ONE-SIDED SCALING LIMIT OF MULTICOLOR BOX-BALL SYSTEM

ATSUO KUNIBA AND HANBAEK LYU

ABSTRACT. A random box-ball system starts with occupying each of the first \( n \) boxes independently with a ball of random color from \( \{0, 1, \cdots, \kappa\} \), where balls of color 0 are considered as empty boxes. The time evolution is defined by a successive application of the combinatorial \( R \), and possesses a \( \kappa \)-tuple of Young diagrams as the complete set of conserved quantities. We show that the induced carrier process is an irreducible Markov chain and that the associated energy function scaled by \( 1/n \) converges as \( n \to \infty \) at an exponential rate. This implies that each of the invariant Young diagrams converges to some limiting shape as \( n \to \infty \) if we scale its rows by \( 1/n \). By establishing a large deviations principle, we show that this limiting shape is unchanged under conditioning the initial measure on the highest states. Using these results, we give an explicit formula for the limiting shape of the invariant Young diagrams by Thermodynamic Bethe Ansatz.

1. INTRODUCTION

The basic \( \kappa \)-color box-ball system (BBS) is a cellular automaton on the half-integer lattice \( \mathbb{N} \). At each discrete time \( t \geq 0 \), the system configuration is given by a coloring \( X_t: \mathbb{N} \to \{0, 1, \cdots, \kappa\} \) with finite support. When \( X_t(x) = i \), we say that site \( x \) is unoccupied at time \( t \) if \( i = 0 \), and occupied with a ball of color \( i \) at time \( t \) if \( 1 \leq i \leq \kappa \). To define the time evolution rule, for each \( 1 \leq \alpha \leq \kappa \), let \( K_\alpha \) be the operator on the set \( \{0, 1, \cdots, \kappa\}^{\mathbb{N}} \) of all \( (\kappa + 1) \)-colorings on \( \mathbb{N} \) defined as follows:

(i) Label the balls of color \( \alpha \) from left to right as \( a_1, a_2, \cdots, a_m \).
(ii) Starting from \( k = 1 \) to \( m \), move ball \( a_k \) to the leftmost unoccupied site to its right.

Now the time evolution \( (X_t)_{t \geq 0} \) of the basic \( \kappa \)-color BBS is given by

\[
X_{t+1} = K_1 \circ K_2 \circ \cdots \circ K_\kappa (X_t) \quad \forall t \geq 0.
\]

A typical 4-color BBS trajectory is shown below.

The basic \( \kappa \)-color BBS was introduced in [25], generalizing the original \( \kappa = 1 \) BBS first invented in 1990 [27]. In the most general form of the BBS, each cite accommodates a
semistandard tableau of rectangular shape with letters from \{0, 1, \cdots, \kappa\} and the time evolution is defined by successive application of the combinatorial \(R\) (cf. \([6, 8, 16, 11]\)). The basic \(\kappa\)-color BBS treated in this paper corresponds to the case where the tableau shape is the single box.

Observe that if there is a string of length \(k\) consecutive balls of non-decreasing colors, then each of the balls moves at least distance \(k\) in one iteration of the update rule. Suppose there is a such sequence of length \(k_1\), followed by a sequence of \(m\) 0’s, and then another non-increasing sequence of balls of length \(k_2\). Also note that if \(k_1 \leq m \leq k_2\), then the two sequences do not interact in one iteration and the spacing becomes \(m + (k_2 - k_1) \geq m\). On the other hand, if \(k_1 > k_2\), then the longer sequence on the left eventually catches up the shorter one and interfere. Since there are only finitely many balls in the initial configuration \(X_0\), it is not hard to observe that after a finite number of iterations, the system decomposes into a disjoint non-interacting sequence of balls of non-increasing colors, whose lengths are non-decreasing from left to right. Each of such non-interacting sequence of balls is called a \emph{soliton}, and such decomposition is called a \emph{soliton decomposition} of the system \((X_0)_{t \geq 0}\).

Given a basic \(\kappa\)-color BBS configuration \(X_0 : \mathbb{N} \rightarrow \{0, 1, \cdots, \kappa\}\), its soliton decomposition may be encoded in a Young tableau whose \(j\)th column corresponds to \(j\)th longest soliton. For instance, below is the Young tableau corresponding to the soliton decomposition of the \(t = 6\) instance of the 4-color BBS given before:

\[
\begin{array}{cccc}
4 & 4 & 1 & 2 \\
2 & 1 & 4 & \\
2 & 1 & 2 & 2 & 1 & 1 & 4 & 2 & 1 \\
\end{array}
\]

(2)

For \(\kappa = 1\), such a Young tableau is filled with all 1’s, so its shape contains all relevant conserved quantities. For \(\kappa > 1\), however, solitons possess not only their length but also their internal degrees of freedom. It turns out that we need a \(\kappa\)-tuple of Young diagrams \((\mu^{(1)}, \mu^{(2)}, \cdots, \mu^{(\kappa)})\) to fully describe all such conserved quantities, where \(\mu^{(1)}\) encodes the lengths of solitons and the other ‘higher order’ Young diagrams describe their internal degrees of freedom. They provide a proper label of \emph{iso-level sets} of the basic \(\kappa\)-color BBS \([16]\). For our running example of 4-color BBS, the four invariant Young diagrams are

\[
\mu^{(1)} = \begin{array}{cccc}
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
\end{array}, \quad \mu^{(2)} = \begin{array}{cccc}
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
\end{array}, \quad \mu^{(3)} = \begin{array}{c}
1 \\
1 \\
1 \\
\end{array}, \quad \mu^{(4)} = \begin{array}{c}
1 \\
1 \\
1 \\
\end{array}
\]

(3)

Recently, Levine, Lyu, and Pike studied various soliton statistics of the \(\kappa = 1\) BBS when the system is initialized according to a Bernoulli product measure with ball density \(p\) on \(n\) boxes \([18]\). One of their main result shows that for any \(p \in (0, 1)\) and integer \(i \geq 1\), the \(i\)th row length of the invariant Young diagram \(\mu^{(1)}\) scales asymptotically linearly in \(n\). This suggests that if we scale the Young diagram horizontally by \(1/n\), then the sequence of random Young diagrams should converge to some limiting shape.

In this paper, we establish a similar convergence result for the basic \(\kappa\)-color BBS with random initial configuration. Our approach is based on realizing the accompanying carrier process as an irreducible Markov chain on a finite state space. This enables us to establish limit theorems of the row lengths such as the strong law of large numbers and
the large deviations principle. The latter pushes the same strong law under conditioning the initial measure on the subset called *highest states*. We are then able to obtain explicit formulas for the limiting shapes of the invariant Young diagrams by exploiting further connections to the Fermionic formula and Thermodynamic Bethe ansatz known in the representation theory of quantum affine algebras and the Yang-Baxter integrable systems (see, e.g., [11]).

1.1. **Notation.** We denote by \( \mathbb{Z} \) the set of integers, and by \( \mathbb{N} \) and \( \mathbb{N}_0 \) the set of positive and nonnegative integers, respectively. When \( a, b \) are integers, we denote by \([a, b]\) the integer interval \( \{k \in \mathbb{Z} : a \leq k \leq b\} \).

1.2. **Organization.** In Section 2, we give a brief introduction to the combinatorial \( R \) and define the invariant Young diagrams associated to a basic \( \kappa \)-color BBS configuration. We give complete statements of our main results in Section 3. In Section 4, we first establish the irreducibility of the carrier process and identify its unique stationary measure (Theorem 1), and then prove various limit theorems for the row lengths of the invariant Young diagrams (Theorems 2, 4.9, and Corollary 4). We then study the effect of conditioning the initial measure on the highest states and prove Corollary 6 in Section 5. In the last section, Section 6, we prove Theorem 7 using a Fermionic formula and then obtain a precise formula for the limiting shape of the invariant Young diagrams (Theorem 8) by the method of Thermodynamic Bethe Ansatz. A more general result in this direction has been obtained recently in [14]. The case treated in this paper corresponds to its one parameter specialization, which deserves an independent report due to the nontrivial factorization of the final result in (31).

2. **THE COMBINATORIAL \( R \) AND THE ENERGY MATRIX**

The basic \( \kappa \)-color BBS has another description in terms of the crystal base theory [12] and the combinatorial \( R \). While the definition of time evolution of BBS given in (1) involves the nonlocal movements of balls, such a crystal theory formulation has a fully local description in terms of the accompanying ‘carrier process’, which was first introduced in [26] for the original \( \kappa = 1 \) BBS. In the multicolor case, a similar carrier version of the time evolution can be defined, and the action of the carrier on each box is given by the combinatorial \( R \). We give a brief introduction in this section, and refer to [11, 17] for more backgrounds and details.

2.1. **Combinatorial \( R \) and the local energy \( H \).** Fix an integer parameter \( \kappa \geq 1 \). For each integer \( 1 \leq m \leq \kappa \) and \( n \geq 1 \), let \( B_n^{(m)} = B_n^{(m)}(\kappa) \) be the set of all semistandard tableaux of rectangular shape \((m \times n)\) with letters from \( \{0, 1, \cdots, \kappa\} \). Equivalently, it is the set of all \((m \times n)\) matrices whose entries are from \( \{0, 1, \cdots, \kappa\} \) and are weakly increasing on the rows and strictly increasing in columns. For a semistandard tableau \( b \) and an integer \( x \geq 0 \), denote by \((b \leftarrow x)\) the tableau obtained by inserting \( x \) into \( b \) using Schensted row insertion. If \( x \) were a row vector \((x_1, x_2, \cdots, x_r)\) of nonnegative integers, then we can define \((b \leftarrow x)\)
similarly by \((\cdots ((b \leftarrow x_1) \leftarrow x_2) \cdots \leftarrow x_r))\). For example,
\[
\begin{bmatrix}
1 & 2 & 3 \\
3 & 4
\end{bmatrix}
\begin{bmatrix}
1 & 2 & 3 \\
4 & 4
\end{bmatrix}
= \begin{bmatrix}
1 & 1 & 3 \\
2 & 4
\end{bmatrix}
\begin{bmatrix}
3 & 4 \\
4
\end{bmatrix}
= \begin{bmatrix}
1 & 1 & 3 & 4 \\
2 & 4 & 3
\end{bmatrix}.
\] (4)

For each element \(B \in B_n^{(m)}\), denote by row\((B)\) the element in \(B_{mn}^{(1)}\) obtained by concatenating the rows of \(B\) from bottom to top to the right. For example,
\[
\text{row}\left(\begin{bmatrix}
1 & 2 \\
3 & 4
\end{bmatrix}\right) = \begin{bmatrix} 3 & 4 & 1 & 2 \end{bmatrix}
\] (5)

Then, it is known that [24] there exists a unique map \(R : B_c^{(a)} \times B_s^{(r)} \to B_s^{(a)} \times B_c^{(r)}\), \((C, B) \to (B', C')\) satisfying
\[
(B \leftarrow \text{row}(C)) = (C' \leftarrow \text{row}(B')).
\] (6)

We call this unique map the \textit{combinatorial} \(R\). We denote \(R_2(C_1, x_1) \in B_c^{(a)}\) denotes the second component of the image \(R(C_1, x_1)\).

The associated \textit{local energy} is a function \(H : B_c^{(a)} \times B_s^{(r)} \to \mathbb{N}_0\) where
\[
H(C, B) = \sum_{i \geq \max(a,r)} \text{length of the } i\text{th row of } (B \leftarrow \text{row}(C)).
\] (7)

For our running example in (4), we have
\[
H\left(\begin{bmatrix}
1 & 2 \\
3 & 4 \\
\end{bmatrix}, \begin{bmatrix}
1 & 3 & 4
\end{bmatrix}\right) = 1.
\] (8)

Since the combinatorial \(R\) is defined through the factorization condition (6), one needs to compute the image given a pair \((C, B)\) of semistandard Young tableaux. An algorithm for such computation is known [22, p.55], even though it is somewhat cumbersome. In the special case of the combinatorial \(R\) acting on \(B_c^{(a)} \times B_s^{(r)}\) with \(a = r = 1\) or \(c = s = 1\), a diagramatic computation rule was given in [21]. In the appendix, we give a simple algorithm for the case \(r = s = 1\), which is sufficient to completely analyze the basic \(\kappa\)-color BBS.

2.2. \textbf{The carrier processes and the energy matrix}. At the beginning of Section 2, we mentioned that the basic \(\kappa\)-color BBS can be formulated in terms of the ‘carrier’ and the combinatorial \(R\). One of the advantages in such formulation is that its entire \(\kappa\)-tuple of invariant Young diagrams can be extracted by simply running carriers with different shapes over a given basic \(\kappa\)-color BBS configuration. In this subsection, we introduce a formal setup to state such observation.

