Wick rotation in two variables
on analytic backgrounds

Michał Wrochna

Abstract. We set up a general framework for Calderón projectors (and their
generalization to non-compact manifolds), associated with complex Laplacians
obtained by Wick rotation of a Lorentzian metric. In the analytic case, we use
this to show that the Laplacian’s Green’s functions have analytic continuation
whose boundary values are two-point functions of analytic Hadamard states.
We then describe how thermal states are obtained as a special case of this
construction.

1. Introduction and summary

1.1. Introduction. One of the cornerstones of Quantum Field Theory on Minko-
wski space is the analytic continuation of Euclidean theories down to the Lorentzian
signature known as the Wick rotation. Its generalization to curved spacetimes is
far from being a settled issue, and one can argue that it is an increasingly pressing
one in view of recent advances in the Euclidean signature [DZ]. Nevertheless, tech-
niques based on a Wick rotation have been successfully applied to several problems,
including local aspects of Hadamard-parametrix based renormalization [Mo], and
global index computations on perturbations of Minkowski space [GHV].

More recently, a new proposal has been made in the context of constructing
linear Klein-Gordon quantum fields via their two-point functions. Building on an
idea due to Gérard [Gé1], it was shown in [GW] that pairs of two-point functions
Λ± ∈ D′(M^2) on an analytic spacetime (M, g) can be constructed in terms of
Calderón projectors for a Wick-rotated elliptic problem. Under global hyperbolici-
ety assumptions for (M, g), it turned out possible to control the properties required
of two-point functions, i.e. their positivity and the microlocal Hadamard condition.

The construction made use of analytically continuing the Klein-Gordon operator
P to its elliptic counterpart, denoted here by K. However, the objects directly
relevant for QFT, namely the Lorentzian two-point functions Λ± and the elliptic
inverse K−1, were connected from the outset only in an indirect way, through
Cauchy data of the former and Calderón projectors associated with the latter.

The main goal of the present work is to show that Λ± and K−1 are actually
directly related by Wick rotation.

Our results are valid in a more general setting than in [GW], where Wick rotation
was tied to the choice of Gaussian normal coordinates, and K−1 was constructed by
imposing Dirichlet boundary conditions close to the Wick-rotated Cauchy surface.
Inspired by ideas from the recent work [Gé2], we use a more covariant framework
for the Calderón projectors, and we also allow for more general operators that are
not projectors. Furthermore, rather than selecting specific boundary conditions,
we work with an abstract set of properties required of K−1, which can be met in
various different situations. Our main motivation was to include cases like thermal

Acknowledgments. The author is very grateful to Christian Gérard for inspiring discussions and
helpful suggestions. Support from the grant ANR-16-CE40-0012-01 is gratefully acknowledged.
states in the form in which they appear in Gérard’s construction of the Hartle-Hawking-Israel state \([\mathcal{G}\mathcal{E}]\) [G2], where periodic boundary conditions have to be imposed.

1.2. Main result. We consider a globally hyperbolic spacetime \((M, g)\), which is a neighborhood of \(\{t = 0\}\) in \(\mathbb{R}_+ \times \Sigma\), with \(\Sigma\) analytic, and where \(g\) is an analytic metric of the form

\[
g = -N^2(t) dt^2 + h_{jk}(t)(dy^j + w^j(t) dt)(dy^k + w^k(t) dt).
\]

We assume that the coefficients are entire and real-analytic in a neighborhood of \(t = 1.2\).

We need \(\Lambda\) imposed.

We consider the Klein-Gordon and ‘complex Wick-rotated complex metric. We assume that the coefficients are entire and real-analytic in

\[t \in \mathbb{R}_+,\]

for the Wick-rotated complex metric. We consider the Klein-Gordon and ‘complex Laplace-Beltrami’ operators:

\[
P = -|g|^{-\frac{1}{2}} \partial_a |g|^{\frac{1}{2}} g^{ab} \partial_b + \lambda, \quad K = -|k|^{-\frac{1}{2}} \partial_a k^{ab} |k|^\frac{1}{2} \partial_b + \lambda.
\]

for some real-analytic function \(\lambda\). Note that \(K\) is not necessarily formally self-adjoint; instead, its formal adjoint \(K^*\) equals \(\kappa \circ K \circ \kappa\), where \((\kappa u)(s, y) = u(-s, y)\).

We need \(K\) to be elliptic and invertible on a suitable domain, which is taken care of by assuming Hypothesis 2.1 and Hypothesis 2.7 in the main part of the text. With these assumptions, disregarding the spatial variables when writing Schwartz kernels, we have:

**Theorem 1** (cf. Thm. 4.9). There exists \(\delta > 0\), a pair of two-point functions \(\Lambda^\pm\) for \(P\), and a pair of holomorphic functions \(F^\pm\) of two variables with values in \(\mathcal{D}'(\Sigma^2)\) such that:

\[
K^{-1}(s_1, s_2) = F^\pm(is_1, is_2), \quad \pm s_1 > 0, \quad \pm s_2 < 0,
\]

\[
\Lambda^\pm(t_1, t_2) = F^\pm((t_1, t_2) \pm i\delta), \quad t_1, t_2 \in [-\delta, \delta],
\]

the last expression meaning the limit \((s_1, s_2) \to 0\) from \(\pm \delta = \{\pm s_1 > 0, \quad \pm s_2 < 0\}\).

Here, we adopt the terminology which is conventional for charged fields, see [GW] for a more detailed introduction. In particular, by two-points functions we mean bi-solutions \(\Lambda^\pm \in \mathcal{D}'(M^2)\) of the Klein-Gordon equation which are Schwartz kernels of positive operators on \(C_c^\infty(M)\), and which satisfy \(\Lambda^+ - \Lambda^- = iG\), with \(G\) a prescribed bi-solution called the Pauli-Jordan or causal propagator. To fulfill those conditions, we construct \(\Lambda^\pm\) as in [GW] by specifying their Cauchy data at \(t = 0\) in terms of operators generalizing the Calderón projectors associated with \(K^{-1}\), and then the fact that \(\Lambda^\pm\) are two-point functions boils down to a careful analysis of these operators. In particular, the property \(\Lambda^\pm \geq 0\) is a consequence of a weak version of reflection positivity at zero imaginary time. The proof of (1.1) makes use of the resulting formulæ and their symmetries, combined with a generalized version of the method developed in [GW], which in turn is a distributional version of an argument due to Schapira in the \(D\)-module setting [Sch].

1.3. Summary. In Section 2 we define and prove basic properties of what we call Calderón operators for complex Laplacians. The framework there is general and does not use analyticity. Section 3 introduces the geometric setup for Wick rotation and describes how the two-point functions \(\Lambda^\pm\) are obtained from Calderón operators. Section 4 contains the proof of the main results of the paper. Finally, in Section 5 we show that the KMS condition for \(\Lambda^\pm\) arises as a simple corollary of periodic boundary conditions in the stationary case.
2. Calderón operators

2.1. Complex metrics. In the present section we will consider a geometric setup introduced recently by Gérard [Gé2 Sec. 9.1], and study operators that generalize the Calderón projectors, considered usually for real Laplacians on compact manifolds, see e.g. [GW]. We also generalize the recent analysis from [GW] [Gé2].

If \( X \) is a smooth manifold, we denote by \( T^p_q(X) \) the space of smooth, real valued \((p, q)\) tensors on \( X \) and by \( \text{CT}^p_q(X) \) its complexification. A complex metric on \( X \) is a symmetric and non-degenerate element \( g = g_{ab}(x)dx^a dx^b \) of \( \text{CT}^0_0(X) \).

Let \( \mathbf{k} = k_{ab}(x)dx^a dx^b \) be a complex metric on an orientable smooth manifold \( X \). We will assume the following:

**Hypothesis 2.1.**

1. \( \mathbf{k} \) is coercive, i.e., there exists a continuous function \( C : X \to ]0, +\infty[ \) s.t.
   \[
   |\text{Im}(\tau^a k_{ab}(x) v^b)| \leq C(x) \text{Re}(\tau^a k_{ab}(x) v^b), \quad \forall x \in X, \quad v \in \text{CT}^0_0 X.
   \]
2. \( |\mathbf{k}(x)| = \det(k_{ab}(x)) > 0, \quad \forall x \in X.\)

**Remark 2.2.** If \( \mathbf{k} \) is coercive then also \( \mathbf{k}^{-1} \) is coercive, i.e., there exists a continuous function \( C : X \to ]0, +\infty[ \) s.t.
   \[
   |\text{Im}(\bar{\tau}_a k^{ab}(x) \xi_b)| \leq C(x) \text{Re}(\bar{\tau}_a k^{ab}(x) \xi_b), \quad \forall x \in X, \quad \xi \in \text{CT}^*_0 X.
   \]

2.2. Laplacians. We can define the Christoffel symbols:
   \[
   \Gamma^c_{ab} := \frac{1}{2} k^{cd} (\partial_a k_{cd} + \partial_b k_{cd} - \partial_d k_{ab}),
   \]
   and the covariant derivative:
   \[
   \nabla^{(k)}_a T^b = \partial_a T^b + \Gamma^b_{ac} T^c.
   \]
   By a direct computation one can show that we have the same identity as in the pseudo-riemannian case, namely:
   \[
   \nabla^{(k)}_a T^a = |\mathbf{k}|^{-\frac{1}{2}} \partial_a (|\mathbf{k}|^{\frac{1}{2}} T^a),
   \]
   see [Gé2 Sec. A.3].

