A Whittaker-Plancherel Inversion Formula for $SL_2(\mathbb{C})$

Zhi Qi and Chang Yang

Abstract. In this paper, we establish a Whittaker-Plancherel inversion formula for $SL_2(\mathbb{C})$ from the analytic perspective of the Bessel transform of Bruggeman and Motohashi. The formula gives a decomposition of the Whittaker-Fourier coefficient of a compactly supported function on $SL_2(\mathbb{C})$ in terms of its Bessel coefficients attached to irreducible unitary tempered representations of $SL_2(\mathbb{C})$.

1. Introduction

Let $G = SL_2(\mathbb{C})$. Define

$$N = \left\{ n(u) = \begin{pmatrix} 1 & u \\ u & 1 \end{pmatrix} : u \in \mathbb{C} \right\}, \quad A = \left\{ s(z) = \begin{pmatrix} z \\ z^{-1} \end{pmatrix} : z \in \mathbb{C}^\times \right\}.$$  

Let $B = AN$ be the Borel subgroup of $G$. Let

$$w = \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}.$$

Let $C_c^\infty(G)$ be the space of smooth and compactly supported functions on $G$. For $\lambda \in \mathbb{C}^\times$, define the additive character $\psi = \psi\lambda$ by

$$\psi\lambda(u) = e(\lambda u + \overline{\lambda} u),$$

with the usual abbreviation $e(x) = e^{2\pi i x}$.

For a function $f \in C_c^\infty(G)$ define the associated Whittaker function by

$$W^\psi_f(g) = \int_\mathbb{C} f(n(u)g)\psi(u)du, \quad g \in G.$$  

where $du$ is twice of the Lebesgue measure on $\mathbb{C}$. The Whittaker-Fourier coefficient of $f$ is defined by

$$W_\psi(f) = W^\psi_f(1) = \int_\mathbb{C} f(n(u))\psi(u)du.$$

Key words and phrases. Whittaker-Plancherel inversion formula, Bessel functions, Bessel transform.

The second author is supported by the Construct Program of the Key Discipline in Hunan Province.

1In number theory, when $f$ is a function on $G$ (not compactly supported) that comes from a Maass cusp form, there is a similar definition of $W^\psi_\varphi(f) = W^\psi_\varphi(1)$ related to the $\varphi$-th Fourier coefficient of $f$. 

Next, we introduce the Bessel coefficients of a function \( f \in C_c^\infty(G) \).

For \( t \in \mathbb{R} \) and \( m \in \mathbb{Z} \), let \( \pi_{it,m} \) denote the principal series representation of \( G \) unitarily induced from the following character of \( J \) (Bessel distribution):

\[
s(z)n(u) \rightarrow |z|^{4it}(z/|z|)^m.
\]

Precisely, \( \pi_{it,m} \) is the representation of \( G \) by right shifts on the space of smooth functions \( \varphi : G \rightarrow \mathbb{C} \) satisfying

\[
\varphi(s(z)n(u)g) = |z|^{4it+2}(z/|z|)^m \varphi(g), \quad g \in G.
\]

It is well known that these \( \pi_{it,m} \) are all the irreducible unitary tempered representations of \( G \), up to the equivalence \( \pi_{it,m} \cong \pi_{-it,-m} \).

Let \( J_\nu(z) \) be the classical Bessel function of the first kind,

\[
J_\nu(z) = \sum_{n=0}^{\infty} \frac{(-1)^n (4z)^{\nu+2n}}{n!\Gamma(\nu+n+1)}.
\]

We first introduce

\[
J_{it,m}(z) = J_{-2it-4m}(z)J_{-2it+4m}(z).
\]

The function \( J_{it,m}(z) \) is well defined in the sense that the expression on the right of (1.5) is independent on the choice of the argument of \( z \) modulo \( 2\pi \). Define

\[
J_{it,m}(z) = \begin{cases} 
\frac{1}{i \sinh(2\pi t)}(J_{it,m}(z) - J_{-it,-m}(z)), & \text{if } m \text{ is even}, \\
\frac{1}{i \cosh(2\pi t)}(J_{it,m}(z) + J_{-it,-m}(z)), & \text{if } m \text{ is odd}.
\end{cases}
\]

It is understood that in the non-generic case when \( t = 0 \) and \( m \) is even the right hand side should be replaced by its limit.

For \( \pi = \pi_{it,m} \) and \( \psi = \psi_\nu \), we define the attached Bessel function \( j_{\pi,\psi} \), supported on the open Bruhat cell \( BuB = NAWN \), such that

\[
j_{\pi,\psi}(s(z)u) = 2\pi^2 |\lambda z|^2 J_{it,m}(4\pi \lambda z),
\]

and that \( j_{\pi,\psi} \) is left and right \( (\psi,N) \)-equivalent, namely,

\[
j_{\pi,\psi}(n(u)s(z)u_n(v)) = \psi(u)\psi(v)j_{\pi,\psi}(s(z)w).
\]

Let \( f \in C_c^\infty(G) \). We now define the Bessel coefficient of \( f \) attached to \( \pi \) by

\[
J_{\pi,\psi}(f) = \int_G f(g)j_{\pi,\psi}(g)dg,
\]

where \( dg \) is the Haar measure on \( G \) defined by \( dg = |z|^{-4}dudv d^\infty z \) for the coordinates \( g = n(u)s(z)u_n(v) \) on the Bruhat cell, where \( d^\infty z = |z|^{-2}dz \) as usual. The Bessel coefficient (Bessel distribution) \( J_{\pi,\psi}(f) \) has been investigated in \([\text{CQ}]\). Some results of \([\text{CQ}]\) will be recollected in Appendix \([\text{B}]\) but at this moment one only needs to know that the integral in (1.9) is convergent for all \( f \in C_c^\infty(G) \).

Our Whittaker-Plancherel inversion formula for \( \text{SL}_2(\mathbb{C}) \) is as follows.
Theorem 1.1. Let notations be as above. For \( f \in C^\infty_c(G) \) we have

\[
W_\psi(f) = \frac{1}{16\pi^2|\lambda|^2} \sum_{m=-\infty}^{\infty} \int_{-\infty}^{\infty} J_{\pi_m, \psi}(f) \left( m^2/4 + 4r^2 \right) dt.
\]

Observe that \( J_{\pi, \psi}(z) \) is an even or odd function according as \( m \) is even or odd. So the formula (1.10) splits into a pair of similar formulae if parity conditions are imposed on \( f \). Also note that \( \pi_m, \psi \) is trivial on the center if and only if \( m \) is even, in which case \( \pi_m, \psi \) may be regarded as representation of \( \text{PSL}_2(\mathbb{C}) \). So the even case of (1.10) is the following formula for \( G/\{ \pm 1 \} = \text{PSL}_2(\mathbb{C}) \).

Corollary 1.2. Suppose that \( f \in C^\infty_c(G) \) is even, namely, \( f(g) = f(-g) \) for all \( g \in G \). Then

\[
W_\phi(f) = \frac{1}{16\pi^4|\lambda|^2} \sum_{d=1}^{\infty} \int_{-\infty}^{\infty} J_{\pi, \psi}(f) \left( d^2 + 4r^2 \right) dt.
\]

Remarks. A similar Whittaker-Plancherel formula for \( G = \text{SL}_2(\mathbb{R}) \) was obtained by Baruch and Mao [BM3]. They employ an analytic Bessel inversion formula of Kuznetsov while developing his celebrated trace formula for \( \text{PSL}_2(\mathbb{Z}) \) in [Kuz]. Both our main results and methods are in parallel with those of [BM3] although the analysis here is quite different. Likewise, the Bessel inversion formula that we use here was discovered by Bruggeman and Motohashi in their work on the Kuznetsov trace formula for \( \text{PSL}_2(\mathbb{Z}[i]) \).