Fix a basic \(\kappa\)-color BBS configuration \(X\), which we may identify with a map \(\mathbb{N} \to B_c^{(1)} = B_1^{(1)}(\kappa)\). Fix integers \((a, c) \in [1, \kappa] \times \mathbb{N}\). Let \(U_c^{(a)} \in B_c^{(a)}\) be the \((a \times c)\) tableau such that each box in its \(i\)th row is filled with \(i - 1 \in \{0, 1, \cdots, \kappa\}\). We define two maps \(\Gamma : \mathbb{N}_0 \to B_c^{(a)}\) and \(X' : \mathbb{N} \to B_c^{(1)}\) as follows. First let \(\Gamma(0) = U_c^{(a)}\) and then recursively for each \(x \geq 1\), we require
\[
R(\Gamma(x - 1), X(x)) = (X'(x), \Gamma(x)) \in B_1^{(1)} \times B_c^{(a)},
\] (9)
where \(R\) is the combinatorial \(R\) defined in the previous subsection.

In words, we run a \(B_c^{(a)}\)-carrier on the array \(X\) starting with the initial tableau \(U_c^{(a)}\). The carrier with a certain state \(\in B_c^{(a)}\) acts on the next site with state \(\in B_1^{(1)}\) according to
the combinatorial \( R \), producing a site state and new carrier state. Hence \( \Gamma(x) \) may be regarded as the carrier state after scanning the sites in the interval \([1, x] \). In this sense, we call \( \Gamma^{(a)}_c = (\Gamma(x))_{x \geq 0} \) the \( B^{(a)}_c \)-carrier process over \( X \) (see Figure 1). The integer parameters \( c \) and \( a \) are called the capacity and height of the carrier, respectively.

\[
\begin{array}{cccccccccccc}
0 & 0 & 0 & 2 & 2 & 0 & 0 & 0 & 3 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 3 \\
1 & 1 & 1 & 1 & 1 & 1 & 2 & 1 & 2 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
\end{array}
\]

**Figure 1.** Initial basic 3-color BBS configuration \( X = (12203100 \cdots) \) (top row) associated \( B^{(2)}_3 \)-carrier process \( \Gamma^{(2)}_3 \) (middle row), and new basic 3-color BBS configuration \( X' = (10011220 \cdots) \) (bottom row). At each crossing in the diagram, a carrier state \( \Gamma(x - 1) \) and a box state \( X(x) \) are mapped to a new box state \( X'(x) \) and a new carrier state \( \Gamma'(x) \) by the combinatorial \( R \).

An important fact is that if \( a = 1 \) and \( c \geq 1 \) is large enough relative to the total number of balls in \( X \), then the induced update map \( \mathcal{F}^{(a)}_c : X \to X' \) in fact agrees with the time evolution of the basic \( \kappa \)-color BBS given in (1) (see e.g., [10]). Hence, this gives an alternate characterization of the basic \( \kappa \)-color BBS defined in the introduction

The major advantage of the above construction of the basic \( \kappa \)-color BBS is that we get conserved quantities by simply running carriers of different capacities and heights. Namely, for a given basic \( \kappa \)-color BBS configuration \( X \) and for each integers \( c \geq 1 \) and \( 1 \leq a \leq \kappa \), we define its (row transfer matrix) energy

\[
E^{(a)}_c(X) = \sum_{x=1}^{\infty} H(\Gamma(x - 1), X(x)),
\]

where \( \Gamma^{(a)}_c = (\Gamma(x))_{x \geq 0} \) is the \( B^{(a)}_c \)-carrier process over \( X \), and \( H \) is the local energy function introduced in the previous subsection. One can see that (10) is convergent from the definition (7). These quantities can be collected as a \((\infty \times \kappa)\) integer matrix \( E(X) \) whose \((c, a)\) entry is \( E^{(a)}_c(X) \), which we call the energy matrix of \( X \). For the running example of 4-color BBS given in the introduction, we have

\[
X = (1121401012142044201200 \cdots) \rightarrow E(X) = \begin{bmatrix}
10 & 5 & 2 & 1 \\
13 & 7 & 3 & 2 \\
15 & 8 & 4 & 3 \\
16 & 9 & 4 & 4 \\
\vdots & \vdots & \vdots & \vdots \\
\end{bmatrix}.
\]

The invariants corresponding to the first column of the energy matrix were introduced in [6]. Based on the successive application of the Yang-Baxter equation for the combinatorial \( R \), the authors also established its time invariance. A similar method shows the

\footnote{The update map \( \mathcal{F}^{(a)}_c \) may not preserve number of balls when \( a > 1 \), as seen in Figure 1. In order to make it a time evolution that preserves number of balls, we need to introduce ‘barriers’ at the right tail of the state space. See [14, Subsection 2.2].}
time invariance of the entire energy matrix. Namely, for any basic $\kappa$-color BBS trajectory $(X_t)_{t \geq 0}$, we have

$$E(X_t) = E(X_0) \quad \forall \ t \geq 0. \quad (12)$$

Given the invariance of the energy matrix, we construct a $\kappa$-tuple of invariant Young diagrams $(\mu^{(1)}(X_t), \ldots, \mu^{(\kappa)}(X_t))$ by setting the length of the $i$th row of the $a$th Young diagram $\mu_i^{(a)}(X_t)$, which we denote by $\rho_i^{(a)}(X_t)$, through the following relation

$$\rho_1^{(a)}(X_t) + \cdots + \rho_i^{(a)}(X_t) = E_i^{(a)}(X_t) \quad \forall \ i \geq 1 \text{ and } 1 \leq a \leq \kappa. \quad (13)$$

We note that there is another construction of these invariant Young diagrams using the Kerov-Kirillov-Reshetikhin bijection [13] The equivalence between the two constructions is proven in [23]. Hence (13) does indeed define valid Young diagrams.

We remark that ‘physical’ meaning of the energy matrix can be given in terms of the soliton decomposition. For instance, let $t \geq 1$ be large enough so that all solitons of different lengths are separated with enough spacing between them. If we run the $B_{c}^{(1)}$-carrier over $X_t$, then the summation (10) for $E_{c}^{(1)}(X_t)$ picks up the left boundaries of distinct solitons, so the corresponding energy equals the total number of solitons, as seen from (13) with $i = a = 1$. More generally, $\rho_{c}^{(1)}(X_t)$ equals the number of solitons of length $\geq t$ (see [6] for a proof). See [16] for soliton interpretations of the higher order Young diagrams.

3. STATEMENT OF RESULTS

Let $p = (p_0, p_1, \ldots, p_\kappa)$ be a probability distribution on $\{0, 1, \cdots, \kappa\}$ such that $p_i > 0$ for all $0 \leq i \leq \kappa$. Let $X^p$ be a random map $\mathbb{N} \rightarrow \{0, 1, \cdots, \kappa\}$ drawn from the product probability measure $\mathbb{P}_p$, where $\mathbb{P}_p(X^p(x) = i) = p_i$ independently for all $x \in \mathbb{N}$ and $0 \leq i \leq \kappa$. For each integer $n \geq 1$, denote by $X^{n,p}$ the random basic $\kappa$-color BBS configuration obtained by the following truncation

$$X^{n,p}(x) = X^p(x) \cdot 1(1 \leq x \leq n). \quad (14)$$

If we run the $B_{c}^{(a)}$-carrier over the infinite i.i.d. basic $\kappa$-color BBS configuration $X^p$, then the associated carrier process $\Gamma_{c}^{(a)} = (\Gamma(x))_{x \geq 0}$ becomes a stochastic process. In fact, since its evolution is determined by the combinatorial $R$ and the i.i.d. input $X^p$, the carrier process becomes a Markov process on the finite state space $B_{c}^{(a)} = B_{c}^{(a)}(\kappa)$. We call this Markov chain as the $B_{c}^{(a)}$-carrier process over $X^p$.

The main subject in this paper is a scaling behavior of the basic $\kappa$-color BBS trajectory $(X_t)_{t \geq 0}$ initialized at the random configuration $X_0 = X^{n,p}$, as $n \rightarrow \infty$. The grounding result in this paper is that the carrier processes over $X^p$ is an irreducible Markov chain with a unique stationary measure, which is given by a simple product form. Furthermore, its partition function (normalization constant) becomes a Schur polynomial.

For a Young diagram $\lambda = (\rho_1, \cdots, \rho_{\kappa+1})$ of row lengths $\rho_1 \geq \cdots \geq \rho_{\kappa+1}$ and for parameters $w_1, \cdots, w_{\kappa+1}$, the Schur polynomial $s_{\lambda}(w_1, \cdots, w_{\kappa+1})$ is defined by

$$s_{\lambda}(w_1, \cdots, w_{\kappa+1}) = \frac{\det(w_{i}^{\rho_{j}+\kappa+1-j})_{i,j=1}^{\kappa+1}}{\det(w_{i}^{\kappa+1-j})_{i,j=1}^{\kappa+1}}. \quad (15)$$

Let $(c^a)$ denote the $(a \times c)$ Young diagram $(c, c, \cdots, c)$. 

Theorem 1. The $B^a_\kappa(X)$-carrier process over $X^p$ is an irreducible Markov chain with a unique stationary measure $\pi^a_\kappa = \pi^a_\kappa(X,p)$. Furthermore, $\pi^a_\kappa$ is given by

$$\pi^a_\kappa(C) = \frac{1}{Z^a_\kappa} \prod_{i=0}^\kappa p_i^{m_i(C)},$$

where $m_i(C)$ denotes the number of $i$’s in the semistandard tableau $C$ and the normalization constant $Z^a_\kappa = Z^a_\kappa(X,p)$ is given by

$$Z^a_\kappa(X,p) = s_{(c^a)}(p_0, p_1, \ldots, p_\kappa).$$

We remark that $Z^a_\kappa = p_0 + p_1 + \cdots + p_\kappa = 1$ and $\pi^a_\kappa = p$. Our proof of the irreducibility depends on an algorithmic characterization of the combinatorial $R$ acting on $B^a_\kappa \times B^a_1$. On the other hand, the stationarity of $\pi^a_\kappa$ is shown by a similar argument for a more general result [14, Prop. 3.2].

With Theorem 1 at hand, we can apply standard limit theorems for additive functionals of Markov chains for the row transfer matrix energy $E^a_\kappa(X^n,p)$. Here we state the strong law of large number (SLLN) and the large deviations principle (LDP). See Theorem 4.9 for limit theorems describing fluctuation of the energy matrix.

Theorem 2. Consider the basic $\kappa$-color BBS initialized at $X^n,p$.

(i) (SLLN) For each integers $c \geq 1$ and $1 \leq a \leq \kappa$, define a constant $\varepsilon^a_\kappa = \varepsilon^a_\kappa(X,p)$ by

$$\varepsilon^a_\kappa(X,p) = \frac{1}{Z^a_\kappa} \sum_{C \in B^a_\kappa} \prod_{j=0}^\kappa p_j^{m_j(C)} \left( \sum_{C(a,1) < l \leq \kappa} p_l \right),$$

where $Z^a_\kappa$ and $m_j(C)$ are as defined before. $C(a,1)$ is the bottom left entry of the semistandard tableau $C$. Then $\varepsilon^a_\kappa \in (0,1)$ and almost surely as $n \to \infty$,

$$n^{-1}E^a_\kappa(X^n,p) \to \varepsilon^a_\kappa.$$  

(ii) (LDP) There exists a convex rate function $\Lambda^*$ such that $\Lambda^* \in (0,\infty)$ on $[0,\nu] \setminus \{\varepsilon^a_\kappa\}$ for some $\nu \in (\varepsilon^a_\kappa,1)$ and

$$\lim_{n \to \infty} \frac{1}{n} \log \mathbb{P}_p\left( \left| n^{-1}E^a_\kappa(X^n,p) - \varepsilon^a_\kappa \right| \geq u \right) = - \min(\Lambda^*(\varepsilon^a_\kappa - u), \Lambda^*(\varepsilon^a_\kappa + u)).$$

Remark 3. The quantity $\varepsilon^a_\kappa$ can also be written as a ratio of Schur polynomials:

$$\varepsilon^a_\kappa(X,p) = \frac{s_{(c^a,1)}(p_0, \ldots, p_\kappa)}{s_{(c^a)}(p_0, \ldots, p_\kappa)}.$$  

A more general result has been given in Example 3.3 and equation (22) in [14], where $\varepsilon^a_\kappa$ is denoted by $h^a_\kappa$.

According to (13), Theorem 2 directly implies the existence of scaling limit of the invariant Young diagrams after scaling their rows by the reciprocal of system size $1/n$.

