient estimate is required to be uniformly bounded. Compared with AdaEMA, AdaUSM not only adopts a general weighted sequence in estimating the adaptive learning rate, but also uses a different unified momentum that covers HB and NAG as special instances. The superiority of HB and NAG momentums over EMA has been pointed out in the above paragraph: Momentum estimation. In Section 5, we also experimentally demonstrate the effectiveness of AdaUSM against AdaEMA.

4.2 RMSProp

Coordinate-wise RMSProp is another efficient solver for training DNNs [12, 24], which is defined as

\[
\begin{align*}
    v_{t,k} &= \beta v_{t-1,k} + (1 - \beta)g_{t,k}^2 \\
    x_{t,k} &= x_{t-1,k} - \eta g_{t,k}/(\sqrt{v_{t,k}} + \epsilon),
\end{align*}
\]

for $k = 1, \ldots, d$.

Define $a_i = \beta^{-i}$. The adaptive learning rate of RMSProp denoted as $\eta_{t,k}^{\text{RMSProp}}$ can be rewritten as

\[
\eta_{t,k}^{\text{RMSProp}} = \frac{\eta}{\sqrt{v_{t,k}} + \epsilon} = \frac{\eta/(1-\beta)}{\sqrt{t \sum_{i=1}^{t} \frac{(1-\beta_2)}{1-\beta_2} \beta_2^{-i-1} g_{i,k}^2 + \frac{\epsilon}{1-\beta}}} = \frac{\eta/(1-\beta)}{\sqrt{t \sum_{i=1}^{t} a_i g_{i,k}^2 + \frac{\epsilon}{1-\beta}}}.
\]

When $\epsilon$ is a sufficiently small constant and $\beta < 1$, it is obvious that $\eta_{t,k}^{\text{RMSProp}}$ has a similar structure to $\eta_{t,k}^{\text{AdaUSM}}$ after $t$ being sufficiently large. Based on the above analysis, AdaUSM can be interpreted as generalized RMSProp with HB and NAG momentums.

5 Experiments

In this section, we conduct experiments to validate the efficacy and theory of AdaHB (AdaUSM with $\lambda = 0$) and AdaNAG (AdaUSM with $\lambda = 1$) by applying them to train DNNs including LetNet [19], GoogLeNet [32], ResNet [11], and DenseNet [13] on various datasets including MNIST [19], CIFAR10/100 [16], and Tiny-ImageNet [5]. The efficacies of AdaHB and AdaNAG are evaluated via the training loss, test accuracy, and test loss vs. epochs, respectively. In the experiments, we fix the batch-size as 128 and the weighted decay parameter as $5 \times 10^{-4}$, respectively.

Optimizers. We compare AdaHB/AdaNAG with five competing algorithms: SGD with momentum (SGDm) [31], AdaGrad [6, 33], AdaEMA [3], AMSGrad [29, 3], and Adam [15]. The parameter settings of all compared optimizers are summarized in Table 1 (see Section D in the supplementary material) and are consistent with [15, 29, 3]. To match the convergence theory, we take the diminishing base learning rate as $\eta/\sqrt{t}$ uniformly across all the tested adaptive optimizers. Moreover, as shown in Theorem 1, we know that the learning rates in AdaHB and AdaNAG will be $1/(1-\beta_1)$ times greater than those in AdaEMA, AMSGrad, and Adam if they share the same constant parameter $\eta$. In addition, too large and small $\eta$ would lead to heavy oscillation and bad stagnation on the training loss, respectively, which would deteriorate the performances of the tested optimizers. Consequently, the base learning rate $\eta$ for each solver is chosen via grid search on the set $\{1, 0.1, 0.01, 0.001, 0.0001\}$. We report the base learning rate of each solver that can consistently contribute to the best performance.

Figures 1-4 illustrate the performance profiles of applying AdaHB, AdaNAG, SGDm, AdaGrad, AdaEMA, AMSGrad, and Adam to train LetNet on MNIST, GoogLeNet on CIFAR10, DenseNet on CIFAR100, and ResNet on Tiny-ImageNet, respectively. More specifically, Figure 1 illustrates the
performance of LeNet on MNIST which covers 60,000 training examples and 10,000 test examples. It can be seen that AdaHB decreases the training loss and test loss fastest among the seven tested optimizers, which simultaneously yields a higher test accuracy than the other tested optimizers. The performances of AdaEMA and AdaGrad are worse than AdaHB but better than SGDm, Adam, and AMSGrad. Figure 2 illustrates the performance of training GoogLeNet on CIFAR10 which covers 50,000 training examples and 10,000 test examples. It can be seen that SGDm decreases the training loss slightly faster than other optimizers, followed by AdaHB and AdaNAG, and that AMSGrad and Adam are the slowest optimizers. The test accuracies of AdaHB, AdaNAG, AdaGrad, and AdaEMA are comparable, which are all slightly better than SGDm and outperform Adam and AMSGrad. Figure 3 illustrates the performance of training DenseNet on CIFAR100 which covers 50,000 training examples and 10,000 test examples. It shows that SGDm has the worst training process and test accuracy, followed by Adam and AMSGrad. While AdaGrad, AdaEMA, AdaHB, and AdaNAG decrease the training loss and increase test accuracy at roughly the same speed. Figure 4 illustrates the performance of training ResNet on Tiny-ImageNet which contains 100,000 training examples and 10,000 test examples. It can be seen that AdaHB and AdaNAG show the fastest speed to decrease the training loss and increase the test accuracy. SGDm is worse than AdaHB and AdaNAG, and better than AdaGrad, AdaEMA, and AMSGrad in terms of the training loss and test accuracy.