Consider the \( \psi \)-Whittaker space \( C^\infty_c(N\backslash G; \psi) \) of smooth functions \( W : G \to \mathbb{C} \), compactly supported modulo \( N \), satisfying

\[
W(nu)g = \psi(u)W(g), \quad g \in G.
\]

Then each Whittaker function in \( C^\infty_c(N\backslash G; \psi) \) is a \( W_\psi(f) \) associated to some \( f \in C^\infty_c(G) \).

Recall that \( W_\phi(f) = W_\psi(f) \). On the other hand, in view of (1.3), we have

\[
J_{\pi, \phi}(f) = \int_{\mathbb{C}^\times} \int_{\mathbb{C}^\times} W_\psi(s(z)uw(v)) j_{\pi, \psi}(s(z)u) \psi(v)|z|^{-4} d^4 z dv.
\]

Hence, by simple comparison, the reader may find that our formula is an analogue to the Plancherel formula of Harish-Chandra for \( \text{SL}_2(\mathbb{C}) \). See for example [Kna, Theorem 11.2]. In contrast, the formula for \( \text{SL}_2(\mathbb{R}) \) in [BM3] is an analogue of [Kna, Theorem 11.6]. As explained in [Kna, §XI.2], the Plancherel formula of Harish-Chandra for \( \text{SL}_2(\mathbb{C}) \) is harder to establish than that for \( \text{SL}_2(\mathbb{R}) \) as there are two non-conjugate Cartan subgroups in \( \text{SL}_2(\mathbb{R}) \). On the contrary, the analysis here for \( \text{SL}_2(\mathbb{C}) \) is more difficult than that for \( \text{SL}_2(\mathbb{R}) \) in [BM3]. See [§5.4] for more details.

Our point here is that the analysis is always harder while the representation theory is relatively simpler when working over \( \mathbb{C} \) instead of \( \mathbb{R} \). We have to deal with the additional complexity arising from the analysis on the circle \( \{ z : |z| = 1 \} \subset \mathbb{C}^\times \), like a radial integral or, in our case, an infinite sum as in (1.10). The reader may find evidences for this general principle in [Q14], [BM2] and [CQ] (see also [Q12], [Q3]).
A general decomposition formula for the space $L^2(N\backslash G; \psi)$ of square integrable $\psi$-Whittaker functions of a real reductive group $G$ was obtained in the final chapter of Wallach’s book [Wal1]. Our formula, in contrast, is point-wise and does not follow from his decomposition formula as indicated in [BM3]. Moreover, our proof is completely different from the proof in [Wal1], since we do not use Harish-Chandra’s Plancherel formula. In particular, our proof brings to the front objects and tools which we think are interesting by themselves: Bessel functions and Bessel distributions of representations, orbital integrals and the Bessel transform of Bruggeman and Motohashi.

**Assumption.** Subsequently, we shall assume, as we may without essential loss of generality, that $\lambda = 1$ so that $\psi(u) = \psi_1(u) = e(u + \pi)$. It is only up to the conjugation by $s(\sqrt{\lambda})$. Also, the $\psi$ will be suppressed from the notations for simplicity.

In fact, for general $\lambda$, we fix a $\sqrt{\lambda}$ and set $f_\lambda(g) = f(s(\sqrt{\lambda})^{-1}g(s(\sqrt{\lambda})))$. Then we readily see that $W_{\phi_\lambda}(f) = W_{\phi_1}(f_\lambda)/|\lambda|^2$. Also, we may verify that $J_{n,\phi_\lambda}(f) = J_{n,\phi_1}(f_\lambda)$. Hence the formula (1.10) in the general case follows from the case $\lambda = 1$.

## 2. Orbital integrals and the Bessel transform

In this section, we start our study with the Bessel coefficients $J_n(f)$ on the right-hand side of (1.10). It will be shown how one can express $J_n(f)$ as the Bessel transform of an orbital integral for $f$ in a simple way.

### 2.1. Orbital integrals.** Recall that $\psi(u) = e(u + \pi)$. For $f \in C_c^\infty(G)$, define

$$O_f(z) = \int \int f(n(u)s(z)uw(v))\psi(u)\psi(v)du dv, \quad z \in \mathbb{C}^\times.$$  

(2.1)

It is easy to check that the integral in (2.1) is absolutely convergent for all $z \in \mathbb{C}^\times$ and gives rise to a smooth function which vanishes around $z = 0$. These orbital integrals were investigated by Jacquet [Jac] §7 in a different context.

By the definitions in (1.9) and (2.1), along with (1.8), we have

$$J_n(f) = \int_G f(g)J_n(g)dg = \int \int \int f(n(u)s(z)uw(v))j_n(n(u)s(z)uw(v)) \cdot |z|^{-4}dudvd^2z$$

$$= \int j_n(s(z)w) \left( \int \int f(n(u)s(z)uw(v))\psi(u)\psi(v)du dv \right) |z|^{-4}d^2z$$

$$= \int j_n(s(z)w)O_f(z)|z|^{-4}d^2z.$$  

More explicitly, in view of (1.7), we have

$$J_{n,\phi}(f) = 2\pi^2 \int_{\mathbb{C}^\times(0)} J_{n,m}(4\pi z)O_f(z)|z|^{-2}d^2z.$$

---

2Recently, it was pointed out in [vdBK] that a lemma in the last chapter of [Wal1] is not correct. In response, Wallach gave a fixed proof of his Whittaker-Plancherel theorem in [Wal2].
Now we set
\[ G_f(z) = O_f(z/4\pi)/|z|^2 \]
so that
\[ J_{n,m}(f) = 32\pi^4 \int_{C\setminus\{0\}} J_{u,m}(z) G_f(z) d^\times z. \]
This immediately brings into mind the Bessel transform of Bruggeman and Motohashi.

2.2. The Bessel transform of Bruggeman and Motohashi. Let \( G(z) \) be a function in the space \( L^1(\mathbb{C} \setminus \{0\}, d^\times z) \). Following \([BMS],[LG]\), we define its Bessel transform by
\[ \hat{G}(it, m) = \int_{C\setminus\{0\}} J_{u,m}(z) G(z) d^\times z. \]

Since \( J_{u,m}(z) \) is of order \( O(1) \) at 0 and \( O(1/|z|) \) at \( \infty \) except for the non-generic case when \( t = 0 \) and \( m \) even (see (4.5) and (4.7)), it follows that these integrals are absolutely convergent if \( (it,m) \) is generic.

