GORENSTEINNESS OF SHORT LOCAL RINGS IN TERMS OF
THE VANISHING OF EXT AND TOR

DIPANKAR GHOSH

Abstract. Let \((R, m)\) be a commutative Noetherian local ring which contains a regular sequence \(x = x_1, \ldots, x_d \in m \setminus m^2\) such that \(m^3 \subseteq (x)\). Let \(M\) be a finite \(R\)-module with maximal complexity or curvature, e.g., \(M\) can be a nonzero direct summand of some syzygy module of the residue field \(R/m\). It is shown that the following are equivalent: (1) \(R\) is Gorenstein, (2) \(\Ext^\gg_0 R(M, R) = 0\), and (3) \(\Tor^R_\gg_0(M, \omega) = 0\), where \(\omega\) denotes a canonical module of \(R\). It gives a partial answer to a question raised by Takahashi. Moreover, the vanishing of \(\Ext^\gg_0 R(\omega, N)\) for certain \(R\)-module \(N\) is also analyzed. Finally, it is studied why Gorensteinness of such local rings is important.

1. Introduction

Let \(R\) be a local ring with the maximal ideal \(m\) and residue field \(k\). For every \(n \geq 0\), \(\Omega_n^R(k)\) denotes the \(n\)th syzygy module in a minimal free resolution of \(k\).

One of the most influential results in commutative algebra is the result of Auslander, Buchsbaum and Serre: \(R\) is regular if and only if projective dimension of \(k\) is finite, which is equivalent to the fact that some syzygy module of \(k\) is free. Dutta, in [Dut89, Cor. 1.3], proved that \(R\) is regular if and only if \(\Omega_n^R(k)\) has a nonzero free direct summand for some \(n \geq 0\). Later, in [Tak06, Thm. 4.3], Takahashi generalized Dutta’s result by showing that \(R\) is regular if and only if \(\Omega_n^R(k)\) has a semidualizing (e.g., \(R\) itself as an \(R\)-module) direct summand for some \(n \geq 0\).

In a joint work [GGP, Cor. 3.2] with Gupta and Puthenpurakal, the author proved a considerably stronger result: If a finite direct sum of syzygy modules of \(k\) maps onto a semidualizing \(R\)-module, then \(R\) is regular.

It follows from Dutta’s result that \(R\) is regular if and only if some \(\Omega_n^R(k)\) \((n \geq 0)\) has a nonzero direct summand of finite projective dimension. A counterpart of this result for injective dimension is shown in [GGP, Thm. 3.7]. In a different direction, Martsinkovsky [Mar96, Prop. 7] generalized Dutta’s result as follows: If a finite direct sum of syzygy modules of \(k\) maps onto a nonzero \(R\)-module of finite projective dimension, then \(R\) is regular. Thereafter, Avramov proved a much more stronger result:

**Theorem 1.1** (Avramov). [Avr96, Cor. 9] Every nonzero homomorphic image \(M\) of a finite direct sum of syzygy modules of \(k\) has maximal complexity and curvature, i.e., \(cx_R(M) = cx_R(k)\) and \(\curv_R(M) = \curv_R(k)\); see Definition 2.2.

*Key words and phrases.* Gorenstein ring; Syzygy module; Complexity; Curvature; Ext; Tor.
\end{flushleft}
1.2. A few consequences of Theorem 1.1 are the following results. Let $M$ be a nonzero homomorphic image of a finite direct sum of syzygy modules of $k$. (1) If projective dimension $\text{pd}_R(M)$ is finite, then $R$ is regular; one may use Lemma 2.3(i)(a).
(2) If complete intersection dimension (as in [AGP97, (1.2)]) of $M$ is finite, then $R$ is a complete intersection ring; use [AGP97, (5.6)] and Proposition 2.5 (ii).

The Gorenstein dimension (in short G-dimension) was introduced by Auslander [Aus67], and was deeply studied by him and Bridger [AB69]. It is well known that $\text{G-dim}_R(k)$ is finite if and only if $R$ is Gorenstein. In this theme, Takahashi showed that $R$ is Gorenstein if and only if $\Omega^n_R(k)$ has a nonzero direct summand of G-dimension 0 for some $0 \leq n \leq \text{depth}(R) + 2$; see [Tak06, Thm. 6.5]. The following question [Tak06, 6.6] of Takahashi is still open: If $\Omega^n_R(k)$ has a nonzero direct summand of G-dimension 0 for some $n > \text{depth}(R) + 2$, then is $R$ Gorenstein?

More generally, in view of Section 1.2, it is now natural to ask the following:

**Question 1.3.** If a finite direct sum of syzygy modules of $k$ maps onto a nonzero $R$-module of finite G-dimension, then is $R$ Gorenstein?

We give a positive answer to Question 1.3 for short local rings:

**Definition 1.4.** The ring $R$ is said to be a short local ring if it contains a regular sequence $x := x_1, \ldots, x_d \in m \setminus m^2$ with the property that $m^3 \subseteq (x)$.

The motivation to work over these rings came from the following results. A commutative local analog of a conjecture of Tachikawa says that if $\text{Ext}^i_R(\omega, R) = 0$ for all $i \geq 1$, then $R$ is Gorenstein, where $\omega$ is a canonical $R$-module. In [ABS05], Avramov, Buchweitz and Segala proved this conjecture in several significant cases. In a particular case, they considered short local rings; see [ABS05, Thm. 5.1]. Many important conjectures that are still open in general have been verified over these rings; see [Les85, Thm. B] and [HSV04, Thm. 2.11 and 4.1]. As it is described in [AIS08, page 459], there are many famous counterexamples too built over these rings. In the present article, inspired by Question 1.3, we prove the following:

**Theorem 1.5** (= 3.3). Let $(R, m, k)$ be a short local ring. Let $\omega$ be a canonical module of $R$. Let $M$ be a nonzero homomorphic image of a finite direct sum of syzygy modules of $k$. Then the following statements are equivalent:

(i) $R$ is Gorenstein.
(ii) $\text{Ext}^i_R(M, R) = 0$ for all $i \gg 0$.
(iii) $\text{Tor}^R_i(\omega, M) = 0$ for all $i \gg 0$.