Corollary 4. Consider the basic $\kappa$-color BBS initialized at $X^n,p$. Let $\varepsilon^a_\kappa = \varepsilon^a_\kappa(X,p)$ be as before. Then for each $i \geq 1$ and $1 \leq a \leq \kappa$, almost surely as $n \to \infty$, we have

$$n^{-1}q^a_\kappa(X^n,p) \to f^a_\kappa(X,p)(i) := \varepsilon^a_i - \varepsilon^a_{i-1} > 0,$$
where we set $\epsilon_0^{(a)} = 0$. Furthermore, a large deviations estimate similar to (20) holds. In particular, if $\kappa = a = 1$ and $q := p_1 / p_0$, then

$$f^{(q)}_{\kappa, p}(i) = \begin{cases} \frac{(q-1)^2 q^i}{(q+1)(q-1)(q^i+1)-1} & \text{if } p_1 \neq 1/2 \\ \frac{1}{2i(i+1)} & \text{otherwise.} \end{cases}$$ \hspace{1cm} (23)

Remark 5. Note that the function $f^{(1)}_{1,p}$ is invariant under the swapping transformation $p = (p_0, p_1) \to p' = (p_1, p_0)$ (see Figure 2). This gives the ‘row version’ of the duality between the supercritical and subcritical BBS with ball densities $p$ and $1 - p$, observed in [18] (see, in particular, Lemma 6.2).

Figure 2. Invariant Young diagram $\mu^{(1)}$ corresponding to the single-color BBS of system size $n = 500000$ with ball densities $p = 1/3$ (left), $1/2$ (middle), and $2/3$ (right). The equations for the limiting curve are obtained as the inverse of $f^{(1)}_{1,p}$ in (23).

Our next set of results consider the random basic $\kappa$-color BBS conditioned on the ‘highest states’. Namely, a given basic $\kappa$-color BBS configuration $X_0 : \mathbb{N} \to \{0, 1, \ldots, \kappa\}$ is said to be a highest state if for all $n \geq 1$,

$$\#(\text{balls of color } i \text{ in } X_0 \text{ over } [1, n]) \geq \#(\text{balls of color } i + 1 \text{ in } X_0 \text{ over } [1, n]),$$

where we interpret balls of color $0$ as empty boxes. The following concentration result is a consequence of Corollary 4 and estimating the probability of sampling a highest state from $X^{n,p}$ using a generalized Ballot theorem.

Corollary 6. Consider the basic $\kappa$-color BBS initialized at $X^{n,p}$ conditioned on the highest states. Suppose $p_0 \geq p_1 \geq \cdots \geq p_k$. Let $f^{(a)}_{\kappa, p}$ be the same function as in Corollary 4. Then for each $i, a \geq 1$,

$$n^{-1} p_i^{(a)}(X^{n,p}) \to f^{(a)}_{\kappa, p}(i)$$

almost surely as $n \to \infty$. \hspace{1cm} (25)

The above corollary implies that the same limiting curve $f^{(a)}_{\kappa, p}$ describing the asymptotic profile of invariant Young diagrams for the i.i.d. BBS $X^{n,p}$ still gives the limiting shape after the highest state conditioning. We call the phenomenon the ‘asymptotic equivalence’
between unconditioned and highest state BBS (see Remark 5.4). This allows us to incorporate powerful techniques developed for BBS started from a highest state.

Indeed, if we condition the random BBS configuration $X^{n,p}$ on the highest states, we are able to obtain a precise law on the invariant Young diagrams of the system using the so-called Fermionic formula. In order to state the result, let us introduce the following quantities (See Figure 3 for illustration).

$$m_i^{(a)} = \text{number of the length } i \text{ columns in } \mu^{(a)},$$

$$C_{ab} = 2\delta_a,b - \delta_a,b-1 - \delta_a,b+1,$$

$$E_i^{(a)} = \sum_{j \geq 1} \min(i, j) m_j^{(a)} = \rho_1^{(a)} + \rho_2^{(a)} + \cdots + \rho_i^{(a)},$$

$$v_i^{(a)} = n\delta_{a,1} - \sum_{b=1}^K C_{ab} E_i^{(b)}.$$  

Here $\delta_{a,b} = 1 (a = b)$ is the Kronecker delta, the matrix $(C_{ab})_{1 \leq a, b \leq K}$ is the Cartan matrix of $sl_{K+1}$, and the quantity $v_i^{(a)}$ is called **vacancy**. Recall that (28) was the defining equation for the row lengths $\rho_i^{(a)}$, where $E_i^{(a)} = E_i^{(a)}(X_0)$ means the row transfer matrix energy.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure3.png}
\caption{Illustration of notation for the of the $a$th Young diagram $\mu^{(a)}$. $E_i^{(a)}$ denotes the area of the shaded region.}
\end{figure}

**Theorem 7.** Consider the basic $\kappa$-color BBS initialized at $X^{n,p}$ conditioned on the highest states. Then the law on the set of all $\kappa$-tuple of invariant Young diagrams is given by

$$P_p(\mu^{(1)}, \ldots, \mu^{(K)}) = \frac{1}{Z_n} e^{-\sum_{a=1}^\kappa \beta_a \sum_{i \geq 1} im_i^{(a)}} \prod_{a=1}^\kappa \prod_{i \geq 1} \left( v_i^{(a)} + m_i^{(a)} \right),$$

where the chemical potentials $\beta_a$ are defined by $e^{\beta_a} = p_{a-1} / p_a$ for $1 \leq a \leq \kappa$ and $Z_n$ is the normalization constant.

For our last result, we specialize the initial configuration by letting $p_i \propto q^i$ for $0 \leq i \leq \kappa$, where $q \in (0, 1)$ is a parameter. In this case, by using Thermodynamic Bethe ansatz we obtain a factorized form of the limiting curve $f_{\kappa,p}^{(a)}$ in Corollary 6. By the ‘asymptotic equivalence’ this in fact applies to the unconditioned BBS.
Theorem 8. Consider the basic $\kappa$-color BBS initialized at $X^{n,p}$, where $p_i \propto q^i$ for all $0 \leq i \leq \kappa$ for some parameter $0 < q < 1$. Then almost surely as $n \to \infty$,

$$n^{-1} \rho_i^{(a)}(X^{n,p}) \sim \frac{q^{i+a-1}(1-q)(1-q^a)(1-q^{\kappa+1-a})}{(1-q^{\kappa+1})(1-q^{i+a-1})(1-q^i)}.$$  \hfill (31)

Note that when $\kappa = a = 1$, the formula (31) agrees with (22) in Corollary 4, which was obtained by a completely different method. We also remark that (31) is a special case $p_i \propto q^i$ of the result for general density $p_0 > p_1 > \cdots > p_\kappa$ in [14, Sec. 6].

4. Limit theorems for the rows

In this section, we first establish the irreducibility and identify the unique stationary measure of the carrier process, as stated in Theorem 1. Since each entry $E_i^{(a)}(X^{n,p})$ of the energy matrix is the sum of a functional of the carrier process augmented with new site states (see (10)), we may apply limit theorems developed for such partial sums. The strong law of large number (Theorem 2 (ii)) and functional CLT and persistence scaling (Theorem 4.9) follow from a standard theory of Markov chains. However, we need some more work to show that the large deviations rate function $\Lambda^*(u)$ is strictly positive for $u \neq \varepsilon^{(a)}_\kappa$ (Theorem 2 (iii)). This will be crucial in pushing the strong law under the highest state conditioning in Section 5.

4.1. Irreducibility and stationarity of the carrier process. We prove Theorem 1 in this subsection. We first take a look at an illustrative example of $B_5^{(1)}(2)$-carrier process.

Example 4.1. Let $\kappa = 2$ and ball density $p = (p_0, p_1, p_2)$, where $p_i > 0$ for all $0 \leq i \leq 2$. Consider the carrier process $\Gamma^{(1)}_5$ over $XP$. We may identify a tableau $C \in B_5^{(1)}(2)$ with an integer vector $(c_1, c_2) \in \mathbb{N}_0^2$ such that $c_1 + c_2 \leq 5$, where $c_i = \#$(balls of color $i \in C$). For example,

$$\begin{pmatrix} 0 & 0 & 1 & 2 \end{pmatrix} \approx (1,2).$$  \hfill (32)

Then by invoking the algorithm for computing the combinatorial $R$ given in the appendix, we can obtain the state space diagram of this chain as shown in Figure 4.

Since $p_i > 0$ for all $0 \leq i \leq 2$, clearly the chain is irreducible. Since the state space is finite, there must be a unique stationary measure, which we may denote by $\pi = \pi^{(1)}_5(\kappa, p)$ in this example. Observe that this stationary measure is characterized by the following detailed balance equations:

$$\begin{align*}
\pi(a, b) &= \pi(a, b + 1)p_0 + \pi(a - 1, b)p_1 + \pi(a + 1, b - 1)p_2 & \text{for } 1 \leq a, b \text{ and } a + b \leq 4 \\
\pi(a, 0) &= \pi(a + 1, 0)p_0 + \pi(a - 1, 0)p_1 + \pi(a, 1)p_0 & \text{for } 1 \leq a \leq 4 \\
\pi(0, b) &= \pi(0, b + 1)p_0 + \pi(1, b - 1)p_2 + \pi(0, b - 1)p_2 & \text{for } 1 \leq b \leq 4 \\
\pi(a, b) &= \pi(a - 1, b)p_1 + \pi(a + 1, b - 1)p_2 + \pi(a - 1, b + 1)p_1 & \text{for } 1 \leq a, b \text{ and } a + b = 5 \\
\pi(0, 0) &= \pi(0, 0)p_0 + \pi(1, 0)p_0 + \pi(0, 1)p_0 \\
\pi(5, 0) &= \pi(4, 0)p_1 + \pi(5, 0)p_1 + \pi(4, 1)p_1 \\
\pi(0, 5) &= \pi(0, 4)p_2 + \pi(1, 4)p_2 + \pi(0, 5)p_2
\end{align*}$$  \hfill (33)
It is straightforward to check that the stationary measure $\pi$ is given by

$$\pi(a, b) = \frac{1}{Z_5^{(1)}} p_0^{5-a-b} p_1^a p_2^b,$$

where the partition function $Z$ can be written as

$$Z_5^{(1)} = \sum_{a, b, c \geq 0} p_0^a p_1^b p_2^c$$

Our proof of the irreducibility of the carrier process relies on Proposition 4.3, which gives an algorithm for direct computation of the combinatorial $R$ and the local energy function $H$ acting on $B_c^{(a)} \times B_1^{(1)}$. This part may be regarded as a special case of the general algorithm known for $B_c^{(a)} \times B_1^{(1)}$ for example in [22, p.55]. Our algorithm consists of two essential steps, namely, the reverse bumping and column insertion. The former is the reverse of the usual Schensted row insertion ($T \leftarrow x$) from the bottom to the top row (See [7, p.8].) The latter is the usual Schensted column insertion from the first to the last column. (See [7, p.186].)

More precisely, we define a map $\tilde{R} : B_c^{(a)} \times B_1^{(1)} \rightarrow B_1^{(1)} \times B_c^{(a)}$, $(T, x) \mapsto (y, S)$, as below. Let $z$ be the number inscribed in the bottom left box in the tableau $T$.

(i) (reverse bumping) Case $x > z$. Replace the rightmost element $x'$ such that $x' < x$ in the bottom row of $T$ by $x$. Replace the rightmost element $x''$ such that $x'' < x'$ in the row above (row $(c - 1)$) of $T$ by $x'$. Perform the similar replacements all the way to the top row. The resulting $(a \times c)$ tableau is $S$, and the last replaced letter from the top row is $y$. The algorithm then halts.

(ii) (column insertion) Case $x \leq z$. Replace the topmost element $x'$ such that $x' \geq x$ in the first column of $T$ by $x$. Replace the topmost element $x''$ such that $x'' \geq x'$ in the second column of $T$ by $x'$. Perform the similar replacements all the way to the...
last column. The resulting \((a \times c)\) tableau is \(S\), and the last replaced letter from the rightmost column is \(y\). The algorithm then halts.