In summary, AdaHB and AdaNAG are more efficient and robust than SGDm, AdaGrad, AdaEMA, Adam, and AMSGrad in terms of both the training speed and generalization capacity. SGDm is also an efficient optimizer but it is highly sensitive to the hand-tuning learning rate. Moreover, the value
of EMA is marginal and not as efficient as heavy ball and Nesterov accelerated gradient momentums, as revealed by the performance curves of AdaEMA, AdaGrad, AdaHB, and AdaNAG.

6 Conclusions

We integrated a novel weighted coordinate-wise AdaGrad with unified momentum including heavy ball and Nesterov accelerated gradient momentums, yielding a new adaptive stochastic algorithm called AdaUSM. Its $O(\log(T)/\sqrt{T})$ convergence rate was established in the non-convex stochastic setting. Our work largely extends the convergence rate of accelerated AdaGrad in [21] to the general non-convex stochastic setting. Moreover, we pointed out that the adaptive learning rates of Adam and RMSProp are essentially special cases of the weighted adaptive learning rate in AdaUSM, which provides a new angle to understand the convergences of Adam/RMSProp. We also experimentally verified the efficacy of AdaUSM in training deep learning models on several datasets. The promising results show that the proposed AdaUSM is more effective and robust than SGD with momentum, AdaGrad, AdaEMA, AMSGrad, and Adam in terms of training loss and test accuracy vs. epochs.

Supplementary Material for “Weighted AdaGrad with Unified Momentum”

In this supplementary we give a complete proof of Theorem 1. The material is arranged as follows. In Section A, we present the detailed iteration schemes of AdaHB and AdaNAG for readability. In Section B, we provide preliminary lemmas that will be used to establish Theorem 1. In Section C, we give the detailed proof of Theorem 1. In Section D, we provide the parameter settings of the compared optimizers including AdaHB, AdaNAG, AdaGrad, SGDm, AdaEMA, AMSGrad, and Adam.

B Preliminary Lemmas

In this section we provide preliminary lemmas that will be used to prove our main theorem. The readers may skip this part for the first time and come back whenever the lemmas are needed.

Lemma 1. Let \( S_T = S_0 + \sum_{i=1}^{T} a_i \), where \( \{ a_i \} \) is a non-negative sequence and \( S_0 > 0 \). We have \( \sum_{t=1}^{T} \frac{a_t}{S_t} \leq \log(S_T) - \log(S_0) \).

Proof. The finite sum \( \sum_{t=1}^{T} \frac{a_t}{S_t} \) can be interpreted as a Riemann sum as follows \( \sum_{t=1}^{T} \frac{1}{S_t} (S_t - S_{t-1}) \).

Since \( 1/x \) is decreasing on the interval \((0, \infty)\), we have

\[
\sum_{t=1}^{T} \frac{1}{S_t} (S_t - S_{t-1}) \leq \int_{S_0}^{S_T} \frac{1}{x} dx = \log(S_T) - \log(S_0).
\]

The proof is finished. \( \square \)

The following lemma is a direct result of the momentum updating rule.

Lemma 2. Suppose \( m_t = \mu m_{t-1} - \eta g_t \) with \( m_0 = 0 \) and \( 0 \leq \mu < 1 \). We have the following estimate

\[
\sum_{t=1}^{T} \| m_t \|^2 \leq \frac{1}{(1 - \mu)^2} \sum_{t=1}^{T} \| \eta g_t \|^2.
\] (13)
Proof. First, we have the following inequality due to convexity of $|| \cdot ||^2$:

$$
||m_t||^2 = ||\mu m_{t-1} + (1-\mu)(-\eta_t g_t/(1-\mu))||^2 \leq \mu ||m_{t-1}||^2 + (1-\mu)||\eta_t g_t/(1-\mu)||^2
$$

(14)

Taking sum of Eq. (14) from $t = 1$ to $t = T$ and using $m_0 = 0$, we have that

$$
\sum_{t=1}^{T} ||m_t||^2 \leq \mu \sum_{t=1}^{T} ||m_{t-1}||^2 + \frac{1}{1-\mu} \sum_{t=1}^{T} ||\eta_t g_t||^2 \leq \mu \sum_{t=1}^{T} ||m_{t-1}||^2 + \frac{1}{1-\mu} \sum_{t=1}^{T} ||\eta_t g_t||^2.
$$

(15)

Hence,

$$
\sum_{t=1}^{T} ||m_t||^2 \leq \frac{1}{(1-\mu)^2} \sum_{t=1}^{T} ||\eta_t g_t||^2.
$$

(16)

The proof is finished.

The following lemma is a result of the USM formulation for any general adaptive learning rate.

**Lemma 3.** Let $\{x_t\}$ and $\{m_t\}$ be sequences generated by the following general SGD with USM momentum: starting from initial values $x_1$ and $m_0 = 0$, and being updated through

$$
\begin{cases}
    m_t = \mu m_{t-1} - \eta_t g_t, \\
x_{t+1} = x_t + m_t + \lambda \mu (m_t - m_{t-1}),
\end{cases}
$$

where the momentum factor $\mu$ and the interpolation factor $\lambda$ satisfy $0 \leq \mu < 1$ and $0 \leq \lambda \leq 1/(1-\mu)$, respectively. Suppose that the function $f$ is $L$-smooth. Then for any $t \geq 2$ we have the following estimate

$$
\langle \nabla f(x_t), m_t \rangle \leq \mu \langle \nabla f(x_{t-1}), m_{t-1} \rangle + \left(1 + \frac{3}{2} \lambda \mu \right) L ||m_{t-1}||^2 + \frac{1}{2} \lambda \mu^2 L ||m_{t-2}||^2 - \langle \nabla f(x_t), \eta_t g_t \rangle.
$$

(17)