Let \( \lambda \in C^\infty(X; \mathbb{R}) \). We consider the elliptic differential operator
   \[
   K := -\nabla^{(k)}_a k^{ab} \nabla^{(k)}_b + \lambda = -|\mathbf{k}|^{-\frac{1}{2}} \partial_a |\mathbf{k}|^{\frac{1}{2}} \partial_b + \lambda
   \]
   The differential operator \(-\nabla^{(k)}_a k^{ab} \nabla^{(k)}_b\) is what one could call the Laplace-Beltrami operator associated to the complex metric \( \mathbf{k} \). Denoting by \( K^* \) the formal adjoint of \( K \) for the scalar product
   \[
   (v|u) := \int_X \overline{\nabla u} |\mathbf{k}|^{\frac{1}{2}} dx,
   \]
   we obtain that:
   \[
   K^* = -|\mathbf{k}|^{-\frac{1}{2}} \overline{\partial_a |\mathbf{k}|^{\frac{1}{2}}} \overline{\partial_b} + \lambda = -\nabla^{(\bar{k})}_a \overline{k}^{ab} \nabla^{(\bar{k})}_b + \lambda.
   \]

2.3. Gauss-Green formula. Let \( \Omega^+ \subset X \) be an open set with a (not necessarily connected) smooth boundary. We denote the complement of its closure by
   \[
   \Omega^- := X \backslash \overline{\Omega^+}.
   \]
   The regions \( \Omega^+ \) and \( \Omega^- \) have a common boundary, which will be denoted by \( \partial \Omega \).
In the complex setting, the outer unit normal vector field to \( \partial \Omega \), denoted by \( n \in \mathcal{C}TX \), is defined by the conditions:

\[
\begin{align*}
    a) & \quad n(x) \cdot k(x)v = 0, \quad \forall v \in T_x \partial \Omega, \\
    b) & \quad n(x) \cdot k(x)n(x) = 1, \\
    c) & \quad \text{Re } n(x) \text{ is outwards pointing.}
\end{align*}
\]

If \( f \in C^\infty(X; \mathbb{R}) \) is a boundary-defining function for \( \partial \Omega \), in the sense that \( \Omega \) is locally given by \( \{ f > 0 \} \) and \( df \neq 0 \) on \( \{ f = 0 \} \), then

\[
    n^a = -\frac{k^a \nabla_b f}{(\nabla_a f k^{ib} \nabla_b f)^{1/2}}.
\]

We will also need the following condition:

\[
    d) \quad \text{Im } n(x) \in T_x \partial \Omega.
\]

This is equivalent to \( \nabla_a f k^{ib} \nabla_b f \in \mathbb{R} \) on \( \partial \Omega \). We will consider the following situation, in which \( d) \) holds:

**Hypothesis 2.3.** Assume there exists a diffeomorphism \( \kappa : X \to X \) such that

\[
    \kappa^* k = \overline{k}, \quad \kappa \circ \kappa = \text{Id}, \quad \kappa : \Omega^+ \to \Omega^- \text{ homeomorphically, and } \kappa : \partial \Omega \to \partial \Omega \text{ for each connected component } \partial \Omega \text{ of } \partial \Omega.
\]

We will denote by the same letter \( \kappa \) the pullback \( \kappa : \mathcal{D}'(X) \to \mathcal{D}'(X) \).

**Lemma 2.4.** Hypothesis \( \text{Lemma}2.3 \) has the following consequences:

\[
\begin{align*}
    1) & \quad D_x \kappa n(x) = -\overline{\nabla}(x) \quad \forall x \in \partial \Omega, \\
    2) & \quad \text{Im } n(x) \in T_x \partial \Omega \quad \forall x \in \partial \Omega, \\
    3) & \quad K^* = \kappa \circ \kappa \circ \kappa.
\end{align*}
\]

**Proof.** We have \( \overline{\nabla}(x) \cdot k(x)v = 0, \quad \overline{\nabla}(x) \cdot \overline{k}(x)\overline{\nabla}(x) = 1 \) and \( \text{Re } \overline{\nabla}(x) \) is outwards pointing for \( x \in \partial \Omega \). Since \( D_x \kappa = 1 \) on \( T_x \partial \Omega \) and \( \kappa^* k = \overline{k} \), this implies that \( D_x \kappa \overline{\nabla} \cdot k(x)v = 0, \quad D_x \kappa \overline{\nabla} \cdot k(x)D_x \kappa \overline{\nabla} = 1 \), and since \( \kappa : \Omega^+ \to \Omega^- \), \( D_x \kappa \overline{\nabla}(x) \) is inwards pointing, hence \( D_x \kappa \overline{\nabla}(x) = -n(x) \), which proves 1).

We also have \( v \in T_x \partial \Omega \) iff \( D_x \kappa v = v \) and \( D_x \kappa \text{Im } n = \frac{1}{2i} D_x \kappa (n-\overline{n}) = \frac{1}{2i} (-\overline{n}+n) \).

This proves 2).

Finally, 3) is a direct corollary of \( \kappa^* k = \overline{k} \) and \( \text{Lemma}2.3 \). \( \Box \)

We denote by \( h \) the complex metric induced by \( k \) on \( \partial \Omega \), by \( \text{dVol}_h = |k|^{|\frac{1}{2}} dx^1 \wedge \cdots \wedge dx^n \) the volume form on \( X \), and by \( \text{dVol}_h \) the volume form on \( \partial \Omega \). The associated densities are \( d\mu_h = |\text{dVol}_h| \) and \( d\sigma_h = |\text{dVol}_h| \).

If \( i : \partial \Omega \to X \) is the injection, \( \omega \in \Lambda^\ast(X) \) and \( V \in TX \), we recall that \( i^* \omega = i^*(V \cdot \omega) \). One can show that

\[
i^* \text{dVol}_h = \text{dVol}_h, \quad i^* d\mu_h = d\sigma_h.
\]

This allows one to obtain the Gauss-Green formula:

\[
\int_{\Omega^+} \nabla_a^{(k)} v^a d\mu_k = \int_{\partial \Omega} v^a n_a d\sigma_h.
\]
2.4. Several identities. We have the following consequences of (2.5).

Lemma 2.5. For any \( u \in C^\infty(X) \) and \( v \in C^\infty(X) \), we have:

\[
\int_{\Omega^+} (\nabla K u - K \nabla^\Omega v) d\mu_k = \int_{\partial\Omega} \left( n^a \nabla_a (\nabla^\Omega u) - \nabla_a (\nabla^\Omega v) u \right) d\sigma_\Omega.
\]

(2.6)

\[
\int_{\Omega^+} \nabla K u + \nabla K \nabla^\Omega v d\mu_k = 2 \int_{\Omega^+} \left( \nabla_a (\nabla^\Omega v) + \lambda \nabla u \right) d\mu_k
\]

- \int_{\partial\Omega} \left( n^a \nabla_a \nabla^\Omega (\nabla^\Omega u) + \nabla_a \nabla^\Omega (\nabla^\Omega v) u \right) d\sigma_\Omega.
\]

(2.7)

Proof. For \( V^a = \nabla_b \nabla^b (\nabla^k u) \) we obtain \( \nabla_a V^a = \nabla_b \nabla^b (\nabla^k u) - \nabla K u \), hence by (2.5):

\[
\int_{\Omega^+} \nabla K u d\mu_k = \int_{\Omega^+} \left( \nabla_a (\nabla^k u) \nabla_b \nabla^k u + \lambda \nabla u \right) d\mu_k - \int_{\partial\Omega} \nabla_a \nabla^k (\nabla^k u) u d\sigma_\Omega.
\]

(2.8)

The same identity replacing \( \nabla^k u \) by \( \nabla^k u \) gives:

\[
\int_{\Omega^+} \nabla K u d\mu_k = \int_{\Omega^+} \left( \nabla_a (\nabla^k u) \nabla_b \nabla^k u + \lambda \nabla u \right) d\mu_k - \int_{\partial\Omega} \nabla_a \nabla^k (\nabla^k u) u d\sigma_\Omega,
\]

which by taking complex conjugates gives:

\[
\int_{\Omega^+} \overline{\nabla K u} d\mu_k = \int_{\Omega^+} \left( \nabla_a (\nabla^k u) \nabla_b \nabla^k u + \lambda \nabla u \right) d\mu_k - \int_{\partial\Omega} \overline{\nabla_a \nabla^k (\nabla^k u) u} d\sigma_\Omega,
\]

(2.9)

since \( \overline{\nabla^k u} = \nabla^k \overline{u} = \nabla^k u \). Subtracting (2.9) from (2.8) gives (2.6).

