Stochastic Phase Space Signal Processing
with Application to Localizing Phase Vocoder

Abstract

This paper focuses on signal processing tasks in which the signal is transformed from the signal space to a higher dimensional space, called phase space, processed in this space, and synthesized to an output signal. For example, in a phase vocoder method, an audio signal is transformed to the time-frequency plane via the short time Fourier transform, manipulated there, and synthesized to an output audio signal. More generally, we study signal processing with continuous frames. We show how to approximate such methods, termed phase space signal processing methods, using a Monte Carlo method. The Monte Carlo method speeds up computations, since the number of samples required for a certain accuracy is proportional to the dimension of the signal space, and not to the dimension of phase space, which is typically higher. We utilize this property for a new phase vocoder method, based on an enhanced time-frequency space, with more dimensions than the classical method. The higher dimension of phase space improves the quality of the method, while retaining the computational complexity of a standard phase vocoder based on regular samples.

1 Introduction

In this paper we consider signal processing tasks in which an input signal $s$ is first analyzed into a feature space representation $V_f[s]$, manipulated in the feature space by first applying a pointwise nonlinearity $r \circ V_f[s]$ and then a linear operator $T$, to produce $T(r \circ V_f[s])$, and finally synthesized back to the signal space via $V_f^*$. The end-to-end pipeline is of the form

$$\mathcal{H} \ni s \mapsto V_f^* T(r \circ V_f[s]).$$

In this paper, we call pipelines of the form (1) phase space signal processing. Here, $\mathcal{H}$ is the signal space, $s$ is the input signal, $V_f$ is the analysis operator of a continuous frame (e.g., the 1D continuous wavelet transform - CWT [32, 16], the short time Fourier transform - STFT [31], the Shearlet transform [34] or the Curvelet transform [6]), and $V_f^*$ is the synthesis operator corresponding to $V_f$. The linear operator $T$ models a global change in the feature space of the signals, while the nonlinearity $r$ allows modifying the feature coefficients term-by-term with respect to their values.

An analysis operator of a continuous frame $V_f$ has the form

$$\mathcal{H} \ni s \mapsto V_f[s] = (s, f(g)) \in L^2(G).$$

where $G$ is a measure space called phase space and usually has some physical interpretation (e.g., in the STFT $G$ is the time-frequency plane), and $(f_g)_{g \in G}$ is a family of atoms that obey some regularity conditions to be discussed later. Accordingly, the synthesis operator $V_f^*$ has the form

$$V_f^*[F] = \int_G F(g)f_g dg.$$
ratio [17]), signal denoising e.g. wavelet shrinkage denoising [19, 17] and Shearlet denoising [35], and phase vocoder [56, 14, 70, 40, 44, 20, 53, 58] (the list is far from exhaustive). In multipliers the nonlinearity is trivial $r(x) = x$, while in wavelet shrinkage the linear operator is trivial $T = I$. In phase vocoder both the nonlinearity and linear operator are non-trivial.

As evident from the above description, phase space signal processing involves integrals, and thus some form of discretization is required. One common approach is to use a grid in phase space (the grid can be uniform or non-uniform). However, this approach has several shortcomings. From a computational standpoint, using a grid typically requires the number of points to grow exponentially with the dimension of the phase space if the grid points are used as quadrature points for approximating integrals, making the method only feasible when the dimension of the phase space is low. From an applicative standpoint, the physical interpretation underlying the design of the phase space is appropriate in the continuous domain but can sometimes fail when discretized using a grid. This can result in a discrete phase space signal processing method that fails to do what its continuous counterpart was designed to. As an example, in Subsection 6.2 we show that the continuous wavelet transform is appropriate for time-frequency analysis, while the discrete wavelet transform is not.

In this paper we propose to use a stochastic phase space signal processing approach, in which the discretization is performed by randomly sampling phase space, i.e. the analysis and synthesis operators are replaced by a Monte Carlo approximation. For example, for the synthesis operator, such approximations read

$$V_f^* [F] \approx C \sum_{k=1}^{K} F(g_k) f_{g_k},$$

where $\{g_k\}_{k=1}^{K}$ are random samples from phase space $G$, and $C$ is some normalization. In Section 3 we formulate Monte Carlo methods for phase space signal processing procedures of the form $V_f^* Dr \circ V_f[s]$, and in Sections 4–5 analyze and prove the convergence of our proposed methods in a general setting.

We demonstrate the utility of our proposed method in the context of a time stretching phase vocoder. First, we enhance the standard phase vocoder method by combining the STFT with the CWT into one time-frequency feature space, and then we add a third axis to the 2D time frequency domain, controlling the time-frequency uncertainty balance. We call the resulting novel transform the localizing time-frequency transform (LTFT). Using our stochastic phase space signal processing method for this phase vocoder, instead of the standard grid based method, solves two problems. First, we show that the interpretation of the CWT transform as a time-frequency transform is only appropriate in the continuous realm, and fails in discrete wavelet transforms. We show that a Monte Carlo method, replacing the regular discretization, preserves better the properties of the continuous transform. Second, as stated above, the additional axis in the feature space increases the computational complexity of grid based methods, while not affecting our method. We note that our method has computational complexity of $O(M \log(M))$, where $M$ is the resolution of the discrete signal. This complexity is comparable to typical grid based methods of a 2D time-frequency phase space, like STFT with windows having a fixed time spread and sample rate proportional to $M$, but we use a 3D phase space.

Randomized algorithms in a context of phase space were presented in the past. In [28], signal denoising based on matching pursuit is sped up using a randomized method. However, the motivation and technique are different from our framework. A related class of problems are randomized matrix approximation methods.

From randomized matrix approximations to randomized operator approximations

Recent years has seen intensive research on randomized matrix approximations. Motivated by the need to analyze and manipulate large data matrices, randomized matrix approximation algorithms seek to replace a data matrix $A$ with a, informally speaking, simpler matrix $B$. Here the term 'simpler' is used in a very wide and informal way, which can mean, for example, a low-rank approximation or a skeleton decomposition (expressing the matrix as a linear combination
of columns and rows), and many others (different goals might be appropriate for different applications). Optimal approximations are often computationally hard to compute, and are often too expensive to compute even if computing the optimal approximation is tractable. Randomized numerical linear algebra seeks to circumvent this issue by using sampling \cite{21} or so-called sketching techniques \cite{68} to quickly find nearly-optimal approximations. For example, in the context of low-rank approximation, one might seek to find a matrix $B$ of prescribed rank such that $|A - B|$ is close to optimal, where the norm might be, for example, the spectral norm (again, different metrics might be appropriate for different applications). We refer the interested reader to recent surveys on this exciting field \cite{45, 68, 69}.

Phase space signal processing requires applying operators on infinite dimensional spaces, and thus requires us to consider a more general setting of randomized operator approximation. Nevertheless, our stochastic phase space signal processing approach is reminiscent of randomized matrix approximations via sampling. To better understand this, it is instructive to consider for a moment a linear finite dimensional analogue of phase space signal processing via Parseval frames.

In a finite dimensional setting, an input signal $s$ is now a finite dimensional vector, i.e. $s \in \mathbb{C}^M$. The phase space is $\mathbb{C}^N$ where $N \gg M$, and the transformation from signal space to the phase space is accomplished by multiplying $s$ on the left by a matrix $V \in \mathbb{C}^{N \times M}$ with orthonormal columns. At this point, the signal is manipulated in phase space, which in the linear finite dimensional context amounts to multiplying on the left by an $N \times N$ matrix $T$. Finally, the signal is synthesized back to $\mathbb{C}^M$ by multiplying by $V^\ast$. Thus, the pipeline is

$$\mathbb{C}^M \ni s \mapsto V^\ast TVs$$

which is clearly analogous to a version of (1) without the nonlinearity. Under a general setting, the cost of the above processing procedure is $O(N^2)$. Even if $T$ possesses a structure that allows fast matrix-vector products, the cost is still $O(MN)$. For a fixed signal size (fixed $M$), the dependence on the size of the phase space ($N$) is undesirable.

One potential randomized approximation scheme for (5) is as follows. Instead of forming the entire phase space signal $Vs$, we form only a small subset of the entries, where the indexes are sampled uniformly over $1, \ldots, N$ (non-uniform sampling based on leverage scores \cite{46} \cite{22} can also be considered). Specifically, we sample indexes $j_1, \ldots, j_K$ where $K$ is a parameter, and compute only the corresponding indexes from $Vs$. The phase space operator $T$ only operates on the computed entries of $Vs$. Furthermore, to avoid $O(N)$ costs when synthesizing the signal, the result of applying $T$ is also sampled: we sample $i_1, \ldots, i_L$ from $1, \ldots, N$, where $L$ is a parameter, and use only these rows from $T$. To describe the complete approximation pipeline, let us define the following scaled sampling matrices $S_a \in \mathbb{R}^{K \times N}$ and $S_b \in \mathbb{R}^{L \times N}$:

$$(S_a)_{IJ} = \begin{cases} \sqrt{N/K} & J = j_I \\ 0 & \text{otherwise} \end{cases}, \quad (S_b)_{IJ} = \begin{cases} \sqrt{N/L} & J = i_J \\ 0 & \text{otherwise} \end{cases}$$

We now approximate $V^\ast TV \approx V^\ast S_a^\ast S_a TS_b^\ast S_b V$ and obtain the following stochastic phase space signal processing method:

$$\mathbb{C}^M \ni s \mapsto V^\ast S_a^\ast S_a TS_b^\ast S_b V$$

Computing (6) costs $O((L + K)M + LK)$, which is attractive if, for example, $L = O(M), K = O(M)$. The flip side is that we need to bound the difference between (5) and (6), and ensure that it is small enough. This can be accomplished by bounding the spectral norm of the difference between the operators, which raises the question: how large should $L, K$ be so that

$$|V^\ast TV - V^\ast S_a^\ast S_a TS_b^\ast S_b V|_2 \leq \epsilon$$

with high probability?

Although schemes similar to (6) have been described and analyzed in the literature \cite{21, 23, 12}, this specific setup has not been presented before. However, instead of analyzing the finite dimensional approximation scheme, as well as answering the aforementioned question, we consider
the natural generalization to infinite dimensional separable Hilbert spaces, i.e. replacing $\mathbb{C}^M$ by a Hilbert space $\mathcal{H}$, replacing $\mathbb{C}^N$ by a Lebesgue space $L^2(G)$, where $G$ is some Radon space (a topological space with measure), replacing $\mathcal{V}$ with a linear embedding $V : \mathcal{H} \rightarrow L^2(G)$, and replacing $\mathcal{T}$ with a linear operator $T : L^2(G) \rightarrow L^2(G)$. We also add a pointwise nonlinearity to the pipeline.

In addition, we assume that $V$ has the following structure. Since the domain $\{1, 2, \ldots, N\}$ is a signal replacing $T$, the mapping $n \mapsto v^*_n$ (where $v_n$ is the nth row of $V$), is replaced by a continuous mapping $g \mapsto f_g$ that takes a point $g \in G$ and returns a vector $f_g \in \mathcal{H}$. Therefore, the matrix $V$ is generalized to an operator that takes a signal $s \in \mathcal{H}$, and returns a function in $L^2(G)$, whose value at any $g \in G$ is given by $(s, f_g)_\mathcal{H}$. Here, $(s, f_g)_\mathcal{H}$ is the inner product in $\mathcal{H}$. Lastly, we assume some regularity condition on $T$, e.g., that it is bounded. The above generalization of $V$, with some additional assumptions, is called the analysis operator of a continuous frame $[1] [30].$

**Main contribution** We summarize our main contribution as follows:

- We develop a stochastic method to approximate phase space signal processing procedures, prove its convergence, and give error bounds. When considering discrete signals of resolution $M$, embedded in the continuous signal space, the error in the stochastic method is of order $O(\sqrt{M/K})$, where $K$ is the number of Monte Carlo samples.

- As opposed to grid based discretization methods of phase space, the computational complexity of our method does not depend on the dimension of phase space. This allows working with high dimensional phase spaces.

- As an application of the theory, we increase the expressive capacity of the time-frequency phase space by increasing its dimension. Used in a phase vocoder scheme, this leads to an efficient novel method with desired properties.

## 2 Background: harmonic analysis in phase space

In this section we review the theory of continuous frames and general wavelet transforms, and give the two important examples of the STFT and the CWT. By convention, all Hilbert spaces in this paper are assumed to be separable. The Fourier transform $\mathcal{F}$ is defined on signals $s : \mathbb{R} \rightarrow \mathbb{C}$ with the following normalization

$$[\mathcal{F}s](\omega) = \hat{s}(\omega) = \int_\mathbb{R} s(t)e^{-2\pi i \omega t} dt, \quad [\mathcal{F}^{-1}\hat{s}](t) = \int_\mathbb{R} \hat{s}(\omega)e^{2\pi i \omega t} d\omega. \quad (7)$$

We denote the induced norm of a vector $v$ in a Hilbert space $\mathcal{H}$ by $\|v\|_{\mathcal{H}}$. For a measure space $\{G, \mu\}$, we denote interchangeably by

$$\|f\|_p = \|f\|_{L^p(G)} = \left( \int_G |f(g)|^p \, d\mu(g) \right)^{1/p}$$

the $p$ norm of the signal $f \in L^p(G)$, where $1 \leq p < \infty$, and denote interchangeably

$$\|f\|_\infty = \|f\|_{L^\infty(G)} = \text{ess sup}_{g \in G} |f(g)|$$

for $f \in L^\infty(G)$. We denote the induced operator norm of operators from a Banach space to itself using the subscript of the Banach space, e.g., for bounded linear operator $T : L^p(G) \rightarrow L^p(G)$, we denote $\|T\|_p$. We denote the operator norm of a bounded linear operator between two different Banach spaces with no subscript. The $L^2(G)$ inner product of $f, h \in L^2(G)$ is defined to be

$$\langle f, h \rangle = \int_G f(g)\overline{h(g)} \, dg,$$

where $\overline{\cdot}$ is the complex conjugate of the complex number $c \in \mathbb{C}$. 

4
2.1 Continuous frames and coherent state systems

A phase space transform decomposes signals to their atomic components, which are basic signals that serve as the building blocks of the transform. The inverse phase space transform recombines atoms with corresponding coefficients to a signal. A continuous frame is a system of atoms with general properties which guarantee that the decomposition of signals to atomic components, and the recombination of atomic components to signals, are both stable. A coherent state system is a special case of a continuous frame, where decomposition and recombination are “perfectly stable”, namely isometric.

The following definitions and claims are from [59] and [30, Chapter 2.2], with notation adapted from the later. We note that in this paper an equality between two $L^p$ functions is always interpreted as an almost-everywhere equality. The measure $\mu$ of a measurable space $G$ is called $\sigma$-finite if there is a countable set of measurable sets $X_1, X_2, \ldots \subset G$ with $\mu(X_n) < \infty$ for each $n \in \mathbb{N}$, such that $\bigcup_{n \in \mathbb{N}} X_n = G$. A topological space $G$ is called locally compact if for every point $g \in G$ there exists an open set $U$ and a compact set $K$ such that $g \in U \subset K$.

Definition 1. Let $\mathcal{H}$ be a Hilbert space, and $(G, \mathcal{B}, \mu)$ a locally compact topological space with $\sigma$-finite Borel measure $\mu$. Let $f : G \to \mathcal{H}$ be a weakly measurable mapping, namely for every $s \in \mathcal{H}$

$$g \mapsto \langle s, f_g \rangle$$

is a measurable function $G \to \mathbb{C}$. For any $s \in \mathcal{H}$, we define the coefficient function

$$V_f[s] : G \to \mathbb{C} \, , \, V_f[s](g) = \langle s, f_g \rangle_{\mathcal{H}}.$$  (8)

1. We call $f$ a continuous frame, if $V_f[s] \in L^2(G)$ for every $s \in \mathcal{H}$, and there exist constants $0 < A \leq B < \infty$ such that

$$A \|s\|^2_{\mathcal{H}} \leq \|V_f[s]\|^2_2 \leq B \|s\|^2_{\mathcal{H}}$$  (9)

for every $s \in \mathcal{H}$.

2. If it is possible to choose $A = B$, $f$ is called a tight frame.

3. We call $\mathcal{H}$ the signal space, $G$ phase space, $V_f$ the analysis operator, and $V_f^*$ the synthesis operator.

4. We call the frame $f$ bounded, if there exist a constant $0 < C \in \mathbb{R}$ such that

$$\forall g \in G, \|f_g\|_{\mathcal{H}} \leq C.$$  

5. We call $S_f = V_f^* V_f$ the frame operator, and call $Q_f = V_f V_f^*$ the Gramian operator.

6. We call $f$ an (admissible) coherent state system, or a Parseval continuous frame, if $V_f$ is an isometry between $\mathcal{H}$ and $L^2(G)$.

Remark 2. A coherent state system is a continuous frame with frame bounds $A = B = 1$.

Given a continuous frame, a concrete formula for the synthesis operator is given by the weak integral [59] Theorem 2.6]

$$V_f^*[F] = \int_G F(g) f_g dg.$$  (10)

This integral is defined by

$$q, \int_G F(g) f_g dg = \int_G \overline{F(g)}(q, f_g) dg,$$  (11)

where $f_G \int_G F(g) f_g dg$ denotes the vector corresponding to the continuous functional defined in the right-hand-side of (11), whose existence is guaranteed by the Riesz representation theorem. We refer in this paper to such integrals as weak vector integrals, and note that they are also called Pettis integral [55]. For more details on weak integrals, see [A].
Remark 3. For a coherent state system, Equation (10), with \( F = V_f[s] \) for a signal \( s \in \mathcal{H} \), gives the reconstruction formula

\[
s = V_f[\mathcal{H}] = \int_G V_f[s](g)f_g dg. \tag{12}
\]

The orthogonal projection upon \( V_f[\mathcal{H}] \) is given by the Gramian operator \( Q_f = V_f V_f^\ast \). When \( f \) is not a coherent state system, the Gramian operator \( Q_f = V_f V_f^\ast \) is self-adjoint but not a projection.

Definition 4. The frame kernel function \( K : G^2 \rightarrow \mathbb{C} \) is defined by

\[
K(g, g') = \langle f_g, f_{g'} \rangle = V_f[f_g](g'). \tag{13}
\]

To stress the distinction between weak integrals and integrals on \( G \), we use the term \( \mu_G \)-integral for integration with respect to the measure \( \mu_G \) of \( G \).

Proposition 5. The Gramian operator \( Q_f \) is a \( \mu_G \)-integral operator with kernel \( K \). Namely, for every \( F \in L^2(G) \)

\[
[Q_f F](g') = \int_G F(g)K(g, g')dg. \tag{14}
\]

Proof.\( \square \)

\[
[Q_f F](g') = [V_f V_f^\ast F](g') = \left\{ \int_G F(g)f_g dg, f_{g'} \right\} \tag{15}
\]

Now, by definition of weak integral, the right-hand-side of (15) is equal to the \( \mu_G \) integral

\[
\int_G F(g)f_g dg, f_{g'} = \int_G \langle F(g)f_g, f_{g'} \rangle dg = \int_G F(g)\langle f_g, f_{g'} \rangle dg.
\]

By Corollary 5.4 of [3], \( Q_f \) is also a weak integral operator.

Proposition 6. The Gramian operator \( Q_f \) is a weak integral operator with kernel \( K \). Namely, for every \( F \in L^2(G) \)

\[
[Q_f F](g') = \int_G F(g)K(g, g')dg. \tag{16}
\]

For a coherent state system, the image space \( V_f[\mathcal{H}] \) is a reproducing kernel Hilbert space, with kernel \( K(g, \cdot) \).

2.2 General wavelet transforms

An important class of coherent state systems are general wavelet transforms, or wavelet transforms in short. The general theory of wavelet transforms gives a procedure for constructing coherent state systems, guaranteeing the properties of Definition 1. Moreover, useful continuous frames that are not wavelet transforms can be constructed using wavelet transforms as building blocks. The theoretical material of this section can be found in [20] Chapters 2.3–2.5, and the classical papers [21, 33].

The coherent state system underlying a wavelet transform is constructed by considering one basic signal \( f \), called a window, and applying a parametric set of transformations on \( f \). To illustrate this idea, we start with the example of the 1D continuous wavelet transform (CWT).

In the CWT, the Hilbert space of signals is \( \mathcal{H} = L^2(\mathbb{R}) \), and the window, also called the mother wavelet, is a signal \( f \in L^2(\mathbb{R}) \) that satisfy some admissibility condition to be described later. The coherent state system is generated by dilating and translating \( f \). Namely, for each position and dilation parameters \( x, \tau \in \mathbb{R} \times (\mathbb{R} \setminus \{0\}) \), consider the unitary operator \( \pi(x, \tau) \) that dilates by \( \tau \) and then translates by \( x \), namely

\[
[\pi(x, \tau)f](t) = \frac{1}{\sqrt{|\tau|}} f\left(\frac{t-x}{\tau}\right).
\]
The reconstruction formula of the wavelet transform is given by

\[ \pi(G) = \{ \pi(x, \tau) \mid (x, \tau) \in \mathbb{R} \times (\mathbb{R} \setminus \{0\}) \} \]

is a group under composition. The composition structure of operators can be pulled back to the parametric space \( G \), endowing \( G \) with a group structure. Namely, we define the multiplication in \( G \) as follows. For every two pairs \((x, \tau) \in G\) and \((x', \tau') \in G\), there is a unique third pair \((x'', \tau'') \in G\) such that \( \pi(x, \tau)\pi(x', \tau') = \pi(x'', \tau'') \). We thus define

\[ (x, \tau)(x', \tau') := (x'', \tau''). \]

The resulting group \( G \) is called the 1D affine group. The mapping \( \pi : G \to U(H) \), where \( U(H) \) is the group of unitary operators in \( H \) with composition, is a homomorphism. A homomorphism between a group \( G \) and \( U(H) \) is also called a unitary representation of \( G \). The space \( G \) is both a smooth manifold and a group, and the group multiplication and inversion are smooth mappings. Such a space is called a Lie group. Any Lie group has a unique Radon measure, up to constant, that is invariant under left translations. Namely, there is a Radon measure \( \mu \) on \( G \), with the left Haar measure, a Hilbert space \( \mathcal{H} \) such that for every \( g' \in G \) and every measurable function \( f : G \to \mathbb{R} \), the following equality holds

\[ \int_G F(g) dg = \int_G F(g'g) dg. \]

This measure is called the left Haar measure of \( G \). It can be shown that for a large class of signals \( f \), the space \( G \), together with the mapping \( (x, \tau) \mapsto \pi(x, \tau)f \), is a bounded coherent state system, with \( C = \|f\|_\mathcal{H} \).

Next, we briefly explain the general setting of wavelet transforms for Lie groups. More details are presented in [31]. The Lie groups in this analysis can be replaced by the more general locally compact topological groups. However, for most application we find that Lie groups are sufficiently general. Consider a Lie group \( G \), with the left Haar measure, a Hilbert space \( \mathcal{H} \), a square integrable representation \( \pi : G \to U(H) \), and a window \( f \in \mathcal{H} \) (see Definition 57 in [31]). The wavelet transform in this setting is defined by

\[ V_f : \mathcal{H} \to L^2(G) \quad \text{, } \quad V_f[s](g) = \langle s, \pi(g)f \rangle. \]

The reconstruction formula of the wavelet transform is given by

\[ s = \frac{1}{\langle A f_2, A f_1 \rangle} \int_G V_{f_1}[s](g) \pi(g)f_2 \ dg. \]

Here, \( A \) is a special positive operator in \( \mathcal{H} \), called the Duflo-Moore operator, uniquely defined for every square integrable representation \( \pi \), that determines the normalization of windows (see Remark 59). It is thus evident that for \( A \)-normalized windows (\( \|A f\|_\mathcal{H} = 1 \)), the mapping \( g \mapsto \pi(g)f \) is a bounded coherent state system.