**Example 4.2.** We give four instances of the map \(\tilde{R}\). In this example we use \(\Rightarrow\) and \(\downarrow\) to indicate the intermediate steps of the reverse bumping and column insertion for single row and column, respectively.

\[
\begin{pmatrix}
0 & 1 & 1 \\
2 & 3 & 4
\end{pmatrix}
\Rightarrow
\begin{pmatrix}
3 \Rightarrow & 0 & 1 & 1 \\
2 & 3 & 4
\end{pmatrix}
\Rightarrow
\begin{pmatrix}
2 \Rightarrow & 0 & 1 & 1 \\
0 & 1 & 1 & 3 & 4
\end{pmatrix}
\Rightarrow
\begin{pmatrix}
1 & 0 & 1 & 2 \\
3 & 3 & 4
\end{pmatrix}
\]

\((36)\)

\[
\begin{pmatrix}
0 & 1 & 1 \\
2 & 3 & 4
\end{pmatrix}
\downarrow
\begin{pmatrix}
2 & 3 & 4
\end{pmatrix}
\Rightarrow
\begin{pmatrix}
2 & 3 & 4
\end{pmatrix}
\Rightarrow
\begin{pmatrix}
3 & 3 & 4
\end{pmatrix}
\Rightarrow
\begin{pmatrix}
4 & 0 & 1 & 1 \\
2 & 2 & 3
\end{pmatrix}
\]

\((37)\)

\[
\begin{pmatrix}
0 & 1 & 1 \\
2 & 2 & 4 \\
4 & 4 & 5
\end{pmatrix}
\downarrow
\begin{pmatrix}
3 & 4 & 5
\end{pmatrix}
\Rightarrow
\begin{pmatrix}
4 & 4 & 5
\end{pmatrix}
\Rightarrow
\begin{pmatrix}
4 & 4 & 5
\end{pmatrix}
\Rightarrow
\begin{pmatrix}
1 & 0 & 0 & 1 \\
2 & 2 & 4 \\
4 & 4 & 5
\end{pmatrix}
\]

\((38)\)

\[
\begin{pmatrix}
0 & 1 & 1 \\
2 & 2 & 4 \\
4 & 4 & 5
\end{pmatrix}
\downarrow
\begin{pmatrix}
0 & 1 & 1 \\
2 & 2 & 4 \\
4 & 4 & 5
\end{pmatrix}
\Rightarrow
\begin{pmatrix}
0 & 1 & 1 \\
2 & 2 & 4 \\
3 & 4 & 5
\end{pmatrix}
\Rightarrow
\begin{pmatrix}
1 & 0 & 0 & 1 \\
2 & 2 & 4 \\
4 & 4 & 5
\end{pmatrix}
\]

\((39)\)

Observe from example \((39)\) that if 0 is inserted, then the algorithm always halts by sliding the top row to the right by a single cell and the \((1,1)\) cell is filled with a new 0. ▲

**Proposition 4.3.** We have \(\tilde{R} = R\) on any \(B_c^{(a)} \times B_1^{(1)}\). Furthermore, the local energy function \(H\) is given by

\[
H(T, x) = 1(x > \text{bottom left element in } T). \tag{40}
\]

**Proof.** Suppose \(R : (T, x) \rightarrow (y, S)\). Then by definition and duality between row and column insertion [7, Appendix A.2], we have

\[
(S \leftarrow y) = (x \leftarrow \text{row}(T)) = (x \leftarrow T), \tag{41}
\]

where the first equality is due to \((6)\) and \(\rightarrow\) denotes the column insertion [7, p186]. The second equality follows from the equivalence of the two constructions of product tableaux based on row and column insertions. Compare the bottom formula on [7, p11] and the top one on [7, p187]. Let \(z\) be the bottom left letter in the tableau \(T\) as in the above algorithm \((i)\) and \((ii)\). \((i)\) Suppose \(x > z\). Then \((x \leftarrow T)\) is obtained by attaching a single box containing \(x\) below the first column of \(T\). To find \((y, S)\) from such \((x \leftarrow T)\) by the postulate \((41)\) is done exactly by the reverse bumping procedure in \((i)\). \((ii)\) Suppose \(x \leq z\). Then \((x \leftarrow T)\) has the shape of a \((a \times c)\) tableau with a single box attached to the right of its first row. Let \(S'\) be its left \((a \times c)\) part and \(y'\) be the remaining single box. Since \(y'\) the largest in the first row of \((x \leftarrow T)\), it follows that \((S' \leftarrow y') = (x \leftarrow T)\). By the uniqueness, it follows that \(S' = S\) and \(y' = y\). Lastly, from \((7)\) we have \(H(T, x) = 1\) for case \((i)\) and \(H(T, x) = 0\) for case \((ii)\), proving \((40)\). □

Now we are ready to prove Theorem 1. We note that the stationarity of \(\pi^{(a)}_c\) has been established in the more general BBS in the recent work [14, Prop. 3.2]. We include a proof
of stationarity here since the argument is short and it becomes more transparent in our current setting of the basic $\kappa$-color BBS.

**Proof of Theorem 1.** We first show that the $B^{(a)}_c$-carrier process over $X^p$ is irreducible. For a tableau $T \in B^{(a)}_c$ and its row word $row(T) = t_1 t_2 \cdots t_{ac}$, we denote the reverse row word by $row'(T) = t_{ac} \cdots t_2 t_1$. For any tableau $C \in B^{(a)}_c$ and a word $x_1 x_2 \cdots x_r$, $0 \leq x_i \leq \kappa$, define

$$R_2(C, x_1 x_2 \cdots x_r) := R_2(\cdots R_2(R_2(C, x_1), x_2) \cdots, x_r) \in B^{(a)}_c.$$  \hfill (42)

For given two tableaux $C, C' \in B^{(a)}_c$, say $C$ reaches $C'$ if

$$R_2(C, x_1 x_2 \cdots x_k) = C'$$ \hfill (43)

for some $x_i \in \{0, 1, \cdots, \kappa\}$, $1 \leq i \leq r$. Lastly, let $V^{(a)}_c$ be the ‘lowest tableau’, whose entries in row $a$ are $(\kappa - i)$ for all $0 \leq i < a$.

For the irreducibility of the carrier process, by the independence in $X^p$ and since we are assuming $p > 0$, it is enough to show that any tableau $C \in B^{(a)}_c$ reaches $V^{(a)}_c$ and vice versa. This is indeed the case since (43) holds for the concatenation $x_1 \cdots x_k = row'(V^{(a)}_c).row'(C')$ for any $C, C' \in B^{(a)}_c$. In fact, using the realization of $R$ by the reverse bumping and the column insertion, it is not hard to see

$$R_2(C, row'(V^{(a)}_c)) = V^{(a)}_c, \quad R_2(V^{(a)}_c, row'(C)) = C.$$ \hfill (44)

See below for an illustration when $\kappa = 5$, where we show $\Rightarrow$ and $\Downarrow$ only for the first step of successive reverse bumping and column insertion for inserting each letter.

This shows the irreducibility of the $B^{(a)}_c$-carrier process over $X^p$.

Next, we show $\pi^{(a)}_c$ is a stationary measure for the $B^{(a)}_c$ carrier process over $X^p$. For each semistandard tableau $T$ (not necessarily rectangular), denote $e^{\text{wt}(T)} = \prod_{i=0}^{\kappa} p_i^{m_i(T)}$, where $m_i(T)$ denotes the total number of letter $i$ in $T$ as before. For any two rectangular tableaux $S, T$, we may denote $S \cdot T = (S \leftarrow \text{row}(T))$ (see (6) and above). Since the total number of letter $i$ is preserved in each row insertion step, we have $m_i(S \cdot T) = m_i(S) + m_i(T)$. Now for any $(C, B) \in B^{(a)}_c \times B^{(1)}_c$ and $(B', C') \in B^{(1)}_c \times B^{(a)}_c$ such that $R(C, B) = (B', C')$, we have $C \cdot B = B' \cdot C'$ by definition so we have

$$e^{\text{wt}(C)} e^{\text{wt}(B)} = e^{\text{wt}(C \cdot B)} = e^{\text{wt}(B' \cdot C')} = e^{\text{wt}(B')} e^{\text{wt}(C')}.$$ \hfill (46)
Moreover, recall the combinatorial $R : B_c^{(a)} \times B_1^{(1)} \rightarrow B_1^{(1)} \times B_c^{(a)}$ is a bijection, so it also gives a bijection between $B_1^{(1)} \times \{C\}$ and its inverse image under $R$. Hence we have
\[
\sum_{(C, B) \in B_c^{(a)} \times B_1^{(1)} \atop R_2(C, B) = C'} \varepsilon_{\text{wt}(C)} \varepsilon_{\text{wt}(B)} = \sum_{(C, B) \in B_c^{(a)} \times B_1^{(1)} \atop R_2(C, B) = C'} \varepsilon_{\text{wt}(B')} \varepsilon_{\text{wt}(C')} = \varepsilon_{\text{wt}(C')} \sum_{B' \in B_1^{(1)}} \varepsilon_{\text{wt}(B')}.
\] (47)

Note that $\varepsilon_{\text{wt}(i)} = p_i$ for each $0 \leq i \leq \kappa$, so the summation in the last expression equals 1. Hence dividing both sides by the partition function $Z_c^{(a)}$ gives
\[
\sum_{(C, i) \in B_c^{(a)} \times B_1^{(1)} \atop R_2(C, i) = C'} \pi_c^{(a)}(C) p_i = \pi_c^{(a)}(C').
\] (48)

This shows that $\pi_c^{(a)}$ is a stationary measure for the $B_c^{(a)}$-carrier process over $X^p$. The uniqueness follows from irreducibility and the fact that the state space $B_c^{(a)}(\kappa)$ is finite. The formula (17) is obvious from an alternative definition of the Schur function as the generating sum of $\varepsilon_{\text{wt}}$ over the semistandard tableaux. \qed

4.2. SLLN and LDP for the energy matrix. In the previous subsection, we have seen that the carrier process $\Gamma^{(a)} = (\Gamma(x))_{x \geq 0}$ over $X^p$ defines an irreducible Markov chain on the finite state space $B_c^{(a)}(\kappa)$. In addition, the infinite i.i.d. basic $\kappa$-color BBS configuration $X^p$ also defines a Markov chain on $B_1^{(1)}(\kappa)$, which is irreducible since $X^p(x)$ is i.i.d. over $x$ and $p$ is positive on every element of $B_1^{(1)}(\kappa)$. Then it follows that the pair $X_t = (\Gamma(x - 1), X^p(x))$ defines an irreducible Markov chain on finite state space $B_c^{(a)} \times B_1^{(1)}$ with unique stationary measure $\pi_c^{(a)} \otimes p$, $(C, x) \rightarrow \pi_c^{(a)}(C)p(x)$. Note that its transition kernel $P$ is given by
\[
P((C_1, x_1), (C_2, x_2)) = 1(C_2 = R_2(C_1, x_1)) p(x_2),
\] (49)

where $R_2(C_1, x_1) \in B_c^{(a)}$ denotes the second component of the image $R(C_1, x_1)$ of the combinatorial $R$.

In the following proposition, we give some basic estimates about the energy matrix $E(X^n, p)$, which will be used in proving Theorem 2.

**Proposition 4.4.** Let $\varepsilon_c^{(a)} = \varepsilon_c^{(a)}(\kappa, p)$ be as in (18).

(i) $\varepsilon_c^{(a)} = \mathbb{E}_{\pi_c^{(a)} \otimes p} [H(C, x)]$ and $\varepsilon_c^{(a)} \in (0, 1)$.

(ii) For any $\varepsilon \in [0, \varepsilon_c^{(a)})$ and $n \geq 1$,
\[
\mathbb{P}_p(n^{-1} E_c^{(a)}(X^n, p) \leq \varepsilon) \geq p_0^n.
\] (50)

(iii) There exists $\nu \in (\varepsilon_c^{(a)}, 1)$ and $\delta \in (0, 1)$ such that for each $\varepsilon \in (0, \varepsilon_c^{(a)})$ and $n \geq 1$,
\[
\mathbb{P}_p(n^{-1} E_c^{(a)}(X^n, p) \geq \varepsilon) \geq \delta^n.
\] (51)

**Proof.** Recall the chain $X_t = (\Gamma(t - 1), X^p(t))$ on $B_c^{(a)} \times B_1^{(1)}$ is irreducible with unique stationary measure $\pi_c^{(a)} \otimes p$.

(i) By Theorem 1 and Proposition 4.3, we have
\[
\mathbb{E}_{\pi_c^{(a)} \otimes p} [H(C, x)] = \frac{1}{Z_c^{(a)}} \sum_{C \in B_c^{(a)}} \sum_{0 \leq i \leq \kappa} 1(C(a, 1) < i) p_i \prod_{j=0}^{\kappa} p_j^{m_j(C)} = \varepsilon_c^{(a)}.
\] (52)
Furthermore, observe that $H(C, 0) = 0$ for all $C \in B_c^{(a)}$ and $H(U_c^{(a)}, \kappa) = 1$ due to Proposition 4.3. Since $\pi_c^{(a)} \otimes \mathbf{p}$ is positive at every element in $B_c^{(a)} \times B_1^{(1)}$, this shows $\varepsilon_c^{(a)} \in (0, 1)$.