Let us now show (2.7). Since \( d\mu_k \) is real we have \( (K u | v) = (u | K v) \), hence using (2.8) twice we obtain:

\[
\int_{\Omega^+} \nabla K u + \nabla K \nabla^\Omega v d\mu_k = \int_{\Omega^+} \left( \nabla_a (\nabla^k u) \nabla_b \nabla^k u + \nabla_b \nabla^k \nabla_a \nabla^k u + 2 \lambda \nabla u \right) d\mu_k
\]

- \int_{\partial\Omega} \left( n^a \nabla_a \nabla^k (\nabla^k u) u + \nabla_a \nabla^k (\nabla^k v) u \right) d\sigma_\Omega,
\]

which yields the desired result. \( \square \)

If \( F(X) \subset \mathcal{D}'(X) \) is a space of distributions, we denote by \( F(\Omega^\pm) \subset \mathcal{D}'(\Omega^\pm) \) the space of restriction of elements of \( F(X) \) to \( \Omega^\pm \). This way, for instance, \( C^\infty(\Omega^\pm) \) is the space of smooth functions on \( \Omega^\pm \), smoothly extendible across \( \partial\Omega \), and with compact support in \( X \). We will also frequently use the spaces \( H^s(\Omega^\pm) \) and \( H^s_{\text{loc}}(\Omega^\pm) \) for \( s \in \mathbb{R} \), which are obtained by restricting elements of the compactly supported and local Sobolev spaces \( H^s(X) \) and \( H^s_{\text{loc}}(X) \).

We set for \( u \in C^\infty(\Omega^\pm) \):

\[
\gamma^\pm u := \left( \frac{u|\gamma^\pm}{\gamma^\pm | u} \right)_{\partial\Omega}.
\]

where the trace is taken from \( \Omega^\pm \). We denote by \( \langle \cdot | \cdot \rangle_{\Omega^\pm} \) the scalar product induced from \( \langle \cdot | \cdot \rangle \) on \( \Omega^\pm \).

Proposition 2.6. Let \( u \in H^1(\Omega^\pm) \) and \( v \in H^1_{\text{loc}}(\Omega^\pm) \), or \( u \in H^1_{\text{loc}}(\Omega^\pm) \) and \( v \in H^1_{\text{loc}}(\Omega^\pm) \). Then:

i) \( \langle v | K u \rangle_{\Omega^\pm} = \langle K^* v | u \rangle_{\Omega^\pm} = \pm (\gamma^\pm v | S \gamma^\pm u)_{\partial\Omega} \),

ii) \( \langle v | K u \rangle_{\Omega^\pm} + \langle K v | u \rangle_{\Omega^\pm} = 2 \int_{\Omega^\pm} (\nabla_a \nabla_b V^a \nabla^b V^b + \lambda u) d\mu_k + (\gamma^\pm v | q \gamma^\pm u)_{\partial\Omega} \),
where
\begin{equation}
q = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad S = \begin{pmatrix} 2ib^* & -1 \\ 1 & 0 \end{pmatrix},
\end{equation}
where \(b = \text{Im} \nu \nabla_a\) and \(b^*\) is the adjoint of \(b\) in \(L^2(\partial \Omega, d\sigma_h)\).

**Proof.** We obtain \((i)\) for \(\Omega^+\) by extending \((2.7)\) by continuity, the proof for \(\Omega^-\) is similar. To prove \((i)\) for \(\Omega^+\) we rewrite \((2.6)\) as:
\[
(v|Ku)_{\Omega^+} - (K^*v|u)_{\Omega^+} = (\nabla v|\kappa)_{\partial \Omega} - (v|\nabla u)_{\partial \Omega}.
\]
Using \(\nabla \cdot \nabla = n \cdot \nabla - 2ib\) finishes the proof. \(\square\)

### 2.5. Inverses of \(K\).
In order to define Calderón projectors we first need inverses of the operators \(K\) and \(K^*\) in an appropriate sense. We choose here to work in a general abstract framework rather than focus on a case-by-case analysis.

**Hypothesis 2.7.** (i) We assume that there exists a continuous operator
\begin{equation}
K^{-1} : H^1_c(X) \to \text{H}^1_{\text{loc}}(X)
\end{equation}
such that \(KK^{-1} = 1\) on \(H^1_c(X)\) and \(K^{-1}K = 1\) on \(H^1_c(X)\).

(ii) For all \(v \in \text{H}^1(\Omega^\pm)\),
\[
\int_{\Omega^\pm} (\nabla_a v \Re k \eta \nabla_b \nu + \eta \nabla \nu) d\mu_\kappa \geq 0.
\]

(iii) There exists a sequence \((\chi_i)\), \(\chi_i \in C^\infty_{\text{c}}(X)\), such that \(\chi_i = \kappa \chi_i \kappa\) and:
   a) For any \(Y \subseteq X\), \(\chi_i = 1\) on \(Y\) for \(i\) sufficiently large.
   b) For all \(i\), \(\partial \Omega \chi_i = 0\) in a neighborhood \(Y_i\) of \(\partial \Omega\).
   c) For all \(u, v \in \text{Ran} K^{-1} =: H^1_{\text{gl}}(X), (v|\chi_i[K, \chi_i]u) \to 0\) as \(i \to \infty\).

The subscript in \(H^1_{\text{loc}}(X)\) stands for ‘global’, as the choice of inverse of \(K\) (note that here we mean ‘inverse’ in a somewhat weak way) in \((2.11)\) is tied to the global behaviour. We remark that \((iii)\) is trivially satisfied if \(X\) is compact, as in that case one can take \(\chi_i = 1\) for all \(i\).

**Example 2.8.** The situation considered in [GW] is a special case of Hypothesis 2.7 (i), (ii) and (iii). In [GW], \(\partial \Omega\) has one connected component (the Wick-rotated Cauchy surface), \(X\) is embedded in a larger manifold, and the choice of inverse of \(K\) corresponds to Dirichlet boundary conditions on the boundary of \(X\).

**Example 2.9.** An intermediary step in the construction of the Hartle-Hawking-Israel state in [Ge2] consists in considering \(K\) on a cylinder \(X = S_\beta \times \Sigma\) for some smooth manifold \(\Sigma\), where \(S_\beta\) is the circle of length \(\beta\). The choice \(\Omega^+ = [0, \beta/2] \times \Sigma\) and \(\Omega^- = [-\beta/2, 0] \times \Sigma\) gives two connected components of \(\partial \Omega\). In the situation of [Ge2], \(K\) defines a closable sesquilinear form on \(C^\infty_{\text{c}}(X)\), the closure of which is sectorial. By the Lax-Milgram theorem, this defines an isomorphism from the form domain to its dual, which allows one to conclude that Hypothesis 2.7 (i) is satisfied.

Thus, the scheme for constructing examples of (i) and (ii) is to study sectorial extensions of \(K\) in the sense of sesquilinear forms, whereas (iii) requires more specific knowledge of the domain. We expect that this analysis could be carried out basing on the recent works [AGN] [GN].

Let us now discuss several consequences of Hypothesis 2.7. Since \(K^* = \kappa \circ K \circ \kappa\) in the sense of formal adjoints, and the spaces \(H^1_c(X), \text{H}^1_{\text{loc}}(X)\) are invariant under \(\kappa\), from \((2.11)\) we immediately conclude that \(K^*\) has an inverse
\[
(K^* - 1)^{-1} := \kappa \circ K^{-1} \circ \kappa : H^1_c(X) \to \text{H}^1_{\text{loc}}(X).
\]
By virtue of the next lemma, the definition of \( K^{-1} \) and \( K^{*-1} \) can be extended to \( H^s_c(X) \) for all \( s < -1 \), and \( KK^{-1} = 1 \) on \( H^s_c(X) \) by continuity.

**Lemma 2.10.** Let \( \varphi_1, \varphi_2 \in C_c^\infty(X) \) with \( \varphi_1 = 1 \) near supp \( \varphi_2 \). Then there exists a classical, properly supported pseudodifferential operator \( Q \) such that the operator \( \varphi_1K^{-1}\varphi_2 - \varphi_1Q\varphi_2 \) has smooth Schwartz kernel.

Despite the setup being more abstract here, the proofs of [GW Lem. 3.3] and [GW Lem. A.1] generalize in a straightforward way.

In what follows we denote by \( r^\pm : D'(X) \to \overline{D'}(\Omega^\pm) \) the respective restriction operators.

The two-sided trace operator is defined by

\[
\gamma_u = \begin{pmatrix} u^\dagger|_{\Omega} & -\partial_n u|_{\Omega} \\ -\partial_n u^\dagger|_{\Omega} & u_{\Omega}\end{pmatrix}, \quad u \in C_c^\infty(X).
\]

We denote by \( \gamma^* \) its formal adjoint, defined using the two densities \( d\mu_k \) and \( d\eta_b \).

For \( f \in C_c^\infty(\partial\Omega)^2 \) we have \( \gamma^*f \in H^{-2}_c(X) \), therefore \( K^{-1}\gamma^*f \) is well defined at least as an element of \( L^2_{\text{loc}}(X) \).