With hypotheses as in Theorem 1.5, we also study the following:

**Question 1.6.** If $\text{Ext}^i_R(\omega, M) = 0$ for all $i \gg 0$, then is $R$ Gorenstein?

Being $\text{G-dim}_R(M)$ finite is much stronger condition than $\text{Ext}^i_R(M, R) = 0$; see [AB69, Remarks after (3.7)]. Hence Theorem 1.5 ensures that Question 1.3 has affirmative answer for short local rings. If $R$ has minimal multiplicity (i.e., if $m^2 = (x)m$ for some $R$-regular sequence $x$) and $M (\neq 0)$ is a direct summand of some syzygy module of $k$, then Question 1.6 has positive answer; see [GP, Thm. 5.9] and [Cho, Thm. 5.5]. In this article, though we are unable to give a complete answer to Question 1.6 but in various attempts, we prove Theorems 3.3, 3.16 and 3.17.

We now describe in brief the contents of this article. In Section 2 we collect some preliminaries for later use. Our main results are shown in Section 3 which provide
necessary and sufficient conditions for a short local ring to be Gorenstein in terms of the vanishing of certain Ext and Tor modules. Finally, in Section 4 we give some reason why Gorensteinness of such local rings is important; see Theorem 4.1 and Example 4.2.

2. Preliminaries

Throughout this article, all rings are assumed to be commutative Noetherian local rings, and all modules (except possibly the injective hulls) are assumed to be finitely generated. Moreover, $R$ always denotes a local ring with the unique maximal ideal $m$ and residue field $k$. For an $R$-module $M$, and integer $n \geq 0$, $\Omega^n_R(M)$ denotes the $n$th syzygy module of $M$ in a minimal free resolution. Though $\Omega^n_R(M)$ depends on the choice of a minimal free resolution of $M$, but it is unique up to isomorphism. For $n \geq 1$, since $\Omega^n_R(M) \subseteq mF$ for some free module $F$, one obtains the following relation between the socle of the ring and the annihilator of the syzygy modules:

**Lemma 2.1.** $\text{Soc}(R) \subseteq \text{ann}_R(\Omega^n_R(M))$ for every $n \geq 1$.

We set $M^* := \text{Hom}_R(M, R)$ and $M^\vee := \text{Hom}_R(M, E)$, where $E := E_R(k)$ is the injective hull of $k$ over $R$. We denote the minimal number of generators of $M$ by $\mu(M)$, and the length of $M$ by $\lambda(M)$. For every $n \geq 0$, the integer $\beta^n_R(M) := \text{rank}_k(\text{Ext}^n_R(M, k))$ is called the $n$th Betti number of $M$. It is equal to the rank of the $n$th component in a minimal free resolution of $M$. In other words, $\beta^n_R(M) = \mu(\Omega^n_R(M))$. Dually, $\mu^n_R(M) := \text{rank}_k(\text{Ext}^n_R(k, M))$ is called the $n$th Bass number of $M$. The formal sums $P^n_M(t) := \sum_{n \geq 0} \beta^n_R(M)t^n$ and $B^n_M(t) := \sum_{n \geq 0} \mu^n_R(M)t^n$ are called the Poincaré series and Bass series of $M$ respectively. The following notions were introduced by Avramov.

**Definition 2.2.**

1. [Avr89, (3.1)] The complexity of $M$, denoted $\text{cx}_R(M)$, is the smallest non-negative integer $b$ such that $\beta^n_R(M) \leq an^{b-1}$ for all $n \gg 0$, and for some real number $\alpha > 0$. If no such $b$ exists, then we set $\text{cx}_R(M) = \infty$.

2. [Avr96, p. 319] Replacing $\beta^n_R(M)$ by $\mu^n_R(M)$ in (1), one obtains the notion of injective complexity $\text{inj cx}_R(M)$. This is called plexity $px_R(M)$ in [Avr89, (5.1)].

3. [Avr96, p. 320] The curvature of $M$, denoted $\text{curv}_R(M)$, is the reciprocal value of the radius of convergence of $P^n_M(t)$, i.e.,

$$\text{curv}_R(M) := \limsup_{n \rightarrow \infty} \sqrt[n]{\beta^n_R(M)}.$$  

We use the following elementary properties of complexity and curvature.

**Lemma 2.3.** Let $M$ and $N$ be $R$-modules. The following statements hold true.

(i) [Avr98, Rmk. 4.2.3]

(a) $\text{pd}_R(M) < \infty \iff \text{cx}_R(M) = 0 \iff \text{curv}_R(M) = 0$.
(b) $\text{cx}_R(M) < \infty \implies \text{curv}_R(M) \leq 1$; the converse is also true for $M = k$ (see [Avr98 8.1.2 and 8.2.2]).
(c) $\text{curv}_R(M)$ is always finite.

(ii) [Avr98, Prop. 4.2.4(2) and (3)]

(a) $\text{cx}_R(M) = \text{cx}_R(\Omega^n_R(M))$ and $\text{curv}_R(M) = \text{curv}_R(\Omega^n_R(M))$ for all $n \geq 1$.
(b) $\text{cx}_R(M \oplus N) = \max\{\text{cx}_R(M), \text{cx}_R(N)\}$.
(c) $\text{curv}_R(M \oplus N) = \max\{\text{curv}_R(M), \text{curv}_R(N)\}$.
Lemma 2.4. Let \( x \in R \) be regular on both \( R \) and \( M \). Then
\[
\text{cx}_{R/(x)}(M/xM) = \text{cx}_R(M), \quad \text{curv}_{R/(x)}(M/xM) = \text{curv}_R(M)
\]
and \( \text{inj cx}_{R/(x)}(M/xM) = \text{inj cx}_R(M) \).