### 2.3 Examples

#### 2.3.1 The short time Fourier transform

The following construction is taken from [31]. Consider the signal space \( L^2(\mathbb{R}) \). Let \( \mathcal{T} : \mathbb{R} \to U(L^2(\mathbb{R})) \) be the translation in \( L^2(\mathbb{R}) \). Namely, for \( x \in \mathbb{R} \) and \( f \in L^2(\mathbb{R}) \), \([\mathcal{T}(x)f](t) = f(t-x)\). Let \( \mathcal{M} : \mathbb{R} \to U(L^2(\mathbb{R})) \) be the modulation in \( L^2(\mathbb{R}) \). Namely, for \( \omega \in \mathbb{R} \) and \( f \in L^2(\mathbb{R}) \), \([\mathcal{M}(\omega)f](t) = e^{2\pi i \omega t}f(t)\). The representations \( \mathcal{T} \) and \( \mathcal{M} \) of the group \( \{\mathbb{R}, +\} \) satisfy the commutation relation

\[ [\mathcal{T}(x), \mathcal{M}(\omega)] := \mathcal{T}(x)^* \mathcal{M}(\omega)^* \mathcal{T}(x) \mathcal{M}(\omega) = e^{-2\pi i \omega t}I, \]

where \( I \) is the identity operator. This shows that by introducing the additional operators \( e^{-2\pi i \omega t}I \), the following set of unitary operators is a group, with composition as the group product

\[ \mathcal{J} = \{ \theta \mathcal{T}(x) \mathcal{M}(\omega) \mid \theta \in e^{i\mathbb{R}}, x, \omega \in \mathbb{R} \}. \]
We can treat $\mathcal{J}$ as a group of tuples $\mathbb{R} \times \mathbb{R} \times e^{i\mathbb{R}}$, with group product derived from $[16]$. The group $\mathcal{J}$ is called the (reduced) Heisenberg group. The mapping
\[
\pi(x,\omega,\theta) = \theta \mathcal{T}(x)\mathcal{M}(\omega)
\]
is a square integrable representation, with Dulfo-Moore operator $A = I$. The Haar measure of $\mathcal{J}$ is the standard Lebesgue measure.

Since the representation of the parameter $\theta$ only multiplies by scalars, it plays no important role in the above wavelet transform. It is standard to omit the parameter $\theta$ from this wavelet transform, to get a Parseval frame transform, as we explain next. The center of $\mathcal{J}$ is given by $Z = \{(x,\omega,\theta) \mid x = \omega = 0\}$. It can be shown that the quotient group $\mathcal{J}/Z$ is $\mathbb{R}^2$ with addition (up to isomorphism). Denote by abuse of notation the restriction of $\pi$ to $\mathbb{R}^2$ by $\pi(x,\omega) = \mathcal{T}(x)\mathcal{M}(\omega)$. For a normalized window $f$, by the fact that the representation of $Z$ is a character, the mapping
\[
\mathbb{R}^2 \ni (x,\omega) \mapsto \pi(x,\omega)f
\]
is a coherent state system, with the standard Lebesgue measure of $\mathbb{R}^2$ $[29]$. The resulting transform
\[
V_f[s](x,\omega) = \langle s, \pi(x,\omega)f \rangle
\]
is called the Short Time Fourier Transform (STFT).

### 2.3.2 The 1D continuous wavelet transform

The following construction is taken from $[22][16]$. Consider the signalspace $L^2(\mathbb{R})$, and the translation $\mathcal{T}$ as in the STFT. Let $S : \mathbb{R} \setminus \{0\} \to \mathcal{U}(L^2(\mathbb{R}))$ be the dilation in $L^2(\mathbb{R})$, defined for $\tau \in \mathbb{R} \setminus \{0\}$ and $f \in L^2(\mathbb{R})$ by $[S(\tau)f](t) = \frac{1}{\sqrt{|\tau|}} \hat{f}(\frac{t}{\tau})$. The set of transformations
\[
\mathcal{A} = \{\mathcal{T}(x)S(\tau) \mid x,\tau \in \mathbb{R} \times (\mathbb{R} \setminus \{0\})\}
\]
is closed under compositions. We can treat $\mathcal{A}$ as a group of tuples $\mathbb{R} \times (\mathbb{R} \setminus \{0\})$, with group product derived from the compositions of operators in $[17]$. The group $\mathcal{A}$ is called the 1D affine group. The mapping
\[
\pi(x,\tau) = \mathcal{T}(x)S(\tau)
\]
is a square integrable representation, with Dulfo-Moore operator $A$ defined by
\[
[F_AF^*\hat{f}](z) = \frac{1}{\sqrt{|z|}} \hat{f}(z).
\]
The resulting wavelet transform is called the Continuous Wavelet Transform (CWT).

Next, we show how the CWT atoms are interpreted as time-frequency atoms, and the CWT is interpreted as a time-frequency transform. Here, by changing variable $\omega = \frac{1}{\tau}$, we obtain the coherent state system
\[
\{\pi'(x,\omega)f(x,\omega) \mid x,\omega \in \mathbb{R} \times (\mathbb{R} \setminus \{0\})\}
\]
based on the representation
\[
\pi'(x,\omega) = \mathcal{T}(x)S(\omega^{-1}).
\]
The parameter $\omega$ is interpreted as frequency. The mapping $\pi'$ is a representation of the 1D affine group with the new parameterization $\omega = \frac{1}{\tau}$, in which the Haar measure is the standard Lebesgue measure of $\mathbb{R} \times (\mathbb{R} \setminus \{0\})$. See $[15]$ for more details.

### 3 Phase space signal processing and its stochastic approximation

In this section we summarize our theory of stochastic phase space signal processing. We define two pipelines for phase space signal processing based on non-Parseval continuous frames. Moreover, we detail our assumptions on the linear operator of the pipeline, and show how to approximate phase space signal processing methods via a Monte Carlo method. We last give the classical phase vocoder as an example, and a novel variant of phase vocoder based on a new non-Parseval continuous frame we call the localizing time-frequency transform (LTFT).
3.1 Non-Parseval phase space signal processing

In the case of a coherent state system, a signal processing method in phase space is any procedure that maps a signal \( s \in \mathcal{H} \) to phase space, applies a pointwise nonlinearity \( r : \mathbb{C} \to \mathbb{C} \) on \( V_f[s] \) (by \( g \mapsto r(V_f[s](g)) \)), applies a linear operator \( T \), and synthesizes back to a signal. Namely, we consider procedures of the form

\[
s \mapsto V_f^* Tr \circ (V_f s).
\]

In this subsection we extend this procedure to non-Parseval phase space signal processing based on continuous frames.

In case \( f \) is a continuous frame, we consider two approaches to phase space signal processing, both generalizing the coherent state formulation. A basic guideline of our construction is to derive computationally tractable formulas. Equations (8) and (10) give constructive formulas for \( V_f \) and \( V_f^* \), and in this paper we present an approach for efficiently approximating these formulas. For example, we show in this paper that the Monte Carlo approximation of the LTFT is computed in \( O(M) \) floating point operations, where \( M \) is the resolution of the signal. We thus suppose that the computation of \( V_f \) and \( V_f^* \) is tractable. We moreover assume that the inverse frame operator \( S_f^{-1} \) is computationally tractable. In the example of the LTFT, we show in this paper that applying \( S_f^{-1} \) takes \( O(M \log(M)) \) operations. Hence, we allow in our formulations of phase space signal processing the application of \( V_f, V_f^* \), and \( S_f^{-1} \), in addition to the phase space operator \( T \) and the pointwise non-linearity \( r \). In the example of stochastic LTFT phase vocoder, the whole signal processing pipeline takes \( O(M \log(M)) \) operations.

For an injective linear operator \( B : \mathcal{V} \to \mathcal{W} \) between the Hilbert spaces \( \mathcal{V} \) and \( \mathcal{W} \), we define the pseudo inverse

\[
B^* : \mathcal{W} \to \mathcal{V}, \quad B^* = (B|_{\mathcal{V} \to \mathcal{BV}})^{-1} R_{\mathcal{BV}},
\]

where \( R_{\mathcal{BV}} : \mathcal{W} \to \mathcal{BV} \) is the surjective operator given by the orthogonal projection from \( \mathcal{W} \) to \( \mathcal{BV} \) and restriction of the image space to the range \( \mathcal{BV} \), and \( B|_{\mathcal{V} \to \mathcal{BV}} \) is the restriction of the image space of \( B \) to its range \( \mathcal{BV} \), in which it is invertible. Note that \( R_{\mathcal{BV}} \) is the operator that takes a vector from \( \mathcal{BV} \) and canonically embeds it in \( \mathcal{W} \), and \( P_{\mathcal{BV}} = R_{\mathcal{BV}}^* R_{\mathcal{BV}} : \mathcal{W} \to \mathcal{W} \) is the orthogonal projection upon \( \mathcal{BV} \). In the following we list basic properties of \( V_f \) and \( V_f^* \).

**Lemma 7.** Let \( f : G \to \mathcal{H} \) be a continuous frame. Then the following properties hold.

1. \( V_f^* V_f = I \).
2. \( V_f V_f^* = P_{V_f[H]} \).
3. \( V_f^* P_{V_f[H]} = V_f^* \).
4. The operator \( V_f^* \) is the pseudo inverse of \( V_f^{**} \), and \( V_f^{**}[H] = V_f[H] \).
5. \( (V_f V_f^*)^{-1} = V_f^* V_f^{**} \).

3.1.1 Synthesis phase space signal processing

Synthesis phase space signal processing is based on the synthesis operator \( V_f^* \) as the basic transform. In this approach, we view phase space signal processing as the procedure of decomposing signals to their different atoms, modifying the coefficients of the atoms, and synthesizing these modified coefficients. The synthesis transform \( V_f^* \), which combines atoms to signals, serves as the inverse transform of the pipeline. The forward transform, which decomposes signals to atoms, is given by \( V_f^{**} \). Note that by Lemma 7 \( V_f^* \) is the pseudo inverse of \( V_f^{**} \). To conclude, synthesis phase space signal processing is the pipeline

\[
s \mapsto V_f^* Tr \circ (V_f^{**}[s]). \tag{19}
\]

To make (19) computationally tractable, it is implemented by

\[
s \mapsto V_f^{**} Tr \circ (V_f S_f^{-1} s). \tag{20}
\]

9
Indeed, by Lemma 7

\[ V_f^* Tr \circ (V_f S f^{-1} s) = V_f^* Tr \circ (V_f V_f^* s) = V_f^* Tr \circ (P_{V_f}[H] V_f^* s) = V_f^* Tr \circ (V_f^* s). \]

### 3.1.2 Analysis phase space signal processing

Analysis phase space signal processing takes the analysis operator \( V_f \) as the basic transform. Here, we view phase space signal processing as the procedure of computing the correlation of the signal with the different atoms to obtain coefficients, modifying these coefficients, and outputting the signal that has these coefficients. The basic transform here is \( V_f \), which computes correlations with the atoms. The inverse transform, which finds the signal that best fits given coefficients, is \( V_f^* \). To conclude, analysis phase space signal processing is the pipeline

\[ s \mapsto V_f^* Tr \circ (V_f[s]). \] (21)

To make (21) computationally tractable, it is implemented by

\[ s \mapsto S_f V_f^* Tr \circ (V_f[s]). \] (22)

Indeed, by Lemma 7

\[ S_f V_f^* Tr \circ (V_f[s]) = V_f^* V_f^* V_f^* Tr \circ (V_f[s]) = V_f^* P_{V_f[H]} Tr \circ (V_f[s]) = V_f^* Tr \circ (V_f[s]). \]

### 3.2 Phase space operators

To accommodate the synthesis and analysis phase space signal processing pipelines, we focus on integral operators between Lebesgue spaces. It is common to define classes of operators by assuming boundedness between some choice of a domain and a range of the operators. Kernel theorems then prove that such operators can be written as integral operators, or more generally defined by the application of a kernel, which generalizes the classical notion of a matrix operator. A classic example is the Schwartz kernel theorem [37, Section 5.2]. In the context of continuous frames, Feichtinger's kernel theorem is for the STFT [27][31, Theorem 14.4.1], and for general wavelet transforms see [4]. In this paper we suppose that our operator \( T \) is a kernel/integral operator as a basic assumption, instead of proving this assumption under a different condition on \( T \).

Integral operators in our context can represent operators in phase space \( T : L^2(G) \to L^2(G) \) and in particular the Gramian operator \( Q \), or synthesis operators \( V_f^* : L^2(G) \to \mathcal{H} \) in case \( \mathcal{H} \) a Lebesgue space \( L^2(G') \) for some measure space \( G' \). Phase space operators, as defined next, are a special case of weak integral operators defined in [13].

**Definition 8.** Let \( T : L^2(G) \to L^2(G') \) be a bounded linear operator between the separable Lebesgue spaces \( L^2(G) \) and \( L^2(G') \), where \( G \) and \( G' \) are locally compact topological spaces with \( \sigma \)-finite Borel measures.

1. We call \( T \) a phase space operator if there exists a measurable function \( R : G' \times G \to \mathbb{C} \) with \( R(\cdot, g) \in L^2(G') \) for almost every \( g \in G \), such that for every \( F \in L^2(G) \), the mapping \( g \mapsto R(\cdot, g) F(g) \) is weakly integrable, and

\[ TF = \int_G^w R(\cdot, g) F(g) dg, \] (23)

where the integral in (23) is a weak \( L^2(G') \) integral.

2. A phase space operator \( T \) is called uniformly square integrable, if there is a constant \( D > 0 \) such that for almost every \( g \in G \)

\[ \|R(\cdot, g)\|_{L^2(G')} = \sqrt{\int_{G'} |R(g', g)|^2 dg'} \leq D. \]
Remark 9. By Definition 25, $\int_G R(\cdot, g) F(g) dg$ is the $L^2(G)$ function such that for every $q \in L^2(G)$
\[
\left\{ q, \int_G R(\cdot, g) F(g) dg \right\} = \int_G \langle q, R(\cdot, g) F(g) \rangle dg.
\]
In particular, inner products in $L^2(G')$ always commute with the integral in the definition of the phase space operator, so “Fubini’s theorem” follows directly from definition.

Example 10. The Gramian operator $Q_f$ of a continuous frame is a phase space operator by Proposition 7.

Example 11. If $\mathcal{H} = L^2(G')$ for locally compact topological spaces $G'$ with $\sigma$-finite Borel measures, the analysis operator $V_f$ is a coefficient operator (Definition 50). Thus, by Proposition 51 the synthesis operator $V^*_f$ is a phase space operator.

3.3 Stochastic approximation of synthesis operators

Monte Carlo methods for synthesizing coefficient functions $F \in L^2(G)$ are based on approximating $V^*_f$ by quadrature formulas
\[
V^*_f F = \int F(g) f_g dg \approx C \sum_n F(g_n) f_{g_n} \tag{24}
\]
for some appropriate normalization $C > 0$. The finite set of points $\{g_n\} \subset G$ in Monte Carlo methods is sampled randomly. In Subsection 3.5 we explain how random sampling is approached.

When analyzing the approximation (24), we do not approximate the synthesis integral $\int F(g) f_g dg$ directly by a quadrature sum over $g$. Rather, we take the detour of approximating $Q_f F$ via a quadrature sum first, and then applying $V^*_f$ as follows. We represent $V^*_f$ as
\[
V^*_f = S^{-1}_f V^*_f Q_f F
\]
and approximate $Q_f F$ by a Monte Carlo method. The formula
\[
[Q_f F](g') = \int K(g, g') F(g) dg
\]
is approximated by the quadrature
\[
[Q_f F](g') \approx C \sum_n K(g_n, g') F(g_n) \tag{26}
\]
for some appropriate normalization $C$. As a result, $S^{-1}_f V^*_f Q_f F$ is approximated by
\[
C S^{-1}_f V^*_f \sum_n K(g_n, \cdot) F(g_n) = C \sum_n S^{-1}_f V^*_f [f_{g_n}] F(g_n)
\]
\[
= C \sum_n S^{-1}_f V^*_f [f_{g_n}] F(g_n) f_{g_n} = C \sum_n F(g_n) f_{g_n}
\]
which coincides with (24). This detour approach allows us to derive error analysis of the synthesis Monte Carlo approximation for general Hilbert spaces $\mathcal{H}$, while directly analyzing (24) only allows error analysis if the signal space $\mathcal{H}$ is some Lebesgue space $L^2(G')$.

Now, synthesis Monte Carlo phase space signal processing takes the form
\[
s \mapsto C \sum_n [\text{Tr} \circ \{V^*_f [S^{-1}_f s]\}] (g_n) f_{g_n}, \tag{27}
\]
and analysis Monte Carlo phase space signal processing takes the form
\[
s \mapsto C S^{-1}_f \sum_n [\text{Tr} \circ \{V_f [s]\}] (g_n) f_{g_n}, \tag{28}
\]
in case $\text{Tr} \circ \{V^*_f [S^{-1}_f s]\}$ and $\text{Tr} \circ \{V_f [s]\}$ can be explicitly evaluated on the sample set $\{g_n\}$.

In Sections 4 and 5 we derive approximation bounds for (24), (27) and (28). Next, we consider three examples of phase space signal processing pipelines with Monte Carlo approximation.
3.3.1 Stochastic phase space diffeomorphism

Let \( f : G \to \mathcal{H} \) be a bounded continuous frame, with bound \( \|f_g\|_\mathcal{H} \leq C \), based on a Riemannian manifold \( G \). Let \( d : G \to G \) be a diffeomorphism (invertible smooth mapping with smooth inverse), with Jacobian \( J_d \in L^\infty(G) \). Consider the diffeomorphism operator \( T \), defined for any \( F \in L^2(G) \) by

\[
[T F](g) = F(d^{-1}(g)).
\]

Let \( r : \mathbb{C} \to \mathbb{C} \) be a function that preserve modulus. Namely, \( |r(z)| = |z| \) for every \( z \in \mathbb{C} \).

By sampling the points \( d(g_n) \), synthesis Monte Carlo phase space diffeomorphism takes the form

\[
s \mapsto C \sum_n r(V_f[S_f^{-1}](g_n))f_{d(g_n)},
\]

and analysis Monte Carlo phase space diffeomorphism takes the form

\[
s \mapsto CS_f^{-1} \sum_n r(V_f[s](g_n))f_{d(g_n)}.\tag{29}
\]

**Example 12** (Integer time stretching phase vocoder). A time stretching phase vocoder is an audio effect that slows down an audio signal without dilating its frequency content. In the classical definition, \( G \) is the time frequency plane, and \( V_f \) is the STFT. Phase vocoder can be formulated as phase space signal processing in case the signal is dilated by an integer \( \Delta \) (see Section 6 for more details). For an integer \( \Delta \), we consider the diffeomorphism operator \( T \) with

\[
d(g_1, g_2) = (\Delta g_1, g_2),
\]

and consider the nonlinearity \( r \), defined by \( r(e^{i\theta} a) = e^{i\Delta \theta} a \), for \( a \in \mathbb{R} \) and \( \theta \in \mathbb{R} \) (for more details see Subsection 6.1). The phase vocoder is defined to be

\[
s \mapsto V_f^* Tr \circ V_f[s].
\]

Note that since the STFT is a coherent state system, there is no difference between analysis and synthesis signal processing.

3.3.2 Phase space multipliers

Given a function \( h \in L^\infty(G) \) called the symbol, and a continuous frame \( \{f_g\}_{g \in G} \), consider the linear operator \( H \) in \( \mathcal{H} \) defined for every \( s \in \mathcal{H} \) by

\[
H s = V_f^* h V_f[s].
\]

Here, \( h V_f[s] \) is the function in \( L^2(G) \) that assigns the value \( h(g)V_f[s](g) \) to each \( g \in G \). The synthesis and analysis phase space multiplier based on the symbol \( h \) and the frame \( f \) are defined respectively by

\[
s \mapsto V_f^* h V_f[S_f^{-1} s], \quad s \mapsto S_f^{-1} V_f^* h V_f[s].
\]

Now, synthesis and analysis Monte Carlo phase space multipliers take the following forms respectively

\[
s \mapsto C \sum_n h(g_n)V_f[S_f^{-1} s](g_n)f_{g_n}, \quad s \mapsto CS_f^{-1} \sum_n h(g_n)V_f[s](g_n)f_{g_n},
\]

for some appropriate normalization \( C \).

3.3.3 Phase space shrinkage

Let \( r : \mathbb{C} \to \mathbb{C} \) be a denoising operator, e.g., the soft thresholding function with threshold \( \lambda \)

\[
r(x) = e^{i\text{Arg}(x)} \max\{0, |x| - \lambda\},
\]

12
where $\text{Arg}(x)$ is the argument of the complex number $x$, namely $x = e^{i\text{Arg}(x)}|x|$. More generally, a denoising operator is any function $r(x)$ that decreases small values of $x$ and approximately retains large values of $x$. The synthesis and analysis phase space shrinkage based on the denoising operator $r$ and the frame $f$ are defined respectively by

$$s \mapsto V_f^* r \circ V_f[S_f^{-1}s], \quad s \mapsto S_f^{-1} V_f^* r \circ V_f[s].$$

Now, synthesis and analysis Monte Carlo phase space shrinkage take the following forms respectively

$$s \mapsto C \sum_n r(V_f[S_f^{-1}s](g_n))f_{g_n}, \quad s \mapsto CS_f^{-1} \sum_n r(V_f[s](g_n))f_{g_n},$$

for some appropriate normalization $C$.

### 3.4 Stochastic approximation of phase space operators

Suppose that $T$ of (19) or (21) is a phase space operator (Definition 8). Namely, there is some $R: G^2 \to \mathbb{C}$ such that

$$TF = \int_G R(\cdot, g)F(g)dg.$$  \hfill (31)

In this case, we consider the Monte Carlo approximation

$$TF = \int_G R(\cdot, g)F(g)dg \approx C \sum_m R(\cdot, y_m)F(y_m)$$  \hfill (32)

for some sample set $\{y_m\}_m \in G$. We then apply Monte Carlo synthesis, and obtain the approximation

$$V_f^*TF \approx C \sum_n \sum_m R(g_n, y_m)F(y_m)f_{g_n},$$  \hfill (33)

for some constant $C > 0$.

Now, synthesis Monte Carlo phase space signal processing takes the form

$$s \mapsto C \sum_n \sum_m R(g_n, y_m)r(V_f[S_f^{-1}s](f_{g_n})), \quad$$  \hfill (34)

and analysis Monte Carlo phase space signal processing takes the form

$$s \mapsto CS_f^{-1} \sum_n \sum_m R(g_n, y_m)r(V_f[s](f_{g_n})).$$  \hfill (35)

In Sections 3.4 and 3.5 we derive approximation bounds for (33), (34) and (35).

### 3.5 Monte Carlo sample sets for discrete signals

In this subsection we address the choice of the sample sets $\{g_n\}, \{y_m\} \subset G$. In the above analysis, the stochastic approximation is implemented directly on the signal processing pipeline, where in general the signal space $H$ is infinite dimensional, or consists of signals of “infinite resolution”. In application, signals are given as discrete entities with finite resolution $M$. Here, the resolution $M$ is defined to be the dimension of the discrete signal space. Apart from describing real-life signals, finite resolution plays to our advantage when constructing sample sets of $G$. In Sections 3.4 and 3.5 we consider phase space transforms of interest, and show that for discrete signals $s_M$ of resolution $M$, most of the energy of $V_f[s_M]$ tends to concentrate on a “small” domain in phase space, of measure/volume proportional to $M$. In this situation, we call the continuous frame linear volume discretizable. Since domains of finite measure can be treated as probability spaces, we can sample points randomly in the phase space of linear volume discretizable continuous frames, and thus define stochastic phase space signal processing. Moreover, in Monte Carlo theory the number of samples required for a certain accuracy is typically proportional to the volume of the domain of integration. Thus, since for linear volume discretizable frames this volume is proportional to $M$,
the required number of samples in the stochastic method is proportional to the resolution of the signal.

In Section 5 we define linear volume discretization. We show that the CWT, STFT, and our novel transform LTFT, defined in Subsection 3.6, are linear volume discretizable. We show that for discrete time signals of resolution $M$, supported in the time interval $[-M/2R, M/2R]$ for some $R > 0$, the frequency content concentrates about the frequency interval $[-R/2, R/2]$. As a result, most of the energy of the CWT, STFT or LTFT of such signals lies in the time-frequency domain $\text{time} \times \text{frequency} = [-M/2R, M/2R] \times [-R/2, R/2]$. This domain has area equal to $M$, which is equal to the resolution of the signals. Hence, stochastic phase space signal processing can be implemented efficiently with $O(M)$ samples. For the STFT, CWT and LTFT, we show that stochastic signal processing takes $O(M \log(M))$ operations, where $M$ is the resolution of the signal. This computational complexity is comparable to typical FFT based time-frequency methods.