(ii) Fix $0 \leq \varepsilon < \varepsilon_c^{(a)}$. Since $\Gamma(0) = U_c^{(a)}$ and $R(U_c^{(a)}, 0) = (0, U_c^{(a)})$, independence in $X^p$ gives
\[
\mathbb{P}_p(n^{-1} E_c^{(a)}(X^n, P) \leq \varepsilon) \geq \mathbb{P}_p(E_c^{(a)}(X^n, P) = 0)
\]
(53)
and
\[
\mathbb{P}_p(X^P(x) \equiv 0 \; \forall 1 \leq x \leq n) \geq p_0^n.
\]
(54)

(iii) Observe that by the irreducibility of the chain $X_t$, there is a positive fraction $\tau > 0$ of times $x \in \mathbb{N}$ at which $\Gamma(x - 1) = U_c^{(a)}$ and $X^P(y) \equiv 0$ for all $y \in [x, x + 3L]$. Call such interval $[x, x + 3L]$ 'frozen' since $\Gamma(y) \equiv U_c^{(a)}$ and $H(\Gamma, y - 1), X^P(y)) \equiv 0$ for all $y \in [x, x + 3L]$. Now if we replace the configuration $X^P$ over the middle third $[x + L, x + 2L]$ appropriately, then we gain additional unit contribution to the energy $E_c^{(a)}$ while maintaining the chain $X_t = (\Gamma(t - 1), X^P(t))$ the same at the beginning and at the end of such interval. By the independence in $X^P$, we can perform such replacement independently over all such frozen intervals of length $3L$ with a positive probability, say, $\delta$. Hence we may perform this replacement for about $\tau n$ such intervals appearing in $[1, n]$ to increase the energy $E_c^{(a)}(X^n, P)$ by $\tau n$ at the cost of exponential probability $\delta^n > 0$. This shows
\[
\mathbb{P}_p(n^{-1} E_c^{(a)}(X^n, P) \geq \varepsilon_c^{(a)} + \tau) \geq \delta^n,
\]
(55)
as desired.

□

Next, we recall a large deviations principle (LDP) for additive functionals of finite-state irreducible Markov chains. Let $(X_t)_{t \geq 0}$ be a Markov chain on a state space $\Omega$ with transition kernel $P: \Omega^2 \to [0, 1]$. Let $g: \Omega \to \mathbb{R}$ be a functional, and define $S_n = \sum_{k=1}^{n} g(X_k)$ with $S_0 = 0$. We may assume that the following (sufficient but not necessary) conditions are satisfied:

(a) The state space $\Omega$ is finite;
(b) The Markov chain $(X_t)_{t \geq 0}$ is irreducible and has a unique stationary distribution $\pi$.

For each $t \in \mathbb{R}$, let $P_{tg}$ be the exponentially weighted transition matrix defined by
\[
P_{tg}(x, y) = P(x, y) e^{tg(y)}.
\]
(56)
Then by Perron-Frobenius theorem, the matrix $P_{tg}$ has a unique principal eigenvalue $\lambda_g(tg) > 0$ for any $t \in \mathbb{R}$. Let $\Lambda(t) := \log \lambda_g(tg)$ and define its Legendre transform
\[
\Lambda^*(u) = \sup_{t \in \mathbb{R}} [ut - \Lambda(t)].
\]
(57)
It is well-known that both $\Lambda$ and $\Lambda^*$ are convex, and that $\Lambda$ is differentiable everywhere in $\mathbb{R}$ (See [2, Section 3.1.1]).

Then Cramér’s theorem for the Markov additive functionals asserts that (see [2, Theorem 3.1.2]) for any closed subset $F \subset \mathbb{R} \setminus \{E \geq g(X_0)\}$,
\[
\lim_{n \to \infty} \frac{1}{n} \log \mathbb{P}(n^{-1} S_n \in F) = - \inf_{u \in F} \Lambda^*(u).
\]
(58)
Now we are ready to prove Theorem 2.
**Proof of Theorem 2.** Fix integers $a, c \geq 1$ and $\kappa \geq a$. Let $\varepsilon_c^{(a)}$ be as in (18). It is well-known that a finite-state irreducible Markov chain is ergodic. So by Proposition 4.4 (i) and the Markov chain ergodic theorem (e.g., [3, Theorem 7.2.1]),

$$n^{-1} E_c^{(a)}(X^n) \to \varepsilon_c^{(a)} \in (0, 1),$$

almost surely as $n \to \infty$. This shows (19).

For the large deviations part, consider the irreducible Markov chain $X_t = (\Gamma(t-1), X^P(t))$ on the finite state space $\Omega = B_{c}^{(a)} \times B^{(1)}_1$, where $\Gamma^{(a)}_c = (\Gamma(t))_{t \geq 0}$ is the carrier process over $X^P$. Let $P$ be the transition kernel of this chain given in (49). Define $\Lambda(t) = \log \lambda (t H)$. Then (20) follows from (58) by taking $F = (-\infty, \varepsilon_c^{(a)} - u] \cup [\varepsilon_c^{(a)} + u, \infty)$.

Lastly, to show the positivity of $\Lambda^*$, let $\nu \in (\varepsilon_c^{(a)}, 1)$ be as in Proposition 4.4 (iii). Then Proposition 4.4 and (58) imply that $\Lambda^*(\varepsilon) \geq \log p_{0}^{-1} > 0$ for all $\varepsilon \in [0, \varepsilon_c^{(a)})$ and that $\Lambda^*(\varepsilon) \geq \log \delta^{-1} > 0$ for any $\varepsilon \in (\varepsilon_c^{(a)}, \nu)$. Then (20) implies that $\Lambda^*(\varepsilon) > 0$ for all $\varepsilon \in [0, \nu) \setminus \{\varepsilon_c^{(a)}\}$, as desired. This shows the assertion. \[\Box\]

**Remark 4.5.** It is elementary to show that $\Lambda^*(\varepsilon_c^{(a)}) = 0$. Using the fact that $\lambda(t H)$ is the largest real root of the characteristic equation $\det(x I - P(t H)) = 0$, it is not hard to show that there are positive constants $v, c, c' > 0$ such that $\Lambda(t) = vt - c + O(1)$ as $t \to \infty$ and $\Lambda(t) = -c + o(1)$ as $t \to -\infty$. Then the definition of $\Lambda^*$ implies that $\Lambda^*$ is strictly decreasing on $[0, \varepsilon_c^{(a)})$, strictly increasing on $(\varepsilon_c^{(a)}, \nu)$, and equals $\infty$ elsewhere. See the following example.

**Example 4.6.** Let $\kappa = 2$ and consider the carrier process $\Gamma^{(1)}$ with uniform density $p = (1/3, 1/3, 1/3)$ (see Example 4.1). The Markov chain $X_t = (\Gamma(t-1), X^P(t))$ is defined on the state space $B_{c}^{(a)} \times B^{(1)}_1$ with a $(18 \times 18)$ transition kernel $P$ given in (49). We apply the LDP for $S_n = \sum_{k=1}^n g(X_k)$ explained in the above to (10) by setting $S_n = E_c^{(a)}(X^n)\nu_p$ and $g = H$, where $H$ is the utility function in (7). Let $\Lambda(t) = \log \lambda (t H)$, where $\lambda(t H)$ be the largest real root of the following characteristic polynomial of $P(t H)$ divided by $x^{12}$:

$$x^6 - x^5 - \frac{2e^t - 1}{3} x^4 + \frac{4e^t - 12e^t + 1}{27} x^3 + \frac{e^t(5e^t - 2)}{27} x^2 + \frac{2e^t(e^t - 2)}{81} x - \frac{e^{3t}(e^t + 8)}{36} = 0. \quad (60)$$

By taking partial derivative in $t$ and plugging in $(t, x) = (0, 1)$, we get

$$\varepsilon_3^{(1)} = \left. \frac{d \Lambda(t)}{dt} \right|_{t=0} = \left. \frac{d \lambda(t H)}{dt} \right|_{t=0} = \frac{4}{9}. \quad (61)$$

Note that as $t \to -\infty$, $\lambda(t H)$ is asymptotically the largest real root of

$$x^3(x - 1/3)^3 = 0, \quad (62)$$

which is $1/3$. Thus $\Lambda(t) = -\log 3 + o(1)$ as $t \to -\infty$. On the other hand, as $t \to \infty$, $\lambda(t H)$ is asymptotically the largest real root of

$$x^6 - \frac{4e^t - 12e^t + 1}{27} x^3 - \frac{e^{3t}(e^t + 8)}{36} = 0, \quad (63)$$

so we get

$$\Lambda(t) = \frac{2t}{3} - \log \left( \frac{3(\sqrt{3} - 1)}{2} \right) + o(1) \quad \text{as } t \to \infty. \quad (64)$$

By definition (57), this implies that $\Lambda^*$ is strictly decreasing on $[0, 4/9)$, strictly increasing on $(4/9, 2/3)$, and equals $\infty$ elsewhere. \[\blacktriangle\]
Proof of Corollary 4. The first part of the assertion is a direct consequence of Theorem 2 with the relation (28). Next, suppose $\kappa = a = 1$. We first compute the partition function $Z_c^{(1)}$. If we denote $q = p_1/p_0$, then
\[
Z_c^{(1)} = p_0^0 p_1^0 + p_0^1 p_1^{c-1} + \cdots + p_0^c p_1^0 = \frac{p_0^0 (1 - q^{c+1})}{1 - q} 1(q \neq 1) + \frac{c + 1}{2c} 1(q = 1).
\] (65)

Hence we obtain
\[
\varepsilon_c^{(1)} = p_1 \mathbb{P}_{c^{(1)}}(C \text{ contains at least one 0}) = p_1 \left(1 - \frac{p_1^c}{Z_c^{(1)}}\right) = p_1 \frac{1 - q^c}{1 - q^{c+1}} 1(p_1 \neq 1/2) + \frac{c}{2(c+1)} 1(p_1 = 1/2).
\] (66)

(67)

Then a simple algebra shows (23). □

Remark 4.7. The first part of Corollary 4 for $\kappa = 1$ case in fact strengthens [18, Lemma 3.4] with a shorter proof, relying on a general large deviations theory for Markov chains. Also, we remark that one can compute $\varepsilon_c^{(1)}$ via a completely different method. Namely, let $(S_k)_{k \geq 0}$ be the simple random walk started at $S_0 = 0$ and jumping to the right with probability $p$ and to the left with probability $1 - p$. Let $\varsigma = \inf\{k > 0 : S_k = 0\}$ be the first return time of $S_k$ to 0. Then according to [18, Theorem 1], we have
\[
\varepsilon_c^{(1)} = \mathbb{P}\left(\max_{0 \leq k \leq \varsigma} S_k \leq c\right).
\] (68)

Now considering $S_k$ as the fortune of a gambler after betting $k$ times, using the Gambler’s ruin probability [3, Ch. 5.7], we arrive at the same expression in (67).

4.3. Fluctuation of the energy matrix. Having established that the rescaled energy matrix $n^{-1}E(X^n, \mathbb{P})$ converges almost surely to some limiting matrix at an exponential rate, a natural next question is about its fluctuation around its mean. We characterize the fluctuation of energy matrix in terms of the functional central limit theorem (FCLT) and its ‘persistence scaling’. Namely, the central limit theorem about the energy matrix states the following convergence in distribution
\[
\frac{E_c^{(a)}(X^n, \mathbb{P}) - \varepsilon_c^{(a)} n}{\sqrt{n}} \Rightarrow \gamma_k Z,
\] (69)

where $Z$ is the standard normal random variable and $\gamma_k$ is a quantity that will be defined shortly. The FCLT gives a stronger version of such diffusive scaling in the process level. On the other hand, persistence scaling gives the asymptotic behavior as $n \to \infty$ of the probability that the energy $E_c^{(a)}(X^n, \mathbb{P})$ beats its mean $\varepsilon_c^{(a)} k$ for all $1 \leq k \leq n$.

To make precise statements, let $X_t = (\Gamma(t-1), X^{\mathbb{P}}(t))$, where $(\Gamma(t))_{t \geq 0}$ is the $B_c^{(a)}$-carrier process over $X^\mathbb{P}$. Let $\pi = \pi_c^{(a)} \otimes \mathbb{P}$ be its unique stationary measure. Define the centered energy $S_n = E^{(a)}(X^n, \mathbb{P}) - \varepsilon_c^{(a)} n$ for all $n \geq 1$. By the independence in $X^\mathbb{P}$, it is not hard to see that the following quantity
\[
\gamma_k^2 := \text{Var}_\pi[H(X_0)] + 2 \sum_{k=1}^\infty \text{Cov}_\pi[H(X_0), H(X_k)]
\] (70)
is positive and finite. Here $\gamma^2_g$ is called the *limiting variance* of the additive process $S_n$. Denote by $\gamma_g$ the positive square root of $\gamma^2_g$.