Proof. (iii) Since \( x \) is regular on both \( R \) and \( M \), for every \( n \geq 0 \), we have that
\[
\beta_n^{R/(x)}(M/xM) = \beta_n^R(M) \quad \text{and} \quad \mu_n^{R/(x)}(M/xM) = \mu_n^R(M);
\]
see, e.g., [Mat86, p. 140, Lem. 2]. Hence the desired equalities follow. □

The following lemma shows that complexity and curvature of the residue field remain same after going modulo a regular element.

Lemma 2.4. Let \( x \in m \setminus m^2 \) be an \( R \)-regular element. Then
\[
\text{cx}_{R/(x)}(k) = \text{cx}_R(k) \quad \text{and} \quad \text{curv}_{R/(x)}(k) = \text{curv}_R(k).
\]

Proof. Set \((-):=(-) \otimes_R R/(x)\). In view of Lemma 2.3(ii) and (iii), we obtain that
\[
\text{cx}_R(k) = \text{cx}_R(\Omega_1^R(k)) = \text{cx}_R(\Omega_1^R(k)) = \text{cx}_R(\Omega_1^R(k) \oplus \Omega_0^R(k)) \quad [\text{by } \text{Tak06 Cor. 5.3}]
\]
\[
= \max \left\{ \text{cx}_R(\Omega_1^R(k)), \text{cx}_R(\Omega_0^R(k)) \right\} = \text{cx}_R(\Omega_1^R(k)).
\]
Similarly, one obtains that \( \text{curv}_R(k) = \text{curv}_{R/(x)}(k) \). □

Let us recall a few well-known properties of complexities of the residue field.

Proposition 2.5.

(i) [Avr96 Prop. 2] The residue field has maximal complexities and curvature:
\[
\text{cx}_R(k) = \sup \{ \text{cx}_R(M) : M \text{ is an } R\text{-module} \} = \sup \{ \text{inj cx}_R(M) : M \text{ is an } R\text{-module} \} = \text{inj cx}_R(k),
\]
and \( \text{curv}_R(k) = \sup \{ \text{curv}_R(M) : M \text{ is an } R\text{-module} \} \).

(ii) [Gul80 (2.3)] If \( \text{cx}_R(k) \) is finite, then \( R \) is a complete intersection ring.

(iii) If \( R \) is a complete intersection ring of codimension \( c \), then it follows from [Tat57 Thm. 6] that \( \text{cx}_R(k) = c \).

(iv) The statements (ii) and (iii) along with Lemma 2.3(i)(b) yield the following:
\( R \) is complete intersection \( \iff \text{cx}_R(k) < \infty \iff \text{curv}_R(k) \leq 1 \).

Definition 2.6. In view of Proposition 2.5(i), an \( R \)-module \( M \) is said to have maximal complexity (resp., curvature) if \( \text{cx}_R(M) = \text{cx}_R(k) \) (resp., \( \text{curv}_R(M) = \text{curv}_R(k) \)).

We need the following elementary fact on vanishing of Exts or Tors.

Lemma 2.7. [Gho 2.6] Let \( M \) and \( N \) be \( R \)-modules. Let \( x \in R \) be an \( R \oplus M \oplus N \)-regular element. Set \((-):=(-) \otimes_R R/(x)\). Suppose \( m \) and \( n \) are positive integers.
If \( \text{Ext}_R^i(M,N) = 0 \) (resp. \( \text{Tor}_R^i(M,N) = 0 \)) for all \( n \leq i \leq n + m \), then
\[
\text{Ext}_R^i(M,N) = 0 \quad \text{for all } n \leq i \leq n + m - 1
\]
(resp. \( \text{Tor}_R^i(M,N) = 0 \) for all \( n + 1 \leq i \leq n + m \)).
The following proposition is a consequence of a result due to Huneke, Šega and Vraciu [HSV04, Prop. 2.9].

**Proposition 2.8.** Let $R$ be a non-Gorenstein local ring such that $m^3 = 0$. Let $M$ be an $R$-module with the property that $\text{Tor}_i^R(M, E) = 0$ for all $i \gg 0$, where $E := E_R(k)$. Then $\beta_n^R(M) = c$ for every $n \geq 1$, where $c$ is a constant.

**Proof.** Let us denote $\Omega(R)$ by $\Omega(M)$. If $M$ is free, then $\beta_n^R(M) = 0$ for every $n \geq 1$. So we may assume that $M$ is not free. Hence, by the Auslander-Buchsbaum Formula, $\Omega(M)$ is also not free. Note that

$$\text{Tor}_i^R(\Omega(M), E) \cong \text{Tor}_{i+1}^R(M, E) = 0 \quad \text{for all } i \gg 0.$$  

Since $m^3 = 0$, we have that $m^2 \subseteq \text{Soc}(R) \subseteq \text{ann}_R(\Omega(M))$ (by Lemma 2.1), and hence $m^2\Omega(M) = 0$. Therefore, by virtue of [HSV04, Prop. 2.9], one can deduce that $\beta_n^R(\Omega(M)) = c$ for every $n \geq 0$, where $c$ is a nonzero constant. Hence $\beta_n^R(M) = \beta_{n-1}^R(\Omega(M)) = c$ for every $n \geq 1$. □

3. Gorensteinness of short local rings

The following theorem shows that modules with extremal complexity or curvature can be used to detect whether a short local ring is Gorenstein.

**Theorem 3.1.** Let $(R, m, k)$ be a short local ring. Let $M$ be an $R$-module such that either $\text{curv}_R(M) = \text{curv}_R(k)$ or $\text{cx}_R(M) = \text{cx}_R(k)$. (Particularly, $\text{cx}_R(M)$ can be infinite). Then the following statements are equivalent:

(i) $R$ is Gorenstein.