In particular, the following estimate holds

$$
\langle \nabla f(x_t), m_t \rangle \leq (1 + 2\lambda)L \sum_{i=1}^{t-1} ||m_i||^2 \mu^{t-i} - \sum_{i=1}^{t} \langle \nabla f(x_i), \eta_t g_i \rangle \mu^{t-i}.
$$

(18)

Proof. Since $m_t = \mu m_{t-1} - \eta_t g_t$, we have

$$
\langle \nabla f(x_t), m_t \rangle = \mu \langle \nabla f(x_{t-1}), m_{t-1} \rangle - \langle \nabla f(x_t), \eta_t g_t \rangle = \mu \langle \nabla f(x_{t-1}), m_{t-1} \rangle + \mu \langle \nabla f(x_t) - \nabla f(x_{t-1}), m_{t-1} \rangle - \langle \nabla f(x_t), \eta_t g_t \rangle.
$$

(19)

Note that by $L$-smoothness of function $f$, we have that

$$
||\nabla f(x_t) - \nabla f(x_{t-1})|| \leq L ||x_t - x_{t-1}|| = L ||m_{t-1} + \lambda \mu (m_{t-1} - m_{t-2})|| \leq (1 + \lambda \mu)L ||m_{t-1}|| + \lambda \mu L ||m_{t-2}||.
$$

(20)

Hence, by Cauchy-Schwartz inequality and Eq. (20), we have that

$$
\langle \nabla f(x_t) - \nabla f(x_{t-1}), m_{t-1} \rangle \leq ||\nabla f(x_t) - \nabla f(x_{t-1})|| ||m_{t-1}|| \leq (1 + \lambda \mu)L ||m_{t-1}||^2 + \lambda \mu L ||m_{t-2}|| ||m_{t-1}|| \leq (1 + \frac{3}{2} \lambda \mu)L ||m_{t-1}||^2 + \frac{1}{2} \lambda \mu L ||m_{t-2}||^2.
$$

(21)

Combining Eq. (19) and Eq. (21), we obtain the desired inequality Eq. (17).

To obtain the second estimate, let $B_t = \langle \nabla f(x_t), m_t \rangle$. If $\mu = 0$, the equality holds trivially. Otherwise $0 < \mu < 1$. We divide $\mu^t$ from both sides of Eq. (17) and obtain

$$
\frac{B_t}{\mu^t} \leq \frac{B_{t-1}}{\mu^{t-1}} + \left(1 + \frac{3}{2} \lambda \mu \right) \frac{L ||m_{t-1}||^2}{\mu^{t-1}} + \frac{1}{2} \lambda L \frac{||m_{t-2}||^2}{\mu^{t-2}} - \langle \nabla f(x_t), \eta_t g_t \rangle \mu^{-t}.
$$

(22)
Note that \( m_0 = 0 \), and \( B_1 = -\langle \nabla f(x_1), \eta_1 g_1 \rangle \). Therefore,

\[
\frac{B_t}{\mu^t} \leq \frac{B_1}{\mu} + (1 + \frac{3}{2} \lambda \mu) L \sum_{i=2}^t \|m_{i-1}\|^2 \mu^{-(i-1)} + \frac{1}{2} \lambda \mu \sum_{i=2}^t \|m_{i-2}\|^2 \mu^{-(i-2)} - \sum_{i=2}^t \langle \nabla f(x_i), \eta_i g_i \rangle \mu^{-i} \leq (1 + 2\lambda) L \sum_{i=1}^{t-1} \|m_i\|^2 \mu^{-i} - \sum_{i=1}^t \langle \nabla f(x_i), \eta_i g_i \rangle \mu^{-i}.
\]

(23)

Multiplying both sides of Eq. (23) by \( \mu^t \), we obtain the desired estimate Eq. (18). The proof is completed.

The following two lemmas, which are first introduced in [33, Theorem 10], are particularly due to the AdaGrad adaptive learning rate. Here we adjust their proofs to the coordinate-wise version for our Weighed AdaGrad adaptive learning rate and represent it here for readers’ convenience.

**Lemma 4** (Proof of Theorem 10 in [33]). Let \( \sigma_t = \sqrt{E_t g_t^2} \) and let

\[
\hat{\eta}_t = \frac{\eta}{\sqrt{\frac{1}{\alpha t} \left( \sum_{i=1}^{t-1} a_i g_i^2 + a_t \sigma_i^2 \right) + \epsilon}}.
\]

Assume that the noisy gradients \( g_t \) satisfy assumptions (A1) and (A2), then we have the following estimate

\[
-E_t \langle \nabla f(x_t), \eta_t g_t \rangle \leq -\frac{1}{2} \|\nabla f(x_t)\|^2_{\hat{\eta}_t} + \frac{2\sigma}{\eta} E_t \|\frac{\sqrt{a_t/\alpha_t}}{\hat{\eta}_t} \|g_t\|^2_{\hat{\eta}_t},
\]

(24)

where \( \|\nabla f(x_t)\|^2_{\hat{\eta}_t} = \sum_{k=1}^d (\eta_t g_t)_{k} |\nabla_k f(x_t)|^2 \), and the constant \( \sigma \) is that in assumption (A2).