### 3.6 Stochastic signal processing with the localizing time-frequency transform

We introduce in this paper a novel time-frequency transform, which we term the localizing time-frequency transform, or LTFT in short. The LTFT is derived from classical time-frequency transforms in two steps. First, by combining the STFT with the CWT we obtain a hybrid transform, and second, the time-frequency plane is enhanced by adding a third dimension.

The combination of the STFT with the CWT was studied in the past. Such frameworks, when based on group representations, are usually called affine Weyl-Heisenberg transforms (see e.g. [65, 66, 38]). In this paper we construct a combination of the STFT and the CWT which is a continuous frame, but not a wavelet transform. We find that omitting the wavelet and Parseval restrictions from our continuous frame makes it more flexible and applicable to signal processing.

When combining the STFT with the CWT, we take care to retain the best of each transform. The CWT is better than the STFT at isolating transient high frequency events, since high frequency wavelet atoms have shorter time supports. On the other hand, low frequency events are smeared by the CWT, since low frequency wavelet atoms have large supports. We thus use STFT atoms to represent low frequencies, and CWT atoms to represent middle frequencies. High frequencies are represented again by STFT atoms with narrow time supports. This is done to avoid false positive detection of very short transient events by very short wavelet atoms, which can produce audible artifacts in audio signal processing.

The LTFT has a 3-dimensional time-frequency phase space, as oppose to the 2-dimensional classical time-frequency plan. For that, we add a third dimension to the time-frequency plane of the hybrid STFT-CWT transform, controlling the number of oscillations in the atoms. The goal is to improve the quality of some time-frequency signal processing tasks, where different signal features are best represented by a different balance between the time and the frequency spreads. In Section 6 we explain in more detail the motivation behind the LTFT.

#### 3.6.1 The localizing time-frequency transform

Consider a non-negative real valued window $h(t)$ supported in $[-1/2, 1/2]$. For example, the Hann window is defined to be $h(t) = (1 + \cos(2\pi t))/2$, and zero for $t \notin [-1/2, 1/2]$. Consider a parameter $\tau$ that controls the number of oscillations in the CWT atoms. We denote by $0 < \tau_1 < \tau_2$ the minimal and maximal number of oscillations of the wavelet atoms. The LTFT phase space is defined to be $G = \mathbb{R}^2 \times [\tau_1, \tau_2]$, where the measure $\mu_3$ on $[\tau_1, \tau_2]$ is any weighted Lebesgue measure with $\mu_3([\tau_1, \tau_2]) = 1$. There are two transition frequencies in the LTFT, where the atoms change from STFT to CWT atoms and back. In general, we allow these transition frequencies $0 < a_\tau < b_\tau < \infty$ to depend on $\tau$.

**Definition 13** (The localizing time-frequency continuous frame). Consider the above setting. The LTFT atoms are defined for $(x, \omega, \tau) \in \mathbb{R}^2 \times [\tau_1, \tau_2]$, where $x$ represents time, $\omega$ frequencies, and $\tau$
the number of wavelet oscillations, by

$$f_{x, \omega, \tau}(t) = \begin{cases} \sqrt{\frac{\omega}{2\pi}} h\left(\frac{a_\tau}{\omega} (t-x)\right)e^{2\pi i\omega(t-x)} & \text{if } |\omega| < a_\tau \\ \sqrt{\frac{\omega}{2\pi}} h\left(\frac{\omega}{a_\tau} (t-x)\right)e^{2\pi i\omega(t-x)} & \text{if } a_\tau \leq |\omega| < b_\tau \\ \sqrt{\frac{\omega}{2\pi}} h\left(\frac{\omega}{b_\tau} (t-x)\right)e^{2\pi i\omega(t-x)} & \text{if } b_\tau \leq |\omega| \end{cases} \tag{36}$$

For $a_\tau \leq |\omega| \leq b_\tau$, we call the atoms $f_{x, \omega, \tau}(t) = \sqrt{\frac{\omega}{2\pi}} h\left(\frac{\omega}{a_\tau} (t-x)\right)e^{2\pi i\omega(t-x)}$ of CWT atoms. We adopt this terminology since $f_{x, \omega, \tau}$ is the translation by $x$ and dilation by $\omega$ of the “mother wavelet”

$$f_\tau(t) = \tau^{-1/2} h(1/\tau) e^{2\pi i t \tau} \tag{37}$$

However, the function $f_\tau$ is not really a mother wavelet, since for a.e. $\tau$ it does not satisfy the wavelet admissibility condition. Indeed, by the fact that $h$ is compactly supported, $h$ is non-zero almost everywhere, so $f_\tau(0) \neq 0$ for almost every $\tau$, and

$$\int \frac{1}{z} |f_\tau(z)|^2 dz = \infty \tag{38}$$

The divergence of (38) is not a problem in our theory, since the admissibility condition does not show up in the analysis of the LTFT. Indeed, high frequencies are analyzed using STFT atoms and not CWT atoms.

**Theorem 14.** The LTFT system $\{f_{x, \omega, \tau}\}_{x, \omega, \tau}^{\mathbb{R}^2 \times [\tau_1, \tau_2]}$ is a continuous frame.

The proof is in [12].

Note that for each $\tau_1 \leq \tau \leq \tau_2$, the support of the low and high frequency STFT windows are $2\tau/a_\tau$ and $2\tau/b_\tau$ respectively. Let us consider three cases for $a_\tau, b_\tau$. First, we may choose $a_\tau = a$ and $b_\tau = b$ constants. Second, if we want the supports of the low and high frequency STFT atoms to be the constants $J_1 > J_2$ respectively, we choose $a_\tau = 2\tau/J_1$ and $b_\tau = 2\tau/J_2$. In this case, the LTFT can be viewed as a CWT transform with variable number of oscillations $\tau$ of the wavelet atoms, where any atom supported on an interval longer than $J_1$ or shorter than $J_2$ is truncated/extended to a STFT atom supported on an interval of length $J_1$ or $J_2$ respectively. Last, we can choose $\tau_1 = \tau_2$, and obtain a hybrid STFT-CWT time-frequency transform with a 2-dimensional phase space.

### 3.6.2 The frame operator of the LTFT

To accommodate a computationally tractable signal processing pipeline, we derive an explicit formula for $S_f^{-1}$. Denote $\mathcal{J}^{\text{low}} = \{\omega \mid |\omega| < a_\tau\}$, $\mathcal{J}^{\text{mid}} = \{\omega \mid a_\tau \leq |\omega| \leq b_\tau\}$, $\mathcal{J}^{\text{high}} = \{\omega \mid b_\tau < |\omega|\}$. Let $\text{band} \in \{\text{low}, \text{mid}, \text{high}\}$, and denote

$$h^{\text{band}}(\tau; \omega; z - \omega) = \begin{cases} \sqrt{\frac{\omega}{2\pi}} h\left(\frac{\omega}{a_\tau} (z - \omega)\right) & \text{if } |\omega| < a_\tau \\ \sqrt{\frac{\omega}{2\pi}} h\left(\frac{\omega}{\omega} (z - \omega)\right) & \text{if } a_\tau \leq |\omega| \leq b_\tau \\ \sqrt{\frac{\omega}{2\pi}} h\left(\frac{\omega}{b_\tau} (z - \omega)\right) & \text{if } b_\tau \leq |\omega| \end{cases} \tag{39}$$

**Definition 15.** The sub-frame filters $\hat{S}_f^{\text{low}}$, $\hat{S}_f^{\text{mid}}$ and $\hat{S}_f^{\text{high}}$ are the functions $\mathbb{R} \rightarrow \mathbb{C}$ defined by

$$\hat{S}_f^{\text{band}}(z) = \int_{\tau_1}^{\tau_2} \int_{\mathcal{J}^{\text{band}}} |h^{\text{band}}(\tau; \omega; z - \omega)|^2 d\omega d\tau \tag{40}$$

The frame filter $\hat{S}_f : \mathbb{R} \rightarrow \mathbb{C}$ is defined by

$$\hat{S}_f = \hat{S}_f^{\text{low}} + \hat{S}_f^{\text{mid}} + \hat{S}_f^{\text{high}}.$$

**Proposition 16.** For any $s \in L^2(\mathbb{R})$, the frame operator is given by

$$\mathcal{F}[S_f s] = \hat{S}_f^{\text{low}} s + \hat{S}_f^{\text{mid}} s + \hat{S}_f^{\text{high}} s.$$
The proof is given in Proposition 16. Proposition 16 shows that $S_f$ is a linear non-negative filter. Proposition 16 also gives an explicit formula for $S_f^{-1}$ as the operator that multiplies by $\hat{S}^{-1}(z)$ in the frequency domain. The integrals (40) can be numerically estimated pre-processing and saved as part of the LTFT transform, and used each time the transform is applied on a signal. The theory guarantees that $\hat{S}_f(z)$ is stably invertible. In practice, for reasonable windows like the Hann window, $\hat{S}_f(z)$ is approximately a constant function, with small disturbances about the transition frequencies $a, b$.

### 3.6.3 Stochastic LTFT phase vocoder

We consider real valued time signals. Such signals are uniquely determined by the positive side of the frequency domain. Thus, in practice we only use atoms of positive frequencies, and reconstruct the negative frequency content post-processing by taking the real part of the output signal and multiplying by 2. The discrete signals we consider are supported at the time interval $[-M/2R, M/2R]$, with time samples at $\{nR\}_{n=-M/2}$. Here, $R > 0$ is the sample rate, and the positive frequency information of discrete signals lies in $[0, R/2]$.

Similarly to Example 12 and in the notations of (36), let $(x_n, \omega_n, \tau_n)$ be random samples from $G_M = [-M/2R, M/2R] \times [0, R/2] \times [\tau_1, \tau_2]$. Let $\Delta \in \mathbb{N}$ be the dilation integer. We define the stochastic integer time dilation phase vocoder as follows. The synthesis formulation is

$$s \mapsto C \sum_n r(V_f[S_f^{-1}s](x_n, \omega_n, \tau_n)) f_{\Delta x_n, \omega_n, \tau_n}. \tag{41}$$

The analysis formulation is

$$s \mapsto C S_f^{-1} \sum_n r(V_f[s](x_n, \omega_n, \tau_n)) f_{\Delta x_n, \omega_n, \tau_n}. \tag{42}$$

where $r$ is defined by $r(e^{i\theta} a) = e^{i\Delta \theta} a$, for $a, \theta \in \mathbb{R}$. Let $\tau_0 = \int_{\tau_1}^{\tau_2} r d\mu_3(\tau)$ be the average number of oscillations. In Subsection 6.3 we show that for discrete signals with $M$ time samples, the stochastic method takes $O(M\tau_0)$ floating point operations to obtain a fixed error tolerance. An additional complexity term of $O(M \log(M))$ is entailed by applying $S_f^{-1}$ via FFT. Note that the method has complexity $O(M \log(M))$, and introducing the third oscillation axis $\tau$ to phase space does not increase computational complexity with respect to classical time-frequency methods.

In Section 6 we discuss in more detail the application of LTFT to phase vocoder. Sound examples and code are available at [https://github.com/RonLevie/LTFT-Phase-Vocoder](https://github.com/RonLevie/LTFT-Phase-Vocoder).

### 4 Stochastic phase space signal processing of continuous signals

In this section we study the approximation properties of the stochastic continuous phase space signal processing methods (27), (28), (34) and (35). We show that the stochastic method coincides on average with the continuous method, and show that the average error between the stochastic method and the continuous method decays like $K^{-1/2}$ in the number of Monte Carlo samples $K$. We moreover present concentration of measure results, showing that the error is small in high probability.
4.1 Sampling in phase space

Let $F \in L^2(G)$, and let $f$ be a continuous frame, with frame kernel $K(g,g')$. The first issue to address is the fact that $G$ in general does not have finite measure, and thus uniform sampling is not defined on $G$. However, when $G$ has infinite measure, functions $F \in L^2(G)$ must decay in some sense “at infinity”, so it is possible to restrict our sampling to a compact domain of $G$, in which $F$ has most of its energy. More accurately, since $G$ is $\sigma$-finite, it is the disjoint union of at most countably many sets of finite measure. Namely, here are disjoint measurable sets $X_n$ of finite measure, with $\bigcup_{n \in \mathbb{N}} X_n = G$, such that for every $F \in L^2(G)$

$$\|F\|_{L^2(G)}^2 = \int_G |F(g)|^2 \, dg = \sum_{n \in \mathbb{N}} \int_{X_n} |F(g)|^2 \, dg = \sum_{n \in \mathbb{N}} \|F\|_{L^2(X_n)}^2. \quad (43)$$

Denote $G_n = \bigcup_{j=1}^n X_n$, and note that $\bigcup_{n \in \mathbb{N}} G_n = G$. Now, (43) is equivalent to

$$\|F\|_{L^2(G)}^2 = \lim_{n \to \infty} \|F\|_{L^2(G_n)}^2. \quad (44)$$

Thus, for every $\epsilon > 0$, there exists an indicator function $\psi_\epsilon$ of a measurable set of finite measure $|\psi_\epsilon|_1$, such that

$$\|\psi_\epsilon F - F\|_2 < \epsilon. \quad (44)$$

In general, we allow positive $\psi_\epsilon \in L^1(G) \cap L^\infty(G)$ with $|\psi_\epsilon|_1$ satisfying (44) and $|\psi_\epsilon|_\infty \leq 1$ which are not necessarily indicator functions. We call such a $\psi_\epsilon$ an envelope on $G$. Note that the function $\psi_\epsilon F$ approximates $F$. Now, samples can be drawn from $G$ according to the probability density $\frac{\psi_\epsilon}{\|\psi_\epsilon\|_1}$, supported on the domain we denote by $G_0 = \text{support}(\psi) \subset G$. In the following analysis we fix $\epsilon$, and replace the notation $\psi_\epsilon$ by $\psi$.

The need to approximate an infinite-measure/non-compact space by a finite-measure/compact one is a standard issue in digital signal processing. In classical discrete signal processing in the frequency domain, the conventional bridge between the analog and digital worlds involves such an approximation. A signal $f \in L^2(\mathbb{R})$ is first restricted to a compact frequency band $[a,b] \subset \mathbb{R}$, and then sampled on a finite grid in $[a,b]$, to produce a finite digital signal. Different signals $f$ require different bands $[a,b]$, in which they are nearly band-limited [57 Chapter 2.5.3]. Even though in this point of view the band $[a,b]$ depends on the signal $f$, it is customary to predefine the band $[a,b]$. Given a predefined band $[a,b]$, it is implicit that we can only treat signals having most of their frequency energy in $[a,b]$. Any frequency information outside of $[a,b]$ is lost or projected into the band, creating aliasing artifacts. Similarly, we restrict ourselves to a “band” in phase space defined by the envelope $\psi$, regardless of a specific function $F$. It is implicit that any data of $F$ outside of this band is lost in our analysis.

4.2 Input sampling in phase space operators

Given a phase space operator $T$ and its kernel function $R$, in this subsection we consider sampling the input variable $g$ of $R(g',g)$, and keeping the output variable $g'$ continuous. In Subsection 4.3 we show that sampling the output variable $g'$ is a special case of the framework developed in this subsection. Let $g \in G$ be a random sample according to the probability distribution $\frac{\psi(g)}{|\psi|_1}$. Consider the random rank one operator $T^0$, defined on $F$ by

$$g \mapsto T^0 F(g) = |\psi|_1 R(\cdot,g) F(g).$$

We also denote

$$T^0 F(g';g) = |\psi|_1 R(g',g) F(g),$$

where $g'$ is the variable of the output vector $T^0 F$ of $T^0$, and $g$ is the random variable of $T^0$. Next, we define the Monte Carlo approximation as a sum of independent $T^0 F$ vectors.
**Proposition 18.** Let $T$ be a phase space operator, and $K \in L^2(G)$. Consider $K$ copies of $G$, $G_k = G$, and a random sample \( \{g_k\}_{k=1}^K \) from $G_1 \times \ldots \times G_K$ according to the probability distribution $\prod_{k=1}^K \frac{\nu(g_k)}{\nu_k}$. Consider the random vectors $T_k^0 F : G_k \to L^2(G)$ defined for $g_k \in G_k$ by $[T_k^0 F](g_k) = [T^0 F](g_k)$, $k = 1, \ldots, K$. Define the random vector $T^K F : G_1 \times \ldots \times G_K \to L^2(G)$ by

$$[T^K F](g'; g^1, \ldots, g^K) = \frac{1}{K} \sum_{k=1}^K [T_k^0 F](g'; g^k) = \frac{1}{K} \sum_{k=1}^K \|v\|_1 R(g'; g^k) F(g^k),$$

We call $T^K F$ the Monte Carlo phase space operator applied on $F$ and based on $K$ samples, approximating $T F$.

When we want to make the distribution of the samples explicit, we denote $T^{\psi,K} F = T^K F$.

The expected value $\mathbb{E}^w(T^K F) \in L^2(G)$ of $T^K F$ is a function in $L^2(G)$ which we define as the weak $L^2(G)$ integral (see Definition 45 in [A])

$$\mathbb{E}^w(T^K F) = \int_{G^K} [T^K F](g; g^1, \ldots, g^K) dg^1, \ldots, dg^K.$$

Similarly, for uniformly square integrable phase space operators, we define the variance $\mathbb{V}^w(T^K F) \in L^{\infty}(G)$ as the weak $L^1(G)$ integral (see Definition 49 in [A])

$$\mathbb{V}^w(T^K F) = \int_{G^K} \|T^K F\|(g; g^1, \ldots, g^K) - \mathbb{E}^w(T^K F)\|^2 dg^1, \ldots, dg^K.$$

To quantify the magnitude of the variance $\mathbb{V}^w(T^K F)$, we would like to compute its $L^1(G)$ norm. However, $\mathbb{V}^w(T^K F)$ is only guaranteed to be in $L^{\infty}(G)$, in which $L^1(G)$ is a proper subspace. To bypass this limitation, we formally define the 1 norm of weak $L^1(G)$ integrals having non-negative integrands as follows. Consider a weakly integrable mapping $\nu : G \to L^1(G)$, where $\nu(g)\|_1 \geq 0$ is real and non-negative for a.e $g, t \in G$. We denote

$$\left\| \int G \nu(g)dg \right\|_1 := \left[ \int G \nu(g)dg \right](1) = \int G \int_{G} \nu(g, t) dg' dg,$$

where $1 \in L^\infty(G)$ is the constant function.

**Proposition 18.** Let $T$ be a phase space operator, and $F \in L^2(G)$. Then

1. The expected value is a weak $L^2(G)$ integral satisfying

$$\mathbb{E}^w(T^K F) = T(\psi F) \quad (45)$$

2. If $T$ is a uniformly square integrable phase space operator, with bound $D$, then

$$\mathbb{V}^w(T^K F) \leq \frac{1}{K} \mathbb{V}^w(T^0 F) \in L^{\infty}(G). \quad (46)$$

Moreover,

$$\left\| \mathbb{V}^w(T^K F) \right\|_1 \leq \frac{1}{K} \|\psi\|_1 D^2 \|F\|_2^2.$$

The proof of Section 1 of Proposition 62 follows directly from the definition of phase space operators as weak integrals. Indeed, for $T^0$,

$$\mathbb{E}^w(T^0 F)(g') = \int_G \frac{\psi(g)}{\|\psi\|_1} R(g', g) F(g) dg = T(\psi F)(g'),$$

and for $T^K$ we use linearity. The proof of Section 2 of Proposition 62 is in [A]. The convergence in Proposition 18 is in the strong topology, namely, pointwise in $F$. We note that convergence in
operator norm of the form “$\mathbb{E}^w(T^K) = T(\psi(\cdot))$” like in the finite dimensional matrix operator case [67] is not possible. Indeed, for any sample set $\{g^k\}_{k=1}^K$ there is a function $F \in L^2(G)$ supported in $G_0 \setminus \{g^k\}_{k=1}^K$, so $T^K F = 0$ and $\|T(\psi(\cdot)) - T^K\|_2 \geq \|T(\psi F) - T^K F\|_2 = \|T(\psi F)\|_2$. We thus focus in this paper on pointwise error estimates.

We can now bound the average square error in approximating $T[\psi F]$ by $T^K F$.

**Proposition 19.** Let $f$ be a continuous frame, and $T$ a uniformly square integrable phase space operator with bound $D$. Then

$$\mathbb{E}\left(\|T^K F - T(\psi F)\|_2^2\right) \leq \frac{\|\psi\|^2}{K} D^2 \|F\|_2^2,$$

where $\mathbb{E}\left(\|T^K F - T(\psi F)\|_2^2\right)$ is defined as a $\mu_G$-integral with respect to the variables $g^1, \ldots, g^K$.

**Proof.** Consider the random variable

$$\|T^K F - T[\psi F]\|_2^2.$$

By integrating against $1 \in L^\infty(G)$ in the definition of the weak $L^1(G)$ integral underlying $\mathbb{V}^w([T^K F])$, we have

$$\mathbb{E}\left(\|T^K F - T[\psi F]\|_2^2\right) = \int_G \int_G \|T^K F(g', g^1, \ldots, g^K) - T[\psi F](g')\|^2 \, dg' \psi(g^1) / |\psi|_1 \ldots |\psi(g^K)| / |\psi|_K \, dg' \ldots dg^K = \|\mathbb{V}^w([T^K F])(g')\|_{1 formal}^w,$$

which, by Proposition 18, completes the proof. \hfill \square

The following special case is important in later constructions.

**Example 20.** Consider the special case where $T = Q_f = V_f V_f^*$ is the Gramian operator, for a bounded continuous frame with $\|f\|_H \leq C$. Let $K$ be the frame kernel. We have

$$Q^K f = \|\psi\|_1 \sum_{k=1}^K F(g_k) K(g_k, \cdot).$$

and

$$\mathbb{E}^w(Q^K f) = Q[\psi F].$$

Let $B$ be the upper frame bound. We have

$$\|K(g, \cdot)\|_2 = \|V_f(f_g)\|_2 \leq B^{1/2} C,$$

so $Q_f$ is a uniformly square integrable phase space operator with bound $B^{1/2} C$. Thus,

$$\|\mathbb{V}^w(Q^K f)\|_{1 formal}^w \leq \frac{1}{K} \|\psi\|_1 B C^2 \|F\|_2^2,$$

and

$$\mathbb{E}\left(\|Q^K f - Q(\psi F)\|_2^2\right) \leq \frac{\|\psi\|^2}{K} B C^2 \|F\|_2^2.$$

**Remark 21.** In case of a bounded coherent state system, with a variable $\|f_g\|_H$, there is a way to improve the constants in the bounds of Example 20 replacing $C^2$ with 1. This is done by sampling $G_0$ non-uniformly as follows. We can define a normalized coherent state system $f_g = \frac{f_g}{\|f_g\|_H}$, and compensate for this normalization in the reconstruction formula by considering the weighted measure $\delta_g = |f_g|^2 \delta g$ on $G$. Working with $\tilde{f}_g$ and $\delta_g$ is equivalent to sampling $f_g$ in $G_0$ non-uniformly in $dg$ and multiplying the samples by corresponding scalars.

This modified sampling scheme is closely related to so-called leverage score sampling, frequently employed in the randomized numerical linear algebra.
4.3 Monte Carlo synthesis

In this subsection we use the results of Subsection 4.2 to define and analyze a Monte Carlo synthesis. The basic idea is to synthesize $F \in L^2(G)$ using only finite many random samples.

**Definition 22.** The Monte Carlo synthesis operator is defined to be

$$V_f^* K F = S_f^{-1} V_f^* Q_f^* F.$$

The following proposition formulates the Monte Carlo synthesis in terms of samples of the continuous frame atoms.

**Proposition 23.** $V_f^* K F = \|\psi\|_1 \sum_{k=1}^{K} F(g^k) f_{g^k}$.

**Proof.** By linearity, it is enough to prove for $K = 1$. By Lemma 7

$$V_f F = S_f V_f Q_f F = (V_f^* V_f^*) \|\psi\|_1 F(g)(g)$$

$$= \|\psi\|_1 F(g) V_f^* P_V(\mathcal{H}) V_f [g] = \|\psi\|_1 F(g) V_f^* V_f [g] = \|\psi\|_1 F(g) f_g.$$

Next, we show that $V_f^* K F$ approximates $V_f^*[\psi F]$.