(ii) $\text{Ext}_R^i(M, R) = 0$ for all $i \gg 0$.

If $R$ has a canonical module $\omega$, then we may add the following:

(iii) $\text{Tor}_i^R(M, \omega) = 0$ for all $i \gg 0$.

**Proof.** Since $z = x_1, \ldots, x_d$ is an $R$-regular sequence such that $m^3 \subseteq (z)$, it can be easily verified that $R$ is Cohen-Macaulay of dimension $d$. If $R$ is Gorenstein, then $\text{Ext}_R^i(M, R) = 0$ for all $i \geq d + 1$ (because in this case $\text{injdim}_R(R) = d$). Moreover, if $R$ is Gorenstein, then $\omega \cong R$, and hence $\text{Tor}_i^R(M, \omega) = 0$ for all $i \geq 1$. So we only need to prove the implications \{(ii) \Rightarrow (i)\} and \{(iii) \Rightarrow (i)\}.

\{\text{ii) or \text{iii)} \Rightarrow (i)\}: We consider the case when $\text{cx}_R(M) = \text{cx}_R(k)$. Another case, i.e., $\text{curv}_R(M) = \text{curv}_R(k)$ can be treated similarly. We prove these implications by using induction on $d$. Assume that $d = 0$. In this case, $m^3 = 0$, and the injective hull $E$ (of $k$ over $R$) is a canonical module of $R$, i.e., $\omega \cong E$. Note that $\text{Ext}_R^i(M, R)^\vee \cong \text{Tor}_i^R(M, E)$ for every $i \geq 0$. Hence, by Matlis Duality, $\text{Ext}_R^i(M, R) = 0$ if and only if $\text{Tor}_i^R(M, E) = 0$. So, in this case, (ii) and (iii) are equivalent. We assume that $\text{Tor}_i^R(M, E) = 0$ for all $i \gg 0$. If possible, assume that $R$ is not Gorenstein. Then, by virtue of Proposition 2.8, we obtain that $\beta_n^R(M) = c$ for every $n \geq 1$, where $c$ is a constant. Therefore $\text{cx}_R(k) = \text{cx}_R(M) \leq 1$. Hence, in view of Proposition 2.3(iv), $R$ is a complete intersection ring, which contradicts the assumption that $R$ is not Gorenstein. Therefore $R$ is Gorenstein.

We now give the inductive step. Assume that $d \geq 1$. It is given that $m^3 \subseteq (z)$, where $z = x_1, \ldots, x_d \in m \setminus m^2$ is $R$-regular. We set $(-) := (-) \otimes_R R/(x_1)$. It can be observed that $(m/(x_1))^3 \subseteq (x_2, \ldots, x_d)$, where $x_2, \ldots, x_d$ (the images of
Proof. Suppose that in view of (3.1.1), by Lemma 2.7, we can deduce that \( \text{Ext}_R^i(\Omega(M), R) \cong \text{Ext}_R^{i+1}(M, R) = 0 \) for all \( i \gg 0 \). Then
\[
(3.1.1) \quad \text{Ext}_R^i(\Omega(M), R) \cong \text{Ext}_R^{i+1}(M, R) = 0 \quad \text{for all } i \gg 0
\]
(respectively, \( \text{Tor}_R^i(\Omega(M), R) \cong \text{Tor}_R^{i+1}(M, R) = 0 \) for all \( i \gg 0 \)).

Since \( x_1 \) is \( R \)-regular and \( \omega \) is a maximal Cohen-Macaulay \( R \)-module, \( x_1 \) is regular on \( \omega \). Note that \( x_1 \) is also \( \Omega(M) \)-regular. Let us denote \( \Omega(M) \) by \( N \). Hence, in view of (3.1.1), by Lemma 2.7, we can deduce that \( \text{Ext}_R^i(\Omega(N), R) = 0 \) (respectively, \( \text{Tor}_R^i(\Omega(N), R) = 0 \)) for all \( i \gg 0 \). (Note that \( \omega \) is a canonical module of \( \Omega(N) \).) On the other hand, by using Lemmas 2.3 and 2.4, we obtain that
\[
\text{cx}_R(\Omega(N)) = \text{cx}_R(N) = \text{cx}_R(M) = \text{cx}_R(k) = \text{cx}_R(k).
\]

Thus there is an \( R \)-module \( \Omega(N) \) such that \( \text{cx}_R(\Omega(N)) = \text{cx}_R(k) \) and \( \text{Ext}_R^i(\Omega(N), R) = 0 \) (respectively, \( \text{Tor}_R^i(\Omega(N), \omega) = 0 \)) for all \( i \gg 0 \). Since \( \dim(\Omega(N)) = d - 1 \), in either case, by induction hypothesis, we get that \( \Omega(N) \) is Gorenstein, and hence \( \Omega(N) \) is Gorenstein.

Remark 3.2. The two conditions ‘\( \text{curv}_R(M) = \text{curv}_R(k) \)’ and ‘\( \text{cx}_R(M) = \text{cx}_R(k) \)’ in Theorem 3.1 are independent of one another. In Example 4.2 assuming \( p > q \), we have \( \text{curv}_R(N) < \text{curv}_R(k) \), but \( \text{cx}_R(N) = \infty = \text{cx}_R(k) \). On the other hand, in Example 4.3 \( \text{curv}_R(N) = \text{curv}_R(k) \). Since \( \beta^R_n(N) = 1 \) for all \( n \geq 0 \), we have \( \text{cx}_R(N) = 1 < 2 = \text{cx}_R(k) \) (by Proposition 2.3(iii)).

As an immediate corollary of Theorem 3.1, we obtain one of our main results.

Corollary 3.3. Let \((R, \mathfrak{m}, k)\) be a short local ring. Let \( \omega \) be a canonical module of \( R \). Let \( M \) be a nonzero homomorphic image of a finite direct sum of syzygy modules of \( k \). Then the following statements are equivalent:
(i) \( R \) is Gorenstein.
(ii) \( \text{Ext}_R^i(M, R) = 0 \) for all \( i \gg 0 \).
(iii) \( \text{Tor}_R^i(\omega, M) = 0 \) for all \( i \gg 0 \).