**Proof.** First, we have

\[
-\langle \nabla f(x_t), \eta_t g_t \rangle = -\langle \nabla f(x_t), \hat{\eta}_t g_t \rangle + \langle \nabla f(x_t), (\hat{\eta}_t - \eta_t) g_t \rangle.
\]

(25)

Note that \( \hat{\eta}_t \) is independent of \( g_t \), and \( E_t g_t = \nabla f(x_t) \) by assumption (A1). Hence,

\[
E_t \langle \nabla f(x_t), \hat{\eta}_t g_t \rangle = \langle \nabla f(x_t), \hat{\eta}_t \nabla f(x_t) \rangle = \|\nabla f(x_t)\|^2_{\hat{\eta}_t}.
\]

(26)

Taking the conditional expectation of Eq. (25) with respect to \( \xi_1, \ldots, \xi_{t-1} \) being fixed, we have

\[
-E_t \langle \nabla f(x_t), \eta_t g_t \rangle = -\|\nabla f(x_t)\|^2_{\hat{\eta}_t} + E_t \langle \nabla f(x_t), (\hat{\eta}_t - \eta_t) g_t \rangle.
\]

(27)

To estimate the second term of Eq. (27), we first have

\[
\langle \nabla f(x_t), (\hat{\eta}_t - \eta_t) g_t \rangle \leq \sum_{k=1}^d |\hat{\eta}_{t,k} - \eta_{t,k}| \|\nabla_k f(x_t)\| |g_{t,k}|.
\]

(28)

Let \( V_t = \frac{1}{\eta_t} \sum_{i=1}^{t-1} a_i g_i^2 \), and \( \hat{V}_t = \frac{1}{\eta_t} \left( \sum_{i=1}^{t-1} a_i g_i^2 + a_t \sigma_i^2 \right) \). Then \( \eta_t = \eta/(\sqrt{V_t} + \epsilon) \) and \( \hat{\eta}_t = \eta/(\sqrt{\hat{V}_t} + \epsilon) \). It follows that

\[
|\hat{\eta}_t - \eta_t| = \frac{\eta |V_t - \hat{V}_t|}{(\sqrt{V_t} + \epsilon)(\sqrt{\hat{V}_t} + \epsilon)(\sqrt{V_t} + \sqrt{\hat{V}_t})} \leq \frac{\eta \hat{\eta}_t (a_t/\alpha_t) g_t^2 - \sigma_t^2}{\eta \sqrt{V_t} + \sqrt{\hat{V}_t}} \leq \frac{\sqrt{a_t/\alpha_t}}{\eta} \hat{\eta}_t (|g_t| + \sigma_t).
\]

(29)

Note that the above inequality is coordinate-wise. By Eq. (28) and Eq. (29), we have

\[
\langle \nabla f(x_t), (\hat{\eta}_t - \eta_t) g_t \rangle \leq \sum_{k=1}^d \frac{\sqrt{a_t/\alpha_t}}{\eta} \hat{\eta}_{t,k} |g_{t,k}| \|\nabla_k f(x_t)\| |g_{t,k}| + \sum_{k=1}^d \frac{\sqrt{a_t/\alpha_t}}{\eta} \sigma_{t,k} \hat{\eta}_{t,k} |g_{t,k}| \|\nabla_k f(x_t)\| |g_{t,k}|.
\]

(30)
We claim that
\[
\mathbb{E}_t \sum_{k=1}^d \frac{\sqrt{(a_t/\bar{a}_t)}}{\eta} \hat{n}_{t,k} \eta_{t,k} |\nabla_k f(x_t)||g_{t,k}| \leq \frac{1}{4} \|\nabla f(x_t)\|_{\eta_t}^2 + \frac{\sigma}{\eta} \mathbb{E}_t \left[ \sqrt{(a_t/\bar{a}_t)} \eta_t g_t \|g_t\|^2 \right].
\] (31)
To see this, first, if \(\sigma_{t,k} > 0\), we apply the arithmetic inequality \(2ab \leq a^2 + b^2\) with
\[
a = \frac{1}{2\sigma_{t,k}} \sqrt{\hat{n}_{t,k} \eta_{t,k} |\nabla_k f(x_t)||g_{t,k}|} \quad \text{and} \quad b = \frac{\sqrt{(a_t/\bar{a}_t)}}{\eta} \sigma_{t,k} \sqrt{\hat{n}_{t,k} \eta_{t,k} |g_{t,k}|}
\]
to the left-hand side of Eq. (31), arriving at
\[
\frac{\sqrt{(a_t/\bar{a}_t)}}{\eta} \hat{n}_{t,k} \eta_{t,k} |\nabla_k f(x_t)||g_{t,k}| \leq \frac{|g_{t,k}|^2}{4\sigma_{t,k}^2} \hat{n}_{t,k} |\nabla_k f(x_t)|^2 + \frac{(a_t/\bar{a}_t)}{\eta^2} \sigma_{t,k}^2 \hat{n}_{t,k} \eta_{t,k} |g_{t,k}|^2.
\] (32)
Note that \(\mathbb{E}_t |g_{t,k}|^2 = \sigma_{t,k}\),
\[
\hat{n}_{t,k} = \frac{\eta}{\sqrt{\frac{1}{a_t} (\sum_{i=1}^{t-1} a_i g_i^2 + a_t \sigma_{t,k}^2) + \epsilon}} \leq \frac{\eta}{\sqrt{(a_t/\bar{a}_t)} \sigma_{t,k}}
\]
and \(\sigma_{t,k} \leq \sqrt{\mathbb{E}_t |g_t|^2} \leq \sigma\) by assumption (A2). Therefore,
\[
\mathbb{E}_t \left[ \frac{\sqrt{(a_t/\bar{a}_t)}}{\eta} \hat{n}_{t,k} \eta_{t,k} |\nabla_k f(x_t)||g_{t,k}| \right] \leq \frac{1}{4} \hat{n}_{t,k} |\nabla_k f(x_t)|^2 + \frac{1}{\eta} \mathbb{E}_t \left[ \sigma_{t,k} \sqrt{(a_t/\bar{a}_t)} |\eta_{t,k} g_{t,k}| \right]^2
\]
\[
\leq \frac{1}{4} \hat{n}_{t,k} |\nabla_k f(x_t)|^2 + \frac{\sigma}{\eta} \mathbb{E}_t \left[ \sqrt{(a_t/\bar{a}_t)} \eta_{t,k} g_{t,k} \right]^2.
\] (33)
On the other hand, if \(\sigma_{t,k} = 0\), then \(g_{t,k} = 0\), and Eq. (33) holds automatically. By taking sum of the components for \(k = 1, 2, \ldots, d\), we then obtain the desired claim Eq. (31).