**Proposition 24 (Synthesis Monte Carlo approximation rate).** Let $f$ be a bounded continuous frame with frame bounds $A, B$, and $\|f_g\|_H \leq C$. Then

$$\mathbb{E}\left( \|V_f^* K F - V_f^*[\psi F]\|_H^2 \right) \leq \frac{1}{K} \|\psi\|_1 A^{-1} B C^2 \|F\|_2^2.$$

**Proof.** By Lemma 7

$$\|V_f^* K F - V_f^*[\psi F]\|_H = \|S_f^{-1} V_f^* Q_f^* F - S_f^{-1} V_f^* Q_f^*[\psi F]\|_H$$

$$= \|V_f^* (Q_f^* F - Q_f^*[\psi F])\|_H$$

$$\leq \|V_f^*\| \|Q_f^* F - Q_f^*[\psi F]\|_2 \leq A^{-1/2} \|Q_f^* F - Q_f^*[\psi F]\|_2.$$

Indeed, by the frame bound $A^{1/2} \|s\|_H \leq |V_f[s]|_2$ for $s = V_f^* F$,

$$\|V_f^* F\|_H \leq A^{-1/2} \|V_f V_f^* F\|_2 = A^{-1/2} \|P_V(\mathcal{H}) F\|_2 \leq A^{-1/2} \|F\|_2.$$

Now, the result follows from Example 20.

4.4 Output sampling in phase space operators

Given a phase space operator $T$ with kernel $R$, to derive a fully discretized method, we sample the output variable $g'$ of $R(g', g)$ in addition to the input variable $g$. Since in a phase space signal processing procedure, $F = Tr \circ V_f[s]$ is then synthesized, it is enough to sample $V_f^* Tr \circ V_f[s]$.

We thus construct the approximation by first applying $T^{\psi,K}$, and then sampling the output variable using stochastic synthesis $V_f^* \eta,L$. Here, $\eta \in L^1(G) \cap L^\infty(G)$ is an envelope in phase space, supported on $G_1$, with the same assumptions as $\psi$, which is supported on $G_0$. Moreover, $L$ is the number of samples, and in general $\{\eta, L\}$ need not coincide with $\{\psi, K\}$. We allow a different sampling distribution for the output, since the domain in phase space that contains most of the energy of the signal may change after applying $T$. For example, a diffeomorphism operator warps the support of $\psi$, and a frame multiplier amplifies and suppresses different locations in phase space.
Definition 25 (Monte Carlo synthesized phase space operator). Consider $K$ random samples of $G_0$, $(g^k)_{k=1}^K$ with probability distribution $\frac{\mu}{\|\mu\|}$, and $L$ random samples of $G_1$, $(y^l)_{l=1}^L$ in the probability distribution $\frac{\phi}{\|\phi\|}$. We define

$$[V_f^*TF]^\eta,\psi,K : G_1^L \times G_0^K \rightarrow \mathcal{H}, \quad [V_f^*TF]^\eta,\psi,K = V_f^*\eta,\psi,K F,$$

as the random vector that maps $(y_1, \ldots, y_L, g_1, \ldots, g_K) \in G_1^L \times G_0^K$ to

$$\frac{\|\eta\|_1}{KL} \sum_{j=1}^L \sum_{k=1}^K R(y^j, g^k) F(g^k) f_{y^j}. \quad (49)$$

In the following we estimate the error of the stochastic method.

Proposition 26. Consider a bounded continuous frame with bound $A, B$, and $\|f\|_\mathcal{H} \leq C$. Let $T$ be a uniformly square integrable phase space operator, with bound $D$, and consider the Monte Carlo operator $T^{\eta,\psi,K}$. Then

$$\mathbb{E}\left( \| [V_f^*TF]^\eta,\psi,K - V_f^*\eta T[\psi F] \|_\mathcal{H}^2 \right) \leq 4 \frac{\|\psi\|_1}{K} D^2 B \|F\|_2^2 + 16 \frac{\|\eta\|_1}{KL} A^{-1} BC^2 D^2 \|F\|_2^2 + 16 \frac{\|\eta\|_1}{L} A^{-1} BC^2 \|T\|_2 \|F\|_2^2$$

$$= O\left( \frac{\|\psi\|_1}{K} + \frac{\|\eta\|_1}{L} + \frac{\|\eta\|_1}{KL} \right).$$

Here, $\mathbb{E}$ is a $\mu_{G,\mathcal{K}}^{L \times K}$-integral.

The proof is in $\mathbb{F}2$.

4.5 Error bounds in high probability

Propositions [19, 24] and [26] estimate the average square error of the stochastic approximations. In this subsection we show how to formulate the results as bounds on the error that hold in high probability. We show how to apply the classical concentration of measure estimates, Markov’s inequality and Bernstein’s inequality, in our setting.

First, we bound the error in Monte Carlo synthesis.

Proposition 27 (Stochastic synthesis concentration of error). Let $f$ be a bounded continuous frame with frame bounds $A$ and $B$, and with $\|f\|_\mathcal{H} \leq C$, and let $F \in L^2(G)$. Let $D^2 = A^{-1} BC^2$. Then with probability more than $1 - \delta$, we have

$$\| V_f^{*,\psi,K} F - V_f^*[\psi F] \|_\mathcal{H} \leq \frac{\sqrt{\|\psi\|_1}}{\sqrt{K}} D \|F\|_2 \kappa(\delta).$$

where $\kappa(\delta)$ can be chosen as one of the following two options.

1. Markov type error bound: $\kappa(\delta) = \delta^{-\frac{1}{2}}$.

2. Bernstein type error bound: $\kappa(\delta) = 4 \sqrt{\ln \left( \frac{1}{\delta} \right) + \frac{1}{4}}$ in case $F \in L^\infty(G)$ and $K$ is large enough, namely,

$$K \geq \|\psi\|_1 D^{-2} \|F\|_2^2 \frac{1}{16} \left( \ln \left( \frac{1}{\delta} \right) + \frac{1}{4} \right) E^2.$$

where $E = D \|F\|_\infty + \frac{1}{\|\psi\|_1} B^2 \|F\|_2$.

The proof is in $\mathbb{E}3$. Next, we bound error in synthesized Monte Carlo phase space operators.
Proposition 28 (Stochastic synthesized phase space operator concentration of error). Let $f$ be a bounded continuous frame with frame bounds $A$ and $B$, and with $\|f\|_H < C$, and let $T$ be a square integrable phase space operator with bound $D$. Let $F \in L^2(G)$. Then with probability more than $(1 - \delta)^2$ we have

$$\| [V^*_f T F]^{y,L,\psi,K} - V^*_f \eta T [\psi F] \|_H$$

$$\leq B^{1/2} D \| F \|_2 \frac{\sqrt{\|\psi\|_1}}{\sqrt{K}} \kappa(\delta) + A^{-1/2} B^{1/2} C D \| F \|_2 \frac{\sqrt{\|\psi\|_1}}{\sqrt{L}} \kappa(\delta)$$

$$+ A^{-1/2} B^{1/2} C \| T \|_2 \| F \|_2 \frac{\sqrt{\|\psi\|_1}}{\sqrt{L}} \kappa(\delta)$$

$$= O \left( \frac{\sqrt{\|\psi\|_1}}{\sqrt{K}} \kappa(\delta) + \frac{\sqrt{\|\psi\|_1}}{\sqrt{L}} \kappa(\delta)^2 \right) \| F \|_2,$$

where $\kappa(\delta)$ can be chosen as one of the following two options.

1. Markov type error bound: $\kappa(\delta) = \delta^{-\frac{1}{2}}$.

2. Bernstein type error bound: $\kappa(\delta) = 4 \sqrt{\ln(\frac{1}{\delta})} + \frac{1}{4}$ if $K$ and $L$ are large enough, $F \in L^\infty(G)$, and the kernel $R$ of $T$ is in $L^\infty(G^2)$.

The proof is in [43].

4.6 Approximation rate of stochastic phase space signal processing

Given the theory of Monte Carlo synthesized phase space operator, we can formulate the stochastic signal processing pipelines (34) and (35) more accurately.

Remark 29. The stochastic phase space signal processing procedure is given by the following pipelines.

1. Synthesis Monte Carlo phase space signal processing:

$$[V^*_f T_{r \circ (V_f)}]^{y,L,\psi,K} S_{f^{-1}}^{1,s} = V^*_f \eta \cdot L^*(T^{\psi,K,r} \circ (V_f[S_{f^{-1}}^{1,s}]))$$

$$= \frac{\|\eta\|_1 \|\psi\|_1}{KL} \sum_{j=1}^{L} \sum_{k=1}^{K} R(y^j, g^k) r \left( V_f[S_{f^{-1}}^{1,s}](g^k) \right) f_{y^j}, \quad (50)$$

2. Analysis Monte Carlo phase space signal processing:

$$S_f^{-1} [V^*_f T_{r \circ (V_f)}]^{y,L,\psi,K} S_f^{-1} = S_f^{-1} \eta \cdot L^*(T^{\psi,K,r} \circ (V_f[s]))$$

$$= S_f^{-1} \frac{\|\eta\|_1 \|\psi\|_1}{KL} \sum_{j=1}^{L} \sum_{k=1}^{K} R(y^j, g^k) r \left( V_f[s](g^k) \right) f_{y^j}, \quad (51)$$

Remark 30. Note that (50) and (51) involve the following computation.

1. For synthesis Monte Carlo phase space signal processing, define $\psi \in \mathbb{C}^K$ by $v_k = V_f[S_{f^{-1}}^{1,s}](g^k)$, and for analysis Monte Carlo phase space signal processing define $\psi \in \mathbb{C}^K$ by $v_k = V_f[s](g^k)$. This requires $K$ inner products.

2. Define the matrix $R \in \mathbb{C}^{K \times L}$ with entries $R_{j,k} = R(y^j, g^k)$.

3. Define $f \in H^k$ as the row signal-valued vector, with entries $f_{y^j}$. 

22
4. For synthesis Monte Carlo phase space signal processing, compute
\[ f \mathbf{R} r(S^{-1}\mathbf{v}), \]
and for analysis Monte Carlo phase space signal processing, compute
\[ S_f^{-1}f \mathbf{R} r(S^{-1}\mathbf{v}). \]

This requires an entry-wise application of \( r \) on \( \mathbf{v} \), a matrix multiplication by \( \mathbf{R} \), and the summation of \( K \) vectors from \( f \).

Propositions 24, 26, 27 and 28 can be now extended to the end-to-end phase space signal processing pipelines (50) and (51). Moreover, in case the envelopes \( \psi \) and \( \eta \) cover most of the energy of the signal in phase space, we can bound the error between the stochastic method and the accurate pipelines (20) and (22). The idea is to decompose the total error to an error due to the stochastic method and an error due to enveloping.

We consider the following two settings, for Monte Carlo synthesis and for synthesized Monte Carlo phase space operators.

**Assumption 31.** Let \( f \) be a bounded continuous frame. Let \( r : \mathbb{C} \rightarrow \mathbb{C} \) satisfy
\[ |r(x)| \leq E |x| \tag{52} \]
for some \( E \geq 0 \). Let \( \mathcal{C} \subset \mathcal{H} \) be a set of signals. Consider an envelope \( \psi \) satisfying
\[ \frac{\|V_f[s] - \psi V_f[s]\|_2}{\|s\|_\mathcal{H}} \leq \epsilon, \tag{53} \]
for every \( s \in \mathcal{C} \), where \( \epsilon > 0 \) is a constant. Let \( T : L^2(G) \rightarrow L^2(G) \) be a bounded operator, that maps most of the energy in the support of \( \psi \) to the support of the envelope \( \eta \), in the sense
\[ \|T\psi - \eta T\psi\|_2 \leq \epsilon. \tag{54} \]

Consider the signal processing pipeline \( \mathcal{H} \ni s \mapsto T s \), where
\[ Ts = V_f^* Tr \circ V_f[S_f^{-1}s] \quad \text{or} \quad Ts = S_f^{-1} V_f^* Tr \circ V_f[S_f^{-1}s]. \tag{55} \]

Suppose that one of the following two options is satisfied.

1. Monte Carlo synthesis: Consider the two stochastic approximations of the two pipelines (55)
\[ [Ts]^{\psi,K} = V_f^* \psi \circ Tr \circ (V_f)[S_f^{-1}s] \quad \text{or} \quad [Ts]^{\psi,K} = S_f^{-1} V_f^* Tr \circ (V_f)[s] \]
respectively. Denote \( M = \|\psi\|_1 \). Consider \( K = ZM \) Monte Carlo samples, where \( Z > 0 \), and denote \( [Ts]^K = [Ts]^{\psi,K} \).

2. Synthesis Monte Carlo phase space operator: Suppose that \( T \) is a square integrable phase space operator. Consider the two stochastic approximations of the two pipelines (55)
\[ [Ts]^{\eta,L;\psi,K} = [V_f^* Tr \circ (V_f)]^{\eta,L;\psi,K} S_f^{-1}s \quad \text{or} \quad [Ts]^{\eta,L;\psi,K} = S_f^{-1} [V_f^* Tr \circ (V_f)]^{\eta,L;\psi,K} s \]
respectively. Denote \( M = \max\{\|\psi\|_1, |\eta|_1\} \). Consider \( K = L = ZM \) Monte Carlo samples, where \( Z > 0 \), and denote \( [Ts]^K = [Ts]^{\eta,L;\psi,K} \).

The above setting assumes the existence of a signal class \( \mathcal{C} \) for which the envelopes cover most of the energy in phase space. In Subsection 5.3, we construct such classes for the STFT and the CWT, which are rich enough to model real-life signals. In Subsection 6.3, we construct such signal classes for the LTFT.

The next theorem studies the error in the stochastic method in the setting of Assumption 31. The theorem is also satisfied under Assumption 35 that will be discussed in Subsection 5.2.
Theorem 32. Consider the setting of Assumption 31 or Assumption 35. Then the following two bounds are satisfied for every \( s \in \mathcal{C} \).

1. 
\[
\mathbb{E}\left( \frac{\|TS - [TS]^K\|^2_{\mathcal{H}}}{\|s\|^2_{\mathcal{H}}} \right) = O(Z^{-1}) + O(\epsilon^2). 
\] (56)

2. With probability more than \( \nu \),
\[
\frac{\|TS - [TS]^K\|_{\mathcal{H}}}{\|s\|_{\mathcal{H}}} = O(Z^{-1/2})\kappa(\delta) + O(\epsilon),
\] (57)
where \( \nu \) is defined to be \( \nu = (1 - \delta) \) in Case 1 of Assumption 31 or 35 and \( \nu = (1 - \delta)^2 \) in Case 2 of Assumption 31 or 35. The term \( \kappa(\delta) \) can be chosen as one of the two following options.

- Markov type error bound: \( \kappa(\delta) = \delta^\frac{\gamma}{2} \).
- Bernstein type error bound: \( \kappa(\delta) = 4\sqrt{\ln \left( \frac{1}{\delta} \right) + \frac{1}{4}} \) if \( K \) is large enough, and
  - in case of 1 of Assumption 31 or 35, \( T \) maps \( L^\infty(G) \) to itself,
  - in case of 2 of Assumption 31 or 35, the kernel \( R \) of \( T \) is in \( L^\infty(G^2) \).

The proof is in [F21]

4.7 Stochastic diffeomorphism operator

In this section we use Proposition 32 of [F21] in the case of a stochastic diffeomorphism operator. Proposition 32 is the version of Theorem 32 with Case 1 of Assumption 31, which does not consider the enveloping error. Consider the diffeomorphism operator \( T \) of Subsection 3.3.1. The stochastic approximations take the form

- Synthesis Monte Carlo phase space diffeomorphism:
\[
[Ts]^{\psi,K} = \|\psi\|_1 \sum_{k=1}^{K} r\left(V_f[S_f^{-1} s](g^k)\right) f_d(g^k). 
\] (58)

- Analysis Monte Carlo phase space diffeomorphism:
\[
[Ts]^{\psi,K} = \|\psi\|_1 S_f^{-1} \sum_{k=1}^{K} r\left(V_f[s](g^k)\right) f_d(g^k). 
\] (59)

Here, the points \( \{g_k\}_{k=1}^{K} \) are sampled from the probability distribution \( \frac{\psi(g)}{\|\psi\|_1} \). This means that the points \( \{d(g_k)\}_{k=1}^{K} \) are sampled from the probability distribution
\[
\frac{\eta(g)}{\|\eta\|_1} = \frac{\psi(d(g))J_d(g)}{\|\psi(d(\cdot))J_d(\cdot)\|_1}. 
\]
where \( \eta(g) = \psi(d(g))J_d(g) \) and \( \|\eta\|_1 = \|\psi(d(\cdot))J_d(\cdot)\|_1 = \|\psi\|_1 \). By Proposition 32 approximates
\[
Ts = V_f^* \eta Tr \circ V_f[S_f^{-1} s],
\]
and (59) approximates
\[
Ts = S_f^{-1} V_f^* \eta Tr \circ V_f[S_f^{-1} s].
\]

In integer time stretching phase vocoder (Example 12), in the notations of Proposition 32, \( \|T\|_2 = \Delta, A = B = C = E = \|S_f^{-1}\| = 1 \), so we have the following two error bounds.
1. We have
\[ \mathbb{E}\left( \| [Ts]^{\psi,K} - Ts \|^2_{\mathcal{H}} \right) \leq \frac{\|\psi\|_G^2}{K} \Delta^2_s \|s\|^2_{\mathcal{H}}. \]

2. with probability more than \( 1 - \delta \), we have
\[ \| [Ts]^{\psi,K} - Ts \|^2_{\mathcal{H}} \leq \frac{\|\psi\|_G^2}{K} \Delta \|s\|_{\mathcal{H}} \kappa(\delta), \]

where \( \kappa(\delta) \) can be chosen as one of the following two options.

- **Markov type error bound**: \( \kappa(\delta) = \delta^{-\frac{1}{2}} \).
- **Bernstein type error bound**: \( \kappa(\delta) = 4\sqrt{\ln(\frac{1}{\delta})} + \frac{1}{2} \) in case \( K \) is large enough.

### 4.8 Integration of continuous frames

In this section we discuss how a set of continuous frames can be integrated into one continuous frame, while preserving the error bounds of the stochastic methods. Many methods can be seen as unifying a collection of frames, or other signal representations, into one. A simple example is the union of two orthonormal bases into one system to promote sparsity [13, 25]. In discrete frame theory for example, the union of a finite set of frames is a frame, and the union of tight frames is a tight frame. Fusion frames generalize the frame atoms of discrete frames to subspaces [9, 10], allowing to take unions of a countable set of frames of “overlapping” subspaces. Another related theory for example, the union of two orthonormal basis into one system to promote sparsity [18, 25]. In discrete frame theory, the union of a finite set of frames is a frame, and the union of tight frames is a tight frame. Fusion frames generalize the frame atoms of discrete frames to subspaces [9, 10], allowing to take unions of a countable set of frames of “overlapping” subspaces. Another related theory for example, the union of two orthonormal basis into one system to promote sparsity [18, 25].

Let \( G \) and \( U \) be two topological spaces with \( \sigma \)-finite Borel measures \( \mu_G, \mu_U \) respectively, with \( \mu_U(U) = 1 \). Suppose that for each \( u \in U \), \( \{f_{g,u}\}_{g \in G} \) is a bounded continuous frame over the phase space \( G \), and the same signal space \( \mathcal{H} \) for all \( u \in U \). Suppose that for every \( u \in U \), the frame bounds of \( \{f_{g,u}\}_{g \in G} \) are the global constants \( A, B \) and \( \|f_{g,u}\|_{\mathcal{H}} \leq C \). Suppose moreover that the mapping \((g,u) \mapsto f_{g,u}\) is continuous. We now consider the mapping \( V_f \) that takes \( s \in \mathcal{H} \) to the function
\[ V_f[s](g,u) = \langle s, f_{g,u} \rangle. \]

By continuity of \((g,u) \mapsto f_{g,u}\), \( V_f[s] \) is continuous for every \( s \in \mathcal{H} \). Indeed
\[ |V_f[s](g,u) - V_f[s](g',u')| = |\langle s, f_{g,u} \rangle - \langle s, f_{g',u'} \rangle| \leq \|s\|_{\mathcal{H}} \|f_{g,u} - f_{g',u'}\|_{\mathcal{H}}. \]

Thus, for every \( s \in \mathcal{H} \), \( V_f[s] : G \times U \rightarrow \mathbb{C} \) is a measurable function. More generally, we may extend the assumption of continuity of \((g,u) \mapsto f_{g,u}\) and assume that for every \( s \in \mathcal{H} \), \( V_f[s] : G \times U \rightarrow \mathbb{C} \) is a measurable function.

For each \( u \in U \), denote by \( V_{f_u} \) the analysis operator corresponding to the continuous frame \( \{f_{g,u}\}_{g \in G} \). By Fubini-Tonelli theorem, for every signal \( s \in \mathcal{H} \)
\[ \|V_f[s]\|^2_{2,\mathcal{H}} = \int_{G \times U} |\langle s, f_{g,u} \rangle|^2 d(g,u) = \int_U \int_G |\langle s, f_{g,u} \rangle|^2 dgdu = \int_U \|V_{f_u}[s]\|^2_{2,\mathcal{H}} du. \]

Therefore,
\[ A \|s\|^2_{\mathcal{H}} = \int_U A \|s\|^2_{\mathcal{H}} du \leq \|V_f[s]\|^2_{2,\mathcal{H}} \leq \int_U B \|s\|^2_{\mathcal{H}} du = B \|s\|^2_{\mathcal{H}}. \]

and \( \{f_{g,u}\}_{(g,u) \in G \times U} \) is a continuous frame with frame bounds \( A, B \).

Suppose that we use the same envelope \( \psi \in L^1(G) \) for each frame \( \{f_{g,u}\}_{g \in G} \). Suppose moreover that for some class \( C \subset \mathcal{H} \) of signals \( s \), the envelope \( \psi \) covers most of the energy of signals \( s \in C \) in all phase spaces \( u \in U \). Namely, for every \( s \in C \) and every \( u \in U \)
\[ |V_{f_u}[s] - \psi V_{f_u}[s]|_2 \leq \epsilon \|V_{f_u}[s]\|_2 \leq \epsilon B^{1/2} \|s\|_{\mathcal{H}} \]

(60)
for some small $\epsilon$. Denote by abuse of notation $\psi \in L^1(G \times U)$ the function $\psi(g, u) = \psi(g)$. Here, $\|\psi\|_{L^1(G \times U)} = \|\psi\|_{L^1(G)} < \infty$. Now, $\psi$ covers most of the energy in the phase space $G \times U$ of signals in $\mathcal{C}$. Indeed, by Fubini-Tonelli theorem

$$|V_f[s] - \psi V_f[s]|_2^2 = \int_U |V_{f_k}[s] - \psi V_{f_k}[s]|_2^2 \, du \leq \epsilon^2 \|V_f[s]\|_2^2 \leq \epsilon^2 B \|s\|_2^2.$$  \hspace{1cm} (61)

In the signal processing pipeline, we consider an operator $T : L^2(G \times U) \rightarrow L^2(G \times U)$ in phase space with the following property. There is an operator $T_G : L^2(G) \rightarrow L^2(G)$ such that for every $F \in L^2(G \times U)$ and a.e $(g, u) \in G \times U$,

$$[TF](g, u) = [T_G F(\cdot, u)](g).$$

For example, $T$ may be a diffeomorphism operator in $L^2(G)$.

**Remark 33.** More generally, it is possible to use weak operator integrals, defined similarly to weak vector integrals by the Riesz representation theorem, and to define $T$ as the weak integration along the $U$ direction of a family of operators $\{T_u : L^2(G) \rightarrow L^2(G)\}_{u \in U}$.

We consider a non-linearity $r$, and denote $F = T \sigma \circ V_f[s]$. We have $F(\cdot, u) = T_G \sigma \circ V_{f_k}[s]$ for a.e $u \in U$. We suppose that property (60) is preserved in the following sense. For a.e $u \in U$,

$$|F(\cdot, u) - \sigma F(\cdot, u)|_2^2 \leq \epsilon |F(\cdot, u)|_2.$$  \hspace{1cm} (62)

Similarly to (61), $F$ has the property

$$\|F - \sigma F\|_2^2 = \int_U |F(\cdot, u) - \sigma F(\cdot, u)|_2^2 \, du \leq \epsilon \|F\|_2.$$  \hspace{1cm} (63)

More generally, we consider $T_G$ and every $\{f_{g,u}\}_{g \in G}$, $u \in U$, all sharing the same conditions of Assumption (61) of Theorem (32) in the phase space $G$. Similarly to the Fubini-Tonelli trick of (63), we can prove by Theorem (32) that

$$\mathbb{E}\left(\frac{|\mathcal{T}s - [\mathcal{T}s]_G^K|^2}{s}_H\right) = O(Z^{-1}) + O(\epsilon^2),$$

and with probability more than $\kappa$,

$$\frac{|\mathcal{T}s - [\mathcal{T}s]_G^K|}{s}_H = O(Z^{-1/2})\kappa(\delta) + O(\epsilon),$$

where $\kappa(\delta) = \delta^{1/2}$ or $\kappa(\delta) = 4 \sqrt{\ln(\frac{1}{\delta}) + \frac{1}{4}}$ in case $K$ is large enough. Here, $\|\mathcal{T}s - [\mathcal{T}s]_G^K\|_H$ is one of the signal processing pipelines with respect to $\mathcal{T}$, in the phase space $G \times U$.