Proof. The corollary follows from Theorems 1.1 and 3.1.

As some other consequences of Theorem 3.1, we obtain the following results.

3.4. With \( R \) and \( \omega \) as in Corollary 3.3, we may recover that if \( \text{Ext}_R^i(\omega, R) = 0 \) (respectively, \( \text{Tor}_R^i(\omega, \omega) = 0 \)) for all \( i \gg 0 \), then \( R \) is Gorenstein.

Proof. Let \( \text{Ext}_R^i(\omega, R) = 0 \) (respectively, \( \text{Tor}_R^i(\omega, \omega) = 0 \)) for all \( i \gg 0 \). If possible, suppose that \( R \) is not Gorenstein. Then \( \text{cx}_R(\omega) = \infty \) by [JL07] Prop. 1.1.(4)]. Hence Theorem 3.1 yields that \( R \) is Gorenstein, a contradiction.

Remark 3.5. In [HSV04] Thm. 2.11, it is shown that if \( \mathfrak{m}^3 = 0 \) and \( \text{Ext}_R^i(\omega, R) = 0 \) for any three consecutive \( i \gg 0 \), then \( R \) is Gorenstein.

3.6. Let \( Q = k[x_1, \ldots, x_d] \) be a positively graded polynomial ring over a field \( k \) of characteristic 0, and \( I \) be a homogeneous ideal containing \( (X_1, \ldots, X_d)^3 \). Set \( R := Q/I \). Let \( C \) denote either \( I/J^2 \) or the module \( \Omega_{R/k} \) of Kähler differentials over \( k \). If \( \text{Ext}_R^i(C, R) = 0 \) (respectively, \( \text{Tor}_R^i(C, \omega) = 0 \)) for all \( i \gg 0 \), then \( R \) is Gorenstein.

Proof. If \( R \) is not Gorenstein, then by [Avr98] Thm. 8.3.3 and 8.3.4, \( \text{curv}_R(C) = \text{curv}_R(k) \). Hence the proof is similar as that of 3.4.
The following result is a counterpart of Theorem 3.1 for injective complexity.

**Theorem 3.7.** With $R$ and $\omega$ as in Corollary 3.3, let $M$ be an $R$-module such that
\[ \text{inj cx}_R(M) = \text{inj cx}_R(k) \text{ and } \text{Ext}^i_R(\omega, M) = 0 \text{ for all } i \gg 0. \]
Then $R$ is Gorenstein.

**Proof.** Let $\text{Ext}^i_R(\omega, M) = 0$ for all $i \gg 0$. Note that $x = x_1, \ldots, x_d$. We use induction on $d$. In the base case, i.e., if $d = 0$, then $\omega \cong E (:= E_R(k))$. Hence
\[ \text{Tor}^R_i(E, M^\vee) \cong \text{Ext}^i_R(E, M)^\vee = 0 \text{ for all } i \gg 0. \]
Thus $\text{Ext}^i_R(M^\vee) = \text{inj cx}_R(M) = \text{inj cx}_R(k) = \text{cx}_R(R)$. So, in view of the implication \{(iii) \Rightarrow (i)\} in Theorem 3.1 we obtain that $R$ is Gorenstein.

We now give the inductive step. Assume that $d \geq 1$. Set $(-):=(-) \otimes_R R/(x_1)$. By virtue of [AB89 Thm. A], we have a maximal Cohen-Macaulay (MCM) approximation of $M$, i.e., a short exact sequence $0 \rightarrow Y \rightarrow N \rightarrow M \rightarrow 0$ of $R$-modules, where $N$ is MCM and $Y$ has finite injective dimension. Hence
\[ \text{Ext}^i_R(\omega, N) \cong \text{Ext}^i_R(\omega, M) = 0 \quad \text{and} \quad \text{Ext}^i_R(\omega, N) \cong \text{Ext}^i_R(\omega, M)^{\vee} \]
for all $i \gg 0$. In particular, $\mu_n^R(N) = \mu_n^R(M)$ for all $n \gg 0$, which yields that $\text{inj cx}_R(N) = \text{inj cx}_R(M) = \text{cx}_R(k)$. Since $\omega$ and $N$ are MCM $R$-modules and $x_1$ is $R$-regular, it follows that $x_1$ is regular on both $\omega$ and $N$. So, in view of (3.7.2), by Lemma 2.7 one obtains that $\text{Ext}^i_R(\omega, N) = 0$ for all $i \gg 0$. It follows from Lemma 2.9(ii) and Lemma 2.7 that $\text{inj cx}_R(N) = \text{inj cx}_R(M) = \text{cx}_R(k) = \text{cx}_R(k)$. Thus there is an $R$-module $\mathcal{N}$ such that $\text{inj cx}_R(\mathcal{N}) = \text{cx}_R(k)$ and $\text{Ext}^i_R(\omega, \mathcal{N}) = 0$ for all $i \gg 0$. Therefore, since $\dim(R) = d - 1$, by induction hypothesis, we get that $\mathcal{N}$ is Gorenstein, and hence $R$ is Gorenstein. \square

As a few consequences of Theorem 3.7 we obtain the following:

**Corollary 3.8.** With $R$ and $\omega$ as in Corollary 3.3, let $M$ be an $R$-module.
\[ \text{(i) If } m^i M \neq 0 \text{ and } \text{Ext}^i_R(\omega, m M) = 0 \text{ for all } i \gg 0, \text{ then } R \text{ is Gorenstein.} \]
\[ \text{(ii) Let } n \geq 1, \text{ such that } (0 : M) m^n \neq (0 : M) m^{n+1}. \text{ If } \text{Ext}^i_R(\omega, M/(0 : M) m^n) = 0 \text{ for all } i \gg 0, \text{ then } R \text{ is Gorenstein.} \]