Similarly, we apply the arithmetic inequality with
\[
a = \frac{1}{2} \sqrt{\hat{n}_{t,k} |\nabla_k f(x_t)|} \quad \text{and} \quad b = \frac{\sqrt{(a_t/\bar{a}_t)}}{\eta} \sigma_{t,k} \sqrt{\hat{n}_{t,k} \eta_{t,k} |g_{t,k}|}
\]
to the second term of Eq. (30), arriving at
\[
\frac{\sigma_{t,k}}{\eta} \hat{n}_{t,k} \eta_{t,k} \nabla_k f(x_t)||g_{t,k}|| \leq \frac{1}{4} \hat{n}_{t,k} |\nabla_k f(x_t)|^2 + \frac{(a_t/\bar{a}_t)}{\eta^2} \sigma_{t,k}^2 \hat{n}_{t,k} \eta_{t,k} g_{t,k} \|g_{t,k}\|^2
\]
\[
\leq \frac{1}{4} \hat{n}_{t,k} |\nabla_k f(x_t)|^2 + \frac{\sigma}{\eta} \sqrt{(a_t/\bar{a}_t)} \eta_{t,k} g_{t,k} \|g_{t,k}\|^2.
\] (34)
Hence,
\[
\mathbb{E}_t \sum_{k=1}^d \frac{\sigma_{t,k}}{\eta} \hat{n}_{t,k} \nabla_k f(x_t)||g_{t,k}|| \leq \frac{1}{4} \|\nabla f(x_t)\|_{\eta_t}^2 + \frac{\sigma}{\eta} \mathbb{E}_t \left[ \sqrt{(a_t/\bar{a}_t)} \eta_t g_t \|g_t\|^2 \right].
\] (35)
Combining Eq. (30), Eq. (33), and Eq. (35), we obtain the following estimate
\[
\mathbb{E}_t (\nabla f(x_t), (\hat{n}_t - \eta_t) g_t) \leq \frac{1}{2} \|\nabla f(x_t)\|_{\eta_t}^2 + \frac{2\sigma}{\eta} \mathbb{E}_t \left[ \sqrt{(a_t/\bar{a}_t)} \eta_t g_t \|g_t\|^2 \right].
\] (36)
The proof is finished by taking the estimate Eq. (36) into Eq. (27).

**Lemma 5.** Assume that the noisy gradient \(g_t\) in each iteration satisfies assumptions (A1) and (A2). We have the following estimate
\[
\mathbb{E} \sum_{t=1}^T (a_t/\bar{a}_t) \|\eta_t g_t\|^2 \leq \eta^2 d \log \left( 1 + \frac{\sigma^2}{\epsilon} \sum_{t=1}^T a_t \right).
\] (37)
Proof. Let $V_t = \frac{1}{a_t} \sum_{i=1}^t a_t g_i^2$. Then $\eta_t = \eta/\sqrt{V_t + \epsilon}$. We have that
\[
\sum_{t=1}^T \left( \frac{a_t}{\bar{a}_t} \right) \| \eta_t g_t \|^2 = \eta^2 \sum_{t=1}^T \sum_{k=1}^d \left( \frac{a_t}{\bar{a}_t} \right) g_{t,k}^2 \leq \eta^2 \sum_{t=1}^T \sum_{k=1}^d \frac{a_t g_{t,k}^2}{\epsilon^2 + V_{t,k}}
\]
\[
= \eta^2 \sum_{t=1}^T \sum_{k=1}^d \frac{a_t g_{t,k}^2}{\epsilon^2 a_t + \sum_{i=1}^t a_i g_{i,k}^2} \leq \eta^2 \sum_{t=1}^T \sum_{k=1}^d \frac{a_t g_{t,k}^2}{\epsilon^2 + \sum_{i=1}^t a_i g_{i,k}^2}.
\]
The last inequality is due to $\bar{a}_t \geq a_1 = 1$. By Lemma 1, we have that
\[
\sum_{t=1}^T \frac{a_t g_{t,k}^2}{\epsilon^2 + \sum_{i=1}^t a_i g_{i,k}^2} \leq \log \left( \epsilon^2 + \sum_{i=1}^T a_i g_{i,k}^2 \right) - \log(\epsilon^2).
\]
On the other hand, since $\log(x)$ is concave, we have
\[
E \left[ \log \left( \epsilon^2 + \sum_{i=1}^T a_i g_{i,k}^2 \right) \right] \leq \log \left( E \left[ \epsilon^2 + \sum_{i=1}^T a_i g_{i,k}^2 \right] \right) \leq \log \left( \epsilon^2 + \sigma^2 \sum_{i=1}^T a_i \right).
\]
Hence,
\[
E \sum_{t=1}^T \left( \frac{a_t}{\bar{a}_t} \right) \| \eta_t g_t \|^2 \leq \eta^2 \sum_{k=1}^d \left( \log \left( \epsilon^2 + \sigma^2 \sum_{i=1}^T a_i \right) - \log(\epsilon^2) \right)
\]
\[
\leq \eta^2 d \log \left( 1 + \frac{\sigma^2}{\epsilon^2} \sum_{i=1}^T a_i \right).
\]

\[\square\]

**Lemma 6** (Proof of Theorem 10 in [33]). Let $\bar{V}_t$ be defined as in Lemma 3. Assume that the noisy gradients $g_t$ satisfy assumptions (A1) and (A2). Let $\tau$ be randomly selected from $\{1, 2, \ldots, T\}$ with equal probability $P(\tau = t) = 1/T$. We have the following estimate
\[
\left( E\| f(x_{\tau}) \|^{4/3} \right)^{3/2} \leq \frac{\sqrt{2\epsilon^2 + 2\sigma^2 T}}{\eta T} E \sum_{t=1}^T \| \nabla f(x_t) \|_{\bar{V}_t}^2.
\]