By the fact that $\|\psi\|_{L^1(G)} = \|\psi\|_{L^1(G \times U)}$, the number of Monte Carlo samples $\{g^k\}_k$ of $\{f_{g,u}\}_{g \in G}$ for fixed $u$, and the number of samples $\{(g^k, u^k)\}_k$ of $\{f_{g,u}\}_{(g,u) \in G \times U}$, required for a fixed error tolerance $Z^{-1} = \frac{|\psi|}{\kappa}$, is identical. In this situation, increasing the dimension of phase space does entail any increase in computational complexity. Note that in regular discretizations (i.e. grid based) of continuous frames, adding a dimension typically multiplies the computational complexity by the number of samples along this dimension.

## 5 Stochastic phase space signal processing of discrete signals

The last step in making the stochastic method practical is discretizing the signal space $\mathcal{H}$. The main goal in this section is to relate the choice of $\|\psi\|_1$ to the resolution $M$ of the discretization.
of \( s \). By this, we can estimate the number of Monte Carlo samples needed to achieve a good approximation, in terms of the \( M \). We show that in time-frequency analysis \( \|s\|_1 = O(M) \) independently of the dimension of phase space, and thus a stochastic signal processing in phase space method requires \( K, L = ZM \) samples (with \( Z > 0 \), for the approximation error of the method to be \( O(\frac{1}{\sqrt{M}}) \).

5.1 Linear volume discretization of continuous frames

In this subsection we define continuous frames and discrete signals, for which most of the energy in phase space lies in a domain of volume proportional to the resolution of the discrete signal space. We start by defining basic notions. For \( \psi \in L^\infty(G) \), denote by abuse of notation the multiplicative operator

\[
\psi : L^2(G) \to L^2(G), \quad [\psi F](g) = \psi(g)F(g)
\]

Let \( \{V_M\}_{M=1}^\infty \) be a sequence of subspaces of \( \mathcal{H} \), where each \( V_M \) has finite dimension \( \dim(V_M) \). Let \( P_M \) be the orthogonal projection upon \( V_M \). If for every \( s \in \mathcal{H} \),

\[
\lim_{M \to \infty} \|P_M s - s\|_\mathcal{H} = 0,
\]

we call \( \{V_M\}_{M=1}^\infty \) a discretization of \( \mathcal{H} \). We call \( \dim(V_M) \) the resolution of the discrete signal space \( V_M \). In our analysis we do not need assumptions on how the discrete spaces \( V_M \) are constructed. For example, \( V_M \) may be spans of subsequences of orthonormal basis or frames for which the projection method works \([11]\).

The idea in discretizing a continuous frame, is to find an envelope \( \psi_M \) for each discrete space \( V_M \), such that for any \( s \in \mathcal{H} \), the approximation error of \( V_f[P_M s] \) by \( \psi_M V_f[P_M s] \) is controlled. The functions \( \psi_M \) are interpreted as finite measure envelopes in phase space, covering domains \( G_M \) in which most of the energy of functions from \( V_f[V_M] \) resides. In Subsection 5.3 we show that in some continuous frames, like STFT and CWT, the required volume of \( G_M \) for some error tolerance is linear in the resolution \( M \). In a sense, the amount of information in phase space, required to describe a discrete signal, is proportional to the resolution of the discrete signal space, or to the amount of information required to define a discrete signal.

In our analysis, we sometimes restrict ourselves to a class of signals \( \mathcal{R} \subset \mathcal{H} \). We typically consider \( \mathcal{R} \) defined by imposing a restriction on signals in \( \mathcal{H} \) which is natural for real life signals of some type. The class \( \mathcal{R} \) need not be a linear space. In this context we consider two notions of discretization. First, we say that \( \{V_M \cap \mathcal{R}\}_{M=1}^\infty \) is a discretization of \( \mathcal{R} \) if for every \( s \in \mathcal{R} \) and every \( M \in \mathbb{N} \) there is \( s_M \in V_M \cap \mathcal{R} \) such that

\[
\lim_{M \to \infty} \|s_M - s\|_\mathcal{H} = 0.
\]

Second, in case \( V_M \) are disjoint from \( \mathcal{R} \), we say that \( \{V_M\}_{M=1}^\infty \) is a discretization of \( \mathcal{R} \) if for every \( s \in \mathcal{R} \) and every \( M \in \mathbb{N} \) there is \( s_M \in V_M \) such that

\[
\lim_{M \to \infty} \|s_M - s\|_\mathcal{H} = 0.
\]

Next, we define the notion of linear volume discretization.

Definition 34. Let \( f : G \to \mathcal{H} \) be a continuous frame. Let \( \mathcal{R} \subset \mathcal{H} \) be a class of signals, such that \( \{V_M \cap \mathcal{R}\}_{M=1}^\infty \) is a discretization of \( \mathcal{R} \), with finite dimension \( \dim(V_M) \) for each \( M \in \mathbb{N} \).

1. The continuous frame \( f \) is called linear volume discretizable with respect to the class \( \mathcal{R} \) and the discretization \( \{V_M \cap \mathcal{R}\}_{M=1}^\infty \), if for every error tolerance \( \epsilon > 0 \) there is a constant \( C^\epsilon > 0 \) and \( M_0 \in \mathbb{N} \), such that for any \( M \geq M_0 \) there is an envelope \( \psi_M \) with

\[
\|\psi_M\|_1 \leq C^\epsilon \dim(V_M)
\]

such that for any \( s_M \in \mathcal{R} \cap V_M \),

\[
\frac{\|V_f[s_M] - \psi_M V_f[s_M]\|_2}{\|V_f[s_M]\|_2} < \epsilon.
\]
2. For a linear volume discretizable continuous frame $f$ with respect to $\mathcal{R}$ and $\{V_M \cap \mathcal{R}\}_{m=1}^\infty$, and a fixed tolerance $\epsilon > 0$ with a corresponding fixed $C^\alpha$ and envelope sequence $\{\psi_M\}_{m=1}^\infty$ satisfying (64) and (65), we call $f$ together with $\mathcal{R}$, $\{V_M \cap \mathcal{R}\}_{m=1}^\infty$, and $\{\psi_M\}_{m=1}^\infty$, an $\epsilon$-linear volume discretization of $f$.

5.2 Error in discrete stochastic phase space signal processing

In this subsection we study the error in discrete stochastic phase space signal processing. For this, we reformulate Assumption 31 to the setting of linear volume discretization.

**Assumption 35.** Let $f$ be a bounded continuous frame. Let $r : \mathbb{C} \rightarrow \mathbb{C}$ satisfy (52) (namely $|r(z)| \leq E|x|$). Suppose that $f$ together with the signal class $\mathcal{R}$, the discretization $\{V_M \cap \mathcal{R}\}_{m=1}^\infty$, and the envelopes $\{\psi_M\}_{m=1}^\infty$, is an $\epsilon$-linear volume discretization of $f$, with constant $C^\alpha$. Let $T$ be a bounded operator that maps most of the energy in the supports of $\psi_M$ to the supports of the envelope $\eta_M$, in the sense

$$\|T\psi_M - \eta_M T\psi_M\|_2 \leq \epsilon. \tag{66}$$

Here, $\{\eta_M\}_{m=1}^\infty$ satisfy

$$\|\eta_M\|_1 \leq C^\alpha \dim(V_M) \tag{67}$$

with the same linear volume constant $C^\alpha$ as $\psi_M$. Consider the signal processing pipeline $\mathcal{H} \circ s \mapsto Ts$, where

$$Ts = V_f^* Tr \circ V_f[S_f^{-1}s] \text{ or } Ts = S_f^{-1} V_f^* Tr \circ V_f[S_f^{-1}s], \tag{68}$$

Suppose that one of the following two options is satisfied.

1. **Monte Carlo synthesis:** Consider the two stochastic approximations of the two pipelines (68)

$$[Ts]_{\psi,K} = V_f^* V_f \circ (V_f)[S_f^{-1}s] \text{ or } [Ts]_{\psi,K} = S_f^{-1} V_f^* Tr \circ (V_f)[s]$$

respectively. Consider $K = ZC^\alpha \dim(V_M)$ Monte Carlo samples, where $Z > 0$, and denote $[Ts]^K = [Ts]_{\psi,K}$.

2. **Synthesis Monte Carlo phase space operator:** Suppose that $T$ is a square integrable phase space operator. Consider the two stochastic approximations of the two pipelines (68)

$$[Ts]_{\psi,K,L} = (V_f^* Tr \circ (V_f))[S_f^{-1}s] \text{ or } [Ts]_{\psi,K,L} = S_f^{-1} [V_f^* Tr \circ (V_f)][S_f^{-1}s]$$

respectively. Consider $K = L = ZC^\alpha \dim(V_M)$ Monte Carlo samples, where $Z > 0$, and denote $[Ts]^K = [Ts]_{\psi,K,L}$.

Now, Theorem 32 is also satisfied under Assumption 35.

**Remark 36** (Error in integration of discretized continuous frames). Using Theorem 32 based on Assumption 65 and similarly to Subsection 4.8, we can show that the error entailed by integrating $\epsilon$-linear discretizations of continuous frames, all sharing the same envelope sequence $\{\psi_M\}_{m=1}^\infty$, signal class $\mathcal{R}$, and volume constant $C^\alpha(\epsilon)$, is independent of the dimension of the integration space $U$.

The property of Remark 36 is useful when the definition of a certain continuous frame depends on free parameters, and a subset of these parameters share the same linear volume discretization. In this situation we may keep these parameters free by adding them as additional dimensions in phase space. For example, in the STFT and the CWT the window function and mother wavelet are free parameters. Instead of fixing the window function, we may consider a parametric set of window functions sharing the same linear volume discretization, and consider the parameters as additional dimensions of phase space. For example, for the CWT we may choose as parameters the spread of the mother wavelet and its chirpiness (the rate at which oscillations become faster in the mother wavelet). In fact, this situation is true for arbitrary generalized wavelet transform, since the window function is always a free parameter. This observation is the basis on which we construct the LTFT (Definition 13).
5.3 Discrete stochastic time-frequency signal processing

In this subsection we present three discretizations under which the CWT and the STFT are linear volume discretizable. In the first two cases we consider the following setting. We analyze time signals \( s : \mathbb{R} \to \mathbb{C} \) by decomposing them to compact time interval sections. Without loss of generality, we suppose that each signal segment is supported in \([-1/2, 1/2]\). Indeed, the restriction of the signal to any compact intervals can be transformed by an affine linear change of variables to the support \([-1/2, 1/2]\). We consider two regimes for segmenting the signal. One option is to restrict the signal \( s : \mathbb{R} \to \mathbb{C} \) to finite intervals \( \{I_k \in \mathbb{R}\}_{k \in \mathbb{Z}} \) to obtain \( s_k = s|_{I_k} \), and suppose that
\[
 s = \sum_{k \in \mathbb{Z}} s_k. \tag{69}
\]

Another option is to consider a partition of unity \( \{\xi_k \in L_2^\infty(\mathbb{R})\}_{k \in \mathbb{Z}} \) where each \( \xi_k \) is supported on a compact interval, positive in its support, and \( \sum_{k \in \mathbb{Z}} \xi_k(x) = 1 \) for every \( x \in \mathbb{R} \). We then consider the signal segments \( s_k = \xi_k s \), and observe that (69) is satisfied. We call the multiplication of \( s \) by \( \xi_k \) enveloping. In either of these two regime, we carry out the time-frequency analysis for each signal segment separately, assuming it is supported in \([-1/2, 1/2]\). For the STFT we also consider discretizing band-limited signals in \( L_2^2(\mathbb{R}) \).

5.3.1 Discrete stochastic CWT

Consider a CWT based on an admissible mother wavelet \( f \in L_2(\mathbb{R}) \) with compact time support \([-S, S]\) for some \( S > 0 \). For the CWT we consider the partition of unity regime, where our signal segment \( q \) is defined as \( q(x) = \xi(x)s(x) \) and both \( \xi \) and \( s \) are supported in \((-1/2, 1/2]\). We assume that \( \xi \) is non-negative, continuously differentiable, and obtains zero only at \(-1/2 \) and \( 1/2 \).

We prove linear discretization for the following class of signals.

**Definition 37.** Let \( C > 0 \). The class \( \mathcal{R}_C \) is the set of all signals \( q \in L_2^2[-1/2, 1/2] \) such that
\[
 \|\xi^{-1}q\|_\infty < C \|q\|_\infty \tag{70}
\]
and
\[
 \|q\|_\infty < C \|q\|_2. \tag{71}
\]

**Remark 38.** We interpret \( \mathcal{R}_C \) as follows.

1. Equation (70) assures that enveloping \( s \) by \( \xi \) does not eliminate most of the content of \( s \). To see this, by \( q = \xi s \), equation (71) can be written as
\[
 \|s\|_\infty < C \|\xi s\|_\infty. \tag{72}
\]

Enveloping \( s \) with \( \xi \) can in principle eliminate the content of \( s \) near \(-1/2 \) and \( 1/2 \), since \( \xi \) is zero there. The signal \( s \) could approach \( \infty \) at \(-1 \) and \( 1 \), but \( q \) would be zero there, so multiplying \( s \) by \( \xi \) discards most of the content of \( s \). However, (72) assures that enveloping \( s \) with \( \xi \) does not eliminate most of the content of \( s \).

2. Equation (71) assures that the energy of \( q \) is well spread on the interval \([-1/2, 1/2]\). Indeed, no small subset of \([-1/2, 1/2]\) can contain most of the energy of \( q \), otherwise \( \|q\|_\infty \) would be significantly larger than \( \|q\|_2 \).

We consider the following discretization of \( L_2^2(-1/2, 1/2) \). For each \( M \in \mathbb{N} \),
\[
 V_M = \text{span}\{e^{2\pi imx}\xi(x)\}_{m=-M}^M. \tag{73}
\]

Namely, \( V_M \) is the space of enveloped trigonometric polynomials of order \( M \). It is easy to see that \( V_M \) is indeed a discretization of \( L_2^2(-1/2, 1/2) \). We moreover have the following.

**Claim 39.** The sequence of spaces \( \{V_M \cap \mathcal{R}_C\}_{M \in \mathbb{N}} \) is a discretization of \( \mathcal{R}_C \).
The proof is in \[F.3\].

Let \( W > 0 \). For each \( M \in \mathbb{N} \) we consider the following phase space domain \( G_M \subset G \), where \( G \) is the wavelet time-frequency plane (see \([E]\)).

\[
G_M = \{(x, \omega) \mid W^{-1}M^{-1} < |\omega| < WM, |x| < 1/2 + S/\omega\}. \tag{74}
\]

The area of \( G_M \) in the time-frequency plane is, for large enough \( M \),

\[
\mu(G_M) = 2 \int_{W^{-1}M^{-1}}^{WM} (1 + 2S/\omega)d\omega \leq 2WM + 8S\ln(WM) \leq 3WM. \tag{75}
\]

Denote

\[
\psi_M(g) = \begin{cases} 1 & , \ g \in G_M \\ 0 & , \ g \notin G_M. \end{cases} \tag{76}
\]

**Proposition 40.** Consider a smooth enough \( \xi \) in the sense

\[
\tilde{\xi}(z) \leq \begin{cases} D & , \ |z| \leq 1 \\ Dz^{-k} & , \ |z| > 1 \end{cases} \tag{77}
\]

for some \( k > 2 \) and \( D > 0 \), and the corresponding discrete spaces \( \{V_M\}_{M \in \mathbb{N}} \). The continuous wavelet transform with a compactly supported mother wavelet \( f \in L^2(\mathbb{R}) \) is linear volume discretizable with respect to the class \( R_C \) and the discretization \( \{V_M\}_{M \in \mathbb{N}} \), with the envelopes \( \psi_M \) defined by (76) for large enough \( W \) that depends only on \( \epsilon \) of Definition \([F.4]\).

The proof is in \([F.5]\).

### 5.3.2 Discrete stochastic STFT

In this subsection we consider signals supported in the time interval \([-1/2, 1/2]\) as before, and the signal class \( \mathcal{R} \) for linear volume discretization is the whole space \( L^2[-1/2, 1/2] \). Let \( V_M \) be the space of trigonometric polynomials or order \( M \) (namely, finite Fourier series expansions). In the frequency domain, signals \( q \in V_M \) are represented by

\[
\hat{q}(z) = \sum_{n=-M}^{M} c_n \text{sinc}(z - n)
\]

where \( c_n \) are the Fourier coefficients of \( q \), and sinc is the Fourier transform of the indicator function of the interval \([-1/2, 1/2]\).

Consider a window function \( f \) supported at the time interval \([-S, S]\) that satisfies the following. There are constants \( C', Y > 0 \), and \( \kappa > 1/2 \), such that for every \( z > Y \) or \( z < -Y \)

\[
\hat{f}(z) \leq C'|z|^{-\kappa}. \tag{78}
\]

Let \( W > 0 \). For each \( M \in \mathbb{N} \) we consider the following phase space domain \( G_M \subset G \), where \( G \) is the STFT time-frequency plane,

\[
G_M = \{(x, \omega) \mid -WM < \omega < WM, |x| < 1/2 + S\}. \tag{79}
\]

The area of \( G_M \) in the time-frequency plane is

\[
\mu(G_M) = 2WM(1 + 2S). \tag{80}
\]

Denote

\[
\psi_M(g) = \begin{cases} 1 & , \ g \in G_M \\ 0 & , \ g \notin G_M. \end{cases} \tag{81}
\]

**Proposition 41.** Under the above setting, the short time Fourier transform is linear volume discretizable with respect to the class \( L^2[-1/2, 1/2] \) and the discretization \( \{V_M\}_{M \in \mathbb{N}} \), with the envelopes \( \psi_M \) defined by (81) for large enough \( W \) that depends only on \( \epsilon \) of Definition \([F.4]\).
The proof is in \[\text{(30)}\]

As a corollary of Proposition \[\text{(40)}\], we can derive a linear volume result on a different signals class. Let \( R > 0 \), and consider the space \( V^R_M \) of time signals \( q \in L^2(-\frac{M}{2R}, \frac{M}{2R}) \) such that the dilated signal \( \tilde{q}\left(\frac{t}{M}\right) \) is in \( V_M \) of the above construction. The spaces \( V^R_M \) discretize the space \( \text{PW}_R \) of band-limited signals with frequency support \([-R, R]\). The space \( \text{PW}_R \) can be seen as a class of signals with constant sample rate: \( R \) samples per time unit. Thus, \( V^R_M \) is seen as a class of signals supported at \((-\frac{M}{2R}, \frac{M}{2R})\) with \( R \) samples per time unit.

Here, the envelopes are defined as follows. Let \( W > 0 \). For each \( M \in \mathbb{N} \) we consider
\[
G^R_M = \left\{(x, \omega) \mid -WR < \omega < WR, -\frac{M}{2R} - S < x < \frac{M}{2R} + S\right\}.
\]  
(82)

The area of \( G^R_M \) is the time-frequency space is
\[
\mu(G^R_M) = WM\mathcal{O}(1).
\]  
(83)

Denote
\[
\psi^R_M(q) = \begin{cases} 
1 & , q \in G^R_M \
0 & , q \notin G^R_M.
\end{cases}
\]  
(84)

**Corollary 42.** Under the above setting, the short time Fourier transform is linear volume discretizable with respect to the class \( \text{PW}_M \) and the discretization \( \{V^R_M\}_{M \in \mathbb{N}} \), with the envelopes \( \psi^R_M \) defined by \[\text{(84)}\] for large enough \( W \) that depends only on \( \epsilon \) of Definition \[\text{(74)}\].

6 Stochastic localizing time-frequency transform and phase vocoder

In this section we recall the classical integer time dilation phase vocoder method, and motivate the stochastic LTFT phase vocoder. We then show that the LTFT is linear volume discretizable, and show that stochastic LTFT phase vocoder takes \( O(M) \) floating point operations, where \( M \) is the resolution of the discrete signal.

6.1 Classical integer time dilation phase vocoder

Phase vocoder is an application of the STFT for audio signal processing \[\text{(70)}\ \text{(40)}\]. Given an audio signal, the goal in time dilation phase vocoder is to slow down, or speed up the signal, without changing its pitch/frequency content. This is achieved by taking the STFT \( V_f[s] \) of the signal \( s \), dilating \( V_f[s] \) along the time direction via \( V_f[s](x/\Delta, \omega) \), modifying the phases by \( F(x, \omega) = \exp(i\theta(x, \omega))|V_f[s](x/\Delta, \omega)| \), for some appropriately defined \( \theta(x, \omega) \), and synthesizing the result to the signal domain by \( V_f^\theta F \). When \( \Delta \) is an integer, the phase modification is \( \theta(x, \omega) = \Delta\arg(V_f[s](x, \omega)) \), where \( \arg(V_f[s](x, \omega)) \) is the argument (angle) of the complex number \( V_f[s](x, \omega) \). This coincides with the nonlinearity \( r \) of Example \[\text{(12)}\].

The above procedure is intuitive, except perhaps for the phase modification step. The idea behind this step comes from the following signal model, in which a signal is a sum of slowly varying pure waves,
\[
s(t) = \sum_{m=0}^{M} A_m(t) \exp(2\pi i \lambda_m(t)).
\]  
(85)

Here, the instantaneous frequency of the \( m \)th component, \( \lambda_m(x) \), and the instantaneous amplitude \( A_m(x) \) are slowly varying. The STFT phase vocoder method is justified for this model, if the frequency spread of the LTFT atoms is narrow enough to separate the instantaneous frequencies \[\text{(40)}\]. Too see this, for a near constant isolated local frequency element
\[
q(t) = A(t)e^{2\pi i \lambda t}
\]
The phase vocoder should return the signal
\[ \tilde{q}(t) = A(t/\Delta)e^{2\pi i\lambda t}. \]

For a slowly varying \( A \) and real valued \( f \) we have
\[ V_f[q](x, \omega) \approx A(x) \int e^{2\pi i\lambda t} T(x) M(\omega) f(t) dt = A(x) \int e^{2\pi i\lambda t} T(x) M(-\omega) f(t) dt \]
and by Lemma [61]
\[ V_f[q](x, \omega) \approx A(x) M(-x) T(-\omega) \tilde{f}(-\lambda) = A(x) e^{2\pi i\lambda \lambda} \tilde{f}(\omega - \lambda). \] (86)

Similarly, by replacing \( x \) by \( \Delta x \) and \( q \) by \( \tilde{q} \) in (86), for the output of the phase vocoder we should have
\[ V_f[\tilde{q}](\Delta x, \omega) \approx A(x) e^{2\pi i\Delta x \lambda} \tilde{f}(\omega - \lambda). \]

By this model, an appropriate definition of phase vocoder should transform the time positions of atoms from \( x \) to \( \Delta x \), and multiply the phase of all coefficients by \( \Delta \). However, it is not possible to simply multiply the phase by \( \Delta \), since the phase is only given modulo \( 2\pi \). However, if \( \Delta \) is an integer,
\[ (2\pi \Delta x \lambda) \mod 2\pi = \left( \Delta \left( (2\pi x \lambda) \mod 2\pi \right) \right) \mod 2\pi, \]
so the multiplication of the phase by \( \Delta \) is allowed directly. When \( \Delta \) is not an integer, the phase modification is defined according to a phase unwrapping process (see e.g. [70, 40, 58]), which is an active research area. In this paper we focus on integer dilation, thus avoiding the phase unwrapping problem.

6.2 Motivation for the LTFT phase vocoder

The signal model ([35]) does not accommodate signals having percussive sounds and transient events, like drums or fast string picking. To accommodate such percussive features, we propose in this paper to replace the STFT with the CWT. Indeed, the CWT is capable of localizing time singularities, and represents more sparsely transient features in audio signals [50]. According to [32] we can treat the CWT as a time-frequency transform, which makes it appropriate for phase vocoder. Some work on wavelet phase vocoder have been done in the past (see, e.g., [61, 62]). More generally, continuous warped time-frequency representations [36] tile the frequency axis arbitrarily, with the wavelet representation as a special case, and their discrete counterparts were proposed in the context of phase vocoder in [29].