The Bessel inversion formula of Bruggeman and Motohashi in \([BMS]\) was originally for \( \text{PSL}_2(\mathbb{C}) \). It was soon generalized to \( \text{SL}_2(\mathbb{C}) \) in the thesis of Lokvenec-Guleska \([LG]\). We reformulate her formula in the following theorem:

**Theorem 2.1 (Bruggeman, Motohashi and Lokvenec-Guleska).** Assume that \( G(z) \in L^1(\mathbb{C} \setminus \{0\}, d^\times z) \cap L^2(\mathbb{C} \setminus \{0\}, d^\times z) \) is continuous and that
\[ \hat{G}(it, m) = O(1/(m^2 + r^2 + 1)^q(|m| + 1)) \]
for some \( q > 1 \). Then
\[ G(z) = \frac{1}{4} \sum_{m=-\infty}^{\infty} \int_{-\infty}^{\infty} (-1)^m J_{u,m}(z) \hat{G}(it, m) (m^2/4 + 4r^2) dt. \]

**Corollary 2.2.** Assume that \( G(z) \) is a smooth function on \( \mathbb{C} \setminus \{0\} \) such that \( G(z) \) vanishes in a neighborhood of 0 and \( G(z) = O(1/|z|^p) \) for some \( p > 0 \). Assume also that \( \hat{G}(it, m) = O(1/(m^2 + r^2 + 1)^q(|m| + 1)) \) for some \( q > 1 \). Then the Bessel inversion formula \((2.5)\) holds for \( G(z) \).

**Remark 2.3.** The formula \((2.5)\) may be found in \([BMS] \) Theorem 11.1\] and \([LG] \) Theorem 12.2.1\], but it is proven only for function \( G(z) \) compactly supported on \( \mathbb{C} \setminus \{0\} \). It is not sufficient for our purpose. They however also proved a Parseval-Plancherel formula for the Bessel transform, and it would enable us to prove \((2.5)\) for \( G(z) \) as in Theorem 2.1.

This will be done in Appendix A.

**Remark 2.4.** This Bessel inversion formula is the bridge to the “Kloosterman form” of the Kuznetsov trace formula for \( \text{SL}_2(\mathbb{C}) \) from its “spectral form” in \([BMS],[LG]\). There is however a direct approach to the Kloosterman form by a representation theoretic method of Cogdell and Piatetski-Shapiro in \([Q5]\). Compare also \([Kuz]\) and \([CPS]\) for \( \text{SL}_2(\mathbb{R}) \).

\(^3\)Note that her Bessel functions are normalized in an unnatural way to be all even.
Remark 2.5. In [QH1] Chapter 3, the Bessel inversion formula for $\text{SL}_2(\mathbb{C})$, along with the $\text{GL}_3(\mathbb{C}) \times \text{GL}_2(\mathbb{C})$ local functional equations, is applied in a formal way to derive a formula of Bessel functions for $\text{GL}_3(\mathbb{C})$. A similar formula is obtained for $\text{GL}_3(\mathbb{R})$ by the Bessel inversion formula of Kontorovich, Lebedev and Kuznetsov.

One of the main technical results of this work is to show that the function $G_f(z)$ satisfies the conditions in Corollary 2.2 for every $f \in C_c^\infty(G)$. For this, we shall first need the results of Jacquet [Jac] on the asymptotic of orbital integrals $O_f(z)$ as $|z| \to \infty$. In particular, Jacquet proves that the Whittaker coefficient $W_f$ on the left-hand side of (1.10) arises in the leading terms of the asymptotic formula for $O_f(z)$ (if $f$ is even or odd).

3. Asymptotic of orbital integrals

We now recollect Jacquet’s results on orbital integrals [Jac §7] as follows. Since it is so elegant, we are prompted to include his proof here.

Theorem 3.1 (Jacquet). Let $f \in C_c^\infty(G)$. Then there are two compactly supported smooth functions $H_+$ and $H_-$ on $\mathbb{C}$ such that
\begin{equation}
O_f(z) = \psi(2z)|z|H_+(1/z) + \psi(-2z)|z|H_-(1/z),
\end{equation}
and
\begin{equation}
H_+(0) = W_f(1)/2, \quad H_-(0) = W_f(-1)/2.
\end{equation}

Remark 3.2. There is an alternative proof of the theorem by Baruch and Mao in [BM3] for $G = \text{SL}_2(\mathbb{R})$, directly using the method of stationary phase. It would however be quite technical to generalize their arguments to $\mathbb{C}$. Jacquet’s original proof applies the Parseval-Plancherel formula of Weil as a substitute for stationary phase. It works not only for $\mathbb{R}$ and $\mathbb{C}$ but also for non-Archimedean local fields.

Proof of Theorem 3.1

Let
\begin{equation}
N^- = \left\{ n^-(u) = \begin{pmatrix} 1 & 0 \\ u & 1 \end{pmatrix} : u \in \mathbb{C} \right\}.
\end{equation}
We have
\begin{equation}
G = N\text{An} \cup N^-\text{AN}.
\end{equation}
Thus we may assume that the support of $f$ is contained in one of these cells. Recall the definitions of $W_f(g)$ and $O_f(z)$ in (1.2) and (2.1). If $f$ is supported on $N\text{An}$, then $W_f(1) = W_f(-1) = 0$ and $O_f(z)$ is compactly supported on $\mathbb{C}^\times$. Now assume that the support of $f$ is contained in $N^-\text{AN}$. Then the function $T$ defined by
\begin{equation}
T(u, z) = \int f(n^-(u)s(z)n(v))\psi(v)dv
\end{equation}
is smooth and compactly supported on the product $\mathbb{C} \times \mathbb{C}^\times$. It is clear that
\begin{equation}
T(0, 1) = W_f(1), \quad T(0, -1) = W_f(-1).
\end{equation}
A Whittaker-Plancherel Inversion Formula for $SL_2(\mathbb{C})$

Note that for $u \in \mathbb{C}^\times$ we have
\[
\left( \begin{array}{cc} 1 & u \\ 1 & z^{-1} \end{array} \right) w \left( \begin{array}{cc} 1 & v \\ u^{-1} & 1 \end{array} \right) = \left( \begin{array}{cc} 1 & z^{-1} u \\ u^{-1} & z u^{-1} \end{array} \right) \left( \begin{array}{cc} 1 & v - z^2 u^{-1} \\ z^{-1} & 1 \end{array} \right).
\]

After suitable changes of variables, $O_f(z)$ may be reformulated as follows
\[
O_f(z) = |z|^2 \int T((uz)^{-1}, u) \psi(z(u + u^{-1})) du.
\]

Since the phase function $u + u^{-1}$ has two stationary points 1 and $-1$, we may introduce a suitable partition of unity and write
\[
O_f = K_0 + K_+ + K_-
\]
so that $K_0$ is a Schwartz function on $\mathbb{C}^\times$ and that $K_\pm$ is of the form
\[
K_\pm(z) = |z|^2 \int T_\pm((uz)^{-1}, u) \psi(z(u + u^{-1})) du;
\]
the function $T_\pm$ is smooth of compact support on $\mathbb{C} \times \mathbb{C}^\times$; furthermore, the projection of the support of $T_\pm$ to the second factor is contained in a small neighborhood of $\pm 1$ and $T_\pm(0, \pm 1) = T(0, 1) = W_f(\pm 1)$.