Proof. We cite the proof form [33]. Let $\hat{V}_t = \frac{1}{a_t} \left( \sum_{i=1}^{t-1} g_i^2 + a_t \sigma_t^2 \right)$, where $\sigma_t = \sqrt{E_i g_i^2}$, we have $\eta_t = \eta/\sqrt{\hat{V}_t + \epsilon})$. By Hölder’s inequality we have $E[XY] \leq (E|X|^p)^{1/p} (E|Y|^q)^{1/q}$ for any $0 < p, q < 1$ with $1/p + 1/q = 1$. Now taking $p = 3/2$ and $q = 3$, we have
\[
X = \left( \frac{\| \nabla f(x_t) \|^2}{\epsilon + \sqrt{\| V_t \|_1}} \right)^{2/3}, \quad Y = \left( \epsilon + \sqrt{\| V_t \|_1} \right)^{1/3},
\]
we have
\[
E\| \nabla f(x_t) \|^{4/3} \leq \left( E\| \nabla f(x_t) \|^2 / \epsilon + \sqrt{\| V_t \|_1} \right)^{2/3} \left( E\left[ \left( \epsilon + \sqrt{\| V_t \|_1} \right)^2 \right] \right)^{1/3}.
\]
Namely,
\[
\left( E\| \nabla f(x_t) \|^{4/3} \right)^{3/2} \leq \left( E\| \nabla f(x_t) \|^2 / \epsilon + \sqrt{\| V_t \|_1} \right) \left( E\left[ \left( \epsilon + \sqrt{\| V_t \|_1} \right)^2 \right] \right)^{1/2}.
\]
Note that
\[
\frac{\| \nabla f(x_t) \|^2}{\epsilon + \sqrt{\| V_t \|_1}} = \sum_{k=1}^d \frac{\| \nabla_k f(x_t) \|^2}{\epsilon + \sqrt{\| V_t \|_1}} \leq \frac{1}{\eta} \sum_{k=1}^d \frac{\eta \| \nabla_k f(x_t) \|^2}{\epsilon + \sqrt{\| V_{t,k} \|_1}} = \frac{1}{\eta} \sum_{k=1}^d \frac{\eta_t \| \nabla_k f(x_t) \|^2}{\epsilon + \sqrt{\| V_{t,k} \|_1}} = \frac{1}{\eta} \| \nabla f(x_t) \|^2.
\]
On the other hand, for any \( t \leq T \) we have
\[
\mathbb{E} \left[ \left( \epsilon + \sqrt{\|\mathbf{V}_t\|_1} \right)^2 \right] \leq \mathbb{E} \left[ 2 \left( \epsilon^2 + \|\mathbf{V}_t\|_1 \right) \right] = 2 \epsilon^2 + 2 \mathbb{E} \sum_{k=1}^{d} \frac{1}{\bar{a}_t} \left( \sum_{i=1}^{t-1} a_i g_{i,k}^2 + a_t \sigma_{i,k}^2 \right)
\]
\[
= 2 \epsilon^2 + 2 \sum_{i=1}^{t} (a_i/\bar{a}_t) \mathbb{E} \|g_i\|^2 \leq 2 \epsilon^2 + 2 \sigma^2 t \leq 2 \epsilon^2 + 2 \sigma^2 T.
\]

Hence, by Eq. (41), Eq. (42), and Eq. (43), we have
\[
\left( \mathbb{E} \| \nabla f(x_t) \|^{4/3} \right)^{3/2} \leq \frac{\sqrt{2 \epsilon^2 + 2 \sigma^2 T}}{\eta} \mathbb{E} \| \nabla f(x_t) \|_{\hat{\eta}_t}^2, \forall t \leq T.
\]
It follows that
\[
\left( \mathbb{E} \| f(x_t) \|^{4/3} \right)^{3/2} = \left( \frac{1}{T} \sum_{t=1}^{T} \mathbb{E} \| \nabla f(x_t) \|^{4/3} \right)^{3/2} \leq \frac{1}{T} \sum_{t=1}^{T} \left( \mathbb{E} \| \nabla f(x_t) \|^{4/3} \right)^{3/2}
\]
\[
\leq \frac{\sqrt{2 \epsilon^2 + 2 \sigma^2 T}}{\eta T} \mathbb{E} \sum_{t=1}^{T} \| \nabla f(x_t) \|_{\hat{\eta}_t}^2.
\]
The proof is completed. \( \square \)

## C Proof of Theorem 1

In this section we prove our main theorem 1. We restate the theorem for readers’ convenience.

**Theorem.** Let \( \{x_t\} \subseteq \mathbb{R}^d \) be a sequence generated by AdaUSM. Assume that the noisy gradient \( g_t \) in each iteration satisfies assumptions (A1) and (A2). Suppose that the sequence of weights \( \{a_t\} \) is non-decreasing. Let \( \tau \) be randomly selected from \( \{1, 2, \ldots, T\} \) with equal probability \( \mathbb{P}(\tau = t) = 1/T \). Then we have the following estimate
\[
\left( \mathbb{E} \left[ \| \nabla f(x_t) \|^{4/3} \right] \right)^{3/2} \leq \text{Bound}(T) = O \left( \log T / \sqrt{T} \right),
\]
where
\[
\text{Bound}(T) = \frac{\sqrt{2 \epsilon^2 + 2 \sigma^2 T}}{T} \left[ \frac{2(f(x_1) - f^*)}{(1 + \lambda \mu) \eta} + \left( \frac{2 \eta (1 + 2 \lambda)^2 Ld}{(1 + \lambda \mu)(1 - \mu)^3} + \frac{4d}{1 - \mu} \right) \log \left( 1 + \frac{\sigma^2}{\epsilon^2} \sum_{t=1}^{T} a_t \right) \right].
\]

The key ingredient of the proof of the theorem is the following estimate which we will prove later.