Another important advantage in using wavelet atoms instead of STFT atoms is for alleviating artifacts such as transient smearing, echo, and loss of presence. These artifacts are manifestation of phasiness [59], the audible artifact resulting from summing two time-frequency atoms with intersecting time and frequency supports, but with out of sync phases. To understand this phenomenon, consider for example two time frequency atoms \( f_1(t) = f(t)e^{2\pi i\omega t} \) and \( f_2(t) = f(t-x)e^{2\pi i\omega' t} \), where \( x \) is smaller than the time support of \( f \) and \( \omega - \omega' \) is smaller than the frequency support of \( f \). Let \( c_1 = r_1 e^{2\pi i\theta_1} \) and \( c_2 = r_2 e^{2\pi i\theta_2} \) be the two coefficients of the atoms. The modulus of the coefficients, \( r_1 \) and \( r_2 \), is clearly interpreted as how much each time-frequency atom is present in the signal. The phase of the coefficients, \( e^{2\pi i\theta_1} \) and \( e^{2\pi i\theta_2} \), has a more subtle role. Typically, phases of neighboring atoms are in sync, in the sense that the superposition of the atoms \( f_1 + f_2 \) does not cancel the modulus of each \( f_1, f_2 \). When the phases are out of sync, the cancellation in the superposition leads to an audible artifact called phasiness. We suggest that the pungency of phasiness is a factor of the number of oscillations inside the window \( f \). The more oscillations there are in the windows, the more opportunity they have to be out of sync. Note that in STFT windows, the higher the frequency the more oscillations there are in each window. This means that high frequencies are more prone to phasiness. However, in CWT atoms the number of oscillations is constant, independent of the frequency, which alleviates the problem of phasiness in high frequencies.
Let us offer another explanation to the advantage of CWT atoms. Middle to high frequency wavelet have small time supports. Therefore, when extracting the middle to high CWT time-frequency coefficients of an audio signal, signal features localized at certain times only affect the coefficients of time-frequency atoms at nearby times. This helps alleviating transient smearing and echo artifacts which are common in phase vocoder.

In the following we list three issues with the CWT approach to time-frequency signal processing, and the way we resolve them. Our solution to these problems leads to the stochastic LTFT method.

First, the standard CWT discretization is incompatible with time-frequency feature extraction. Indeed, the discretization of the CWT is based on an exponential grid in the frequency direction, e.g., the dyadic frequencies \( \{2^j\}_{j \in \mathbb{Z}} \), while polyphonic audio signals typically have time-frequency features which are well spread in the time-frequency plane. This means that generic high frequency features cannot be accurately localized in the time-frequency plane using discrete wavelets. On the other hand, the measure in the time-frequency plane of the CWT is uniform, and does not exhibit any degradation in high frequencies. A continuous Monte Carlo CWT method is preferable to the discrete wavelet transform for time-frequency feature extraction, since random samples capture the uniform measure of the time-frequency plane.

Second, to avoid overly large time supports for large frequencies, we combine the STFT with the CWT into one coherent state system. In this combined system, small frequencies are analyzed using the STFT, and middle frequencies are analyzed using the CWT. To avoid atoms supported on time interval which are too short, high frequencies are also analyzed using STFT windows. This is done to avoid false detection of very short transient events by very short wavelet atoms, which can produce audible artifacts.

The last issue is related to the fact that windows are subject to the uncertainty principle. The better a time-frequency atom is equipped to accurately measure frequency, the less accurately it measures time. Different signal features call for a different balance between the time and the frequency measurement accuracy. In polyphonic signals we expect a range of such appropriate balances, which means that no choice of window is appropriate for all features. We thus introduce a new axis to the time-frequency phase space, controlling the balance between time accuracy and frequency accuracy. For a fixed time-frequency location, the new parameter specifies the number of oscillations in the atom, or equivalently, the time spread of the atom, thus controlling the time and frequency uncertainty tradeoff. By Subsection 4.8, the introduction of this new axis does not require an increase in Monte Carlo samples, and the computational complexity of the Monte Carlo method is not affected. Thus, the new axis is another justification for using a Monte Carlo method rather than a grid method. We remark that working with Gabor atoms without a fixed spread was studied in \[53\]. However, in \[52\] the spread of the window is fixed for each time, where in our approach we have all of the spreads in all times. The resulting system consists of the atoms of the localizing time-frequency transom of Definition \[36\].

The integer time dilation phase modification \( r \) is said to preserve the horizontal phase coherence \[51\], and deals well with slowly varying instantaneous frequencies. When the instantaneous frequency of a component of \[55\] changes rapidly, the phase modification \( r \) is not sufficient in the classical phase vocoder, and methods for “locking” the phase to a frequency bin outside the horizontal line are used \[59, 40\]. Since in our case we use CWT atoms which have shorter time supports than STFT atoms, we find that using the simple horizontal phase coherence gives satisfactory results for polyphonic audio signals.

Let us last compare our method to phase unwrapping.

To showcase the LTFT phase vocoder, we consider outtakes from songs by the power metal band DragonForce.\(^1\) The overall sound of the band, and specifically the electric guitars with distortion, together with the lyrics, bass guitar, and fast paced drumming, constitutes highly polyphonic audio signals. LTFT phase vocoder can accommodate the different audio features simultaneously via the number of oscillations axis. Moreover, since LTFT is based on wavelet atoms, which are more localized in time than STFT atoms, phasiness is alleviated with respect to classical phase vocoder. The sound examples and code are available at \( \text{https://github.com/RonLevie/LTFT-Phase-Vocoder} \).

33
6.3 Linear volume discretization of the LTFT

For the LTFT we consider the same discretization as in the linear volume result of the STFT (Corollary 42). We repeat the construction here for the convenience of the reader. Let $R > 0$ denote the band or the fidelity of the signal class. Consider the space $PW_R$ of band-limited signals with frequency support $[-R,R]$. The space $PW_R$ can be seen as a class of signals with constant sample rate: $R$ samples per time unit.

Consider an LTFT with high transition frequency satisfying $b_\tau < R$ for every $\tau \in [\tau_1,\tau_2]$. For each $M$, let $V^R_M$ be the space of signals $q \in L^2(\mathbb{R})$ supported at $(-\frac{M}{2R},\frac{M}{2R})$ with Fourier series

$$\forall t \in (-M/(2R), M/(2R)), \quad q(t) = \sum_{n=-M}^{M} \sqrt{R/M} c_n e^{2\pi i n \frac{R}{M} t}.$$  

The spaces $V^R_M$ discretize $PW_R$. Elements in $V^R_M$ are seen as signals supported at $(-M/(2R), M/(2R))$ with $R$ samples per time unit.

The phase space envelopes are defined as follows. Let $W > 0$. For each $M \in \mathbb{N}$ we consider

$$G^R_M = \{(x,\omega,\tau) \mid \tau_1 \leq \tau \leq \tau_2, -WR < \omega < WR, -M/(2R) - \tau_2/\alpha R < x < M/(2R) + \tau_2/\alpha R\}. \quad (87)$$

Note that the boundary along the $x$ axis in (87) can be improved to

$$|x| \leq \frac{M}{2R} + \begin{cases} \tau/\alpha R & \text{if } |\omega| < \alpha R \\ \tau/\omega & \text{if } \alpha R \leq |\omega| < b_\tau \\ \tau/b_\tau & \text{if } |\omega| \geq b_\tau. \end{cases}$$

Recall that the measure $\mu_\tau$ along the $\tau$ axis satisfies $\mu_\tau([\tau_1,\tau_2]) = 1$. Thus, the area of $G^R_M$ is the time-frequency space is

$$\mu(G^R_M) = WMO(1). \quad (88)$$

Denote

$$\psi^R_M(g) = \begin{cases} 1, & g \in G^R_M \\ 0, & g \notin G^R_M. \end{cases} \quad (89)$$

**Proposition 43.** Under the above setting, the LTFT is linear volume discretizable with respect to the class $PW_R$ and the discretization $(V^R_M)_{M \in \mathbb{N}}$, with the envelopes $\psi^R_M$ defined by (89) for large enough $W$ that depends only on $\epsilon$ of Definition 33.

The proof is in [32].

Given a real valued time signal $s \in L^2(\mathbb{R})$, the values of $\hat{s}(\omega)$ at the negative frequencies $\omega < 0$ are uniquely determined by $\hat{s}(\omega)$ for $\omega > 0$. Thus, in practice, we consider only LTFT atoms with $\omega > 0$. After the signal processing pipeline, we post-process the output signal by taking its real part and multiplying by $2$. Moreover, in practice we sample from the phase space domain $G_M = [\frac{M}{2R} - \tau_2, \frac{M}{2R} + \tau_2] \times [0, RW/2]$, with $W \geq 1$ close to $1$ (e.g. $W = 1$ or $W = 1.1$), even though the $\epsilon$ error of (65) in this case is not guaranteed to be uniformly small in $s$. This choice of $G_M$ is reasonable, since the positive discrete frequency information of any $s \in V^R_M$ resides in $[0, R/2]$, and the signal content due to atoms with frequencies $\omega > R$ is typically negligible.

6.4 Computational complexity of stochastic LTFT phase vocoder

In this subsection we compute the computational complexity of the STFT phase vocoder. Since the method is stochastic, we compute the average number of floating point operations. Suppose that $M \in \mathbb{N}$ is even. Consider a time signal in $V^R_M$, given by $M+1$ samples at the times $\{\frac{m}{M}R\}_{m=-M/2}^{M/2}$. For simplicity, we consider the LTFT transform with fixed transition frequencies $a, b$. Let $0 < a < \beta < 1$, and suppose that the transition frequencies are $a = \alpha R$ and $b = \beta R$. Consider the constant $W = 1$ for the phase space domain (87). Let $\tau_0 = \int_{\tau_0}^{\tau_1} \tau d\tau$ be the average number of oscillations. Let $K = ZM$ be the number of Monte Carlo samples. In the following we list the average number of floating point operation performed by the different bands, given a random $x$, $\tau$ and $\omega$ in the corresponding band.
1. **Low STFT.** Time support of the atom: \( \frac{2\tau}{\alpha} \). Number of time samples in the atom: \( R \frac{2\tau}{\alpha} = \frac{2\tau}{\alpha} \). Probability of sampling low STFT atoms: \( \alpha \). Average number of low windows sampled: \( \alpha K \). Overall average number of operations: \( \alpha K \frac{2\tau}{\alpha} = 2K\tau_0 \).

2. **High STFT.** Time support of the atom: \( \frac{2\tau}{\beta} \). Number of time samples in the atom: \( R \frac{2\tau}{\beta} = \frac{2\tau}{\beta} \). Probability of sampling high STFT atoms: \( 1 - \beta \). Average number of low windows sampled: \( K(1 - \beta) \). Overall average number of operations in the low band: \( K(1 - \beta) \frac{2\tau}{\beta} = \frac{2\tau}{\beta} K(1 - \beta) \).

3. **Middle CWT.** Time support of the atom (for frequency \( \omega \)): \( \frac{2\tau}{\omega} \). Number of time samples in the CWT atoms: \( R \frac{2\tau}{\omega} \). Average number of time samples in CWT atoms: \( \frac{1}{R\beta - Ra} \int_r^\frac{R\beta}{R\alpha} 2R\tau/\omega d\omega d\tau = \frac{2\tau}{R\alpha} \ln(\omega) \bigg|_R^{R\beta} = \frac{2\tau}{\beta - \alpha} \left( \ln(R) + \ln(\beta) - \ln(R) - \ln(\alpha) \right) = \frac{2\tau}{\beta - \alpha} \ln \left( \frac{b}{a} \right) \).

Probability of sampling CWT atoms: \( \beta - \alpha \). Average number of CWT atoms sampled: \( K(\beta - \alpha) \). Overall average number of operations: \( 2\tau_0 K \ln \left( \frac{b}{a} \right) \).

**Proposition 44.** For \( K = ZM \), the expected number of floating point operations performed by the LTFT phase vocoder, is

\[
E(\#\text{operations}) = 2\tau_0 ZM \left( 1 + \frac{(1 - \beta)}{\beta} + \ln \left( \frac{b}{a} \right) \right) + O(M \log M),
\]

where \( O(M \log M) \) is the number of operations entailed by applying \( \mathcal{S}^{-1} \) via FFT.

**References**

A Weak vector integrals

Weak vector integrals, also called Pettis integral, were introduced in [55].

Definition 45. Let $H$ be a separable Hilbert space, and $G$ a measure space. Let $v : G \to H$ be a mapping such that the mapping $s \mapsto \int_G \langle s, v(g) \rangle dg$ is continuous in $s \in H$. Then the weak vector integral (or weak $H$ integral) is defined to be the vector

$$\int_G^w v(g)dg \in H$$

such that

$$\forall s \in H : \int_G \langle s, v(g) \rangle dg = \left( s, \int_G^w v(g)dg \right).$$

The existence of such a vector is guaranteed by Riesz representation theorem. In this case, $v$ is called a weakly integrable function.

Example 46.

1. If $G$ is a Radon space which is a probability space, $v : G \to H$ is continuous, and $g \mapsto \|v(g)\|_H$ is in $L_\infty(G)$, then $\int_G v(g)dg$ is a weak integral.

2. The synthesis integral (10) of a continuous frame is a weak integral.

Proposition 47. Let $v : G \to H$ be a weakly integrable function, and $T$ a bounded linear operator in $H$. Then $Tv$ is weakly integrable and

$$\int_G^w Tv(g)dg = T \int_G^w v(g)dg.$$

Proof. Let $s \in H$. We have

$$\left( s, T \int_G^w v(g)dg \right) = \left( T^* s, \int_G^w v(g)dg \right).$$

By definition of $\int_G^w v(g)dg$ as the vector that realizes the continuous functional $s \mapsto \int_G \langle s, v(g) \rangle dg$, we have

$$\left( T^* s, \int_G^w v(g)dg \right) = \int_G \langle T^* s, v(g) \rangle dg = \int_G \langle s, Tv(g) \rangle dg$$

where by definition, we have

$$\int_G \langle s, Tv(g) \rangle dg = \left( s, \int_G^w Tv(g)dg \right).$$

Indeed, the linear functional $s \mapsto \int_G \langle s, Tv(g) \rangle dg$ is continuous, since

$$\int_G \langle s, Tv(g) \rangle dg = \left( T^* s, \int_G^w v(g)dg \right)$$
and $s \mapsto T^* s$ and $q \mapsto \int_G^w v(g)dg$ are continuous. To conclude, for every $s \in \mathcal{H}$,

$$\left\langle s, T \int_G^w v(g)dg \right\rangle = \left\langle s, \int_G^w Tv(g)dg \right\rangle$$

so

$$T \int_G^w v(g)dg = \int_G^w Tv(g)dg.$$

\[\Box\]

**Remark 48.** When $G$ is a probability space, $v : G \to \mathcal{H}$ is termed a random vector, and if $v$ is weakly integrable the expected value

$$E^w(v) = \int_G^w v(g)dg$$

is well defined. By Proposition 47, for any bounded linear operator $T$ in $\mathcal{H}$, $E^w(Tv) = T E^w(v)$.

Weak vector integrals can be also defined on Banach spaces and their continuous duals. We consider here the $L^1(G)$ case, where $G$ is a measure space.

**Definition 49.** Let $G$ be a measure space. Let

$$v : G \to L^1(G) \quad , g \mapsto v(g, \cdot)$$

be a mapping such that

$$L^\infty(G) \ni s \mapsto \int_G \int_G s(g') v(g, g') dg' dg \in \mathbb{C}$$

is a continuous functional (in $L^\infty(G)^*$). Then the weak $L^1(G)$ integral is defined to be the functional

$$\int_G^w v(g, \cdot)dg \in L^\infty(G)^*$$

such that

$$\forall s \in \mathcal{H} \quad . \quad \int_G \int_G s(g') v(g, g') dg' dg = \int_G^w v(g, \cdot)dg[s].$$

In this case, $v$ is called a weakly $L^1(G)$ integrable function.

**B Coefficient operators and weak integral operators**

Next we define general coefficient operators, and weak integral operators, generalizing the analysis and synthesis operators of continuous frames.

**Definition 50.** Let $G$ be a measure space, and $\mathcal{H}$ a Hilbert space.

1. Let $G \ni g \mapsto R(g) \in \mathcal{H}$ be a mapping such that for every $s \in \mathcal{H}$

$$\langle s, R(\cdot) \rangle \in L^2(G).$$

If $s \mapsto \langle s, R(\cdot) \rangle \in L^2(G)$ is a bounded operator, we call it a coefficient operator.

2. Let $G \ni g \mapsto R(g) \in \mathcal{H}$ be a mapping such that for every $F \in L^2(G)$, $g \mapsto F(g)R(g)$ is weakly $L^2(G)$ integrable. Let $D$ be defined by

$$DF = \int_G^w F(g)R(g)dg.$$

If $D$ is a bounded operator, we call it a weak integral operator.
For example, the analysis operator $V : \mathcal{H} \to L^2(G)$ of a continuous frame is a coefficient operator. Moreover, the synthesis operator $V^* : L^2(G) \to \mathcal{H}$ is a weak integral operator.

The next proposition shows that every coefficient operator is the adjoint of a weak integral operator and vice versa.

**Proposition 51.** Let $G$ be a measurable with a $\sigma$-finite measure, and $\mathcal{H}$ a Hilbert space. Then the following two properties hold.

1. If $[Ds](g) = \{s, R(g)\}$ is a coefficient operator, then
   $$D^*F = \int_G F(g)R(g)dg$$
   is a weak integral operator.

2. If $DF = \int_G F(g)R(g)dg$ is a weak integral operator, then
   $$[D^*s](g) = \{s, R(g)\}$$
   is a coefficient operator.

To prove Proposition 51, we use the following lemma and its corollary.

**Lemma 52.** Consider a measure space $X$ of finite measure $\mu_X(X) < \infty$, and two measurable functions $h, r : X \to \mathbb{R}$. If for any measurable set $E \subset X$

$$\int_E (h(g) - r(g))dg = 0,$$

then $h = r$ almost everywhere.

**Proof.** For any measurable set $E \subset X$, let $\chi_E : X \to \{0, 1\}$ denote the indicator function of the set $E$. For any $a < b \in \mathbb{Q}$, denote $\{h > b, r \leq a\} = \{x \mid h(x) > b, r(x) \leq a\}$, and observe

$$b\mu_X(\{h > b, r \leq a\}) = \int_X b\chi_{(h>\!b, r\leq a)}(x)d\mu_X(x) \leq \int_X h(x)\chi_{(h>\!b, r\leq a)}(x)d\mu_X(x)$$

$$= \int_X r(x)\chi_{(h>\!b, r\leq a)}(x)d\mu_X(x) \leq \int_X a\chi_{(h>b, r\leq a)}(x)d\mu_X(x) = a\mu_X(\{h > b, r \leq a\}).$$

Thus, for all $a < b \in \mathbb{Q}$

$$\mu_X(\{h > b, r \leq a\}) = 0. \quad (90)$$

By summing (90) on all $a < b \in \mathbb{Q}$, and by $\sigma$-subadditivity of the measure, we get

$$0 \leq \mu_X(\{x \mid h(x) > r(x)\}) \leq \sum_{a \in \mathbb{Q}} \mu_X(\{h > b, r \leq a\}) = 0.$$

Similarly,

$$\mu_X(\{x \mid h(x) < r(x)\}) = 0. \quad \square$$

**Corollary 53.** Consider a measure space $X$ with $\sigma$-finite measure $\mu_X$, and let if $h, r : X \to \mathbb{C}$ be two measurable functions. If for any measurable set $E \subset X$ of finite measure

$$\int_E (h(g) - r(g))dg = 0.$$

then $h = r$ almost everywhere.
Proof. Consider an exhausting sequence of measurable sets with finite measures \( \{X_n\}_{n \in \mathbb{N}} \).

By considering the real and the imaginary parts of \( h, r \) separately, we may assume without loss of generality that \( h, r \) are real valued. By Lemma 52, for each \( X_n \),

\[
\mu_X(\{x \mid h(x) \neq r(x)\} \cap X_n) = 0.
\]

Now take the union over \( n \in \mathbb{N} \), and sum the measures, to get

\[
\mu(\{x \mid h(x) \neq r(x)\}) = 0.
\]

Proof of Proposition 51. Consider the coefficient operator \( Ds = (s, R(\cdot)) \). By boundedness, for every \( F \in L^2(G) \),

\[
s \mapsto \int_G \overline{F(g)} \langle s, R(g) \rangle \, dg = \int_G \langle s, F(g) R(g) \rangle \, dg
\]

is a bounded linear functional on \( s \in \mathcal{H} \). Thus, \( F(g) R(g) \) is weakly integrable and

\[
\int_G \overline{F(g)} \langle s, R(g) \rangle \, dg = \left\langle s, \int_G \overline{F(g)} R(g) \, dg \right\rangle.
\]

On the other hand,

\[
\int_G \overline{F(g)} \langle s, R(g) \rangle \, dg = \langle Ds, F \rangle_{L^2(G)} = \langle s, D^* F \rangle_{\mathcal{H}}.
\]

We thus have, for every \( s \in \mathcal{H} \) and \( F \in L^2(G) \),

\[
\left\langle s, \int_G \overline{F(g)} R(g) \, dg \right\rangle = \langle s, D^* F \rangle.
\]

Equation (92), for fixed \( F \), and all \( s \), gives

\[
D^* F = \int_G \overline{F(g)} R(g) \, dg.
\]

This is true for any \( F \), which proves section 1 of Proposition 51.

Let us now prove 2 of Proposition 51. Let \( DF = \int_G \overline{F(g)} R(g) \, dg \) be a weak integral operator. By the fact that \( D \) is a weak integral operator

\[
\langle F, D^* s \rangle_{L^2(G)} = \langle DF, s \rangle_{\mathcal{H}} = \left\langle \int_G \overline{F(g)} R(g) \, dg, s \right\rangle_{\mathcal{H}} = \int \langle F(g) R(g), s \rangle_{\mathcal{H}} \, dg = \int \overline{F(g)(s, R(g))} \, dg.
\]

Now, by choosing \( F \) to be indicator functions of measurable sets of finite measure, and by Corollary 53, we have

\[
\langle s, R(g) \rangle_{\mathcal{H}} = D^* s \in L^2(G),
\]

which means that \( D^* \) is a coefficient operator.

Corollary 54. Let \( G \) be a measurable space with a \( \sigma \)-finite measure. An operator \( D \) is a self-adjoint coefficient operator if and only if it is a self adjoint weak integral operator with the same kernel. Namely,

\[
[Ds](g') = \langle s, R(\cdot, g') \rangle = \int_G s(g) R(g', g) \, dg.
\]

If moreover \( R \) satisfies either one of the following three conditions
1. either \( \max_{g' \in G} \sqrt{\int |R(g, g')|^2 \, dg} < \infty \),
2. or \( R \in L^2(G^2) \),
3. or \( R \in L^\infty(G) \),
then \( R(g, g') = R(g', g) \) for almost every \( g, g' \in G \).

**Proof.** The first part of Corollary 54 is a direct result of Proposition 51 and 

\[
\int s(g)\overline{R(g, g')} \, dg = (s, R(\cdot, g')) = [D_1 s](g') = [D_2 s](g') = \int_G s(g)R(g', g) \, dg.
\]

Next, we show \( R(g, g') = R(g', g) \) under either of the assumptions of Corollary 54. For any \( q \in L^2(g) \) we have

\[
\int \int s(g)\overline{R(g, g')} q(g) \, dg \, dg' = \int \int s(g)\overline{R(g, g')} dq(g') \, dg' = \int \int s(g)R(g', g)q(g') \, dg' \, dg = \int \int s(g)R(g', g)q(g') \, dg' \, dg' \tag{93}
\]

and in any case of 1–3 of Corollary 54 the integral (94) is finite.