In the integral for $K_\pm$, we first introduce a new variable given by $u + u^{-1} = \pm 2 + w^2$, $w = u^{1/2} \mp u^{-1/2}$, where the square root is chosen to be the principal branch. We find then
\[
K_\pm(z) = \psi(\pm 2z)|z|^2 \int \Phi_\pm(z^{-1}, w) \psi(zw^2) dw,
\]
with
\[
\Phi_\pm(z, w) = T_\pm(z u^{-1}, u) |dw/du|^{-2}.
\]

At this point, we invoke the Parseval-Plancherel identity of Weil,
\[
(3.3) \quad \int \hat{\Phi}(u) \psi(\frac{i}{2} z u^2) du = |z|^{-1} \int \hat{\Phi}(u) \psi(-\frac{i}{2} z^{-1} u^2) du,
\]
in which $\Phi$ is a Schwartz function on $\mathbb{C}$ and $\hat{\Phi}$ is its Fourier transform
\[
\hat{\Phi}(v) = \int \Phi(v) \psi(w) dw.
\]
As a consequence of (3.3), we have
\[
K_\pm(z) = \psi(\pm 2z)|z|H_\pm(1/z),
\]
where we have set
\[
H_\pm(z) = \frac{1}{2} \int \hat{\Phi}_\pm(z, w) \psi(-\frac{1}{4} w^2 z) dw,
\]
\[
\hat{\Phi}_\pm(z, w) = \int \Phi_\pm(z, v) \psi(wv) dv.
\]
Now $H_\pm$ is certainly smooth near 0 and
\[
2H_\pm(0) = \int \hat{\Phi}_\pm(0, w) dw = \Phi_\pm(0, 0) = T_\pm(0, \pm 1) = W_f(\pm 1).
\]
Q.E.D.
3.1. The main analytic theorem. We now expand $H_+(1/z)$ in Taylor series at $1/z = 0$ up to the fourth order in terms of $1/z$ and $1/\bar{z}$. We also localize the resulting terms by a smooth function $w(z)$ which is equal to 1 around $\infty$ and vanishes in a neighborhood of 0. In this way, we may write the function $G_f(z)$ defined in (2.2) as follows,

$$G_f(z) = \sum_{\pm} \sum_{\alpha + \beta \leq 4} C_{\alpha \beta}^{\pm} w(z) e^{\frac{\pm (z + \bar{z})}{\zeta^{3/2} + \alpha \zeta^{1/2} + \beta}} + G^4(z),$$

in which

$$C_{\alpha \beta}^{\pm} = W_f(1)/2, \quad C_{\alpha \beta}^{-} = W_f(-1)/2,$$

and $G^4(z)$ is a smooth function which vanishes around 0 and vanishes at $\infty$ to the sixth order.

$$\left(\partial/\partial z\right)^\gamma \left(\partial/\partial \bar{z}\right)^\delta G^4(z) \ll_{\gamma, \delta} 1/|z|^6, \quad \gamma, \delta = 0, 1, 2, \ldots.$$  

In light of these, we state our main analytic theorem as follows. Its proof is in §5.

**Theorem 3.3.** Let $w(z)$ be a smooth function on $\mathbb{C} \setminus \{0\}$ which is equal to 1 around $\infty$ and vanishes in a neighborhood of 0.

(1) For $\alpha, \beta = 0, 1, 2, \ldots$, define $G_{\alpha \beta}(z) = w(z) e^{(z + \bar{z})/2|z|^{1/2} + \alpha z^{1/2} + \beta}$. Then

$$\tilde{G}_{\alpha \beta}(i t, m) = O \left(1/(m^2 + r^2 + 1)^{3/2} \right)$$

for any $0 \leq r < 1/3$. Furthermore, when $\alpha$ or $\beta = 0$, we have

$$\tilde{G}_{\alpha \beta}(i t, m) = O \left(1/(m^2 + r^2 + 1)^{3/2} \right)$$

for arbitrary $A > 0$.

(2) Let $G^4(z)$ be a smooth function which vanishes around 0 and vanishes at $\infty$ to the sixth order as in (3.6). Then

$$G^4(i t, m) = O \left(1/(m^2 + r^2 + 1)^{3} \right)$$

for any $0 \leq r < 1/3$.

**Corollary 3.4.** We have $\tilde{G}_f(i t, m) = O \left(1/(m^2 + r^2 + 1)^{3} \right)$ for any $r$ with $0 \leq r < 1/3$.

3.2. Proof of Theorem 1.1. Granted that Theorem 3.3 and hence Corollary 3.4 hold, we are now ready to prove Theorem 1.1. Still one assumption is needed in the course of the proof. We leave its justifications to §5.

Let $f \in C^\infty_0(G)$. We can write $f$ as the sum of an even and an odd function. So, by linearity, we may well assume that $f$ is itself even or odd. As the arguments for the two cases are similar, we shall only prove the even case, that is, Corollary 1.2.

Now let $f$ be even. Then $O_f(z)$ and hence $G_f(z)$ are even functions on $\mathbb{C} \setminus \{0\}$. Observe that

$$W_f(1) = W_f(-1) = W(f).$$
It follows from (2.2), (3.1) and (3.2) that
\[
W(f) = \lim_{z \to \infty} \frac{4\pi|z|G_f(z)}{\cos(z + \bar{z})},
\]
where the limit is taken on a set of \(z\) such that the denominator \(\cos(z + \bar{z})\) is bounded away from 0. In view of Theorem 3.1 and Corollary 3.4, it is clear that \(G_f\) satisfies the condition of Corollary 2.2. Then
\[
G_f(z) = \frac{1}{4} \sum_{d = -\infty}^{\infty} \int_{-\infty}^{\infty} J_{n,2d}(z) \tilde{G}_f(it, 2d)(d^2 + 4r^2)dt.
\]
Hence \(W(f)\) is equal to
\[
(3.7) \quad \lim_{z \to \infty} \frac{\pi|z|}{\cos(z + \bar{z})} \sum_{d = -\infty}^{\infty} \int_{-\infty}^{\infty} J_{n,2d}(z) \tilde{G}_f(it, 2d)(d^2 + 4r^2)dt.
\]
Assume now that it is legitimate to interchange the order of the limit, summation and integration in (3.7). This will be justified using the dominated convergence theorem in §5.3. We then have
\[
W(f) = \sum_{d = -\infty}^{\infty} \int_{-\infty}^{\infty} \frac{\pi|z|J_{n,2d}(z)}{\cos(z + \bar{z})} \tilde{G}_f(it, 2d)(d^2 + 4r^2)dt.
\]
It follows from the asymptotic formula for \(J_{n,2d}(z)\) (see (4.7)) that
\[
\lim_{z \to \infty} \frac{\pi|z|J_{n,2d}(z)}{\cos(z + \bar{z})} = 2,
\]
Consequently,
\[
W(f) = 2 \sum_{d = -\infty}^{\infty} \int_{-\infty}^{\infty} \tilde{G}_f(it, 2d)(d^2 + 4r^2)dt.
\]
In view of (2.3) and (2.4), we conclude that
\[
W(f) = \frac{1}{16\pi^4} \sum_{d = -\infty}^{\infty} \int_{-\infty}^{\infty} J_{n,2d}(f)(d^2 + 4r^2)dt.
\]

4. Estimates for the Bessel function \(J_{\mu,m}(z)\)

4.1. Preliminaries on the Bessel function \(J_{\mu,m}(z)\). In this section, we recollect some results on the Bessel function \(J_{\mu,m}(z)\) for \(\mu \in \mathbb{C}\) and \(m \in \mathbb{Z}\). We do not feel necessary to restrict ourselves to Bessel functions \(J_{\mu,m}(z)\) of pure imaginary order.