**Lemma 2.11.** The operator \( r^\pm K^{-1}\gamma^* \) maps continuously \( C_c^\infty(\partial\Omega)^2 \to \overline{C_c^\infty(\Omega^\pm)} \), with range contained in \( \overline{H^1_{\text{gl}}(\Omega^\pm)} \).

### 2.6. Calderón operators and their properties.

**Definition 2.12.** We will call

\[
C^\pm := \mp\gamma^\pm K^{-1}\gamma^* S
\]

the Calderón operators associated with \( K^{-1} \).

By Lemma 2.11 \( C^\pm : C_c^\infty(\partial\Omega)^2 \to C_c^\infty(\partial\Omega)^2 \) continuously.

If \( X \) is compact then \( C^\pm \) are the Calderón projectors. However, if \( X \) is not compact then \( C^\pm \) are not necessarily projections even if \( \partial\Omega \) is compact. This can arise for instance if \( X = I \times \partial\Omega \) with \( X \) an open interval.

In what follows, by slight abuse of notation, if \( \chi \in C_c^\infty(\partial\Omega) \) and \( \partial_n \chi = 0 \) near \( \partial\Omega \) then we simply write \( \chi \) instead of \( \chi|_{\partial\Omega} \). Recall that \( q \) was defined in (2.10).

**Lemma 2.13.** For any \( \chi \in C_c^\infty(X) \) such that \( \partial_n \chi = 0 \) near \( \partial\Omega \), and any \( f, g \in C_c^\infty(\partial\Omega)^2 \), we have:

\[
\begin{align*}
(\chi C^\pm f|q \chi C^\pm f)|_{\Omega} &= \pm \eta^\pm(\chi u^\pm, \chi u^\pm) \mp 2 \Re\langle u^\pm | [K, \chi] u^\pm \rangle_{\Omega}, \\
(\chi C^- g|q \chi C^+ f)|_{\Omega} &= (w^+ | \bar{\chi} [K, \chi] u^+ | w^+)_{\Omega^+} - (\chi [K^*, \bar{\chi}] w^+ | u^+ | \Omega^+),
\end{align*}
\]

where \( u^\pm = f K^{-1}\gamma^* S f, \quad w^\pm = f K^{-1}\gamma^* S g, \quad \bar{\chi} = \kappa \chi \) and \( \eta^\pm(\cdot, \cdot) \) is a positive-definite sesquilinear form.

**Proof.** We apply Prop. 2.6 \( ii) \) to \( u = v = \chi u^\pm \) as above. We obtain that:

\[
2 \Re\langle \chi u^\pm | [K, \chi] u^\pm \rangle_{\Omega} = \eta^\pm(\chi u^\pm, \chi u^\pm) \mp (\gamma^\pm \chi u^\pm | q \gamma^\pm \chi u^\pm | \Omega),
\]

where

\[
\eta^\pm(\cdot, \cdot) = \int_{\Omega^\pm} (\nabla_n \overline{\tau} \Re k^{ab} \nabla_b u + \lambda \overline{u} u) d\mu_k.
\]

Since \( K u^\pm = 0 \) on \( \Omega^\pm \) we can replace \( K \chi u^\pm \) by \( [K, \chi] u^\pm \). In view of \( \gamma^\pm \chi u^\pm = \chi C^\pm f \) this implies (2.12).

Next, by Prop. 2.6 \( i) \) applied to \( u = \chi u^+ \) and \( v = \bar{\chi} w^+ \) we obtain:

\[
(\gamma^\pm \chi w^+ | K \chi u^+ | \Omega) = (\gamma^\pm \chi w^+ | S \gamma^\pm \chi u^+ | \Omega).
\]
We have $Ku^+ = 0$ in $\Omega^+$ and by $K^* = \kappa K \kappa$ we have $K^* w^+ = 0$ in $\Omega^+$. Therefore we can rewrite (2.14) as
\[(2.15) \quad (w^+ | \chi[K, \chi] u^+)_\Omega^+ - (\chi[K^*, \chi] w^+ | u^+)_\Omega^+ = (\gamma^+ \bar{\chi} w^+ | S\gamma^+ \chi u^+ )_{\partial\Omega}.
\]
By (2.3) i) we have
\[(n \cdot \nabla u \circ \kappa)|_{\partial\Omega} = -(\nabla \cdot \nabla u)|_{\partial\Omega}.
\]
Therefore,
\[(2.16) \quad \gamma^+ u \circ \kappa = I\gamma^- u, \quad I = \begin{pmatrix} 1 & 0 \\ -\frac{1}{2ib} & -1 \end{pmatrix},
\]
where we recall that $b = \text{Im} \, n \cdot \nabla$. Thus,
\[(\gamma^+ \bar{\chi} w^+ | S\gamma^+ \chi u^+ )_{\partial\Omega} = (I\chi C^- g | S\gamma C^+ f)_{\partial\Omega} = (\chi C^- g | I^* S\gamma C^+ f)_{\partial\Omega}
\]
Noting that
\[I^* S = \begin{pmatrix} 1 & -\frac{1}{2ib} \\ 0 & -1 \end{pmatrix} \begin{pmatrix} 2ib & -1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} 0 & -1 \\ -1 & 0 \end{pmatrix} = -q,
\]
we obtain
\[(2.17) \quad (\gamma^+ \bar{\chi} w^+ | S\gamma^+ \chi u^+ )_{\partial\Omega} = (\chi C^- g | q \chi C^+ f)_{\partial\Omega}.
\]
Comparing (2.17) with (2.19) yields (2.13). \(\square\)

**Theorem 2.14.** Assume Hypotheses (2.7) (coercivity and positivity of $K$), (2.8) (existence of isometric involution $\kappa$), (2.7) (i) (existence of $K^{-1}$) and (ii) (sufficient non-negativity of mass). Then the Calderón operators $C^\pm$ are well-defined and satisfy
\[(2.18) \quad C^+ + C^- = 1 \text{ on } C_{\infty}^2(\partial\Omega)^2.
\]
If moreover, the global condition Hypothesis (2.7) (iii) is satisfied, then
\[(2.19) \quad \pm (f | q C^\pm f) \geq 0, \quad \forall f \in C_{\infty}^\infty(\partial\Omega)^2.
\]
**Proof.** Let $f, g \in C_{\infty}^\infty(\partial\Omega)^2$, $u^\pm = \mp r^\pm K^{-1} \gamma^* Sf$ and $v \in C_{\infty}^\infty(X)$ such that $\gamma v = g$. We have:
\[(g | S(C^+ + C^-) f)_{\partial\Omega} = (\gamma^+ r^+ v | SC^+ f)_{\partial\Omega} + (\gamma^- r^- v | SC^- f)_{\partial\Omega}
\]
\[= (r^+ v | Ku^+ )_{\Omega^+} - (r^+ K^* v | u^+)_{\Omega^+}
\]
\[- (r^- v | Ku^- )_{\Omega^-} + (r^- K^* v | u^- )_{\Omega^-}
\]
\[= -(r^+ K^* v | u^+ )_{\Omega^+} + (r^- K^* v | u^- )_{\Omega^-} = (K^* v | K^{-1} \gamma^* Sf)
\]
\[= (v | \gamma^* Sf) = (\gamma v | Sf)_{\partial\Omega} = (g | Sf)_{\partial\Omega}.
\]
In line 1 we use that $\gamma v = \gamma^\pm v$ since $v \in C_{\infty}^\infty(X)$. In line 2 we use Prop. (2.6) i). Then we use that $Ku^\pm = 0$ in $\Omega^\pm$ and the definition of $u^\pm$. Since $S$ is invertible with $S^{-1} = \begin{pmatrix} 0 & 1 \\ -1 & 2ib \end{pmatrix}$ this implies (2.13).

Next, let $\chi_n$ be as in Hypothesis (2.7). For $n$ large enough,
\[(f | q C^+ f)_{\partial\Omega} = (\chi_n^2 f | q C^+ f)_{\partial\Omega} = (\chi_n f | q \chi_n C^+ f)_{\partial\Omega}
\]
\[= (\chi_n C^+ f | q \chi_n C^+ f)_{\partial\Omega} + (\chi_n C^- f | q \chi_n C^+ f)_{\partial\Omega}
\]
\[= \eta^+(\chi_n u^+, \chi_n u^+ ) + c_n
\]
where $\eta^+(\cdot, \cdot)$ is a positive-definite sesquilinear form and
\[c_n = -2 \text{Re}(u^+ | \chi_n [K, \chi_n] u^+ )_{\Omega^+} + (w^+ | \chi_n [K, \chi_n] u^+ )_{\Omega^+}
\]
\[- (\chi_n [K^*, \chi_n] w^+ | u^+ )_{\Omega^+}.
\]
with \( u^+, w^+ \in H^1_{\ell_1}(\Omega^+) \) by Lemma 2.13. By Hypothesis 2.2 (ii), \( c_n \to 0 \) as \( n \to +\infty \).