**Lemma 7.** Assume the same setting as Theorem 1. We have the following estimate
\[
\mathbb{E} \left[ \sum_{t=1}^{T} \| \nabla f(x_t) \|_{\hat{\eta}_t}^2 \right] \leq \frac{2(f(x_1) - f^*)}{1 + \lambda \mu} + \left( \frac{2(1 + 2 \lambda)^2 Ld}{(1 + \lambda \mu)(1 - \mu)^3} + \frac{4d}{\eta (1 - \mu)} \right) \mathbb{E} \left[ \sum_{t=1}^{T} (a_t/\bar{a}_t) \| g_t \|^2 \right].
\]

where \( \hat{\eta}_t \) is defined as in Lemma 4.

**Proof of Theorem.** The theorem is an immediate result of Lemma 7, Lemma 5, and Lemma 6. \( \square \)

**Proof of Lemma 7.** Since \( x_{t+1} = x_t + m_t + \lambda \mu (m_t - m_{t-1}) \), it follows by Lipschitz continuity of the gradient of \( f \) and the descent lemma in [25] that
\[
f(x_{t+1}) \leq f(x_t) + \langle \nabla f(x_t), m_t + \lambda \mu (m_t - m_{t-1}) \rangle + \frac{L}{2} \| m_t + \lambda \mu (m_t - m_{t-1}) \|^2.
\]
Since \( m_t = \mu m_{t-1} - \eta_t g_t \), it follows that
\[
f(x_{t+1}) \leq f(x_t) + \langle \nabla f(x_t), (1 + \lambda \mu - \lambda) m_t - \lambda \eta_t g_t \rangle + \frac{L}{2} \| m_t + \lambda \mu (m_t - m_{t-1}) \|^2
\]
\[
\leq f(x_t) + (1 + \lambda \mu - \lambda) \langle \nabla f(x_t), m_t \rangle - \lambda \langle \nabla f(x_t), \eta_t g_t \rangle + \frac{L}{2} \| m_t + \lambda \mu (m_t - m_{t-1}) \|^2.
\]
By Lemma 3, we have

\[
\langle \nabla f(x_i), m_t \rangle \leq (1 + 2\lambda) L \sum_{i=1}^{t-1} \|m_i\|^2 \mu^{t-i} - \sum_{i=1}^{t} \langle \nabla f(x_i), \eta_t g_t \rangle \mu^{t-i}. \tag{49}
\]

Note that \(1 + \lambda \mu - \lambda \geq 0\) since \(\lambda \leq 1/(1 - \mu)\). Combining Eq. (48) and Eq. (49), we have

\[
f(x_{t+1}) \leq f(x_t) + (1 + \lambda \mu - \lambda)(1 + 2\lambda)L \sum_{i=1}^{t-1} \|m_i\|^2 \mu^{t-i} + \frac{L}{2} \|m_t + \lambda \mu (m_t - m_{t-1})\|^2 \\
- (1 + \lambda \mu - \lambda) \sum_{i=1}^{t} \langle \nabla f(x_i), \eta_t g_t \rangle \mu^{t-i} - \lambda \langle \nabla f(x_t), \eta_t g_t \rangle. \tag{50}
\]

On one hand, by arithmetic inequality, we have

\[
\|m_t + \lambda \mu (m_t - m_{t-1})\|^2 \leq 2(1 + \lambda \mu)^2 \|m_t\|^2 + 2(\lambda \mu)^2 \|m_{t-1}\|^2. \tag{51}
\]

Hence,

\[
(1 + \lambda \mu - \lambda)(1 + 2\lambda)L \sum_{i=1}^{t-1} \|m_i\|^2 \mu^{t-i} + \frac{L}{2} \|m_t + \lambda \mu (m_t - m_{t-1})\|^2 \\
\leq (1 + \lambda \mu)(1 + 2\lambda)L \sum_{i=1}^{t-1} \|m_i\|^2 \mu^{t-i} - \lambda(1 + 2\lambda)\mu L \|m_{t-1}\|^2 + (1 + \lambda \mu)^2 L \|m_t\|^2 + (\lambda \mu)^2 L \|m_{t-1}\|^2 \\
\leq (1 + 2\lambda)^2 L \sum_{i=1}^{t} \|m_i\|^2 \mu^{t-i}. \tag{52}
\]

Summarize Eq. (50) and Eq. (52), we have the following cleaner inequality:

\[
f(x_{t+1}) \leq f(x_t) + (1 + 2\lambda)^2 L \sum_{i=1}^{t} \|m_i\|^2 \mu^{t-i} - (1 + \lambda \mu - \lambda) \sum_{i=1}^{t} \langle \nabla f(x_i), \eta_t g_t \rangle \mu^{t-i} \\
- \lambda \langle \nabla f(x_t), \eta_t g_t \rangle. \tag{53}
\]

On the other hand, by Lemma 3, we have that

\[
-\mathbb{E}_i(f(x_i), \eta_t g_t) \leq -\frac{1}{2} \|\nabla f(x_i)\|_{\eta_i}^2 + \frac{2\sigma}{\eta} \mathbb{E}_i \left[ \sqrt{(a_i/\bar{a}_i)}\|\eta_t g_t\|^2 \right] \\
\leq -\frac{1}{2} \|\nabla f(x_i)\|_{\eta_i}^2 + \frac{2\sigma}{\eta} \mathbb{E}_i \left[ (a_i/\bar{a}_i)\|\eta_t g_t\|^2 \right], \forall i. \tag{54}
\]