Let \(J_v(z)\) be the Bessel function of the first kind of order \(v\). Let \(H^{(1)}_v(z)\) and \(H^{(2)}_v(z)\) be the Hankel functions of order \(v\). They all satisfy the Bessel differential equation
\[
(4.1) \quad z^2 \frac{d^2w}{dz^2} + z \frac{dw}{dz} + (z^2 - v^2)w = 0.
\]

4.1.1. We have the definition
\[
J_{\mu,m}(z) = \begin{cases} 
\frac{1}{\sin(2\pi\mu)}(J_{\mu,m}(z) - J_{-\mu,-m}(z)), & \text{if } m \text{ is even,} \\
\frac{1}{i \cos(2\pi\mu)}(J_{\mu,m}(z) + J_{-\mu,-m}(z)), & \text{if } m \text{ is odd.}
\end{cases}
\]
with

\[(4.3) \quad J_{\mu,m}(z) = J_{-2\mu-\frac{2}{m}}(z)J_{-2\mu+\frac{2}{m}}(z).\]

When \(v\) is not a negative integer, we have the bound (see [Wat] 3.13 (1))

\[J_v(z) \ll_v |z|^v, \quad |z| \leq 1.\]

It follows that if \(\mu\) is generic, that is \(4\mu \notin 2\mathbb{Z} + m\), then

\[(4.4) \quad J_{\mu,m}(z) \ll_{\mu,m} \|z\|^{-4\mu} + \|z\|^{4\mu}, \quad |z| \leq 1.\]

In particular,

\[(4.5) \quad J_{0,m}(z) \ll_{m} \log(2/|z|), \quad |z| \leq 1, \quad (m \text{ even}).\]

We have a second expression of \(J_{\mu,m}(z)\) in terms of Hankel functions. Define

\[H_{\mu,m}^{(1,2)}(z) = H_{2\mu+\frac{2}{m}}^{(1,2)}(z)H_{2\mu-\frac{2}{m}}^{(1,2)}(z).\]

By the connection formulae [Wat] 3.6 (1),(2), we have

\[J_{\mu,m}(z) = \frac{i}{2} \left( (-1)^m e^{2\pi i \mu} H_{0,m}^{(1)}(z) - e^{-2\pi i \mu} H_{0,m}^{(2)}(z) \right).\]

From the asymptotic formula of Hankel functions [Wat] 7.2 (5),(6), we deduce that

\[(4.7) \quad J_{\mu,m}(z) \sim \frac{1}{\pi |z|} ((-1)^m e ((z + \bar{z})/2) + e ((z + \bar{z})/2)), \quad |z| \to \infty.\]

Moreover, it follows from [Olv] §7.13.1 that

\[(4.8) \quad J_{\mu,m}(z) \ll 1/|z|, \quad |z| > |\mu|^2 + m^2 + 1,\]

where the implied constant is absolute.

4.1.2. Recurrence formulae. Recall the following recurrence formula [Wat] 3.2 (2),

\[(4.9) \quad 2J_{\nu}'(z) = J_{\nu-1}(z) - J_{\nu+1}(z).\]

By (4.9), it is straightforward to derive the corresponding recurrence formulae

\[(4.10) \quad 2i\partial J_{\mu,m}(z)/\partial z = J_{\mu+\frac{2}{m}+1}(z) + J_{\mu-\frac{2}{m}+1}(z),\]

\[2i\partial J_{\mu,m}(z)/\partial \bar{z} = J_{\mu+\frac{2}{m}+1}(z) + J_{\mu-\frac{2}{m}+1}(z).\]

It follows from (4.7)–(4.8) and (4.10) that

\[(4.11) \quad \partial J_{0,m}(z)/\partial z, \partial J_{0,m}(z)/\partial \bar{z} = O(1/|z|), \quad |z| \to \infty.\]

4.1.3. Differential equations. Define

\[(4.12) \quad \nabla = z^2 \frac{\partial^2}{\partial z^2} + z \frac{\partial}{\partial z} + \bar{z}^2 = \left( z \frac{\partial}{\partial z} \right)^2 + \bar{z}^2,\]

and its conjugation

\[(4.13) \quad \nabla = \bar{z}^2 \frac{\partial^2}{\partial \bar{z}^2} + \bar{z} \frac{\partial}{\partial \bar{z}} + z^2 = \left( \bar{z} \frac{\partial}{\partial \bar{z}} \right)^2 + z^2.\]
It is clear from (4.1)-(4.3) that $J_{\mu,m}(z)$ is an eigenfunction of both $\nabla$ and $\nabla^*$:

\begin{align}
\nabla J_{\mu,m}(z) &= (2\mu + m/2)^2 J_{\mu,m}(z), \\
\nabla J_{\mu,m}(z) &= (2\mu - m/2)^2 J_{\mu,m}(z).
\end{align}

4.1.4. An integral representation. In the polar coordinates, we have the following integral representation of $J_{\mu,m}(xe^{i\phi})$ (see [Qi44, Corollary 6.17] or [BMS Theorem 12.1]),

\begin{equation}
J_{\mu,m}(xe^{i\phi}) = \frac{2(-i)^m}{\pi} \int_0^\infty y^{\mu-1}E(ye^{i\phi})^{-m}J_m(xy) \, dy,
\end{equation}

with

\begin{equation}
Y(z) = |z + z^{-1}|, \quad E(z) = (z + z^{-1})/|z + z^{-1}|.
\end{equation}

The integral in (4.16) is absolutely convergent only when $|\text{Re}\mu| < \frac{1}{8}$.

**Lemma 4.1.** We have

\begin{equation}
J_{it,m}(z) \ll \begin{cases} 
\exp \left( \frac{|z|^2/4}{|t|} \right) \left( 1 + \frac{1}{\sqrt{t^2 + m^2}} \right), & \text{if } m \text{ is even}, \\
\exp \left( \frac{|z|^2/2}{\sqrt{t^2 + m^2}} \right), & \text{if } m \text{ is odd}.
\end{cases}
\end{equation}

**Proof.** Let us assume that $(it, m)$ is generic, as otherwise (4.18) is trivial.

Recall from [Wat 3.13 (1)] that for $\nu \neq -1, -2, -3, ...$

\begin{equation}
J_\nu(z) = \frac{(z/2)^\nu}{\Gamma(\nu + 1)} (1 + \theta),
\end{equation}

where

\begin{equation}
|\theta| < \exp \left( \frac{|z|^2}{4|y_0 + 1|} \right) - 1,
\end{equation}

and $|y_0 + 1|$ is the smallest of the numbers $|\nu + 1|$, $|\nu + 2|$, $|\nu + 3|,...$. Note that the bound in (4.20) is awful when $|y_0 + 1|$ is very close to 0. By modifying the arguments in [Wat §2.11], we may also prove

\begin{equation}
|\theta| < \exp \left( \frac{|z|^2/4}{|y_0 + 1|} - 1 \right).
\end{equation}

We now apply these to $J_{it,m}(z)$ as defined in (1.5). For $\nu = -2it \pm \frac{1}{2}m$, we have

\begin{equation}
|y_0 + 1| \geq \begin{cases} 
2|t|, & \text{if } m \text{ is even}, \\
|2it + \frac{1}{2}|, & \text{if } m \text{ is odd}.
\end{cases}
\end{equation}
Also note that
\[
\left| \frac{(z/2)^{-2it+\frac{1}{2}m}(\tilde{z}/2)^{-2it-\frac{1}{2}m}}{\Gamma(-2it-\frac{1}{2}m+1)\Gamma(-2it+\frac{1}{2}m+1)} \right| = \begin{cases} \frac{|\sinh(2\pi t)|}{\pi \sqrt{4t^2 + m^2/4}}, & \text{if } m \text{ is even,} \\ \frac{\cosh(2\pi t)}{\pi \sqrt{4t^2 + m^2/4}}, & \text{if } m \text{ is odd.} \end{cases}
\]

It then follows from (4.19)-(4.21) that
\[
(4.22)
\]
and that when \(0 \leq \frac{1}{t}\) is bounded. Then follows (4.22) and the lemma. Q.E.D.