**Theorem 4.9.** Let $\pi$, $(S_n)_{n \geq 1}$, and $\gamma_g$ be as before.

(i) (FCLT) Let $[S](\cdot): [0, \infty) \to \mathbb{R}$ denote the linear interpolation of the points $(n, S_n)_{n \geq 0}$ with setting $S_0 = 0$. Let $C[0, 1]$ be the set of all continuous functions $[0, 1] \to \mathbb{R}$. Then for any continuous functional $F: C[0, 1] \to \mathbb{R}$, where $B = (B_s : 0 \leq s \leq 1)$ is the standard Brownian motion.

\[
\lim_{n \to \infty} \mathbb{E}_\pi[F(n^{-1/2}[S](ns) : 0 \leq s \leq 1)] = \mathbb{E}_\pi[F(\gamma_g B)],
\]

(ii) (Persistence) As $n \to \infty$, \[\mathbb{P}_p (S_1 \geq 0, \ldots, S_n \geq 0 | S_0 = 0) \sim \frac{\gamma_g}{(1 - e(\alpha))\sqrt{2\pi}} n^{-1/2}.\]  

**Proof.** The Markov chain $X_t = (\Gamma(t-1), X^p(t))$ is not started at the stationary measure $\pi$, but being a finite-state irreducible chain, it mixes to the stationarity in finite time. Hence we can apply known limit theorems about stationary ergodic Markov chains. For (i), we refer to [1, Corollary 3] or [20, Theorem 17.4.4]. For (ii), see [19, Theorem 2]. \[\square\]

## 5. Conditioning on the highest states

In this section we prove Corollary 6. The key question we need to address to do so is the following: *How probable is it to sample a highest state from the i.i.d. basic $\kappa$-color BBS configuration $X^n_p$?* This question can be phrased in terms of lattice paths as follows. Let $e_1, \ldots, e_{\kappa+1}$ be the standard basis vectors of the $(\kappa + 1)$-dimensional lattice $\mathbb{Z}^{\kappa + 1}$. The Weyl chamber of dimension $\kappa + 1$ is the subset $W_{\kappa + 1} := \{(x_1, \ldots, x_{\kappa+1}) \in [\mathbb{N}_0^{\kappa+1} : x_1 \geq x_2 \geq \cdots \geq x_{\kappa+1}\}$. Given a basic $\kappa$-color BBS configuration $X_0: \mathbb{N} \to (0, 1, \ldots, \kappa)$, define an associated $(\kappa + 1)$-dimensional lattice path $S_k$ by $S_0 = (0, \ldots, 0)$ and 

\[
S_k - S_{k-1} = \sum_{i=0}^{\kappa} e_{i+1} \mathbb{1}(X_0(k) = i). \quad (73)
\]

Namely, if there is a ball of color $i - 1 \geq 0$ (calling empty box as ball of color 0) at $k^{th}$ box, then the walk moves a unit step in the $i^{th}$ direction. Then observe that $X_0$ is a highest state if and only if $S_k$ lies entirely in the Weyl chamber.

For example, if we let $\kappa = 1$, $p = (1 - p, p)$, and $X_0 = X^n_p$, then $S_k$ becomes a simple directed random walk in $\mathbb{N}_0^2$. If $p > 1/2$, certainly the probability of sampling a path that is contained in the 2-dimensional Weyl chamber $W_2$ will decay to zero exponentially fast as $n \to \infty$. If $0 < p < 1/2$, then this probability converges to a nontrivial value in $(0, 1)$. For the general case $\kappa \geq 1$, when the ball densities strictly decrease, an elementary probabilistic argument shows that $X^n_p$ is a highest state for all $n \geq 1$ with a positive probability. This is the content of the following proposition.

**Proposition 5.1.** If $p_0 > p_1 > \cdots > p_\kappa$, then 

\[
\mathbb{P}_p (S_k \in W_{\kappa+1} \forall k \geq 0) > \delta > 0. \quad (74)
\]
Proof. For each integer \( i, j \geq 1 \), define a simple random walk \( S_k^{ij} \) by \( S_0^{ij} = 0 \) and
\[
S_k^{ij} = \#(\text{balls of color } i \text{ in } [1, k]) - \#(\text{balls of color } j \text{ in } [1, k]).
\] (75)
If \( i < j \), then the random walk \( S_k^{ij} \) has positive drift so there exists a finite random time \( \tau_k^{ij} \) such that \( S_k - S_{\tau_k^{ij}} \geq 0 \) for all \( k \geq \tau_k^{ij} \). Define a random time \( \tau = \max_{0 \leq j < i \leq k}(\tau_k^{ij}) \). Then \( \tau \) is almost surely finite, so we may choose \( N_1 \geq 1 \) large enough so that
\[
\mathbb{P}(\tau \leq N_1) > \delta_1 > 0.
\] (76)
By using independence of the ball colors, choose \( N_2 \geq 1 \) large enough so that
\[
\mathbb{P}\left(S_{N_2}^{ij} > 2N_1 \text{ for all } 0 \leq i < j \leq k\right) > \delta_2 > 0.
\] (77)
In other words, \( S_{N_2} \in W_{k+1} \) and is at least \( 2N_1 \) steps away from the boundary of \( W_{k+1} \). Hence \( S_{N_1+N_2} \in W_{k+1} \) with probability \( > \delta_2 \). Since the restarted lattice path \( (S_k)_{k \geq N_2} \) has the same law as \( (S_k)_{k \geq 0} \) by the Markov property, by using the independence of increments and (76), we get
\[
\mathbb{P}(S_k \in W_{k+1} \text{ for all } k \geq 0) \geq \mathbb{P}(S_{N_1+N_2} \in W_{k+1}) \mathbb{P}(S_{k+N_1} - S_{N_1+N_2} \in W_{k+1} \forall k \geq N_2) \geq \delta_1 \delta_2 > 0.
\] (79)
This shows the assertion. \( \square \)

Remark 5.2. When \( \kappa = 1 \) and \( p_0 > p_1 \), a simple application of Wald’s equation [3, Exercise 4.1.13] gives
\[
\mathbb{P}_p(S_k \in W_2 \forall k \geq 0) = \frac{2p_0 - 1}{p_0}.
\] (80)

Now consider the critical case \( \rho = 1/2 \) when \( \kappa = 1 \). Then the resulting 2-dimensional lattice walk has no bias, and the probability that \( S_k \in W_2 \) for all \( k \geq 1 \) is the same as the ‘survival probability’ of a simple symmetric random walk, and the following asymptotic is known (see, e.g., [4, Theorem XII.7.1a]):
\[
\mathbb{P}((S_k)_{1 \leq k \leq n} \text{ is contained in } W_2) \sim \sqrt{\frac{2}{\pi n}}.
\] (81)
In general, if some of the inequalities \( p_0 \geq p_1 \geq \cdots \geq p_\kappa \) are equalities, then we expect the probability that \( S_k \) stays in \( W_{k+1} \) for \( n \) steps decays to zero at a polynomial rate. This claim can be justified by using a high dimensional Ballot theorem, as we shall explain below.

Suppose \( \rho = 1/2 \) and after \( n \) steps we knew that there were \( n_0 \) empty boxes and \( n_1 \) balls in the initial configuration. Then what is the probability of a highest state given that there are \( n_0 \) empty boxes and \( n_1 \) balls? This is a classic problem in probability theory known as the Ballot problem (see., e.g., [5, Ch. III.1]). This problem has been generalized to the higher dimensions and addressed in [28], giving a general Ballot theorem that enumerates the number of lattice paths within the Weyl chamber from the origin to a fixed destination. Namely, for each point \( \mathbf{m} = (m_1, \cdots, m_r) \in W_r \) in the \( r \)-dimensional Weyl chamber, let \( G(\mathbf{m}) \) be the number of lattice paths from the origin to \( \mathbf{m} \) that is contained in the Weyl chamber. Then
\[
G(\mathbf{m}) = (m_1 + \cdots + m_r)! \prod_{1 \leq i < j \leq r} (m_i - m_j + j - i) / (m_1 + r - 1)!m_2 + r - 2)! \cdots m_r!.
\] (82)
Using this enumeration, we can estimate the probability of sampling a highest state from an i.i.d. BBS configuration.

**Proposition 5.3.** Suppose \( p_0 \geq p_1 \geq \cdots \geq p_x \). Then there exists constants \( c_1, c_2 > 0 \) such that for all \( n \geq 1 \),

\[
c_1 n^{-a/2} \leq \mathbb{P}_p(X^n_P \text{ is a highest state}) \leq c_2 n^{-a/2},
\]

where \( a = \sum_{0 \leq i < j \leq x} 1(p_i = p_j) \).

**Sketch of proof.** For simplicity of the argument, we show the assertion for the special case of \( k = 2 \). Observe that each sample path with \( m_1 \) empty boxes, \( m_1 \) balls of color 1, and \( m_2 \) balls of color 2 occurs with the same probability \( p_0^{m_1} p_1^{m_2} p_2^{m_1} \). Hence using (82), we can write

\[
\mathbb{P}_p(X^n_P \text{ is a highest state}) = \sum_{m_1 + m_2 + m_3 = n} \frac{(m_1 - m_2 + 1)(m_2 - m_3 + 1)(m_1 - m_3 + 2)}{(m_1 + 1)(m_1 + 2)(m_2 + 1)} p_0^{m_1} p_1^{m_2} p_2^{m_3}.
\]

By law of large numbers, each ball count \( m_i \) is of order \( O(n) \). If \( p_0 > p_1 > p_2 \), then each \( m_i - m_j \) for \( i < j \) grows asymptotically linearly in \( n \), so the above summation is of order \( O(1) \). On the other extreme, suppose \( p_0 = p_1 = p_2 = 1/3 \). Then the sum gets the most contribution when each \( m_i - m_j \) is of order \( O(\sqrt{n}) \), so in this case the sum is of order \( O(n^{-3/2}) \). For the general case, each term \( m_i - m_j = O(\sqrt{n}) \) contributes a factor of \( O(n^{-1/2}) \), so the general asymptotic formula follows in this manner. \( \square \)

Now Corollary 6 follows immediately from Theorem 2.

**Proof of Corollary 6.** By the relation (28), it suffices to show the assertion for the energy function \( E_c^{(a)}(X^n_P) \) instead of the row length \( p_c^{(a)}(X^n_P) \). Let \( \Lambda^\ast \) be the rate function in Theorem 2, which is positive in an open neighborhood of \( \varepsilon_c^{(a)} > 0 \). Write

\[
\hat{\Lambda}^\ast(u) = \min(\Lambda^\ast(\varepsilon_c^{(a)} - u), \Lambda^\ast(\varepsilon_c^{(a)} + u)).
\]

Theorem 2 yields that for all sufficiently small \( u > 0 \), there exists \( N(u) \geq 1 \) such that

\[
\mathbb{P}_p \left( \left| n^{-1} E_c^{(a)}(X^n_P) - \varepsilon_c^{(a)} \right| \geq u \right) = \exp \left( n \left( n^{-1} \log \mathbb{P}_p \left( \left| n^{-1} E_c^{(a)}(X^n_P) - \varepsilon_c^{(a)} \right| \geq u \right) \right) \right) \leq \exp \left( -\left( \hat{\Lambda}^\ast(u)/2 \right) n \right)
\]

for all \( n \geq N(u) \).

Suppose \( p_0 \geq p_1 \geq \cdots \geq p_x \). Then by Proposition 5.3, there exists a constant \( c_1 > 0 \) such that

\[
\mathbb{P}_p \left( \left| n^{-1} E_c^{(a)}(X^n_P) - \varepsilon_c^{(a)} \right| \geq u \left| X^n_P \text{ is highest} \right) \leq \frac{\mathbb{P}_p \left( \left| n^{-1} E_c^{(a)}(X^n_P) - \varepsilon_c^{(a)} \right| \geq u \right)}{\mathbb{P}_p(X^n_P \text{ is highest})} \leq c_1 n^{k(k+1)/2} \exp\left( -(\hat{\Lambda}^\ast(u)/2) n \right),
\]

for sufficiently small \( u > 0 \) and all \( n \geq N(u) \).

By using the continuity of \( \Lambda^\ast \) at \( \varepsilon_c^{(a)} \) and its positivity near \( \varepsilon_c^{(a)} \), we may choose a sequence \( u_r > 0 \) such that \( u_r \to 0 \) and \( \hat{\Lambda}^\ast(u_r) \geq r^{-1/2} \) as \( r \to \infty \). Then we have

\[
\mathbb{P}_p \left( \left| n^{-1} E_c^{(a)}(X^n_P) - \varepsilon_c^{(a)} \right| \geq u_r \left| X^n_P \text{ is highest} \right) \leq c_1 n^{k(k+1)/2} \exp\left( -n u_r \right)
\]
for all \( r \geq 1 \) and \( n \geq N(u_r) \). Note that the right hand side is summable for any sequence \( n = n_r \) as long as \( n_r \to \infty \) as \( r \to \infty \). This implies that for any sequence \((n_r)_{r \geq 1}\) of integers such that \( n_r \geq N(u_r) \), the above probabilities are summable over all \( n_r \). By Borel-Cantelli lemma, this yields

\[
n^{-1}E_\varepsilon^{(a)}(X_{n_r}, p) \to \varepsilon_c^{(a)}(92)\]

almost surely as \( r \to \infty \). It follows that if we are given any sequence \( n_k \to \infty \), we may take a further subsequence \( n_r := n_{k_r} \to \infty \) along which we have the above almost sure convergence to the common value \( \varepsilon_c^{(a)} \). This shows (25), as desired. □

Remark 5.4. The conclusion of Corollary 6 can be schematically summarized as

BBS started with \( X^n, p \) \( \Rightarrow \) BBS started with \( X^n, p \)

conditioned on the highest states

provided \( p_0 \geq p_1 \geq \ldots \geq p_k \), where \( \Rightarrow \) means that the rescaled energy matrices have the same limit. In [14], we adopted this as a hypothesis for the generalized BBS initialized at a similar product measure on \( (B_s^{(r)})^N \). Despite irreducibility of the corresponding carrier process in this general situation is still in question, we suspect a large deviations principle can be established in the general case as in Theorem 2. Then the hypothesis of asymptotic equivalence is justified if the probability that \( X^n, p \) is a highest state decays sub-exponentially in \( n \), following a similar method we used in the proof of Corollary 6. We leave verification of this for a future work.