Thus, by FubiniTonelli theorem on (93), for any \( s, q \in L^2(X_n) \),

\[
\int \left( \int s(g)\overline{R(g, g')} \, dg \right) q(g') \, dg' = \int \left( \int s(g)R(g', g) \, dg \right) \overline{q(g')} \, dg'.
\]

We now apply Lemma 53 for indicator functions \( q \) and any fixed \( s \), to obtain

\[
\int s(g)\overline{R(g, g')} \, dg = \int s(g)R(g', g) \, dg.
\]

where equality is almost everywhere. We then apply Lemma 53 for indicator functions \( s \), to obtain \( R(g, g') = R(g', g) \) almost everywhere.

\( \square \)

**Proposition 55.** If \( H(\cdot, g) \) is weakly \( L^1(G) \) integrable \( (H(\cdot, g) \in L^1(G) \) for all \( g \in G \) with \( \int \infty H(g', g) \, dg \in L^1(G) \),

then \( \text{Re} H(\cdot, g) \) is also weakly \( L^1(G) \) integrable with

\[
\int \infty \text{Re} H(g', g) \, dg = \text{Re} \int \infty H(g', g) \, dg.
\]
Thus, by Corollary 53, we must have for almost every \( g \):

\[
\int W(g') q(g') dg' 
\]

Let us first show that this shows for every real valued \( q \) is a bounded linear functional \( \int W(g') q(g') dg' \).

In Proposition 55 we assume that \( \int W(g',g) dg \in L^1(G) \).

Proof of Proposition 55: Let us first show that \( \int W(g',g) dg \) is a weak \( L^1(G) \) integral. For any real valued \( q \in L^\infty(G) \), by definition

\[
\int q(g') \int W(g',g) dg' dg = \int q(g') \int W(g',g) dg' dg + i \int q(g') \Im H(g',g) dg' dg
\]

where by definition of complex Lebesgue integrals, and by the fact that continuity of functions mapping to \( \mathbb{C} \) is equivalent to continuity of the complex and the real parts separately, we have

\[
L^\infty(G;\mathbb{R}) \ni q \mapsto \int q(g') \Re H(g',g) dg' dg
\]

is continuous for real valued \( q \in L^\infty(G;\mathbb{R}) \). By decomposing a complex valued \( q \) to the real and imaginary part,

\[
L^\infty(G) \ni q \mapsto \int q(g') \Re H(g',g) dg' dg
\]

is a bounded linear functional \( L^\infty(G) \to \mathbb{C} \).

Now, for every real valued \( q \in L^\infty(G) \),

\[
\int q(g') \Re(H(g',g)) dg' dg = \Re(\int q(g') H(g',g) dg' dg)
\]

This shows for every real valued \( q \in L^\infty(G) \),

\[
\int q(g') \Re(H(g',g)) dg' dg' = \int q(g') \Re(\int H(g',g) dg) dg'.
\]

Thus, by taking \( q \) indicator functions, for any measurable \( E \) of finite measure

\[
\int E \int H(g',g) dg' = \Re(\int H(g',g) dg)
\]

Thus, by Corollary 55, we must have

\[
\int H(g',g) dg = \Re(\int H(g',g) dg)
\]

for almost every \( g' \in G \).

\[\Box\]

C Wavelets based on square integrable representations

The material in this section is based on [30, Chapters 2.3–2.5] and [24, 33]. Consider a Lie group \( G \), with the left Haar measure, a Hilbert space \( \mathcal{H} \), and a unitary representation \( \pi : G \to \mathcal{U} \mathcal{H} \). A subspace \( W \subset \mathcal{H} \) is called invariant under the unitary representation \( \pi \) if for every \( v \in W \) and \( g \in G \), \( \pi(g) v \in W \). The representation \( \pi \) is called irreducible, if the only invariant subspaces of \( \mathcal{H} \) under \( \pi \) are \{0\} and \( \mathcal{H} \). The representation \( \pi \) is called strongly continuous if it is continuous from \( G \) to \( \mathcal{U} \mathcal{H} \) endowed with the strong topology [60, Page 65].
Definition 57. Let \( G \) be a Lie group, and consider the Hilbert space \( L^2(G) \) based on the left Haar measure of \( G \). Let \( \pi \) be an irreducible strongly continuous unitary representation of \( G \) in the Hilbert space of signals \( \mathcal{H} \). An element \( f \in \mathcal{H} \) such that the function \( G \ni g \mapsto (f, \pi(g))f \) is in \( L^2(G) \), is called a window. Given a window \( f \), the mapping \( V_f : \mathcal{H} \rightarrow L^\infty(G) \) defined for signals \( s \in \mathcal{H} \) and evaluated at the point \( g \in G \), given by
\[
V_f[s](g) = (s, \pi(g)f),
\]
is called the wavelet transform based on the window \( f \). An irreducible strongly continuous unitary representation, for which there exists a window \( f \), is also called a square integrable representation.

Proposition 58. Let \( f_1, f_2 \in \mathcal{H} \) be windows, and let \( s_1, s_2 \in \mathcal{H} \).

1. The wavelet transform \( V_{f_1} \) is a scalar times an isometric embedding of \( \mathcal{H} \) into \( L^2(G) \).

2. There exists a unique, densely defined positive (self-adjoint) operator \( A \) in \( \mathcal{H} \), with densely defined inverse, called the Duflo-Moore operator, such that the domain of \( A \) is the set of windows, and
\[
\langle V_{f_1}[s_1], V_{f_2}[s_2] \rangle_{L^2(G)} = \langle s_1, s_2 \rangle_{\mathcal{H}} \langle Af_2, Af_1 \rangle_{\mathcal{H}}.
\]

Remark 59.

1. Equation \( \text{(96)} \) can be read off as a weak reconstruction formula. Namely, by taking \( s_1 = s \) and two windows \( f_1, f_2 \), against an arbitrary \( s_2 \), we get
\[
s = \frac{1}{\langle Af_2, Af_1 \rangle} \int_G V_{f_1}[s] \pi(g) f_2 \, dg,
\]
where the integral is in the weak sense.

2. By taking \( f_1 = f_2 = f \), equation \( \text{(96)} \) shows that for any window \( f \), \( V_f \) is an isometric embedding of \( \mathcal{H} \) to \( L^2(G) \), up to a global normalization dependent on \( f \).

3. The wavelet transform \( V_f \) is also called the analysis operator corresponding to the window \( f \). \( V_f^* \) is called the synthesis operator corresponding to \( f \). For \( F \in L^2(G) \), we have
\[
V_f^*(F) = \int_G F(g) \pi(g) f \, dg
\]
where the integral is defined in the weak sense. The reconstruction formula \( \text{(97)} \) can be written in the form \( s = \frac{1}{\langle Af_2, Af_1 \rangle} V^*_f V_{f_1}[s] \).

By choosing a single window for analysis and synthesis \( f_1 = f_2 = f \), Proposition \( \text{58} \) and Remark \( \text{59} \) show that wavelet transforms based on windows with \( \|Af\|_\mathcal{H} = 1 \) are bounded coherent state systems, with \( C = \|f\|_\mathcal{H} \).

D Transforms associated with time-frequency analysis

In this section we formulate translation, modulation, and dilation, and derive their formulas in the frequency domain.

Definition 60. Translation by \( x \) of a signal \( s : \mathbb{R} \rightarrow \mathbb{C} \) is defined by
\[
[T(x)s](t) = s(t - x).
\]

Modulation by \( \omega \) of a signal \( s : \mathbb{R} \rightarrow \mathbb{C} \) is defined by
\[
[M(\omega)s](t) = s(t)e^{2\pi i \omega t}.
\]

Last, dilation by \( \tau \) of a signal \( s : \mathbb{R} \rightarrow \mathbb{C} \) is defined by
\[
[D(\tau)s](t) = s^{1/2}(\tau t).
\]
In (101), the dilation parameter \( \tau \) is interpreted as a frequency multiplier. Indeed, if \( \hat{s} \) is concentrated about frequency \( z_0 \), then \( \mathcal{F}(\mathcal{D}(\tau)s) \) is concentrated about frequency \( \tau z_0 \), as is shown in the following lemma.

**Lemma 61.** Translation, modulation, and dilation take the following form in the frequency domain.

1. \( \mathcal{F}(\mathcal{T}(x)s) = \mathcal{M}(-x)\hat{s} \).
2. \( \mathcal{F}(\mathcal{M}(\omega)s) = \mathcal{T}(\omega)\hat{s} \).
3. \( \mathcal{F}(\mathcal{D}(\tau)s) = \mathcal{D}(\tau^{-1})\hat{s} \).

### E The CWT as a time-frequency transform

Often, general wavelet transforms are interpreted as procedures of measuring physical quantities, or features, of signals (see [43, 41] for a systematic approach). In the STFT, the translation of the window \( f \) is a way of changing the time of the window, and the modulation of the window is a way of changing its frequency. Thus, \( x \) is interpreted as time, and \( \omega \) as frequency, \( \mathcal{G} \) is the time-frequency phase space, and \( \pi(x, \omega) f \) is interpreted as a time-frequency atom localized at the time-frequency pair \( (x, \omega) \). The inner product \( \langle s, \pi(x, \omega)f \rangle \) is interpreted as a measurement of the content of the signal \( s \) at the time-frequency pair \( (x, \omega) \).

In the CWT, \( x \) is interpreted as time, \( \tau \) as scale, and \( \langle s, \pi(x, \tau)f \rangle \) is the measurement of the content of \( s \) at the time-scale pair \( (x, \tau) \).

Both frequency and scale are features of signals quantifying rates of oscillations, and it is thus natural to transform the time-scale representation of the CWT to a time-frequency-representation. Indeed, often the CWT is regarded as a time-frequency transform (see e.g. [64]), as explained next. Consider a CWT window function \( f \), and for simplicity we assume that both \( \hat{f} \) and \( \hat{s} \) are supported in \((0, \infty)\). Suppose that \( \hat{f} \) is centered about the frequency \( \omega_0 \) in the sense that the mean frequency of \( \hat{f} \) is \( \omega_0 \). Namely,

\[
\mathcal{E}_f = \int z |\hat{f}(z)|^2 \, dz = \omega_0. \tag{102}
\]

Denote the frequency variance by

\[
\sigma^2_F = \int (z - \omega_0)^2 |\hat{f}(z)|^2 \, dz. \tag{103}
\]

Assume that the mean time is

\[
\mathcal{E}_T = \int t |f(t)|^2 \, dt = 0 \tag{104}
\]

and denote the time variance by

\[
\sigma^2_T = \int t^2 |f(t)|^2 \, dt. \tag{105}
\]

The CWT is is computed in the frequency domain by

\[
V_f[s](x, \tau) = \int_0^\infty \hat{s}(z) \sqrt{\tau} e^{-\pi i x z} \hat{f}(\tau z) \, dz
\]

with reconstruction

\[
f(z) = \int_{-\infty}^\infty \int_0^\infty V_f[s](x, \tau) \sqrt{\tau} e^{-\pi i x z} \hat{f}(\tau z) \, dx \frac{1}{\tau^2} \, d\tau. \tag{106}
\]

It is easy to check that the dilated window \( \sqrt{\tau} \hat{f}(\tau z) \) is centered at the frequency \( \omega_0 \), with frequency variance \( \sigma^2_F / \tau \), and centered at time 0 with time variance \( \tau \sigma^2_T \). Thus, the scale \( \tau \) corresponds to the frequency \( \omega = \frac{\omega_0}{\tau} \). Moreover, the change of variable \( \omega = \frac{\omega_0}{\tau} \) in the reconstruction
formula (106), transforms phase space into a time-frequency space. By change of variable, the CWT reconstruction formula is given in terms of time-frequency by

\[ \hat{f}(z) = \int_0^\infty \int_{-\infty}^\infty V_f[s](x, \frac{\omega}{\omega}) \sqrt{\frac{\omega}{\omega}} e^{-\pi i x^2} \hat{f}(\frac{\omega}{\omega}) \, dx \, d\omega, \]  

where \( x \) is the time variable in phase space, and \( \omega \) is the frequency variable. Based on this construction, we can think of the CWT as a version of the STFT, with the time spread of the window inverse proportional to the frequency. In other words, all time-frequency atoms have the same number of oscillations, irrespective of their frequency. Also, note that (107) states that the correct measure to use in the time-frequency plane of the CWT is the standard Lebesgue measure.

F Proofs

F.1 Proofs of Subsection 4.2

Proposition 62. Let \( T \) be a phase space operator, with kernel \( R(q', g) \), and let \( F \in L^2(G) \). Then

1. The expected value of \( T^0 \) is a weak \( L^2(G) \) integral, that satisfies

\[ \mathbb{E}_w(T^0F) = D(\psi F). \]  

2. If \( T \) is a uniformly square integrable phase space operator, then \( \mathbb{V}_w(T^0F) \) and \( \mathbb{E}_w\left( \|\psi\|_1 R(\cdot, g)F(g)^2 \right) \) are weak \( L^1(G) \) integrals, and

\[ \mathbb{V}_w(T^0F) = \mathbb{E}_w\left( \|\psi\|_1 R(\cdot, g)F(g)^2 \right) - \|\mathbb{E}_w(T^0F)\|^2. \]  

Here \( \mathbb{E}_w(\nu(g)) \) denotes the weak integral expected value of \( g \mapsto \nu(g) \).

3. If \( T \) is a uniformly square integrable phase space operator, with bound \( D \), then

\[ \left\| \mathbb{V}_w(T^0F) \right\|_1 \leq \|\psi\|_1 D^2 \|F\|^2. \]

Proof.

1. \( \mathbb{E}_w(T^0F)(g') = \int_G \frac{\psi(g)}{\|\psi\|_1} R(q', g)F(g) \, dg = T(\psi F)(g'). \)

2. First we show that \( \int_G \psi(g)R(q', g)F(g) \mathbb{E}_w(T^0F)(g') \, dg \) is a weak \( L^1(G) \) integral. Continuity in \( q \in L^\infty(G) \) follows from

\[ \left| \int_G \psi(g) \int_G q(g') R(q', g) F(g) \mathbb{E}_w(T^0F)(g') \, dg' \, dg \right| = \left| \int_G \psi(g) \int_G q(g') R(q', g) F(g) T(\psi F)(g') \, dg' \, dg \right| \]

and by Proposition 51

\[ = \left| \int_G \psi(g) F(g) T^*(\mathbb{Q} T(\psi F))(g) \, dg \right| \]

where \( \mathbb{Q} T(\psi F) \in L^2(G) \) since \( q \in L^\infty(G) \) and \( T(\psi F) \in L^2(G) \). Thus, since \( \|\psi\|_\infty = 1 \),

\[ \left| \int_G \psi(g) \int_G q(g') R(q', g) F(g) \mathbb{E}_w(T^0F)(g') \, dg' \, dg \right| \leq \|F\|_2 \|T^*\|_2 \|q\|_\infty \|T\|_2 \|F\|_2. \]

This proves continuity in \( q \), so \( \int_G \psi(g)R(q', g)F(g) \mathbb{E}_w(T^0F)(g') \, dg \) is a weak \( L^1(G) \) integral.
Moreover, by Section 1, for every \( q \in L^\infty(G) \)
\[
\int_G q(g') \int_G^w \psi(g) R(g', g) F(g) \overline{\mathbb{E}^w(T^0 F(g'))} dg' dg
= \int_G \int_G q(g') \psi(g) R(g', g) F(g) \overline{\mathbb{E}^w(T^0 F(g'))} dg' dg
= \int_G \int_G \psi(g) R(g', g) F(g) dg\overline{\mathbb{E}^w(T^0 F(g'))} q(g') dg' = \int_G q(g') |\mathbb{E}^w(T^0 F(g'))|^2 dg',
\]
which means
\[
\int_G^w \psi(g) R(g', g) F(g) \overline{\mathbb{E}^w(T^0 F(g'))} dg = |\mathbb{E}^w(T^0 F(g'))|^2 \in L^1(G). \quad (110)
\]

Let us now show that \( \mathbb{V}^w(T^0 F)(g') \) is weak \( L^1(G) \) integrals. To show boundedness, for any
\( q \in L^\infty(G) \)
\[
\int_G \int_G q(g') \frac{\psi(g)}{\|\psi\|^1_1} \|\psi\|^1_1 R(g', g) F(g) - \mathbb{E}^w(T^0 F(g'))^2 dg' dg
= \int_G \int_G q(g') \frac{\psi(g)}{\|\psi\|^1_1} \|\psi\|^1_1 R(g', g) F(g)^2 dg' dg
- 2 \int_G \int_G q(g') \frac{\psi(g)}{\|\psi\|^1_1} \|\psi\|^1_1 R(g', g) F(g) \overline{\mathbb{E}^w(T^0 F(g'))} dg' dg
+ \int_G \int_G q(g') \frac{\psi(g)}{\|\psi\|^1_1} |\mathbb{E}^w(T^0 F(g'))|^2 dg' dg,
\]
so by the above analysis of the weak integrability of \( |\psi|^1_1 R(g', g) F(g) \overline{\mathbb{E}^w(T^0 F(g'))} \),
\[
\int_G \int_G q(g') \frac{\psi(g)}{\|\psi\|^1_1} \|\psi\|^1_1 R(g', g) F(g) - \mathbb{E}^w(T^0 F(g'))^2 dg' dg
= \int_G \int_G q(g') \frac{\psi(g)}{\|\psi\|^1_1} \|\psi\|^1_1 R(g', g) F(g)^2 dg' dg
- 2 \int_G \int_G q(g') \frac{\psi(g)}{\|\psi\|^1_1} \|\psi\|^1_1 R(g', g) F(g) \overline{\mathbb{E}^w(T^0 F(g'))} dg' dg
+ \int_G \int_G q(g') \frac{\psi(g)}{\|\psi\|^1_1} |\mathbb{E}^w(T^0 F(g'))|^2 dg' dg.
\]

By Proposition 55,
\[
\int_G \int_G q(g') \frac{\psi(g)}{\|\psi\|^1_1} \|\psi\|^1_1 R(g', g) F(g) - \mathbb{E}^w(T^0 F(g'))^2 dg' dg
= \int_G \int_G q(g') \frac{\psi(g)}{\|\psi\|^1_1} \|\psi\|^1_1 R(g', g) F(g)^2 dg' dg
- 2 \int_G q(g') Re \left( \int_G^w \frac{\psi(g)}{\|\psi\|^1_1} \|\psi\|^1_1 R(g', g) F(g) \overline{\mathbb{E}^w(T^0 F(g'))} dg \right) dg'
+ \int_G q(g') |\mathbb{E}^w(T^0 F(g'))|^2 dg',
\]
and by (110)
\[
= \int_G \int_G q(g') \frac{\psi(g)}{\|\psi\|^1_1} \|\psi\|^1_1 R(g', g) F(g)^2 dg' dg - \int_G q(g') |\mathbb{E}^w(T^0 F(g'))|^2 dg'. \quad (111)
\]
We also have all mixed terms

\[ k \]

Now,

\[ \int_G \int_{g'} |q(g')| \frac{\psi(g)}{\| \psi \|_1^1} R(g', g) \, d\psi \int_{g'} \left( |R(g', g)|^2 \psi(g) |F(g)|^2 \right) \, dg' \, dg \]

\[ \leq \int_G \int_{g'} |q(g')| \frac{\psi(g)}{\| \psi \|_1^1} R(g', g) \, d\psi \int_{g'} \left( |R(g', g)|^2 \psi(g) |F(g)|^2 \right) \, dg' \, dg \]

and by (111) with \( |q| \) substituting \( q \),

\[ \leq \int_G \int_{g'} |q(g')| \frac{\psi(g)}{\| \psi \|_1^1} (R(g', g) |F(g)|^2 \, d\psi \int_{g'} \left( |R(g', g)|^2 \psi(g) |F(g)|^2 \right) \, dg' \, dg \]

\[ = \| \psi \|_1^1 \int_G \int_{g'} |q(g')| \left( |R(g', g)|^2 \right) \, d\psi \int_{g'} \left( |R(g', g)|^2 \psi(g) |F(g)|^2 \right) \, dg' \, dg \]

\[ \leq \| \psi \|_1^1 \int_G \left| q \right|_{\infty} D^2 \psi(g) |F(g)|^2 \, dg \leq \| \psi \|_1^1 \left| q \right|_{\infty} D^2 \| F \|_1^2 \]

which proves continuity in \( q \in L^\infty(G) \). Equations (109) now follows from (111).

3. By integrating against \( q = 1 \in L^\infty(G) \) in (112),

\[ \| \mathcal{V}^w(T, F) \|_{1}^{\text{formal}} \leq \| \psi \|_1^1 D^2 \| F \|_1^2 \]

Proof of Proposition (18)

1. By linearity of expected value and Proposition 62.

2. Let \( \eta \in L^\infty(G) \). We would like to show that

\[ \int_{(g_1, \ldots, g_K)} \int_{g'} \frac{1}{K^2} \sum_{k=1}^{K} \left[ T^w_k F(g') - E^w(T K F)(g') \right] \, dg' \| \psi \|_1^{-K} \psi(g_1) \, d\psi \int_{g'} \left( \psi(g) |F(g)|^2 \right) \, dg' \, dq \]

\[ \leq \frac{1}{K^2} \sum_{k=1}^{K} \left[ T^w_k F(g') - E^w(T K F)(g') \right] \, dg' \| \psi \|_1^{-K} \psi(g_1) \, d\psi \int_{g'} \left( \psi(g) |F(g)|^2 \right) \, dg' \, dq \]

\[ \leq \frac{1}{K^2} \sum_{k=1}^{K} \left[ T^w_k F(g') - E^w(T K F)(g') \right] \, dg' \| \psi \|_1^{-K} \psi(g_1) \, d\psi \int_{g'} \left( \psi(g) |F(g)|^2 \right) \, dg' \, dq \]

\[ \leq \frac{1}{K^2} \sum_{k=1}^{K} \left[ T^w_k F(g') - E^w(T K F)(g') \right] \, dg' \| \psi \|_1^{-K} \psi(g_1) \, d\psi \int_{g'} \left( \psi(g) |F(g)|^2 \right) \, dg' \, dq \]

Note that \( \eta \left( \left[ T^w_k F \right](g_k; \cdot) - E^w(T K F)(\cdot) \right) \in L^2(G) \) for a.e. \( g_k \), so

\[ \int_{g_k} \int_{g'} \eta(g') \left( \left[ T^w_k F \right](g_k; g') - E^w(T K F)(g') \right) \frac{1}{K^2} \times \]

\[ \cdots \int_{g_k} \left( \left[ T^w_k F \right](g_k; g') - E^w(T K F)(g') \right) \| \psi \|_1^{-K} \psi(g_k) \, d\psi \int_{g'} \left( \psi(g) |F(g)|^2 \right) \, dg' \, dq \]

\[ \cdots \int_{g_k} \left( \left[ T^w_k F \right](g_k; g') - E^w(T K F)(g') \right) \| \psi \|_1^{-K} \psi(g_k) \, d\psi \int_{g'} \left( \psi(g) |F(g)|^2 \right) \, dg' \, dq \]
Also note that
\[
\int_{g_k} \left[ \langle T_k^0 F \rangle \langle g_k; g' \rangle - \mathbb{E}^w (T^K F) \langle g' \rangle \right] \psi \| \psi \|_1^1 \psi (g_k) dg_k \\
= \int_{g_k} \left[ \langle T_k^0 F \rangle \langle g_k; g' \rangle \| \psi \|_1^1 \psi (g_k) \right] dg_k - \mathbb{E}^w (T_k^0 F) \langle g' \rangle = 0.
\]

We thus have
\[
\int_{(g_1, \ldots, g_K)} \left[ \eta (g') \left| \frac{1}{K} \sum_{k=1}^K \langle T_k^0 F \rangle \langle g_k; g' \rangle - \mathbb{E}^w (T^K F) \langle g' \rangle \right|^2 \right] \psi \| \psi \|_1^1 \psi (g_1) \ldots \psi (g_K) \right] \cdot \ldots \| \psi \|_1^1 \psi (g_K) dg_K \\
= \frac{1}{K^2} \sum_{k=1}^K \int_{g_k} \left[ \eta (g') \left| \langle T_k^0 F \rangle \langle g_k; g' \rangle - \mathbb{E}^w (T^K F) \langle g' \rangle \right|^2 \right] \psi \| \psi \|_1^1 \psi (g_k) \right] \\
= \frac{1}{K^2} \sum_{k=1}^K \left[ \mathbb{V} \mathbb{E} \langle T_k^0 F \rangle \right] (\eta) = \frac{1}{K} \left[ \mathbb{V} \mathbb{E} \langle T_k^0 F \rangle \right] (\eta).
\]

The rest follows from Section 3 of Proposition 26.

\[ \Box \]

### F.2 Proofs of Subsection 4.4

We use the following simple observation to prove Proposition 26.