The second inequality is due to that \((a_i/\bar{a}_i) \geq 1\), so \(\sqrt{(a_i/\bar{a}_i)} \leq (a_i/\bar{a}_i)\). Combining Eq. (53) and Eq. (54), taking sum from 1 to \(T\) and taking expectation, followed by moving the gradient square terms to the left-hand side, we obtain that

\[
(1 + \lambda \mu - \lambda) \mathbb{E} \sum_{t=1}^{T} \sum_{i=1}^{t} \frac{1}{2} \|\nabla f(x_i)\|_{\eta_i}^2 \mu^{t-i} + \lambda \mathbb{E} \sum_{t=1}^{T} \frac{1}{2} \|\nabla f(x_t)\|_{\eta_t}^2 \\
\leq f(x_1) - f^* + (1 + 2\lambda)^2 L \mathbb{E} \sum_{t=1}^{T} \sum_{i=1}^{t} \|m_i\|^2 \mu^{t-i} \\
+ \frac{2\sigma}{\eta} \left[ (1 + \lambda \mu - \lambda) \mathbb{E} \sum_{t=1}^{T} \sum_{i=1}^{t} (a_i/\bar{a}_i)\|\eta_t g_t\|^2 \mu^{t-i} + \lambda \mathbb{E} \sum_{t=1}^{T} (a_i/\bar{a}_i)\|\eta_t g_t\|^2 \right] \\
\leq f(x_1) - f^* + (1 + 2\lambda)^2 L \mathbb{E} \sum_{t=1}^{T} \sum_{i=1}^{t} \|m_i\|^2 \mu^{t-i} + \frac{2\sigma(1 + \lambda \mu)}{\eta} \mathbb{E} \sum_{t=1}^{T} \sum_{i=1}^{t} (a_i/\bar{a}_i)\|\eta_t g_t\|^2 \mu^{t-i}. \tag{55}
\]
The last inequality is due to $\lambda \sum_{t=1}^{T}(a_t/\bar{a}_t)\|\eta_t g_t\|^2 \leq \lambda \sum_{t=1}^{T} \sum_{i=1}^{t}(a_i/\bar{a}_i)\|\eta_t g_t\|^2 \mu^{t-i}$. Similarly, for the left-hand side, note that $1 + \lambda \mu - \lambda \geq 0$ since $\lambda \leq 1/(1 - \mu)$, we have that
\[
(1 + \lambda \mu - \lambda) \sum_{t=1}^{T} \sum_{i=1}^{t} \|\nabla f(x_t)\|_{\eta_t}^2 \mu^{t-i} + \lambda \sum_{t=1}^{T} \|\nabla f(x_t)\|_{\eta_t}^2 \geq (1 + \lambda \mu - \lambda) \sum_{t=1}^{T} \|\nabla f(x_t)\|_{\eta_t}^2 + \lambda \sum_{t=1}^{T} \|\nabla f(x_t)\|_{\eta_t}^2
\]
\[
= (1 + \lambda \mu) \sum_{t=1}^{T} \|\nabla f(x_t)\|_{\eta_t}^2.
\]

Now we are left to estimate the third term and the last term in the right-hand side of Eq. (55). We apply the double-sum trick\[
\sum_{t=1}^{T} \sum_{i=1}^{t} \|\eta_t g_t\|^2 \mu^{t-i} = \sum_{t=1}^{T} \sum_{i=1}^{t} \|\eta_t g_t\|^2 \mu^{t-i} \leq \frac{1}{1 - \mu} \sum_{t=1}^{T} \|\eta_t g_t\|^2.
\]
\[
\sum_{t=1}^{T} \sum_{i=1}^{t} \|\eta_t g_t\|^2 \mu^{t-i} = \sum_{t=1}^{T} \sum_{i=1}^{t} \|\eta_t g_t\|^2 \mu^{t-i} \leq \frac{1}{1 - \mu} \sum_{t=1}^{T} \|\eta_t g_t\|^2.
\]
Combining Eq. (55), Eq. (56), Eq. (57), and Eq. (58), we have\[
\frac{1 + \lambda \mu}{2} \mathbb{E} \left[ \sum_{t=1}^{T} \|\nabla f(x_t)\|_{\eta_t}^2 \right] \leq f(x_1) - f^* + \frac{(1 + 2\lambda)^2 L}{1 - \mu} \mathbb{E} \left[ \sum_{t=1}^{T} \|m_t\|^2 \right] + \frac{2\sigma(1 + \lambda \mu)}{\eta(1 - \mu)} \mathbb{E} \left[ \sum_{t=1}^{T} (a_t/\bar{a}_t)\|\eta_t g_t\|^2 \right].
\]
\[
\mathbb{E} \left[ \sum_{t=1}^{T} \|m_t\|^2 \right] \leq \frac{1}{(1 - \mu)^2} \mathbb{E} \sum_{t=1}^{T} \|\eta_t g_t\|^2 \leq \frac{1}{(1 - \mu)^2} \mathbb{E} \left[ \sum_{t=1}^{T} (a_t/\bar{a}_t)\|\eta_t g_t\|^2 \right].
\]
Combining Eq. (59) and Eq. (60), we obtain\[
\mathbb{E} \left[ \sum_{t=1}^{T} \|\nabla f(x_t)\|_{\eta_t}^2 \right] \leq \frac{2(f(x_1) - f^*)}{1 + \lambda \mu} + \left( \frac{(1 + 2\lambda)^2 L}{(1 + \lambda \mu)(1 - \mu)} + \frac{4\sigma}{\eta(1 - \mu)} \right) \mathbb{E} \left[ \sum_{t=1}^{T} (a_t/\bar{a}_t)\|\eta_t g_t\|^2 \right].
\]
The proof is completed.