Also note that
\[
12 \text{ ZHI QI AND CHANG YANG}
\]

See for example [AS 9.1.60]. Moreover, the following bounds are obtained by Landau [Lan] in his study of monotonicity properties of Bessel functions,
\[
|J_\nu(x)| < b/|x|^{1/3}, \quad |J_\nu(x)| \leq c/|x|^{1/3},
\]
with \(b = 0.674885...\) and \(c = 0.785746...\). Combining the bounds above, we deduce easily that, for any \(0 \leq t \leq 1/3\),
\[
(4.23)
\]
\[
J_\nu(x) \ll t, \quad \frac{1}{(\nu + 1)^{1/2} |x|^{1/3 - r}}, \quad x \text{ real, } \nu \geq 0.
\]

We now return to the proof. By the integral representation (4.16, 4.17), we have
\[
|J_{\nu,m}(xe^{i\phi})| \leq \frac{2}{\pi} \int_0^\infty |J_m(xY(\nu e^{i\phi}))| \frac{dy}{y},
\]
with \(Y(\nu e^{i\phi})\) defined as in (4.17). Applying (4.23), we get
\[
J_{\nu,m}(xe^{i\phi}) \ll \frac{1}{(\nu + 1)^{1/2} |x|^{1/3 - r}} \int_0^\infty \frac{dy}{y} Y(\nu e^{i\phi})^{1/3 - r}.
\]

Note that we always have
\[
Y(\nu e^{i\phi}) \geq |y - 1/y|,
\]
and that when \(0 \leq r < 1/3\) the integral
\[
\int_0^\infty \frac{dy}{y} |y - 1/y|^{1/3 - r}
\]
is bounded. Then follows (4.22) and the lemma. Q.E.D.

Finally a uniform bound for \(|z|J_{\nu,m}(z)\) will be needed in 4.5.3.
Lemma 4.3. We have

\[ |z| J_{\mu,m}(z) \ll (m^2 + r^2 + 1)^{2/3}. \]

Proof. When \(|z| > m^2 + r^2 + 1\), the bound \(J_{\mu,m}(z) \ll 1/|z|\) in (4.8) is more than sufficient. When \(|z| \leq m^2 + r^2 + 1\), it follows from (4.22) with \(r = 0\) that

\[ J_{\mu,m}(z) \ll \frac{1}{|z|^{1/3}} \ll \frac{(m^2 + r^2 + 1)^{2/3}}{|z|}. \]

Q.E.D.

5. Bounds on the Bessel transform

5.1. A formula for partial integration. It will be very convenient to integrate on differential forms in terms of \(z\) and \(\bar{z}\). In particular, the volume form on \(\mathbb{C}\) is \(idz \wedge d\bar{z}\) (there is a slight abuse of notation as \(d\bar{z}\) was the Haar measure on \(\mathbb{C}\)). By Stokes’ theorem, one can easily derive the following formula; the proof is left to the reader as an exercise.

Lemma 5.1. Let \(F, G \in C^\infty(\mathbb{C} \setminus \{0\})\). Assume that \(F(z)G(z) = o(1)\) for both \(|z| \to 0\) and \(|z| \to \infty\). We have

\[ \int_{\mathbb{C}\setminus\{0\}} \frac{\partial F(z)}{\partial z} \cdot G(z) \frac{idz \wedge d\bar{z}}{z\bar{z}} = -\int_{\mathbb{C}\setminus\{0\}} F(z) \cdot \frac{\partial G(z)}{\partial \bar{z}} \frac{idz \wedge d\bar{z}}{z\bar{z}}. \]

Corollary 5.2. Let \(\nabla\) be defined as in (4.12). Let \(G(z)\) be a smooth function that vanishes around 0 and such that \(G(z) = o(1), \partial G(z)/\partial \bar{z} = o(1)\). We have

\[ \int_{\mathbb{C}\setminus\{0\}} J_{\mu,m}(z) \cdot G(z) d^2z = \frac{1}{(2it + m/2)^2} \int_{\mathbb{C}\setminus\{0\}} J_{\mu,m}(z) \cdot \nabla G(z) d^2z. \]

Proof. The identity (5.1) follows from two applications of Lemma 5.1 along with \(\nabla J_{\mu,m}(z) = (2it + m/2)^2 J_{\mu,m}(z)\).

See (4.14). Note that the condition of Lemma 5.1 may be verified by the bounds for \(J_{\mu,m}(z)\) and \(\partial J_{\mu,m}(z)/\partial \bar{z}\) in (4.5) and (4.11) together with the conditions for \(G(z)\) here. Q.E.D.

A first application of Corollary 5.2 is for smooth functions \(G(z)\) compactly supported in \(\mathbb{C} \setminus \{0\}\). See also [BMS (11.5)].

Corollary 5.3. Let \(G(z) \in C^\infty(\mathbb{C} \setminus \{0\})\). We have for any \(A > 0\),

\[ G(it, m) = O_A(1/(m^2 + r^2 + 1)^d), \]

with the implied constant depending only on \(A\) and the function \(G(z)\).

5.2. Proof of Theorem 3.3

5.2.1. Proof of Theorem 3.3 (2). We start with the case in Theorem 3.3 (2). As the function \(G^2\) has a high order of vanishing at \(\infty\), this case would be easier presumably.

In view of (3.6), the function \(G^2\) has an order of vanishing at least sixth, while \(\nabla\) has the effect of decreasing the order by two, so we are allowed to apply (5.1) in Corollary 5.2

...
thrice to $G^j$, $\nabla G^j$ and $\nabla^2 G^j$. Thus

\[ G^j(\alpha \beta) = \int_{C \setminus \{0\}} J_{\alpha \beta}(z) G^j(z) \frac{d^2 z}{(2\pi)^2} \]

(5.2)

Note that $\nabla^3 G^j$ vanishes around 0 and is bounded according to (3.6). It follows from the uniform bound (4.22) for $J_{\alpha \beta}(z)$ that

\[ \int_{C \setminus \{0\}} J_{\alpha \beta}(z) \nabla^3 G^j(z) d^2 z = O(1/(|m| + 1)^r), \]

for any $0 < r < 1/3$. Also note the trivial bound

\[ G^j(it, 0) = O(1), \quad |t| < 1. \]

We conclude from (5.2)-(5.4) that

\[ G^j(it, m) = O\left(1/(m^2 + r^2 + 1)^3(|m| + 1)^r\right). \]

5.2.2. Proof of Theorem 5.3 (1). Now we turn to the proof of Theorem 5.3 (1). Set

\[ E_{\alpha \beta}(z) = e((z + \frac{1}{2})/2\pi) \frac{z^{1/2 + \alpha} z^{1/2 + \beta}}{\pi^2}, \]

so that $G_{\alpha \beta}(z) = w(z) E_{\alpha \beta}(z)$. We divide the treatment for the $G_{\alpha \beta}$'s into two cases.