By positivity of the \( \eta^+ \) term in (2.21) we have \( (f|qC^+f)_{\delta^s} \geq c_n \), thus letting \( n \to +\infty \) we obtain the ‘+’ version of (2.19). The ‘−’ variant is proved analogously. □

We end this section with a simple auxiliary lemma, thanks to which the positivity statement (2.19) can be interpreted as ‘reflection positivity’ of \( K^{-1} \) at \( \partial \Omega \).

**Lemma 2.15.** We have \( C^+ q = \gamma^+ K^{-1} \kappa \gamma^* \).

**Proof.** Recall that the operator \( I \) was defined in (2.16). We have

\[
S^{-1} I^* = \begin{pmatrix} 0 & 1 \\ -1 & 2ib^* \end{pmatrix} \begin{pmatrix} 1 & -2ib^* \\ 0 & -1 \end{pmatrix} = \begin{pmatrix} 0 & -1 \\ -1 & 0 \end{pmatrix} = -q.
\]

Using the identity \( \kappa \gamma^* = \gamma^* I^* \) and (2.21) we obtain

\[
\gamma^+ K^{-1} \kappa \gamma^* = \gamma^+ K^{-1} \gamma^* I^* = \gamma^+ K^{-1} \gamma^* SS^{-1} I^* = -\gamma^+ K^{-1} \gamma^* S q = C^+ q
\]

as claimed. □

3. Two-point functions from Calderón operators

3.1. Geometric setup.

If \( \Sigma \) is a smooth manifold, we write \( \mathcal{C}(\mathbb{C}; \mathbb{C}T^0_0(\Sigma)) \) for the space of holomorphic functions with values in complex \((p, q)\)-tensors on \( \Sigma \).

We now consider the following setup, in which \( \partial \Omega \) has only one connected component:

1) Let \( \Sigma \) be a connected smooth manifold.
2) Let \( h \in \mathcal{O}(\mathbb{C}; \mathbb{C}T^0_0(\Sigma)), N \in \mathcal{O}(\mathbb{C}; \mathbb{C}T^0_0(\Sigma)), \) and \( w \in \mathcal{O}(\mathbb{C}; \mathbb{C}T^1_0(\Sigma)) \) be real-analytic.
3) Writing \( z = t + is \), we define the following two complex metrics on \( \mathbb{R} \times \Sigma \):

\[
g := -N^2(t)dt^2 + h_{jk}(t)(dy^j + w^j(t)dt)(dy^k + w^k(t)dt),
\]

\[
k := N^2(is)ds^2 + h_{jk}(is)(dy^j + iw^j(is)ds)(dy^k + iw^k(is)ds).
\]

We assume that \( k \) is coercive and positive in the sense of Hypothesis 2.1.

4) Let \( \kappa : \mathbb{R} \times \Sigma \to \mathbb{R} \times \Sigma \) be the diffeomorphism \( \kappa(s, y) := (-s, y) \).

5) Let \( X \) be a \( \kappa \)-invariant neighborhood of \( \{0\} \times \Sigma \). We set:

\[
\Omega^\pm := X \cap \{s > 0\}, \quad \partial \Omega = \{s = 0\}.
\]

In 2), by real-analyticity we mean analyticity in the variable \( z = t + is \), and:

\[
\overline{h(z)} = h(\overline{z}), \quad \overline{N(z)} = N(\overline{z}), \quad \overline{\lambda(z)} = \lambda(\overline{z}), \quad \overline{w'(z)} = w'(\overline{z}), \quad z \in \mathbb{C}.
\]

This implies that the metric \( g \) introduced in 3) is real. The metric \( k \) is the Wick-rotated counterpart of \( g \), and does not need to be real.

The definitions 1)–6) match the setup of Section 2 with Hypothesis 2.1 and Hypothesis 2.3 satisfied. Recall that we have defined there

\[
K = -|k|^2 \partial_a k^a b |k|^2 \partial_b + \lambda.
\]

If in addition, we have an inverse of \( K \) in the sense of Hypothesis 2.7, then all the results of Section 2 apply and we have a pair of Calderón operators \( C^\pm \).

Our main object of interest is the Klein-Gordon operator \( P \) for the Lorentzian metric \( g \), namely:
6) Let \((M, g)\) be the globally hyperbolic spacetime defined as the domain of dependence of \(\{0\} \times \Sigma\).

7) On \(M\) we consider the Klein-Gordon operator
\[
P = -|g|^{-\frac{1}{2}} \partial_\mu |g|^{\frac{1}{2}} g^{ab} \partial_b + \lambda.
\]

**Remark 3.1.** We remark that Chruściel and Delay have derived a method to obtain non-singular real-analytic solutions of Einstein equations of the form 3), though they applied it to the negative cosmological constant case [CD]. Here we limit ourselves to globally hyperbolic regions due to the use of analytic propagation of singularities theorems in the proof of Prop. 4.2.

### 3.2. Two-point functions.

Let \(n \in TM\) be the outer unit normal vector field to \(t_0 u \hat{\Sigma}\). For \(f \in D'(\Sigma)^2\) we denote by \(Uf \in D^1_p \Sigma\) the unique solution of \(Pu = 0\) with Cauchy data at \(t = 0\) given by
\[
\begin{pmatrix}
u|\Sigma \\ i^{-1} \partial_n u|\Sigma 
\end{pmatrix} = f.
\]

Let \(G\) be the difference of the retarded and advanced propagators for \(P\). It is well known that
\[UqU^* = iG,
\]
where \(U^*\) is the formal adjoint of \(U\) w.r.t. the canonical \(L^2(M, g)\) scalar product.

As a direct corollary of Theorem 2.14 and (3.1), in the setup of definitions 1)–8) we have:

**Proposition 3.2.** Let \(C^\pm\) be the (generalized) Calderón projectors associated with an inverse of \(K\) satisfying Hypothesis 2.7. Set
\[
\Lambda^\pm := UC^\pm qU^* : C^p_c(M) \to C^p_c(M).
\]
Then \(\Lambda^\pm\) is a pair of two-point functions, i.e.
\[\Lambda^\pm \geq 0, \ P\Lambda^\pm = \Lambda^\pm P = 0, \text{ and } \Lambda^+ - \Lambda^- = iG \text{ on } C^p_c(M).
\]

We refer the reader to e.g. [GW] for an explanation of the importance of the conditions (3.3) in Quantum Field Theory.

### 4. Wick rotation in analytic case

#### 4.1. Geometric setup.
From now on we consider the same setup as in Subsection 3.1 but supposing in addition that \(\Sigma, g\) and \(\lambda\) are analytic (rather than merely real-analytic in the time variable).

#### 4.2. Boundary values of holomorphic functions.
Let us introduce the conventions and basic notions used throughout this section.

- We write \(A \subseteq B\) if \(A\) is relatively compact in \(B\).
- If \(\Gamma, \Gamma'\) are two cones of vertex 0 in \(\mathbb{R}^n\) we write \(\Gamma' \subseteq \Gamma\) if \((\Gamma' \cap S^{n-1}) \subseteq (\Gamma \cap S^{n-1})\).
- Let \(\Gamma\) be an arbitrary convex, open and proper cone of vertex 0 in \(\mathbb{R}^n\), or in short, an open cone. Its polar is then defined by
\[
\Gamma^\circ := \{\xi \in \mathbb{R}^n : \xi \cdot y \geq 0, \ \forall y \in \Gamma\}.
\]
- Let \(\Omega \subset \mathbb{R}^n\) be open. Then a tuboid of profile \(\Omega + i\Gamma\) is a complex domain \(D \subset \Omega + i\Gamma\) such that for all \(x \in \Omega\) and any subcone \(\Gamma' \subseteq \Gamma\) there exists a neighborhood \(\Omega'\) of \(x\) in \(\Omega\) and a constant \(r > 0\) such that
\[
\Omega' + i\{y \in \Gamma' : 0 < |y| \leq r\} \subset D.
\]
- We write $F \in \mathcal{E}_{\text{temp}}(\Omega + i\Gamma)$ if $F$ is a holomorphic function on some tuboid $D$ of profile $\Omega + i\Gamma$, and $F$ is \textit{temperate}, i.e. for any $K \subseteq \Omega$, any subcone $\Gamma' \subseteq \Gamma$ and any $r > 0$ such that $K + i[y \in \Gamma' : 0 < |y| \leq r] \subset D$, there exists $C, r' > 0$ and $N \in \mathbb{N}$ such that
  \[ |F(x + iy)| \leq C|y|^{-N}, \quad x \in K, \ y \in \Gamma', \ 0 < |y| \leq r'. \]

The importance of temperate holomorphic functions is that their boundary values are distributions. This is stated precisely in the next theorem (see e.g. [Ko, Thm. 3.6] for the proof).