**Proof.** With the above hypotheses, by [Avr96 Thm. 4 and Prop. 7],
\[ \text{inj cx}_R(m M) = \text{inj cx}_R(k) \quad \text{and} \quad \text{inj cx}_R(M/(0 : M) m^n) = \text{inj cx}_R(k). \]
Hence the proof follows from Theorem 3.7. \square

**Remark 3.9.** Let $M$ be a module over an arbitrary local ring $R$ such that $m M \neq 0$. It is true in general that if $\text{Ext}^i_R(\omega, m M) = 0$ for all $i \gg 0$, then $\text{pd}_R(\omega)$ is finite, and hence $R$ is Gorenstein; see [TTY07 Thm. 1.5(a)] and the proof of [LV68 Thm. 1.1]. But Corollary 3.8(ii) was not known. However, we would like to state Corollary 3.8 as applications of Theorem 3.7.

**Corollary 3.10.** With $R$ and $\omega$ as in Corollary 3.3, let $M$ be a nonzero homomorphic image of a finite direct sum of copies of $\Omega^R_1(k) (= m)$ and $\Omega^R_0(k) (= k)$. Then $R$ is Gorenstein if and only if $\text{Ext}^i_R(\omega, M) = 0$ for all $i \gg 0$. 

Proof. We only need to prove the ‘if’ part. Let \( \text{Ext}^i_R(\omega, M) = 0 \) for all \( i \gg 0 \). In view of Lemma 3.12, \( M \cong mL \oplus k^{\oplus u} \) for some \( R \)-module \( L \) and integer \( u \gg 0 \). Hence \( \text{Ext}^i_R(\omega, mL) = 0 \) for all \( i \gg 0 \). Therefore, if \( mL \neq 0 \), by Corollary 3.8(i), \( R \) is Gorenstein. So we may assume that \( mL = 0 \), hence \( u \gg 1 \). Thus \( \text{Ext}^i_R(\omega, k) = 0 \) for all \( i \gg 0 \), which yields that \( \text{pd}_R(\omega) < \infty \), equivalently, \( R \) is Gorenstein. \( \square \)

Remark 3.11. Corollary 3.10 provides a partial answer to Question 1.6.

The author is grateful to Anjan Gupta for making the following:

Lemma 3.12. Over an arbitrary local ring \((R, m, k)\), a homomorphic image of a finite direct sum of copies of \( \Omega^R_i(k) (= m) \) and \( \Omega^R_0(k) (= k) \) can be written as \( mL \oplus k^{\oplus u} \) for some \( R \)-module \( L \) and integer \( u \gg 0 \), where \( k^{\oplus u} \) denotes the direct sum of \( u \) many copies of \( k \).

Proof. Let \( M \) be an \( R \)-module, and \( N \) be a submodule of \( M \oplus k \). We claim that

\[(3.12.1) \quad (M \oplus k)/N \cong (M/N) \oplus k \quad \text{or} \quad M/M' \]

for some submodule \( M' \) of \( M \). To prove the claim, assume that \( N \) is generated by \((x_1, \overline{a_1}), \ldots, (x_n, \overline{a_n})\) for some \( x_i \in M \) and \( a_i \in R \). If \( \overline{a_i} = 0 \) for all \( 1 \leq i \leq n \), then \( N \) is a submodule of \( M \), and hence \((M \oplus k)/N \cong (M/N) \oplus k\). In another case, without loss of generality, we may assume that \( a_1 = 1 \). Note that

\[(3.12.2) \quad \frac{M \oplus k}{\langle (x_1, 1) \rangle} \cong \frac{(M \oplus R)/((0 \oplus k))}{\langle (x_1, 1) \rangle + (0 \oplus k)} \]

The map \( \varphi : M \oplus R \rightarrow M \) given by \( \varphi((y, b)) = y - bx_1 \) induces an isomorphism

\[(3.12.3) \quad \frac{(M \oplus R)/\langle (x_1, 1) \rangle}{\langle (x_1, 1) \rangle} \cong M. \]

Thus we have

\[
\frac{M \oplus k}{N} \cong \frac{(M \oplus k)/\langle (x_1, 1) \rangle}{N'} \quad \text{for some } N' \\
\cong \frac{(M \oplus R)/\langle (x_1, 1) \rangle + (0 \oplus k)}{N'} \quad \text{[by (3.12.2)]} \\
\cong \frac{(M \oplus R)/\langle (x_1, 1) \rangle}{M'} \quad \text{for some } M' \\
\cong M/M' \quad \text{[by (3.12.3)].}
\]

Using (3.12.1) repeatedly, one can deduce that

\[
\frac{m^{\oplus s} \oplus k^{\oplus t}}{U} \cong \frac{(m^{\oplus s})/U'}{U} \oplus k^{\oplus u} \cong m(R^s/U') \oplus k^{\oplus u}
\]

for some \( 0 \leq u \leq t \) and submodule \( U' \) of \( m^{\oplus s} \). Now set \( L := R^s/U' \) to get the desired result. \( \square \)

With hypotheses as in Corollary 3.3, we now investigate whether \( R \) is Gorenstein when \( \text{Ext}^i_R(\omega, M) = 0 \) for all \( i \gg 0 \). Let us consider the case when \( R \) is Artinian.