6. Scaling limit of Young diagrams from TBA

In this section, we prove Theorems 7 and 8. Our argument is based on the Fermionic form and Thermodynamic Bethe Ansatz. Throughout in this section, we consider the basic \( \kappa \)-color BBS started at random initial configuration \( X^n, p \) conditioned on the highest state. A similar treatment for the generalized BBS where each site is initially occupied with an \((r \times s)\) tableau is elaborated in [14]. Throughout in this section, we assume \( p_0 > p_1 > \ldots > p_k \).

6.1. Fermionic formula and grand canonical ensemble. When a basic \( \kappa \)-color BBS is started at a highest state, extracting the \( \kappa \)-tuple of invariant Young diagram \((\mu^{(1)}, \ldots, \mu^{(k)})\) can be done most universally by the map called Kerov-Kirillov-Reshetikhin bijection\(^2\) [13]. The bijection is defined recursively and complicated in general, so we refer to [16, Section 2.7] for details.

Fortunately, it is well known that the number of highest states corresponding to the prescribed \( \kappa \)-tuple of Young diagrams \((\mu^{(1)}, \ldots, \mu^{(k)})\) can be written down explicitly as the so-called Fermionic form (cf. [9]):

\[
\prod_{a=1}^{\kappa} \sum_{i \geq 1} \left( \frac{v_i^{(a)} + m_i^{(a)}}{m_i^{(a)}} \right),
\]

where the vacancy \( v_i^{(a)} \) and soliton multiplicity \( m_i^{(a)} \) for the \( a \)-th Young diagram \( \mu^{(a)} \) are as in (26) and (29), respectively.

\(^2\)It was invented in a very different context in 1980’s and is later found [16] to linearize the BBS dynamics.
Since $m_i^{(a)} = 0$ for sufficiently large $i$, the apparent infinite product (94) is convergent. For (94) not to vanish, $v_i^{(a)} \geq 0$ must hold, which imposes nontrivial constraints among $\mu^{(1)}, \ldots, \mu^{(k)}$. Also note that for (28) and (29), we set

$$v_i^{(a)} = n \delta_{a,1} - \sum_{b=1}^{n} C_{ab} |\mu^{(b)}|, \quad E_\infty = \sum_{i=1}^{\infty} i m_i^{(a)} = |\mu^{(a)}|. \quad (95)$$

Now let us derive the probability measure on the set of $\kappa$-tuple of Young diagrams $(\mu^{(1)}, \ldots, \mu^{(k)})$, as stated in Theorem 7. We recall from [16] that the size of the Young diagrams $(\mu^{(1)}, \ldots, \mu^{(k)})$ are related to the color content of the BBS state $X_0$ by

$$|\mu^{(a)}| = \#(\text{balls of color } \geq a \text{ in } X_0) \quad \forall a \leq \kappa. \quad (96)$$

**Proof of Theorem 7.** According to (96), the number of empty boxes and the color $a$ balls contained in a BBS state are $n - |\mu^{(1)}|$ and $|\mu^{(a)}| - |\mu^{(a+1)}|$ for $a = 1, \ldots, \kappa$ with $|\mu^{(\kappa+1)}| = 0$. Then

$$P_{\mu^{(1)}, \ldots, \mu^{(k)}}(\kappa) = p_0^{n-|\mu^{(1)}|} p_1^{|\mu^{(1)}|-|\mu^{(2)}|} \cdots p_{\kappa-1}^{|\mu^{(\kappa-1)}|-|\mu^{(\kappa)}|} p_\kappa^{\mu^{(\kappa)}} \prod_{a=1}^{\kappa} \left( \frac{v_i^{(a)} + m_i^{(a)}}{m_i^{(a)}} \right). \quad (97)$$

Denote $e^{\beta x} = p_{a-1}/p_a$ for all $1 \leq a \leq \kappa$ as in the statement of the assertion. Using (96) and the second half of (95), we can write

$$p_0^{-|\mu^{(1)}|} p_1^{\mu^{(1)}-\mu^{(2)}} \cdots p_{\kappa-1}^{\mu^{(\kappa-1)}-\mu^{(\kappa)}} p_\kappa^{\mu^{(\kappa)}} = e^{-\beta_1 |\mu^{(1)}| - \cdots - \beta_\kappa |\mu^{(\kappa)}|} \quad (98)$$

$$= e^{-\sum_{a=1}^{\kappa} \beta_a \sum_{i=1}^{m_i} m_i^{(a)}} \quad (99)$$

$$= e^{-\sum_{a=1}^{\kappa} \frac{v_i^{(a)} + m_i^{(a)}}{m_i^{(a)}}}. \quad (100)$$

Therefore omitting the common factor $p_0^n$ from (97), we arrive at (30) with following partition function

$$Z_n = e^{-\sum_{a=1}^{\kappa} E_\infty^{(a)} \beta_a} \prod_{a=1}^{\kappa} \left( \frac{v_i^{(a)} + m_i^{(a)}}{m_i^{(a)}} \right), \quad (101)$$

where the outer sum extends over $m = (m_i^{(a)})_{(a,i) \in [1, \kappa] \times \mathbb{N}}$. This shows the assertion. □

Note that the right hand side of (101) depends on the system size $n$ via (29). The parameters $\beta_1, \ldots, \beta_\kappa$ play the role of chemical potentials or inverse temperatures in the context of the generalized Gibbs ensemble.

6.2. **Y-system as the equilibrium condition.** Our next aim is to determine the “equilibrium”, i.e., most probable tuple of Young diagrams $(\mu^{(1)}, \ldots, \mu^{(k)})$ under the probability distribution (30) in the large $n$ limit. It will be done by the method of grand canonical ensemble with the partition function given in (101).

In the large $n$ limit, Corollary 6 and definitions in (26)-(29) guarantee the following asymptotic relation

$$m_i^{(a)} = p_i^{(a)} - p_{i-1}^{(a)} \sim n \xi_i^{(a)}, \quad v_i^{(a)} \sim n \varphi_i^{(a)}, \quad E_i^{(a)} \sim n \varepsilon_i^{(a)} \quad (102)$$

almost surely as $n \to \infty$, where $\xi_i^{(a)}, \varphi_i^{(a)}, \varepsilon_i^{(a)}$ are suitable positive constants. Here the symbol $\varepsilon_i^{(a)}$ is taken over from (92). Moreover, by (96), we have

$$|\mu^{(a)}| \sim n(p_a + p_{a+1} + \cdots + p_\kappa). \quad (103)$$
Then after normalizing the equations (26)–(28) by $n$, we get

$$
\varphi_i^{(a)} = \delta_{a,1} - \sum_{b=1}^{\kappa} C_{ab} \xi_j^{(b)}, \quad \xi_j^{(a)} = \sum_{j=1}^{\infty} \min(i,j) \xi_j^{(a)}, \quad (104)
$$

$$
\varphi_i^{(a)} = \delta_{a,1} - \sum_{b=1}^{\kappa} C_{ab} \xi_j^{(b)}, \quad \xi_j^{(a)} = \sum_{j=1}^{\infty} j \xi_j^{(a)} = p_a + p_{a+1} + \cdots + p_\kappa, \quad (105)
$$

where (104) is due to (28) and (29), and (105) follows from (95), (102), and (103).

This allows us to define the “free energy per site”, which is the limit of $(-1/n)$ times the logarithm of the summand in (101) as $n \to \infty$. After applying Stirling’s formula, this reads

$$
F[\xi] = \sum_{a=1}^{\kappa} \beta_a \sum_{j=1}^{l} \iota \xi_j^{(a)} - \sum_{a=1}^{\kappa} \sum_{j=1}^{l} \left( \xi_j^{(a)} + \varphi_i^{(a)} \log(\xi_j^{(a)} + \varphi_i^{(a)}) - \xi_j^{(a)} \log \xi_j^{(a)} - \varphi_i^{(a)} \log \varphi_i^{(a)} \right),
$$

where $\xi = (\xi_j^{(a)})$ and we have introduced the cutoff $l$ for $i$. We will take $l \to \infty$ later. Note that the assumption (102) is consistent with the extensivity of the free energy, which enabled us to remove the system size $n$ as the common overall factor.

According to Theorem 7, the equilibrium is achieved at $\xi$ which minimizes $F[\xi]$. Noting that $\partial \varphi_i^{(b)} / \partial \xi_j^{(a)} = -C_{ab} \min(i,j)$, the equilibrium condition $\partial F[\xi] / \partial \xi_j^{(a)} = 0$ is expressed as the following Thermodynamic Bethe ansatz (TBA) equation

$$
-i \beta_a + \log(1 + y_i^{(a)}) = \sum_{b=1}^{\kappa} C_{ab} \sum_{j=1}^{l} \min(i,j) \log(1 + (y_j^{(b)})^{-1}) \quad (107)
$$

in terms of the ratio

$$
y_i^{(a)} = \varphi_i^{(a)} / \xi_j^{(a)} \quad \forall 1 \leq i \leq \kappa. \quad (108)
$$

By taking double difference, this is equivalent to the Y-system

$$
\frac{(1 + y_i^{(a)})^2}{(1 + y_i^{(a)}) (1 + y_{i+1}^{(a)})} = \prod_{b=1}^{\kappa} (1 + (y_i^{(b)})^{-1}) C_{ab} \quad (109)
$$

with the boundary condition

$$
y_0^{(a)} = 0, \quad 1 + y_{\kappa+1}^{(a)} = e^{\beta_a} (1 + y_i^{(a)}). \quad (110)
$$

The Y-system is known to follow from the Q-system

$$
(Q_i^{(a)})^2 = Q_i^{(a)} Q_{i+1}^{(a)} + \prod_{C_{ab}=-1} Q_i^{(b)}, \quad (111)
$$

by the substitution (see [15, Prop. 14.1])

$$
y_i^{(a)} = \frac{Q_i^{(a)} Q_{i+1}^{(a)}}{\prod_{C_{ab}=-1} Q_i^{(b)}}, \quad 1 + y_i^{(a)} = \prod_{b=1}^{\kappa} (Q_i^{(b)}) C_{ab}, \quad 1 + (y_i^{(a)})^{-1} = \frac{(Q_i^{(a)})^2}{Q_{i+1}^{(a)} Q_{i+1}^{(a)}}. \quad (112)
$$

The solution of the Q-system satisfying $Q_0^{(1)} = \cdots = Q_0^{(\kappa)} = 1$ contains $\kappa$ parameters $z_1, \cdots, z_\kappa$ and is given by the Schur function

$$
Q_i^{(a)} (z_1, \cdots, z_\kappa) = s^{(i+1)} (w_1, \cdots, w_{\kappa+1}), \quad (113)
$$
where we set
\[ w_a = z_a / z_{a-1} \quad \forall 1 \leq a \leq \kappa + 1, \quad z_0 = z_{\kappa + 1} = 1. \] (114)

Note that this is the character of the irreducible $s_{\kappa + 1}$ module (Schur function) associated with the Young diagram of $a \times i$ rectangular shape. The property $Q_i^{(a)} \in \mathbb{Z}[z_1^{\pm 1}, \ldots, z_\kappa^{\pm 1}]$ holds. The simplest one reads
\[ Q_1^{(1)} = \sum_{a=0}^{\kappa} \frac{z_{a+1}}{z_a}. \] (115)

To validate the Q-system (111) at $i = 0$, we set $Q_{-1}^{(a)} = 0$.