First, we consider the $G_{\alpha \beta}$ with $\alpha, \beta \neq 0$. Then $\alpha + \beta \geq 2$ and hence

\[ G_{\alpha \beta}(z) = O(1/|z|^3). \]

Not all these $G_{\alpha \beta}$ have sufficiently high order of vanishing at $\infty$ like $G^j$. Fortunately, the order of vanishing of each $G_{\alpha \beta}$ decreases only by \textit{one (not two)} each time we apply $\nabla$, so we may still apply (5.1) thrice in this case. In fact, by a simple computation, we find that

\[ \nabla^\gamma E_{\alpha \beta}(z) = P_\alpha(z) E_{\alpha \beta}(z), \quad \gamma = 1, 2, 3, \]

where $P_\alpha(z)$ is a polynomial of degree $\gamma$, explicitly given by

\[ P_1(z) = (1/2 + \alpha)z \mp 2\alpha iz, \quad P_2(z) = (1/2 + \alpha)^2 \mp \alpha(1 + 4\alpha^2)iz + 4\alpha(1 - \alpha)z^2, \]

\[ P_3(z) = (1/2 + \alpha)^6 \mp \alpha(3 + 4\alpha^2)(1 + 12\alpha^2)iz/8 \]

\[ + \alpha(1 - \alpha)(11 - 12\alpha + 12\alpha^2)z^2 \pm 8\alpha(1 - \alpha)(2 - \alpha)iz^3. \]

Also, observe that $G_{\alpha \beta}(z)$ is equal to $E_{\alpha \beta}(z)$ around $\infty$. It is then implied that

\[ \nabla^\gamma G_{\alpha \beta}(z) = O(1/|z|^{3 - \gamma}), \quad \gamma = 0, 1, 2, 3, \]

and that $G_{\alpha \beta}$, $\nabla G_{\alpha \beta}$ and $\nabla^2 G_{\alpha \beta}$ all satisfy the condition of Corollary 5.2. Consequently,

\[ \tilde{G}_{\alpha \beta}(it, m) = \int_{C \setminus \{0\}} J_{\alpha \beta}(z) \nabla^3 G_{\alpha \beta}(z) d^2 z. \]

By the same arguments in 5.2.1 for $G^j$, we conclude that

\[ \tilde{G}_{\alpha \beta}(it, m) = O\left(1/(m^2 + r^2 + 1)^3(|m| + 1)^r\right). \]

Second, consider those $G_{\alpha \beta}$ with $\alpha$ or $\beta = 0$. For example, we take $\alpha = 0$. We simply change $\nabla$ to $\bar{\nabla}$ in what follows if $\beta = 0$.

At a first glance, it seems that handling this case is a mission impossible as, in the worst case scenario, $G_{00}$ only vanishes at $\infty$ to the first order. However we find that $E_{00}$ is
also an eigenfunction of the differential operator $\nabla$ like $J_{\alpha,m}$:
\begin{equation}
\nabla E_{\nu}(\xi) = \frac{1}{\xi} E_{\nu}(\xi)
\end{equation}
This would actually lead to an estimate for $\hat{G}_{\nu}(it, m)$ so strong as if $G_{\nu}$ were compactly supported in $\mathbb{C} \setminus \{0\}$.

We now return to the proof. It is easy to check that $G_{\nu}$ satisfies the condition of Corollary 5.2. Applying (5.1), we get
\begin{equation}
\hat{G}_{\nu}(it, m) = \int_{\mathbb{C} \setminus \{0\}} J_{\alpha,m}(\xi) G_{\nu}(\xi) d^\infty \xi = \frac{1}{(2it + \xi)^2 - \frac{1}{4}} \int_{\mathbb{C} \setminus \{0\}} J_{\alpha,m} \nabla G_{\nu}(\xi) d^\infty \xi.
\end{equation}
Recall that $G_{\nu}(\xi) = w(\xi) E_{\nu}(\xi)$ and that $w(\xi)$ vanishes around 0 and is equal to 1 near $\infty$.

It follows from (5.11) that the function $V(\xi)$ defined by
\begin{equation}
V(\xi) = \nabla G_{\nu}(\xi) - \frac{1}{4} G_{\nu}(\xi)
\end{equation}
is smooth of compact support on $\mathbb{C} \setminus \{0\}$. By (5.11) and (5.12), we have
\begin{equation}
\hat{G}_{\nu}(it, m) = -\frac{1}{(2it + \xi)^2 - \frac{1}{4}} V(it, m).
\end{equation}
By Corollary 5.3 we conclude that
\begin{equation}
\hat{G}_{\nu}(it, m) = O\left(\frac{1}{(m^2 + r^2 + 1)^A}\right)
\end{equation}
for any $A > 0$.

### 5.3. Change of order of limit, summation and integration.
Finally, we prove that the expression inside the limit in (5.7) is convergent absolutely and uniformly in $\xi$. By (4.24), we have
\begin{equation}
\frac{|\xi| U_{\alpha,2\delta}(\xi)}{\cos(\xi + \bar{\xi})} \ll (d^2 + r^2 + 1)^{2/3},
\end{equation}
which is uniform on the set of $\xi$ such that $|\cos(\xi + \bar{\xi})| > \frac{1}{2}$ say. Moreover, according to Corollary 5.4
\begin{equation}
\hat{G}_{\nu}(it, 2d) \ll \frac{1}{(d^2 + r^2 + 1)^3}.
\end{equation}
Consequently,
\begin{equation}
\sum_{d = -\infty}^{\infty} \int_{-\infty}^{\infty} \frac{\pi |\xi| U_{\alpha,2\delta}(\xi)}{\cos(\xi + \bar{\xi})} |\hat{G}_{\nu}(it, 2d)| (d^2 + 4r^2) dt \ll \sum_{d = -\infty}^{\infty} \int_{-\infty}^{\infty} \frac{dt}{(d^2 + r^2 + 1)^{4/3}} < \infty.
\end{equation}
Hence we can use the dominated convergence theorem to move the limit into the sum and integral in (5.7). Similar is the odd case.

### 5.4. Comparison with the analysis of Baruch and Mao for $SL_2(\mathbb{R})$.
At the beginning of the analysis in [BMA, \S 5], Baruch and Mao studied the following integrals
\begin{equation}
\int_{0}^{\infty} J_{\alpha}(\xi) \cos(\xi) x^{s-1} dx = \frac{2^{\nu-1} \Gamma(1/2 - s) \Gamma(\nu/2 + s/2)}{\Gamma(1/2 - \nu/2 - s/2) \Gamma(1 + \nu - s)}.
\end{equation}

---

Note: The reader might have already noticed that it follows from the formulae $J_{\alpha}(\xi) = (2/\pi \xi)^{\alpha} \sin \xi$ and $J_{\alpha}(\xi) = (2/\pi \xi)^{\alpha} \cos \xi$ (see [Wat] \S 3.4 (3), (6)).
applying the recurrence formula. However these two key steps in their arguments break down in our complex case. Also note that the admissible range of $s$ the vanishing order by the recurrence formula would not work for repeatedly applied to increase the order of vanishing of the Bessel functions at $x = 0$,

$$J_v(x) = J_{v+2}(x) + 2J_{v+1}(x).$$

Also note that the admissible range of $s$ for the integral formulae above is extended after applying the recurrence formula. However these two key steps in their arguments break down in our complex case.

First of all, there is currently no analogue of these integral formulae for $J_{\mu,m}(z)$, and the analogous integrals

$$\int_{C\setminus\{0\}} J_{\mu,m}(z) \cos(z + z)|s|^d z, \int_{C\setminus\{0\}} J_{\mu,m}(z) \sin(z + z)|s|^d z,$$

are simultaneously convergent only for $|Re\mu| < s < 1$. Also the mechanism of increasing the vanishing order by the recurrence formula would not work for $J_{\mu,m}(z)$. Actually, the asymptotic of $J_{\mu,m}(z)$ is of the order of $|z|^{-\mu} + |z|^{\mu}$ when $|z| \to 0$ (compare (4.14)), so $J_{it,m}(z)$ already has the optimal asymptotic at $z = 0$. Any application of the recurrence formulae in (4.10), for example, results in shifting the order to $it \pm \frac{1}{4}$ or $it \pm \frac{1}{4}$ and would only make it worse. Yet another issue is that the integral representation of $J_{\mu,m}(z)$ in (4.16) fails to be absolutely convergent if the order $\mu$ is $it \pm \frac{1}{4}$ or $it \pm \frac{1}{4}$.