**Theorem 4.1.** Let $F$ be a holomorphic function on a tuboid of profile $\Omega + i\Gamma$. Then the following are equivalent:

a) $F \in \mathcal{E}_{\text{temp}}(\Omega + i\Gamma)$;

b) The set $\{F(x + iy) : y \in \Gamma', |y| < r\}$ is bounded in $\mathcal{D}'(\Omega)$ for all $r > 0$ and some closed cone $\Gamma' \subseteq \Gamma$;

c) The set $\{F(x + iy) : y \in \Gamma', |y| < r\}$ is bounded in $\mathcal{D}'(\Omega)$ for all $r > 0$ and all closed cones $\Gamma' \subseteq \Gamma$;

d) The limit $F(x + i\Gamma) := \lim_{\Gamma \ni y \to 0} F(x + iy)$
exists in $\mathcal{D}'(\Omega)$ for any $\Gamma' \subseteq \Gamma$.

We will need a generalization to distribution-valued holomorphic functions. Let $Z$ be a smooth manifold, and let us denote by $\langle \cdot, \cdot \rangle$ the duality bracket between $\mathcal{D}'(Z)$ and $C^\infty_c(Z)$.

- We write $F \in \mathcal{E}_{\text{temp}}(\Omega + i\Gamma; \mathcal{D}'(Z))$ if $F$ is a $\mathcal{D}'(Z)$-valued holomorphic function on some tuboid $D$ of profile $\Omega + i\Gamma$, and for each $K \subseteq \Omega$ there exist $r > 0, N \in \mathbb{N}$ such that for each bounded set $B \subseteq C^\infty_c(Z)$, there exists $C_B > 0$ such that
  \[ \sup_{\varphi \in B} |\langle F(x + iy, \cdot), \varphi(\cdot) \rangle| \leq C_B|y|^{-N}, \quad x \in K, \ 0 < |y| \leq r. \]

- By convention, $\Omega - i\Gamma = \Omega + i(-\Gamma)0$.

- If $I \subseteq \mathbb{R}$ is an open interval and $\Gamma = ]0, +\infty[$ then we simply write $I \pm i0$ in the place of $I \pm i\Gamma$.

By Theorem 4.1 if $F \in \mathcal{E}_{\text{temp}}(\Omega \pm i\Gamma; \mathcal{D}'(Z))$ then

\[ \langle F(x \pm i\Gamma, 0), \varphi(0) \rangle = \lim_{\Gamma \ni y \to 0} \langle F(x \pm iy, \cdot), \varphi(\cdot) \rangle \]
defines uniquely a distribution in $\mathcal{D}'(\Omega \times Z)$.

**4.3. Analytic Hadamard condition.** In [GW] Prop. 5.2] it was shown (in a less general context) that solutions of $Pu = 0$ with Cauchy data in the range of $C^+$ are boundary values of holomorphic functions from $\{s > 0\}$. The crucial observation for us is that if we view this as an analytic continuation result for solutions of $Kw = w$ with $w$ supported on $\partial \Omega = \Sigma$, then the proof extends to much more general situations. The trick is not to try to study solutions of $Kw = w$ directly on $X$, but instead restrict $v$ to $\Omega^+$ and then extend it by zero to $X$.

If $I \subseteq \mathbb{R}$, we set $I^\pm = I \cap \{s \geq 0\}$. We will write $F \in \mathcal{E}_{\text{temp}}(I^+ \times iI^+; \mathcal{D}'(Y \times Z))$ if $F \in \mathcal{E}_{\text{temp}}(I^+ \times iI^+; \mathcal{D}'(Z))$ and $F$ is holomorphic in $I^+ \times iI^+$ (rather than merely on a subdomain).

**Proposition 4.2.** Suppose that $\Sigma$, $g$ and $\lambda$ are analytic. Let $v \in \mathcal{B}(\Omega^+; \mathcal{D}'(Z))$ for $Z$ a smooth manifold and suppose that

\[ (K \otimes 1_Z)v (s, y, z) = 0 \quad \text{in a neighborhood of } \{0\} \times \Sigma \times Z. \]
Let \( u = (U\gamma^+ \otimes \mathbf{1}_Z)v \in \mathcal{D}'(M \times Z) \). Then for any \( y^0 \in \Sigma \) there exists a neighborhood \( Y \subset \Sigma \), an interval \( I = ]-\delta, \delta[ \), and a distribution-valued function \( F \in \mathcal{O}_{\text{temp}}(\mathbb{I}^+ \times i\mathbb{I}^+; \mathcal{D}'(Y \times Z)) \) such that:

\[
\begin{align*}
  v(s, y, z) &= F(is, y, z), \quad s \in \mathbb{I}^+, \\
  u(t, y, z) &= F(t + i0, y, z), \quad t \in \mathbb{I}.
\end{align*}
\]

(4.5)

Proof. Let \( v_{\text{ext}} = (e^+ \otimes \mathbf{1}_Z)v \), where \( e^+ : \overline{\mathcal{D}'}(\Omega^+) \rightarrow \mathcal{D}'(X) \) is the distributional extension by zero. Then \( (K \otimes \mathbf{1}_Z)v_{\text{ext}} \) is supported in \( \{ s = 0 \} \). We can now repeat the steps in the proof of Prop. 5.2 in [GW] to get the desired result. To explain this very briefly, one writes \( v_{\text{ext}}(s) \) as the difference \( v_{\text{ext}}^i(s) - v_{\text{ext}}^l(s) \) of two boundary values \( s \pm i0 \). Wick-rotating \( v_{\text{ext}}^i \) and \( v_{\text{ext}}^l \) yields two distributions \( u^i(t) \) and \( u^l(t) \) defined on \( \{ t > 0 \} \), which solve \( Pu^{\uparrow}(t) = w(t + i0) \) for a suitable temperate \( w \) (in general different from the one considered in [GW]) obtained by Wick-rotating \( K_{\text{ext}} \). One can extend \( u^{\uparrow} \) to all \( t \in \mathbb{R} \) using the hyperbolicity of \( P \), and then one represents the resulting distribution as a boundary value of some temperate \( v_{\text{ext}} \), which is possible by analytic wave front set arguments. The difference \( F = v_{\text{ext}}^i - v_{\text{ext}}^l \) satisfies the stated properties. \( \square \)

In the same way as in Prop. 5.3 in [GW] we can also show:

Proposition 4.3. Let \( \Lambda^\pm \) be as in Prop. 5.3. Suppose that \( \Sigma, g \) and \( \lambda \) are analytic, and that \( \lambda \) and the coefficients of \( g \) do not depend on \( t \). Then the pair \( \Lambda^\pm \) satisfies the analytic Hadamard condition in \( M \), i.e.

\[
\WF_{\mathbb{C}}(\Lambda^\pm) \subset \mathcal{N}^\pm \times \mathcal{N}^\pm,
\]

(4.6)

where, denoting by \( V_{x \pm} \) the future/past (solid) lightcones in \( T_x M \) and by \( o \) the zero section of \( T^*M \),

\[
\mathcal{N}^\pm = \{(x, \xi) \in T^*M \setminus o : \xi \cdot g^{-1}(x)\xi = 0 \text{ and } \xi \cdot v > 0 \ \forall v \in V_{x \pm} \text{ s.t. } v \neq 0 \}.
\]

The analytic Hadamard condition was introduced by Strohmaier, Verch and Wollenberg [SVW], see [GW] for the equivalence between the original formulation and the one above, inspired by [SV]. In (4.6), \( \WF_{\mathbb{C}}(\Lambda^\pm) \) stands for the analytic wave front set of the Schwartz kernel \( \Lambda^\pm(t_1, y_1, t_2, y_2) \in \mathcal{D}'(M^2) \) of \( \Lambda^\pm \). Instead of recalling the precise definition (see e.g. [LK] Thm. 3.9]) we prefer to indicate the consequences of (4.6) which will be directly relevant for our analysis. Focusing on \( \Lambda^+ \), we will actually only need the following weaker inclusion:

\[
\WF_{\mathbb{C}}(\Lambda^+) \subset V^\circ, \quad V^\circ = \{ t_1 > c|k_1|, \ t_2 < -c|k_2| \},
\]

(4.7)

where we wrote \( (t_i, k_i) \) for the dual variables of \( (t_i, y_i) \). Above, \( V^\circ \) is the polar of \( V = \{ s_1 > c|y_1|, \ s_2 < -c|y_2| \} \). This implies (see e.g. [LK] Thm. 3.9]) that there exists an interval \( I \) and \( F \in \mathcal{O}_{\text{temp}}(I \times \Sigma)^2 + iV0 \) such that

\[
\Lambda^+(t_1, y_1, t_2, y_2) = F((t_1, y_1, t_2, y_2) + iV0).
\]

(4.8)

This statement will be the starting point for us.

In the next lemma we give a variant of (4.8) in terms of holomorphic functions with values in Schwartz kernels on \( \Sigma \). Let

\[
\Gamma = \{ s_1 > 0, \ s_2 < 0 \} \subset \mathbb{R}^2.
\]

Note that \( \Gamma^\circ = \Gamma \).