Proposition 3.13. Suppose \( m^3 = 0 \), and \( 2 \cdot \mu(m) \neq \lambda(R) \). Set \( E := \text{Ext}^3_R(k) \). Let \( M \) be an \( R \)-module such that \( \text{Ext}^i_R(E, M) = 0 \) for three consecutive values of \( i \geq 3 \). Then either \( E \cong R \) or \( M \) is injective.
Proposition 3.17. Let \( E \not\cong R \) and \( M \) is not injective. Note that \( E \not\cong R \) is equivalent to that \( R \) is not Gorenstein. Moreover, since \( E \) is indecomposable as an \( R \)-module, \( E \) is not free. As \( M \) is not injective, by Matlis Duality, we can deduce that \( \beta(M') \) is not free. Hence it follows that \( \Omega(M') \) is not free. Since \( m^3 = 0 \), we have \( m^2\Omega(M') = 0 \) (by Lemma 3.14). Note that
\[
\text{Tor}_i^R(E, \Omega(M')) \cong \text{Tor}_{j+1}^r(E, M') \cong \text{Ext}_{i+1}^j(E, M') = 0
\]
for three consecutive values of \( j \geq 1 \). Therefore, in view of [GGP, Cor. 3.4], we obtain that
\[
\text{Tor}_i^R(N, E) = 0 \text{ for all } i \geq 1.
\]
To get the last equality, one may compute \( \text{Ext}_i^R(N, R) \) by considering the minimal free resolution of \( N: \cdots \overset{z}{\rightarrow} R \overset{y}{\rightarrow} R \overset{x}{\rightarrow} R \rightarrow 0 \).

Remark 3.15. In Example 3.14 we should note that \( \text{Ext}_i^R(E, M) = 0 \) for every \( i \geq 1 \), but neither of \( \text{pd}_R(E) \) and \( \text{injdim}_R(M) \) is finite. Moreover, \( \text{Tor}_i^R(N, E) = 0 \) for every \( i \geq 1 \), but neither of \( \text{pd}_R(N) \) and \( \text{pd}_R(E) \) is finite.

As a consequence of Proposition 3.13, we obtain the following:

Corollary 3.16. Let \( m^3 = 0 \), and \( 2 \cdot \mu(m) \neq \lambda(R) \). Set \( E := E_R(k) \). Let \( M \) be a nonzero homomorphic image of a finite direct sum of syzygy modules of \( k \). If \( \text{Ext}_i^R(E, M) = 0 \) for three consecutive values of \( i \geq 3 \), then \( R \) is Gorenstein.

Proof. If \( \text{Ext}_{3i}^R(E, M) = 0 \) for three consecutive values of \( i \geq 3 \), then by Proposition 3.13, either \( E \cong R \) or \( M \) is injective. If \( E \cong R \), then \( R \) is Gorenstein. If \( M \) is injective, then in view of [GGP, Cor. 3.4], we obtain that \( R \) is regular, and hence \( R \) is Gorenstein. Thus, in both cases, \( R \) is Gorenstein.

The following proposition provides us another class of modules \( M \) for which the vanishing of \( \text{Ext}_{i}^{R}(E, M) \) ensures that \( R \) is Gorenstein.

Proposition 3.17. Let \( m^3 = 0 \). Let \( M \) be a nonzero \( R \)-module such that \( m^2M = 0 \) and \( \mu(M) \leq \lambda(mM) \). If \( \text{Ext}_i^R(E, M) = 0 \) for all \( i > 0 \), then \( R \) is Gorenstein.

Proof. Let \( \text{Ext}_i^R(E, M) = 0 \) for all \( i > 0 \). Hence \( \text{Tor}_i^R(E, M') = 0 \) for all \( i > 0 \). If possible, assume that \( R \) is not Gorenstein. Then, by Proposition 2.8, we have \( \beta_n^R(M') = c \) for every \( n \geq 1 \), where \( c \) is a constant. Thus, in view of (3.7.1), we obtain that \( \mu_n^R(M) = c \) for every \( n \geq 1 \). Set \( a := \mu(M) \) and \( b := \lambda(mM) \). Note that \( mM \) is annihilated by \( m \). Moreover, \( \text{rank}_k(mM) = b \) and \( \text{rank}_k(M/mM) = a \).
So there is a short exact sequence $0 \to k^b \to M \to k^a \to 0$, which yields an exact sequence $\text{Ext}^n_R(k, k^n) \to \text{Ext}^n_R(k, k^b) \to \text{Ext}^n_R(k, M)$ for every $n \geq 1$. From this exact sequence, for every $n \geq 1$, it follows that

$$b \cdot \beta^R_n(k) \leq a \cdot \beta^R_{n-1}(k) + \mu^R_n(M) = a \cdot \beta^R_{n-1}(k) + c$$

$$b \cdot \beta^R_{n-1}(k) + c \quad \text{[because } a \leq b]\$$

$$a \cdot \beta^R_{n-2}(k) + 2c \quad \text{[using the 1st inequality for } n-1]\$$

and so on.

Therefore, since $b \geq a > 0$, we get that $\beta^R_n(k) \leq (c/b) \cdot n + (a/b)$ for every $n \geq 1$. This implies that $cx_R(k)$ is finite. Hence, by Proposition $2.3$, $R$ is a complete intersection ring, which contradicts the assumption that $R$ is not Gorenstein. So $R$ must be Gorenstein. \hfill \square

**Remark 3.18.**

(i) In Proposition $3.17$, $M$ can be taken as $R/I$, where $I$ is an ideal of $R$ such that $m^2 \subseteq I \subseteq m$.

(ii) Let $M$ be a homomorphic image of a finite direct sum of syzygy modules of $k$. We should note that if $m^3 = 0$, then we have $m^2M = 0$, but $M$ need not satisfy the condition $'\mu(M) \leq \lambda(mM)'$.

The condition $'\mu(M) \leq \lambda(mM)'$ cannot be omitted from Proposition $3.17$.

**Example 3.19.** [JL07, Example 2.8] Let $R$, $M$ and $N$ be as in Example $3.14$. Note that $m^3 = 0$, $M \neq 0$ and $m^2M = 0$. Moreover, $\text{Ext}^i_R(E, M) = 0$ for every $i \geq 1$, but $R$ is not Gorenstein. One can verify that $\mu(M) \not\leq \lambda(mM)$. Indeed,

$$(3.19.1) \quad \mu(M) = \text{type}(N) \quad \text{[see, e.g., [BH98, 3.2.12(d)]]}$$

$$= \text{rank}_k((0 :_N m)) = \text{rank}_k((xz, yz)) = 2$$

and $\lambda(mM) = \lambda(M) - \mu(M) = \lambda(N) - 2 = 1$.