### Appendix A. Proof of Theorem 2.1

Recall the Bessel transform defined in (2.4). We have the following Parseval-Plancherel formula due to Bruggeman, Motohashi and Lokvenec-Guleska ([BMS] Theorem 11.1) and [LG] Theorem 12.1)

(A.1) \[ \int_{C\setminus\{0\}} G(z)F(z)d^*z = \frac{1}{4} \sum_{m=-\infty}^{\infty} \int_{-\infty}^{\infty} \check{G}(it, m)\tilde{F}(it, m)(m^2/4 + 4t^2)dt, \]

for functions $G, F \in C^\infty_c(\mathbb{C} \setminus \{0\})$. Observe that \[ \tilde{F}(it, m) = (-1)^m \tilde{F}(it, m). \]

It follows from (A.1) that the Bessel transform establishes an (abstract) isometry between the Hilbert spaces

$$L^2(\mathbb{C} \setminus \{0\}, d^*z) \longrightarrow L^2(\mathbb{Z} \times \mathbb{R}, (m^2/4 + 4t^2)dt).$$

Now let $G(z) \in L^1(\mathbb{C} \setminus \{0\}, d^*z) \cap L^2(\mathbb{C} \setminus \{0\}, d^*z)$ and $F(z) \in C^\infty_c(\mathbb{C} \setminus \{0\})$ so that their Bessel transform $\check{G}(it, m)$ and $\tilde{F}(it, m)$ given as in (2.4) are both well defined. We may then write (A.1) in the following way

$$\int_{C\setminus\{0\}} G(z)F(z)d^*z = \frac{1}{4} \sum_{m=-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{C\setminus\{0\}} (-1)^m \check{G}(it, m)J_{it,m}(z)(m^2/4 + 4t^2)\tilde{F}(z)d^*zdt.$$
Thus the Bessel inversion formula (2.5) in Theorem 2.1 follows immediately if \( G(z) \) is continuous and the right hand side converges absolutely. This in turn follows from our assumption \( \hat{G}(t, m) = O(1/(m^2 + t^2 + 1)^{q(|m| + 1)}) \) \( (q > 1) \) in Theorem 2.1 along with the uniform bounds for \( J_{it,m}(z) \) in Lemma 4.1 and 4.2. In fact, by the estimates in (4.18) and (4.22), we have

\[
J_{it,m}(z) \leq \begin{cases} \frac{1}{||t|+|m||}, & \text{if } |t| > 1, \\ 1, & \text{if } |t| \leq 1, \end{cases}
\]

which is uniform on any given compact subset of \( \mathbb{C} \setminus \{0\} \), say on the support of \( F \). Hence the sum of integrals on the right hand side of (2.5) is uniformly and absolutely bounded by

\[
\sum_{m=-\infty}^{\infty} \frac{1}{|m|+1} \left( \int_{-\infty}^{-1} + \int_{1}^{\infty} \frac{dt}{(|t|+|m|)^{2q-1}} + \int_{-1}^{1} \frac{dt}{(|m|+1)^{2q-1}} \right) < \infty,
\]

as desired.

### Appendix B. Representation theory of Bessel functions and distributions for \( SL_2(\mathbb{C}) \)

In this appendix, we give a brief review of Bessel distributions and Bessel functions for \( SL_2(\mathbb{C}) \) in [CQ]. For additional results on Bessel distributions and Bessel functions see [Bar1] [BM4], [CPS] and [Mot].

#### B.1. Bessel distributions for \( SL_2(\mathbb{C}) \)

The Bessel distribution \( J_{\pi,\psi} \) given by (1.5)-(1.9) were defined in an ad hoc way. The definition of \( J_{\pi,\psi} \) in representation theory is another story.

Let \( \pi \) be an infinite dimensional irreducible unitary representation of \( G \) on a Hilbert space \( H \) and \( \langle \cdot, \cdot \rangle \) be a \( G \)-invariant nonzero inner product on \( H \). Let \( H_{\infty} \) be the subspace of smooth vectors in \( H \). Let \( \psi \) be an additive character as defined in (1.1). It is well known that there exists a nonzero continuous \( \psi \)-Whittaker functional \( L \) on \( H_{\infty} \), unique up to scalars, satisfying

\[
L(\pi(n(u))v) = \psi(u)L(v), \quad n(u) \in N, \quad v \in H_{\infty}.
\]

Let

\[
W_\psi(g) = L(\pi(g)v), \quad v \in H_{\infty}, \quad g \in G,
\]

be the Whittaker function corresponding to \( v \). We normalize the Whittaker functional \( L \) so that

\[
\langle v_1, v_2 \rangle = \int_{\mathbb{C}^*} W_{\psi_1}(s(z))W_{\psi_2}(s(z))d^* z.
\]

It is well known that for every \( v_1, v_2 \in H_{\infty} \), the integral above is absolutely convergent and indeed gives a \( G \)-invariant inner product on \( H_{\infty} \).

For every \( f \in C_c^\infty(G) \) and \( v \in H \) we define

\[
\pi(f)v = \int_G f(g)\pi(g)v \, dg,
\]

where \( dg \) is the Haar measure on \( G \) defined in Introduction.
Let \( \{v_i\} \) be an orthonormal basis in \( H_\infty \). We define the Bessel distribution \( J_{\pi,\psi} \) by
\[
J_{\pi,\psi}(f) = \sum_i L(\pi(f)v_i)\overline{L(v_i)}.
\]
(B.1)
The distribution is independent on the choice of orthonormal basis.

The main result on Bessel distributions for \( \text{SL}_2(\mathbb{C}) \) is a regularity theorem in \([CQ]\).

**Theorem B.1.** Let \( \pi \) be an irreducible unitary representation of \( G \). Then there exists a real analytic function \( j_{\pi,\psi} : \mathcal{B}_w \rightarrow \mathbb{C} \) which is locally integrable on \( G \) such that
\[
J_{\pi,\psi}(f) = \int_G f(g)j_{\pi,\psi}(g)dg,
\]
for all \( f \in C_c^\infty(G) \).

**B.2. Bessel functions for \( \text{SL}_2(\mathbb{C}) \).** The interpretation in representation theory of Bessel functions \( j_{\pi,\psi} \) defined as in \((1.5)-(1.8)\) is the following kernel formula.

**Theorem B.2.** Let \( \pi \) be an irreducible unitary representation of \( G \). We have
\[
W_v(s(y)w) = \int_{\mathbb{C}^\times} j_{\pi,\psi}(s(yz)w)W_v(s(z))d^\times z,
\]
for all \( v \in H_\infty \).

This kernel formula is proven in \([Q14]\) Chapter 4 in full generality; some of its special cases may be found in \([BM1, Mot]\) and \([BBA]\). It is first introduced in \([CPS]\) for \( \text{SL}_2(\mathbb{R}) \).

It is proven in \([CQ]\) that the function \( j_{\pi,\psi} \) in Theorem B.1 is exactly the Bessel function defined as in \((1.5)-(1.8)\). Thus the two Bessel distributions \( J_{\pi,\psi} \) defined in Introduction and \((B.1)\) coincide.