Next we take the boundary condition (110) into account. The left one $y_0^{(a)} = 0$ is automatically satisfied due to $Q_{-1}^{(a)} = 0$. On the other hand the right condition in (110) is expressed as
\[ e^{\beta a} = \prod_{b=1}^{\kappa} \left( \frac{Q_{l+1}^{(b)}}{Q_l^{(b)}} \right)^{C_{ab}}. \] (116)

Suppose the parameters $z_1, \ldots, z_\kappa > 0$ are chosen such that
\[ \prod_{b=1}^{\kappa} z_{C_{ab}} > 1 \quad \forall 1 \leq a \leq \kappa. \] (117)

Then one can invoke the result [9, Th. 7.1 (C)]. In the present notation it says
\[ \lim_{l \to \infty} \left( Q_{l+1}^{(a)}/Q_l^{(a)} \right) = z_a \quad \forall 1 \leq a \leq \kappa. \] (118)

Thus the large $l$ limit of (116) can be taken, giving
\[ e^{\beta a} = \prod_{b=1}^{\kappa} z_{C_{ab}}^{C_{ab}}, \quad z_a = \exp \left( \sum_{b=1}^{\kappa} (C^{-1})_{ab} \beta_b \right) = \exp \left( \sum_{b=1}^{\kappa} \left( \min(a, b) - \frac{ab}{\kappa + 1} \right) \beta_b \right). \] (119)

Noting the definitions of $\beta_a$ given in Theorem 7, one finds that the variables $z_1, \ldots, z_\kappa$ are related to the ball density as
\[ z_a = u^{-\frac{a}{\kappa + 1}} p_0 p_1 \cdots p_{a-1}, \quad u = p_0 p_1 \cdots p_\kappa \quad (1 \leq a \leq \kappa). \] (120)

From this it follows that the assumption we made in (117) is equivalent to $p_0 > p_1 > \cdots > p_\kappa$, which is our grounding assumption in this section.

In what follows, the quantities like $\xi_{i}^{(a)}, \varphi_{i}^{(a)}, \epsilon_{i}^{(a)}$ are to be understood as the equilibrium values.

6.3. Equation of state and consistency. Here we derive the equation of state of the system and show that it is indeed satisfied by (120) to demonstrate the consistency of the analysis. First we calculate the equilibrium value of the free energy per site (106). Using (108) rewrite (106) as
\[ F[\xi_{eq}] = \sum_{a=1}^{\kappa} \beta_a \sum_{i=1}^{l} \xi^{(a)}_i - \sum_{a=1}^{\kappa} \sum_{i=1}^{l} \left( \xi^{(a)}_i \log(1 + y_i^{(a)}) + \varphi^{(a)}_i \log(1 + (y_i^{(a)})^{-1}) \right). \] (121)
On the other hand taking the linear combination of the TBA equation as \( \sum_{a=1}^{\kappa} \sum_{i=1}^{l} (107) \times \xi_i^{(a)} \) we get
\[
\sum_{a=1}^{\kappa} \beta_a \sum_{i=1}^{l} i \xi_i^{(a)} = \sum_{a=1}^{\kappa} \sum_{i=1}^{l} \xi_i^{(a)} \log(1 + y_i^{(a)}) - \sum_{a,b=1}^{\kappa} C_{ab} \sum_{i,j=1}^{l} \min(i,j) \xi_i^{(a)} \log(1 + (y_j^{(b)})^{-1}).
\]

(122)

Substituting this into the first term on the RHS of (121) and using \( \phi_i^{(a)} \) from (104) we find
\[
F[\xi_{eq}] = - \sum_{i=1}^{l} \log(1 + (y_i^{(l)})^{-1}) = - \log \left( \frac{Q_1^{(l)}}{Q_{l+1}^{(l)}} \right) \sim - \log \left( z_1^{-1} Q_1^{(l)} \right),
\]

(123)

where (112) is used and the last step is due to (118).

Now we resort to the general relation
\[
F[\xi_{eq}] = - \lim_{n \to \infty} \frac{1}{n} \log Z_n.
\]

(124)

From (95), (101) and (103) one has the equation of state \( p_0 + p_{a+1} + \cdots + p_k = \frac{\partial F[\xi_{eq}]}{\partial \beta_a} \) for \( 1 \leq a \leq \kappa \). In view of (119) it is convenient to take the linear combination of it as follows:
\[
\sum_{b=1}^{\kappa} C_{ab} (p_b + p_{b+1} + \cdots + p_k) = \left( \sum_{b=1}^{\kappa} C_{ab} \frac{\partial}{\partial \beta_a} \right) F[\xi_{eq}] = z_a \frac{\partial F[\xi_{eq}]}{\partial z_a}.
\]

(125)

Substituting (123) we obtain the equation of state:
\[
z_a \frac{\partial}{\partial z_a} \log Q_1^{(l)} = \delta_{a,1} - \sum_{b=1}^{\kappa} C_{ab} (p_b + p_{b+1} + \cdots + p_k).
\]

(126)

From (115), it reads explicitly as \( z_0 = z_{k+1} = 1 \)
\[
z_a \frac{\partial}{\partial z_a} \log \left( \sum_{b=0}^{\kappa} \frac{z_{b+1}}{z_b} \right) = \delta_{a,1} - \sum_{b=1}^{\kappa} C_{ab} (p_b + p_{b+1} + \cdots + p_k).
\]

(127)

These \( n \) equations relate the two sets of variables \( p_1, \cdots, p_k \) and \( z_1, \cdots, z_k \). The former are densities of balls in the BBS while the latter are essentially the fugacities \( e^{-\beta_1}, \cdots, e^{-\beta_k} \) as seen in (119). It is an elementary exercise to check that the substitution (120) satisfies (127) under the normalization condition \( p_0 + p_1 + \cdots + p_k = 1 \). The relation (127) is also consistent with \( e^{\beta_a} = p_{a-1}/p_a \) given in Theorem 7.

6.4. Difference equation characterizing equilibrium Young diagrams. Recall from (28) and (102) that
\[
\varepsilon_i^{(a)} = \lim_{n \to \infty} \frac{1}{n} (\# \text{ of boxes in the first } i \text{ rows of } \mu_i^{(a)}).
\]

(128)

Therefore in order to determine the scaled Young diagrams in the equilibrium, it suffices to characterize \( \varepsilon_i^{(a)} \) or \( \phi_i^{(a)} \) related to it by (104) for \( (a, l) \in [1, \kappa] \times \mathbb{Z}_{\geq 1} \). This is done as follows. Taking the double difference of the first relation in (104) leads, by using (108), to
\[
\phi_{i-1} - 2 \phi_i + \phi_{i+1} = \sum_{b=1}^{\kappa} C_{ab} (y_i^{(b)})^{-1} \phi_i \quad (i \geq 1, a \in [1, \kappa]).
\]

(129)
Here we have introduced \( \varphi_i^{(a)} = \delta_{a,1} \). Since (129) is second order as a difference equation with respect to \( i \), we are yet to specify \( \varphi_i^{(a)} \) at another \( i \). Such a point is available at \( i = \infty \) from (105). This completes a characterization of the scaled vacancy \( \varphi_i^{(a)} \) hence the equilibrium Young diagrams \( \mu^{(1)}, \cdots, \mu^{(k)} \) in the scaling limit.

The procedure is summarized as follows:

1. Given the ball densities in the region \( 1 > p_0 > \cdots > p_k > 0 \), specify \( z_1, \cdots, z_n \) as (120) and calculate \( \varphi_i^{(a)} \) by (112) and (15).
2. Find the unique solution to (129) satisfying the boundary condition:
   
   \[
   \varphi_0^{(a)} = \delta_{a,1}, \quad \varphi_{\infty}^{(a)} = \delta_{a,1} - \sum_{b=1}^{k} C_{ab}(p_b + p_{b+1} + \cdots + p_k).
   \]  

(130)

3. The quantity (128) is determined as \( \epsilon_i^{(a)} = \sum_{b=1}^{k} (C^{-1})_{ab}(\delta_{b,1} - \varphi_i^{(b)}) \).

Admittedly the second step in the above is nontrivial since the boundary condition is imposed at the two most distant points \( i = 0 \) and \( i = \infty \). In [14] the same problem for the most general BBS has been treated and the solution linked to the crystal base theory has been given. In the next subsection we present an explicit solution for a special choice of \( p_0, \cdots, p_k \), which deserves an independent demonstration in the light of the neat factorization not happening in the general case.

6.5. Explicit solution under principal specialization. We prove Theorem 8 in this subsection. To begin, fix a parameter \( 0 < q < 1 \) and consider the one parameter specialization of the \( p_0, \cdots, p_k \) as

\[
p_a = \frac{q^a}{1 + q + \cdots + q^k} = \frac{q^a(1-q)}{1-q^{k+1}}.
\]

(131)

This certainly gives a probability measure on \( \{0, 1, \cdots, k+1\} \) and fulfills the condition \( 1 > p_0 > \cdots > p_k > 0 \). Then the equation of state (127) is satisfied by

\[
z_a = q^{-a(k+1-a)/2},
\]

(132)

and such choice of \( z_a \) is known as the principal specialization reducing characters to the so-called \( q \)-dimensions.

Under this specialization, \( Q_i^{(a)} \) in (15) becomes

\[
Q_i^{(a)} = \prod_{b=1}^{k} \prod_{j=1}^{[x]} \frac{|x+j-b|}{|a-b+i-j+1|}, \text{ with } [x] = q^{x/2} - q^{-x/2}.
\]

Thus \( \varphi_i^{(a)} \) is reduced to

\[
y_i^{(a)} = \frac{q^{-i}(1-q^i)(1-q^{i+k+1})}{(1-q^a)(1-q^{k+1-a})}.
\]

(133)

It remains to solve (129) with the boundary condition (130). By a direct calculation one can establish the following result.

**Proposition 6.2.** The following satisfies the difference equation (129) and the boundary condition (130).

\[
\varphi_i^{(a)} = \frac{q^{a-1}(1-q)^2(1-q^i)(1-q^{i+k+1})(1+q^{i+a})}{(1-q^{k+1})(1-q^{i+a-1})(1-q^{i+a})(1-q^{i+a+1})}.
\]

(134)
As a corollary of Proposition 6.2, we deduce
\[ \xi^{(a)}_i = \frac{q_1^{i+a-1}(1-q)^2(1-q^a)(1-q^{k+1-a})(1+q^{i+a})}{(1-q^{k+1})(1-q^{i+a-1})(1-q^{1+a})(1-q^{i+a})} \]  
(135)

from (108) and (133).

Now Theorem 8 immediately follows.

**Proof of Theorem 8.** By Corollary 6 and the relation (28), we get
\[ \lim_{n \to \infty} n^{-1} \rho_i^{(a)}(X^n_\mathrm{P}) = \xi^{(a)}_i - \xi^{(a)}_{i-1}. \]  
(136)

By using the first relation in (104), we then obtain
\[ \lim_{n \to \infty} n^{-1} \rho_i^{(a)}(X^n_\mathrm{P}) = \sum_{b=1}^{\kappa} (C^{-1})_{ab} (q_1^{a(b)} - q_1^{b(b)}) \]  
(137)
\[ = \frac{q_1^{i+a-1}(1-q)(1-q^a)(1-q^{k+1-a})}{(1-q^{k+1})(1-q^{i+a-1})(1-q^{1+a})}, \]  
(138)

where the last step is due to (134) and \((C^{-1})_{ab} = \min(a,b) - \frac{ab}{\kappa+1}\) which has already appeared in (119).

**Remark 6.3.** Observe that in the limit \(q \to 1\) from below, we approach the uniform distribution \(p_0 = \cdots = p_\kappa = \frac{1}{\kappa+1}\), and (138) tends to the rational form
\[ \lim_{n \to \infty} n^{-1} \rho_i^{(a)}(X^n_\mathrm{P}) = \frac{a(\kappa + 1 - a)}{(\kappa + 1)(i + a - 1)(i + a)}. \]  
(139)

When \(i = 1\) the result (138) agrees with the value obtained by a direct calculation of the Markov process of the carries induced by interaction with the random BBS states. When \(\kappa = a = 1\), the formulas (138) and (139) reproduce the function \(f_1^{(1)}(i)\) in Corollary 4.

To make another observation, consider the sum
\[ \sum_{i \geq \lambda} \xi^{(a)}_i = \frac{q_1^{i+a-1}(1-q)(1-q^a)(1-q^{k+1-a})}{(1-q^{k+1})(1-q^{i+a-1})(1-q^{1+a})}, \]  
(140)

where \(\lambda\) is a \(\mathbb{N}\)-valued parameter. The scaling behavior of the lengths \(\lambda^{(1)}_1, \ldots, \lambda^{(\kappa)}_1\) of the first columns of the equilibrium Young diagrams \(\mu^{(1)}, \ldots, \mu^{(\kappa)}\) may be inferred by setting
\[ n \sum_{i \geq \lambda^{(1)}_1} \xi^{(a)}_i \sim 1. \]  
(141)

This postulate leads to a crude estimate
\[ \lambda^{(a)}_1 \sim \frac{1}{\log q} \log \left( \frac{q^{a-1}(1-q)(1-q^a)(1-q^{k+1-a})n}{1-q^{k+1}} \right) \sim \frac{\log n}{\log q} \quad (n \to \infty). \]  
(142)

When \(\kappa = a = 1\), this logarithmic scaling reproduces \(\mu_n\) in [18, Th.2 (i)] as \(\mu_n = \lambda^{(1)}_1|_{q=\theta^{-1}}\).