Lemma 4.4. As a consequence of (4.8), there exists \( F \in \mathcal{O}_{\text{temp}}(\mathbb{R}^2 + i\Gamma^0; \mathcal{D}'(\Sigma^2)) \) such that

\[
\Lambda^+(t_1, y_1, t_2, y_2) = F((t_1, t_2) + i\Gamma^0, y_1, y_2).
\]

(4.9)
Proof. Recall that $\Lambda^\ast(t_1, y_1, t_2, y_2) = \lim_{(\xi_1, \xi_2) \to 0} F((t_1, y_1) + i\xi_1, (t_2, y_2) + i\xi_2)$ in $\mathcal{D}'((I \times \Sigma)^2)$, where the limit $(\xi_1, \xi_2) \to 0$ is taken from any closed cone $W \subseteq V$. We stress that the notion of closed and compact refers here to the intersection of the various sets with the unit sphere. In particular we can take $W = \{s_1 > 0, s_2 < 0, y_1 = y_2 = 0\}$.

Accordingly, we can view $F(z_1, z_2, y_1, y_2)$ as a $\mathcal{D}'(\Sigma^2)$-valued function, holomorphic in $(z_1, z_2) \in I^2 + i\Gamma 0$. By Theorem [4.11], $F(t_1 + is_1, t_2 + is_2, y_1, y_2)$ is bounded in $\mathcal{D}'((I \times \Sigma)^2)$ when $(s_1, s_2) \in \Gamma$. This means that if $B$ is a bounded set in $C^2(\Sigma^2)$ then

$$F(\gamma(t_1 + is_1, t_2 + is_2) := \langle F(t_1 + is_1, t_2 + is_2), \varphi \rangle$$

is bounded in $\mathcal{D}'(I^2)$ for $(s_1, s_2) \in \Gamma$ and $\varphi \in B$. Equivalently, by Theorem [4.14], there exists $N \in \mathbb{N}$ and $C > 0$ such that

$$|F_\varphi(t_1 + is_1, t_2 + is_2)| \leq C|s_1|^{-N}|s_2|^{-N}, \varphi \in B, (s_1, s_2) \in \Gamma.$$

Furthermore, for $\psi \in C^2(\Sigma^2)$ we have

$$\langle F_\varphi((t_1, t_2) + i\Gamma 0), \psi \rangle = \langle F((x_1, x_2) + i\Gamma 0), \psi \otimes \varphi \rangle,$$

hence:

$$\Lambda^\ast(t_1, y_1, t_2, y_2) = F((t_1, t_2) + i\Gamma 0, y_1, y_2),$$

and $F(z_1, z_2, y_1, y_2) \in \mathcal{D}'(I^2 + i\Gamma 0; \mathcal{D}'(\Sigma^2))$. □

4.4. Wick rotation in two variables. In what follows we will show that the Schwartz kernels of $K^{-1}$ and $\Lambda^\ast$ are related by Wick rotation in two variables.

Lemma 4.5. For $y_0^r \in \Sigma$ there exists a neighborhood $Y_1$ of $y_0^r$, a neighborhood $U$ of $\{0\} \times \Sigma$ and $F^+ \in \mathcal{D}'(I_1^+ \times I_1^+; \mathcal{D}'(Y_1 \times U))$ such that

$$\Lambda^+(t_1, y_1, t_2, y_2) = F^+(t_1 + i0, y_1, t_2, y_2),$$

for $t_1 \in I_1$, $y_1 \in Y_1$, $(t_2, y_2) \in U$,

$$K^{-1}K^*U^*\big((s_1, y_1, t_2, y_2) = F^+(is_1, y_1, t_2, y_2),$$

for $s_1 \in I_1^+$, $y_1 \in Y_1$, $(t_2, y_2) \in U$.

Proof. For any $y_0^r \in \Sigma$, Prop. [4.2] applied to the Schwartz kernel of $K^{-1}K^*U^*$ gives the existence of an interval $I_1$, a neighborhood $Y_1$ of $y_0^r$ in $\Sigma$, a neighborhood $U$ of $\{0\} \times \Sigma$ in $\mathbb{R} \times \Sigma$ and $F_1 \in \mathcal{D}'(I_1^+ \times I_1^+; \mathcal{D}'(Y_1 \times U))$ such that

$$K^{-1}K^*U^*\big((s_1, y_1, t_2, y_2) = F_1(is_1, y_1, t_2, y_2),$$

for $s_1 \in I_1^+$, $y_1 \in Y_1$, $(t_2, y_2) \in U$,

$$U^*K^{-1}K^*U^*\big((t_1 + i0, y_1, t_2, y_2) = F_1(t_1, y_1, t_2, y_2),$$

for $t_1 \in I_1$, $y_1 \in Y_1$, $(t_2, y_2) \in U$.

Using Lemma [4.15] and the definition of $\Lambda^+ = UC^+qU^*$, we can rewrite (4.13) as

$$\Lambda^+(t_1, y_1, t_2, y_2) = F_1(t_1 + i0, y_1, t_2, y_2),$$

for $t_1 \in I_1$, $y_1 \in Y_1$, $(t_2, y_2) \in U$

as claimed. □

In the geometric setup summarized in 1)–8) in Subsect. [3.1] our main result is the following theorem. In (4.14) below, the limit from $\Gamma$ is meant as in (4.4), and the spatial variables $y_1, y_2$ are omitted in the notation.
Theorem 4.6. Assume $\Sigma$, $g$ and $\lambda$ are analytic. Let $K^{-1}$ an inverse of $K$ satisfying Hypothesis \cite{2}. Let $\Gamma = \{s_1 > 0, s_2 < 0\}$. There exists an interval $I = \delta, \delta$ and $F \in \mathcal{G}_{\text{temp}}(\mathbb{R}^2 + i\mathbb{R}; \mathcal{D}(\Sigma_\gamma^2))$ such that:

\begin{equation}
(4.14)
K^{-1}(s_1, s_2) = F(is_1, is_2), \quad s_1 > 0, \quad s_2 < 0,
\end{equation}

Proof. For $y_0^2 \in \Sigma$, Prop. \cite{4.2} applied to $v = K^{-1}(s_2, y_2, s_1, y_1)$ and $X = \Omega^-$ gives the existence of an interval $I_2$, a neighborhood $Y_2$ of $y_0^2$ and $F_2 \in \mathcal{G}_{\text{temp}}(I_2^+ \times iI_2^+; \mathcal{D}'(Y_2 \times \Omega^-))$ such that

\begin{equation}
(4.22)
K^{-1}(s_2, y_2, s_1, y_1) = F_2(t_2, \tau, y_2, s_1, y_1),
\end{equation}

for $t_2 \in I_2$, $y_2 \in Y_2$, $(s_1, y_1) \in \Omega^-$.

Taking formal adjoints of (4.15), we get

\begin{equation}
(4.17)
(K^*)^{-1}(s_1, s_2, y_2) = F_2^*(s_2, s_1, y_2),
\end{equation}

and

\begin{equation}
(4.18)
(K^{-1})^{-1}(s_1, s_2, y_2) = F_2(s_2, s_1, y_2),
\end{equation}

for $(s_1, y_1) \in \Gamma^+$, $s_2 \in I_2^+$, $y_2 \in Y_2$.

Taking formal adjoints of (4.19) gives:

\begin{equation}
(4.20)
(K^{-1})^{-1}(s_1, s_2, y_2) = F_2^*(s_2, s_1, y_2),
\end{equation}

for $(s_1, y_1) \in \Omega^-$, $t_2 \in I_2$, $y_2 \in Y_2$.

Setting $F_2(z) := F_2(\overline{z})$ and using $(K^*)^{-1} = \kappa K^{-1} \kappa$, we rewrite (4.18) and (4.19) as:

\begin{equation}
(4.21)
(K^{-1})^{-1}(s_1, s_2, y_2) = F_2^*(s_2, s_1, y_2),
\end{equation}

for $(s_1, y_1) \in \Omega^+$, $s_2 \in I_2^+$, $y_2 \in Y_2$.

Lemma \cite{4.3} gives the existence of an interval $I_1$, a neighborhood $Y_1$ of $y^0_i$ in $\Sigma$, a neighborhood $U$ of $\{0\} \times \Sigma$ in $\mathbb{R} \times \Sigma$ and $F_1 \in \mathcal{G}_{\text{temp}}(I_1^+ \times iI_1^+; \mathcal{D}'(Y_1 \times U))$ such that

\begin{equation}
(4.22)
K^{-1}(\kappa, s_1, t_2, y_2) = F_1(s_1, y_1, t_2, y_2),
\end{equation}

for $s_1 \in I_1^+$, $y_1 \in Y_1$, $(t_2, y_2) \in U$.

\begin{equation}
(4.23)
\Lambda^+(t_1, y_1, t_2, y_2) = F_1(t_1 + i0, y_1, t_2, y_2),
\end{equation}

for $t_1 \in I_1$, $y_1 \in Y_1$, $(t_2, y_2) \in U$.

On the other hand, by Lemma \cite{4.4} there exists $F \in \mathcal{G}_{\text{temp}}(\mathbb{R}^2 + i\mathbb{R}; \mathcal{D}'(\Sigma \times \Sigma))$ such that

\begin{equation}
(4.24)
\Lambda^+(t_1, y_1, t_2, y_2) = F((t_1, t_2) + i\Gamma 0, y_1, y_2).
\end{equation}
By comparing (4.23) and (4.24) we obtain that:

\[ F_1(z_1, y_1, t_2, y_2) = F(z_1, t_2 - i0, y_1, y_2) \]
for \( y_1 \in Y_1, \ t_2 \in I_2, \ z_1 \in I_1 + iI_1^+ \).