As a consequence of Proposition $3.17$, we can recover a result of Jorgensen and Leuschke (which is a part of [JL07, Thm. 2.5]).

**Corollary 3.20.** Let $m^3 = 0$. Let $N$ be a nonzero $R$-module such that $m^2N = 0$ and $\lambda(mN) \leq \mu(N)$. If $\text{Ext}^i_R(N, R) = 0$ for all $i \gg 0$, then $R$ is Gorenstein.\hfill \square

**Proof.** If $k$ is a direct summand of $N$, then $\text{Ext}^i_R(N, R) = 0$ for some $i \geq 1$ implies that $R$ is Gorenstein. So we may assume that $k$ is not a direct summand of $N$. Set $M := N^\vee$. In view of $(3.19.1)$, $\mu(M) = \text{rank}_k(\text{soc}(N)) = \lambda(mN)$ by [HSV04, 2.3]. Hence $\lambda(mM) = \lambda(M) - \mu(M) = \lambda(N) - \lambda(mN) = \mu(N)$. Thus $m^2M = 0$ and $\mu(M) \leq \lambda(mM)$. In view of $(3.14.1)$, $\text{Ext}^i_R(E, M) \cong \text{Ext}^i_R(N, R)$ for every $i \geq 1$. So the result follows from Proposition $3.17$.

With the hypotheses as in Theorem $3.1$ one may ask that if $\text{Ext}^i_R(\omega, M) = 0$ for all $i \gg 0$, then is $R$ Gorenstein? In this situation, $R$ is not necessarily Gorenstein. The author is grateful to Ryo Takahashi for pointing out this fact with the following:

**Example 3.21.** Consider a non-Gorenstein local ring $(R, m, k)$ such that $m^3 = 0$. In this case, Betti number of the canonical module $\omega$ grows exponentially, due to [JL07, Prop. 1.1.(4)]. Therefore $cx_R(\omega) = \infty$. In this situation, although $cx_R(\omega) = \infty$.\hfill \square
Note that every 1 \leq i \leq 2. Set \( I := \langle x_1, \ldots, x_p \rangle \). Since Tor\(^i\)(M, N) = 0 for all i \gg 0. By Lemma 2.7, \( \text{curv}_R(M, N) = \text{curv}_R(k) \). Similarly, \( \text{curv}_R(N) = \text{curv}_R(k) \). Therefore, by induction hypothesis, \( R \) is regular, and hence \( R \) is regular.

The following example shows that Theorem 4.1 does not necessarily hold true over arbitrary (i.e., non-Gorenstein) short local rings.

Example 4.2. Let \( R = \mathbb{k}[x_1, \ldots, x_p, y_1, \ldots, y_q]/((x_1, \ldots, x_p)^2 + (y_1, \ldots, y_q)^2) \). Note that \( m^3 = 0 \), where \( m \) is the maximal ideal of \( R \). Set \( I := \langle x_1, \ldots, x_p \rangle \), \( J := \langle y_1, \ldots, y_q \rangle \), \( M := R/I \) and \( N := R/J \). It is well known that Tor\(^i\)(R/I, R/J) = (I \cap J)/IJ. Since \( I \cap J = JI \), Tor\(^i\)(M, N) = 0. Note that \( M \cong \langle x_i \rangle \) for every 1 \leq i \leq p. Then \( \Omega^1_R(M) = I = (x_1) + \cdots + (x_p) \cong \mathbb{M}^p \). By induction,
\[ \Omega_n^R(M) \cong M^{p^n} \] for every \( n \geq 1 \). Therefore
\[
\text{Tor}_n^R(M, N) \cong \text{Tor}_n^R(\Omega_1^R(M), N) \cong \cdots \cong \text{Tor}_1^R(\Omega_{n-1}^R(M), N)
\]
\[ \cong \text{Tor}_1^R(M^{p^{n-1}}, N) \cong \text{Tor}_1^R(M, N)^{p^{n-1}} = 0 \]
for every \( n \geq 2 \). Following [Les85, 3.8(2)], we have \( \text{curv}_R(M) = p = \text{curv}_R(k) \) and \( \text{curv}_R(N) = q \). We now assume that \( p \geq q \geq 2 \). It follows from Lemma 2.3(i)(b) that \( \text{cx}_R(M) = \infty = \text{cx}_R(N) \). Thus \( M \) and \( N \) have maximal complexity, and \( \text{Tor}_n^R(M, N) = 0 \) for every \( n \geq 1 \), but \( R \) is not regular. Note that \( \text{Soc}(R) = IJ \), which is not cyclic, hence \( R \) is not Gorenstein.

Unlike Theorem 3.1 in Theorem 4.1, the word ‘complexity’ cannot be replaced by ‘curvature’.

**Example 4.3.** Let \( R = k[x, y]/(x^2, y^2) \). Clearly, \( R \) satisfies the hypotheses of Theorem 4.1. Set \( M := R/(x) \) and \( N := R/(y) \). In view of Example 4.2, \( M \) and \( N \) have maximal curvature, \( \text{Tor}_i^R(M, N) = 0 \) for all \( i \geq 1 \), but \( R \) is not regular.

As a consequence of Theorems 1.1 and 4.1 we obtain the following:

**Corollary 4.4.** Let \( R \) be a Gorenstein short local ring. Let \( M \) and \( N \) be nonzero homomorphic images of finite direct sums of syzygy modules of \( k \). (Possibly, \( M = N \)). Then \( R \) is regular if and only if \( \text{Tor}_i^R(M, N) = 0 \) for all \( i \gg 0 \).