By comparing (4.21) with (4.22) we obtain that:

\[ F_1(is_1, y_1, t_2, y_2) = F_2(t_2 - i0, y_2, \kappa(s_1, y_1)) \]
for \( y_1 \in Y_1, \ s_1 \in I_1^+, \ t_2 \in I_2 \),

hence by (4.20):

\[ F_2(t_2 - i0, y_2, \kappa(s_1, y_1)) = F(is_1, t_2 - i0, y_1, y_2) \]
for \( y_1 \in Y_1, \ s_1 \in I_1^+, \ t_2 \in I_2 \),

In particular we obtain:

\[ F_2(is_2, y_2, \kappa(s_1, y_1)) = F(is_1, is_2, y_1, y_2) \]
for \( y_1 \in Y_1, \ s_1 \in I_1^+, \ s_2 \in I_2^- \).

By (4.20) this gives:

\[ (K^{-1}\kappa)(s_1, y_1, -s_2, y_2) = F_3(is_1, is_2, y_1, y_2) \]
for \( y_1 \in Y_1, \ s_1 \in I_1^+, \ s_2 \in I_2^- \),

hence

\[ K^{-1}(s_1, y_1, s_2, y_2) = F(is_1, is_2, y_1, y_2) \]
for \( y_1 \in Y_1, \ s_1 \in I_1^+, \ s_2 \in I_2^- \).

Using the fact that \( y_1^n, y_2^n \) were arbitrary we obtain the desired statement.

In an analogous way we obtain a statement for \( \Lambda^{-} \), with the limit taken from \(-\Gamma\) instead of \(\Gamma\).

5. Stationary case

5.1. KMS condition. We will now show some extra conclusions from our analysis in the special case when \( K \) has coefficients independent of \( s \). We work in the geometric setup summarized in 1)–8) in Subsect. 3.1, with \( K \) independent of \( s \).

\[ \lim_{s \to \beta/2} (K^{-1}v)(s) = \lim_{s \to \beta/2+} (K^{-1}v)(s), \quad v \in H^{-2}_{\alpha}(X). \]

Then there exists \( F_1 \in \mathcal{O}_{\text{temp}}(\mathbb{R} + i0; \mathcal{D}'(\mathbb{R} \times \Sigma^2)) \) such that:

\[ F_1( i0^+ , y , t_2 , y_2 ) = \Lambda^+(0, y , t_2 , y_2), \]

\[ F_1( i\beta^-, y , t_2 , y_2 ) = \Lambda^-(0, y , t_2 , y_2), \]

and \( F_2 \in \mathcal{O}_{\text{temp}}(\mathbb{R} - i0; \mathcal{D}'(\mathbb{R} \times \Sigma^2)) \) such that:

\[ F_2(t_1, y_1, i0^+, y) = \Lambda^-(t_1, y_2, 0, y), \]

\[ F_2(t_1, y_1, i\beta^-, y) = \Lambda^+(t_1, y_2, 0, y). \]
Proof. By Lemma 4.5 and its direct analogue with minuses replaced with pluses, there exist $F^\pm \in \mathcal{C}_0^\infty(\mathbb{R} \times \Sigma)$ such that for small $|t_1|$ and $|s_1|$, 

\begin{equation}
F^+(t_1 + i0, y_1, t_2, y_2) = \Lambda^+(t_1, y_1, t_2, y_2),
\end{equation}

\begin{equation}
F^+(i s_1, y_1, t_2, y_2) = (K^{-1} \kappa \gamma^* U^*)(s_1, y_1, t_2, y_2), \quad s_1 > 0,
\end{equation}

and

\begin{equation}
F^-(t_1 - i0, y_1, t_2, y_2) = \Lambda^-(t_1, y_1, t_2, y_2),
\end{equation}

\begin{equation}
F^-(i s_1, y_1, t_2, y_2) = (K^{-1} \kappa \gamma^* U^*)(s_1, y_1, t_2, y_2), \quad s_1 < 0.
\end{equation}

Let us consider $K$ as a differential operator on $\mathbb{R} \times \Sigma$ (rather than just on $X$). By (5.27), we can extend the right hand side of (5.31) to a $\beta$-periodic distribution $w$ that solves $Kw = 0$ in $\{0 < s_1 < \beta\}$. Let

$$w_{s_1}(y_1, t_2, y_2) := \overline{w(s_1, y_1, t_2, y_2)},$$

and define

$$\tilde{F}^+(t_1 + i s_1, y_1, t_2, y_2) := (U w_{s_1})(t_1, y_1, t_2, y_2),$$

where $U$ (see Subsect. 3.2) acts in the $y_1$ variables only. For the sake of simplicity, let us assume that $g = -dt^2 + h$, with $h$ a (real) Riemannian metric on $\Sigma$. We have

\begin{equation}
(\partial_{t_1}^2 - \Delta_{h(y_1)} + \lambda) \tilde{F}^+ = 0.
\end{equation}

Furthermore, $(-\partial_{s_1}^2 - \Delta_{h(y_1)} + \lambda) \tilde{F}^+ = 0$ also solves a wave equation in $(t_1, y_1)$, and it has vanishing Cauchy data if $s_1 \in [0, \beta]$, hence

\begin{equation}
(-\partial_{s_1}^2 - \Delta_{h(y_1)} + \lambda) \tilde{F}^+ = 0
\end{equation}

for $s_1 \in [0, \beta]$. Combining (5.34) with (5.35), we get $(\partial_{t_1}^2 + \partial_{s_1}^2) \tilde{F}^+ = 0$. This implies

$$(\partial_{t_1}^2 + \partial_{s_1}^2) \tilde{F}^+ = 0$$

for

$$\tilde{F}^+_{\varphi}(s_1, t_1) := \langle \tilde{F}^+(s_1, t_1, \cdot), \varphi(\cdot) \rangle, \quad \varphi \in C_0^\infty(\mathbb{R} \times \Sigma^2).$$

By ellipticity of $\partial_{t_1}^2 + \partial_{s_1}^2$, we have $\tilde{F}^+ \in \mathcal{C}(\mathbb{R} + i \mathbb{R} \times \mathbb{R}^2 + i \mathbb{R} \times \mathbb{R}^2)$. This gives the analytic continuation of $\tilde{F}^+$. This argument can be easily extended to general $g$.

We will prove that (5.28) holds true with $F_1 = \tilde{F}^+$. The first identity in (5.28) is simply (5.31) with $t_1 = 0$. Let us now prove the second identity in (5.28). Using (5.31), then $\beta$-periodicity, and then (5.33) and (5.32), we obtain

$$F_1(i \beta^-, y_1, t_2, y_2) = w(\beta^-, y_1, t_2, y_2)$$

$$= (K^{-1} \kappa \gamma^* U^*)(0^-, y_1, t_2, y_2)$$

$$= F^-(0^-, y_1, t_2, y_2)$$

$$= \Lambda^-(0, y_1, t_2, y_2).$$

The two identities (5.29) are proved similarly. □

The identities (5.28)–(5.29) are equivalent to the KMS condition with respect to translations in $t$ for the quasi-free state associated with $\Lambda^\pm$.

We remark that this result can also be obtained (even without imposing analyticity of the space-time) by more explicit, though more lengthy computations on the level of Cauchy data, see [Ge1, Ge2].
Remark 5.2. Note that in our framework we have a pair of two-point functions \( \Lambda^{\pm} \) and thus a pair of identities for the KMS condition: this is because we are using the terminology for charged fields. Recall that the abstract formulation of the KMS condition with respect to a given one-parameter group of automorphisms \( \{ \tau_t \} \) is

\[
\omega (\tau_t A \tau_t^{-1} B) = \omega (BA),
\]

for all \( A, B \), see e.g. [BR, 5.3.1] for the details. Here the (gauge-invariant) quasi-free state \( \omega \) is defined from \( \Lambda^{\pm} \) in such way that

\[
\langle \varphi, \Lambda^+ \varphi \rangle = \omega (\psi(v) \bar{\psi}(u)), \quad \langle \varphi, \Lambda^- \varphi \rangle = \omega (\bar{\psi}(u) \psi(v)), \quad v, u \in C^\infty_c (M),
\]

in terms of the abstract charged fields \( v \mapsto \psi^*(v), \psi(v) \), see [GW]. For such states it is sufficient to check (5.36) for all \( A \) of the form \( \psi^*(v) \) and \( B \) of the form \( \bar{\psi}(u) \), and then for \( A = \psi^*(u) \) and \( B = \psi(v) \). Applied to \( \tau_t \psi^*(v) = \psi(v) (\cdot + t) \), this corresponds precisely to (5.28) and (5.29). The more standard ‘neutral’ terminology is recovered by re-writing everything in terms of the real fields \( \phi(v) := \frac{1}{\sqrt{2}} (\psi(v) + \bar{\psi}(v)) \).