**Lemma 63.** Let $Z_1, \ldots, Z_m \in L^1 (U)$ be a set of positive integrable functions, where $U$ is a measure space. Denote by $Z \in L^1 (U)$ the function given a.e by $Z(u) = \max \{ Z_1 (u), \ldots, Z_m (u) \}$. Then
\[
\int Z (u) du \leq \sum_{j=1}^m \int Z_j (u) du.
\]

**Proof of Proposition 26.** By the triangle inequality,
\[
\left\| V_f^{\eta, L \psi, K} F - V_f^{\eta} \psi T \psi F \right\|_\mathcal{H} \leq \left\| V_f^{\eta, L \psi, K} F - V_f^{\eta} \eta T \psi K F \right\|_\mathcal{H} + \left\| V_f^{\eta} \eta T \psi K F - V_f^{\eta} \eta T \psi F \right\|_\mathcal{H}.
\]

By the fact that $\| V_f \| = \| V_f^\eta \| \leq B \frac{1}{J^2}$ and $0 \leq \eta (g) \leq 1$,
\[
\left\| V_f^{\eta, L \psi, K} F - V_f^{\eta} \eta T \psi F \right\|_\mathcal{H} \leq \left\| V_f^{\eta, L \psi, K} F - V_f^{\eta} \psi \psi K F \right\|_\mathcal{H} + B \frac{1}{J^2} \left\| \psi K F - T \psi F \right\|_2.
\]

Thus,
\[
\left\| V_f^{\eta, L \psi, K} F - V_f^{\eta} \eta T \psi F \right\|^2_\mathcal{H} \leq 4 Z (F) \tag{114}
\]

where
\[
Z (F) = \max \left\{ \left\| V_f^{\eta, L \psi, K} F - V_f^{\eta} \eta T \psi K F \right\|_\mathcal{H}, B \left\| \psi K F - T \psi F \right\|_2 \right\}. \tag{115}
\]

Note that the maximum in (115) is pointwise in the samples $g = \{ g^1, \ldots, g^K \}, y = \{ y^1, \ldots, y^K \}$, namely the argument that maximizes it is different for different samples in general. When calculating the conditional expected value of $\left\| V_f^{\eta, L \psi, K} F - V_f^{\eta} \eta T \psi F \right\|^2_\mathcal{H}$, with respect to a fixed $y$ (denoted here by $E (\cdot | y)$), we use the bound (114), Lemma 63 and Proposition 13 to get
\[
E \left( \left\| V_f^{\eta, L \psi, K} F - V_f^{\eta} \eta T \psi F \right\|_\mathcal{H} | y \right) \leq 4 \frac{\| \psi \|_1^1}{K} B \| F \|^2_2 + 4 E \left( \left\| V_f^{\eta, L \psi, K} F - V_f^{\eta} \eta T \psi K F \right\|_\mathcal{H}^2 | y \right).
\]
Thus
\[
\mathbb{E}\left( \left\| V_f^{\eta, L} T^{\psi,K} F - V_f^{\eta} T[\psi F] \right\|_{\mathcal{H}}^2 \right) \leq 4 \frac{\|\psi\|_1}{K} D^2 B \| F \|_2^2 + 4 \mathbb{E}\left( \left\| V_f^{\eta, L} T^{\psi,K} F - V_f^{\eta} T[\psi,K] F \right\|_{\mathcal{H}}^2 \right),
\]
where \( \mathbb{E} \) denotes the expected value with respect to both input and output samples \( g, y \). Note that Fubini-Tonelli theorem is satisfied in the computation of \( \mathbb{E}\left( \left\| V_f^{\eta, L} T^{\psi,K} F - V_f^{\eta} T[\psi,K] F \right\|_{\mathcal{H}}^2 \right) \) as a repeated integral of \( y \) and \( g \), since the integrand is positive and the measure is \( \sigma \)-finite.

Next, we bound \( \mathbb{E}\left( \left\| V_f^{\eta, L} T^{\psi,K} F - V_f^{\eta} T[\psi,K] F \right\|_{\mathcal{H}}^2 \right) \). We have by Proposition 24 \[
\mathbb{E}\left( \left\| V_f^{\eta, L} T^{\psi,K} F - V_f^{\eta} T[\psi,K] F \right\|_{\mathcal{H}}^2 \right) \leq \frac{\|\eta\|_1}{L} A^{-1} B C^2 \left\| T^{\psi,K} F \right\|_2^2,
\]
where \( \mathbb{E}( \cdot | g) \) denotes the conditional expected value with respect to a fixed \( g \). Now,
\[
\left\| T^{\psi,K} F \right\|_2 \leq \left\| T^{\psi,K} F - T[\psi F] \right\|_2 + \left\| T[\psi F] \right\|_2,
\]
so
\[
\left\| T^{\psi,K} F \right\|_2 \leq 4 X(F)
\]
where
\[
X(F) = \max\{ \left\| T^{\psi,K} F - T[\psi F] \right\|_2, \left\| T[\psi F] \right\|_2 \}.
\]
Therefore, by Proposition 19 and the fact that \( 0 \leq \psi(g) \leq 1 \),
\[
\mathbb{E}\left( \left\| V_f^{\eta, L} T^{\psi,K} F - V_f^{\eta} T[\psi,K] F \right\|_{\mathcal{H}}^2 \right) \leq \frac{\|\eta\|_1}{L} A^{-1} B C^2 \left( 4 \frac{\|\psi\|_1}{K} D^2 \| F \|_2^2 + 4 \| T \|_2^2 \| F \|_2^2 \right).
\]
Altogether,
\[
\mathbb{E}\left( \left\| V_f^{\eta, L} T^{\psi,K} F - V_f^{\eta} T[\psi,K] F \right\|_{\mathcal{H}}^2 \right)
\leq 4 \frac{\|\psi\|_1}{K} D^2 B \| F \|_2^2 + 16 \frac{\|\eta\|_1}{L} A^{-1} B C^2 \left( \frac{\|\psi\|_1}{K} D^2 \| F \|_2^2 + \| T \|_2^2 \| F \|_2^2 \right)
= 4 \frac{\|\psi\|_1}{K} D^2 B \| F \|_2^2 + 16 \frac{\|\eta\|_1}{L} A^{-1} B C^2 \| F \|_2^2 + 16 \frac{\|\eta\|_1}{L} A^{-1} B C^2 \| T \|_2^2 \| F \|_2^2.
\]

\( \Box \)

### F.3 Proofs of Subsection 4.5 and Bernstein’s inequality in Hilbert spaces

We start with a Markov type error bound of stochastic phase space operators.

**Proposition 64** (Markov type error bound). Let \( f \) be a bounded continuous frame with frame bounds \( A, B, \) and \( \| f \|_\mathcal{H} \leq C \). Let \( T \) be a square integrable phase space operator with bound \( D \), and \( F \in L^2(G) \). Let \( 0 < \delta < 1 \).

1. Consider the Monte Carlo approximation \( T^{\psi,K} \). Then with probability of at least \((1 - \delta)\), we have
\[
\left\| T^{\psi,K} F - T[\psi F] \right\|_2 \leq \sqrt{\frac{\|\psi\|_1}{\sqrt{K}} D \| F \|_2} \delta^{-\frac{1}{4}}.
\]

2. Consider the Monte Carlo approximation \( [V_f^{\eta, L} T F]^{\eta, L, \psi,K} \). Then with probability of at least \((1 - \delta)\),
\[
\left\| [V_f^{\eta, L} T F]^{\eta, L, \psi,K} - V_f^{\eta} T[\psi F] \right\|_{\mathcal{H}}^2
\leq \left( 4 \frac{\|\psi\|_1}{K} D^2 B \| F \|_2^2 + 16 \frac{\|\eta\|_1}{L} A^{-1} B C^2 D^2 \| F \|_2^2 + 16 \frac{\|\eta\|_1}{L} A^{-1} B C^2 \| T \|_2 \| F \|_2^2 \right) \delta^{-\frac{1}{4}}.
\]
Proof. We prove 1, and note that 2 is similar. By Markov’s inequality
\[ \Pr\left( \| [T^K F] - T[\psi F] \|_2^2 \geq \mathbb{E}\left( \| [T^K F] - T[\psi F] \|_2^2 \right) \delta^{-1} \right) \leq \delta \]
so by Proposition 19
\[ \Pr\left( \| [T^K F] - T[\psi F] \|_2^2 \geq \frac{1}{K} \| \psi \|_1 D^2 \| F \|_2^2 \delta^{-1} \right) \leq \delta. \]
Therefore, with probability more than 1 - \( \delta \),
\[ \| [T^K F] - T[\psi F] \|_2^2 \leq \frac{\sqrt{\| \psi \|_1 D^2 \| F \|_2^2}}{\sqrt{K}} \delta^{-\frac{1}{2}}. \]

Next, we improve the dependency of the bound on the failure probability \( \delta \), in case it is small, using a variant of Bernstein’s inequality. For that we introduce a Hilbert space version of Bernstein’s inequality.

**Theorem 65 (Hilbert space Bernstein’s inequality).** Let \( \mathcal{H} \) be a separable Hilbert space, and \( G_0 \) a probability space. Let \( \{v_k\}_{k=1}^K : G_0^\mathcal{H} \to \mathcal{H}^K \) be a finite sequence of independent random weakly integrable vectors. Suppose that for every \( k = 1, \ldots, K, \mathbb{E}^w(v_k) = 0 \) and \( \|v_k\|_H \leq B \) a.s. and assume that \( \rho^2_K > \sum_{k=1}^K \mathbb{E}\|v_k\|^2_H \) for some constant \( \rho_K \in \mathbb{R} \). Then for all \( 0 \leq t \leq \rho^2_K/B \),
\[ P\left( \left\| \sum_{k=1}^K v_k \right\|_H \geq t \right) \leq \exp\left(-\frac{t^2}{8\rho^2_K} + \frac{1}{4}\right). \]

When doing asymptotic analysis in \( K \), Theorem 65 is useful in situations where \( \rho_K \) decays to zero as \( K \) goes to infinity. Here, the vectors \( \{v_k^K\}_{k=1}^K = \{v_k\}_{k=1}^K \) can be in general a completely different set of random vectors for each \( K \). We note that existing variants of Bernstein’s inequality of [49] is limited to trace class operators, and is thus too exclusive for us. Indeed, even the identity operator in \( L^2(G) \) is not trace class in general. Since \( V_j^* \psi V_j s = V_j^* Q \psi Q V_j[s] \), it is reasonable to replace the identity with the trace class self-adjoint operator \( Q \psi Q \). However, for a computationally tractable algorithm, we sample \( V_j[s] \) before applying \( Q \psi \). This is a sample of the identity operator \( I \) in \( L^2(G) \), which is not trace class.

The proof of Theorem 65 is based on the finite dimensional counterpart, presented in [71 Theorem 2.6]. There, the theorem is formulated for vectors in \( \mathbb{R}^n \). However, there is a simple extension of the theorem to \( \mathbb{C}^n \), by realificating \( \mathbb{C}^n \) to \( \mathbb{R}^{2n} \). Namely, we consider the real vector space \( \mathbb{C}^n \) taken as the vectors of the complex vector space \( \mathbb{C}^n \), and restricting the scalar field to \( \mathbb{R} \) (for realification see [13 Page 117]). The complex finite dimensional theorem follows.

**Theorem 66 (Finite dimensional Bernstein inequality).** Let \( \{v_k\}_{k=1}^K \subset \mathbb{C}^d \) be a finite sequence of independent random vectors. Suppose that \( \mathbb{E}(v_k) = 0 \) and \( \|v_k\|_2 \leq B \) a.s. and assume that \( \rho^2_K > \sum_{k=1}^K \mathbb{E}\|v_k\|^2 \). Then for all \( 0 \leq t \leq \rho^2_K/B \),
\[ P\left( \left\| \sum_{k=1}^K v_k \right\|_2 \geq t \right) \leq \exp\left(-\frac{t^2}{8\rho^2_K} + \frac{1}{4}\right). \]

**Proof of Theorem 65**. For a fixed \( K \) we denote \( \rho = \rho_K \). Let \( \{P_j\}_{j \in \mathbb{N}} \) be an increasing sequence of self-adjoint projections to finite dimensional subspaces \( \{\mathcal{H}_j\}_{j \in \mathbb{N}} \) of \( \mathcal{H} \), such that \( \lim_{j \to \infty} P_j = I \) in the strong topology. Namely, for any \( j < j' \), \( \mathcal{H}_j \subset \mathcal{H}_{j'} \), and for every \( w \in \mathcal{H} \), \( \lim_{j \to \infty} P_j w = w \). Such a sequence can be constructed e.g. by projecting to finite spans of orthogonal basis elements. Let us use Theorem 63 on the random vectors \( \{v_k^j\}_{k=1}^K = \{P_j v_k\}_{k=1}^K \), as vectors of \( \mathbb{C}^{d_j} \), for fixed \( j \). By Remark 13 we have
\[ \mathbb{E}^w(v_k^j) = \mathbb{E}^w(P_j v_k) = P_j \mathbb{E}^w(v_k) = \mathbb{E}(v_k) = 0. \]
Next, by the fact that $P_j$ is a projection
\[ \|v_k^j\|_2 = \|P_j v_k\|_H = \|v_k\|_H \leq B. \]

Last, the pointwise bound $\|P_j v_k\|^2_H \leq \|v_k\|^2_H$ carries to the integrals in the calculation of the expected values, so
\[ \sum_{k=1}^K \mathbb{E}\|v_k^j\|^2_2 = \sum_{k=1}^K \mathbb{E}\|P_j v_k\|^2_H \leq \sum_{k=1}^K \mathbb{E}\|v_k\|^2_H \leq \rho^2. \]

Thus, Theorem 60 gives
\[ \forall \ 0 \leq t \leq \rho^2/B : \quad P\left( \left\| \sum_{k=1}^K v_k^j (g) \right\|_H \geq t \right) \leq \exp \left( -\frac{t^2}{8J} + \frac{1}{4} \right). \] (116)

Next, we show that (116) carries also in the limit as $j \to \infty$. Consider the following functions in the probability space $G^K_0$, the characteristic function $\chi$ of the set
\[ \left\{ g \mid \left\| \sum_{k=1}^K v_k(g) \right\|_H > t \right\}, \]
and characteristic function $\chi_j$ of
\[ \left\{ g \mid \left\| \sum_{k=1}^K v_k^j(g) \right\|_2 > t \right\}. \]

By the fact that projections reduce norms, $\chi_j(g) \leq \chi(g)$ for every $g \in G^K_0$. Moreover, $\chi_j$ is a pointwise monotone sequence of measurable functions. By the strong convergence of the projections $P_j$ to $I$, we have
\[ \forall g \in G^K_0, \quad \lim_{j \to \infty} \chi_j(g) = \chi(g). \]

This is shown as follows. Let $g = (g_1, \ldots, g_K)$ be a fixed point. If $\chi(g) = 0$ then it is trivial to see $\lim_{j \to \infty} \chi_j(g) = \chi(g)$. Otherwise, for every $\epsilon > 0$ there is a big enough $J_\epsilon, \epsilon \in \mathbb{N}$ such that for every $j > J_\epsilon$, we have
\[ \left\| \sum_{k=1}^K v_k(g_k) \right\|_H - \left\| \sum_{k=1}^K v_k^j(g_k) \right\|_2 < \epsilon. \]

Since $\chi(g) = 1$, we have
\[ \left\| \sum_{k=1}^K v_k(g_k) \right\|_H = r > t. \]

Therefore, for $\epsilon < 0.5(r-t)$, and any $j > J_\epsilon$
\[ t < r - \epsilon < \left\| \sum_{k=1}^K v_k^j \right\|_2 < r + \epsilon \]
so
\[ \chi_j(g) = 1 \]
which proves that $\lim_{j \to \infty} \chi_j(g) = \chi(g)$.

We can now use Beppo Levi’s monotone convergence theorem, namely
\[ P\left( \left\| \sum_{k=1}^K v_k \right\|_H \geq t \right) = \int_{G^K_0} \chi(g) dg = \lim_{j \to \infty} \int_{G^K_0} \chi_j(g) dg \]
\[ = \lim_{j \to \infty} P\left( \left\| \sum_{k=1}^K v_k^j \right\|_2 \geq t \right) \leq \exp \left( -\frac{t^2}{8J} + \frac{1}{4} \right), \]
where the last inequality is due to the fact that upper bounds are preserved under limits. \qed
We can now prove a Bernstein type error bound for stochastic phase space operators.

**Proposition 67** (Bernstein type error bound). Let \( f \) be a continuous frame, \( T \) a uniformly square integrable phase space operator with bound \( D \), and \( F \in L^2(G) \cap L^\infty(G) \). Let \( E = \left( D \| F \|_\infty + \frac{1}{\| \psi \|_1} \| T \|_2 \| F \|_2 \right) . \) Then provided that \( K \) is large enough, namely

\[
K \geq \| \psi \|_1 D^{-2} \| F \|_2^2 16 \left( \ln \left( \frac{1}{\delta} \right) + \frac{1}{4} \right) E^2, \tag{117}
\]

with probability of at least \( 1 - \delta \) we have

\[
\| T^K F - T(\psi F) \|_2 \leq \frac{\sqrt{\| \psi \|_1}}{\sqrt{K}} D \| F \|_2 4 \sqrt{\ln \left( \frac{1}{\delta} \right) + \frac{1}{4}}. \tag{118}
\]

Note that for a fixed \( F \), the lower bound on \( K \) in (117) is of order \( \| \psi \|_1 \ln \left( \frac{4}{\delta} \right) \).

**Proof of Proposition 67** Denote \( \gamma^2 = D^2 \| F \|_2^2 \). We first prove that for every \( 0 \leq t \leq \gamma^2 / E \)

\[
P \left( \| T^K F - T(\psi F) \|_2 \geq t \right) \leq \exp \left( - \frac{t^2}{8 \gamma^2 \| \psi \|_1} + \frac{1}{4} \right), \tag{119}
\]

using Theorem 65. For that, define the random vectors

\[
v_k = \frac{1}{K} (T_k^0 F - T(\psi F)), \ k = 1, \ldots, K
\]

where \( T_k^0 F : g^k \mapsto [T^0 F](g^k) \). By Proposition 15 \( \mathbb{E}^\nu(v_k) = 0 \), and by Proposition 19

\[
\mathbb{E}(\| v_k \|^2) \leq \frac{\| \psi \|_1}{K^2} D^2 \| F \|_2^2.
\]

Therefore

\[
\sum_{k=1}^K \mathbb{E}(\| v_k \|^2) \leq \frac{\| \psi \|_1}{K} D^2 \| F \|_2^2 = \frac{\| \psi \|_1}{K} \gamma^2.
\]

Moreover, for every \( g^k \in G_0 \)

\[
\| v_k \|_2 \leq \frac{1}{K} \left( \| \| \psi \|_1 R(\cdot, g^k) F(\psi F) \|_2 + \| T(\psi F) \|_2 \right) \leq \frac{1}{K} \left( \| \| \psi \|_1 D \| F \|_\infty + \| T \|_2 \| F \|_2 \right)
\]

\[
= \frac{\| \psi \|_1}{K} \left( D \| F \|_\infty + \frac{1}{\| \psi \|_1} \| T \|_2 \| F \|_2 \right) = \frac{\| \psi \|_1}{K} E.
\]

Now, (119) follows from Theorem 65.

Last, to get (118), set

\[
\delta = \exp \left( \frac{t^2}{8 \gamma^2 \| \psi \|_1} + \frac{1}{4} \right)
\]

\[
t \leq 4 \gamma \sqrt{- \ln(\delta) + \frac{1}{4} \frac{\sqrt{\| \psi \|_1}}{\sqrt{K}} D \| F \|_2^4 \sqrt{- \ln(\delta) + \frac{1}{4}}}
\]

and demand

\[
\frac{\sqrt{\| \psi \|_1}}{\sqrt{K}} D \| F \|_2^4 \sqrt{\ln \left( \frac{1}{\delta} \right) + \frac{1}{4}} \leq \gamma^2 E
\]
Since Proposition 67 is equivalent to Proposition 64 in the dependency on $\sqrt{\|\psi\|_1/K}$. However, Proposition 67 replaces the constant $\delta - \frac{1}{2}$ by the tighter $4\sqrt{\ln(1/\delta)} + 1/4$.

Proposition 24 is now proved similarly to Proposition 24 and based on Propositions 64 and 67.

**Proof of Proposition 24** By the triangle inequality

$$\|[V_f^*TF]^{\eta,L;\psi,K} - V_f^*\eta T[\psi F]\|_H \leq \|V_f^{\eta,L;\psi,K} F - V_f^*\eta T[\psi F]\|_H + \|V_f^*\eta T[\psi F] - V_f^*\eta T[\psi F]\|_H,$$

and by the fact that $\|V_f\| = \|V_f^*\| \leq B^{1/2}$ and $0 < \eta(g) \leq 1$,

$$\|[V_f^*TF]^{\eta,L;\psi,K} - V_f^*\eta T[\psi F]\|_H \leq \|V_f^{\eta,L;\psi,K} F - V_f^*\eta T[\psi F]\|_H + B^{1/2} \|T[\psi F] - T[\psi F]\|_2.$$  

Note that in the Bernstein type error bound case we have $T^{\psi,K} F \in L^\infty(G)$ where $\|T^{\psi,K} F\|_\infty$ is bounded from above by a constant independent of $K$. Indeed, since $R(g',g) \in L^\infty(G)$ for every $g \in G$, by Definition 17

$$\|T^{\psi,K} F\|_\infty = \frac{1}{K} \|\psi\|_1 \sum_{k=1}^K R(g',g^k) F(g)\|_\infty \leq \|\|\psi\|_1 \sum_{k=1}^K R(g') F(g^k)\|_\infty \leq \|\|\psi\|_1 \sum_{k=1}^K R_1(\psi) F(g^k)\|_\infty \leq \|\psi\|_1 \sum_{k=1}^K R_2(\psi^2) F(g^k)\|_\infty.$$

By independence of the input and output samples, and by Proposition 24 in probability of at least $(1 - \delta)$ in the $y$ variable, for any fixed $g$ and large enough $L$, we have

$$\|[V_f^*TF]^{\eta,L;\psi,K} - V_f^*\eta T[\psi F]\|_H \leq \frac{\|\eta\|_1}{\sqrt{L}} A^{1/2} B^{1/2} C \|T^{\psi,K} F\|_2 \kappa(\delta) + B^{1/2} \|T^{\psi,K} F - T[\psi F]\|_2,$$

$$\leq \frac{\|\eta\|_1}{\sqrt{L}} A^{1/2} B^{1/2} C \left( \|T^{\psi,K} F - T[\psi F]\|_2 + \|T[\psi F]\|_2 \right) \kappa(\delta) + B^{1/2} \|T^{\psi,K} F - T[\psi F]\|_2,$$

$$= \left( \frac{\|\eta\|_1}{\sqrt{L}} A^{1/2} B^{1/2} C \kappa(\delta) + B^{1/2} \right) \|T^{\psi,K} F - T[\psi F]\|_2 + \frac{\|\eta\|_1}{\sqrt{L}} A^{1/2} B^{1/2} C \|T[\psi F]\|_2 \kappa(\delta).$$

Here, the lower bound of $L$ in the Bernstein type error bound case is treated as follows. We suppose that $L$ satisfies (117), with $L$ instead of $K$, $\|F\|_\infty$ of (117) replaced by the bound (120), and $\|F\|_2$ of (117) replaced by the bound

$$\|T^{\psi,K} F\|_2 \leq \|T^{\psi,K} F - T[\psi F]\|_2 + \|T[\psi F]\|_2.$$  

Let us show how $\|T^{\psi,K} F - T[\psi F]\|_2$ of (121) can be bounded from above independently of $K$, for large enough $K$, in our situation. In the following we restrict $g$ to the probability event corresponding to Proposition 67 for which $\|T^{\psi,K} F - T[\psi F]\|_2$ is bounded by (118), independently of $g$, for large enough $K$. Overall, for the event corresponding to Proposition 67 the lower bound on $L$ is global, and does not depend on $g$, $K$ or $L$. The Markov type error bound $L$ and $K$ are not restricted.

Now, by Proposition 67 in probability more than $(1 - \delta)^2$ in $y$ and $g$ and for large enough $L$ and $K$,

$$\|[V_f^*TF]^{\eta,L;\psi,K} - V_f^*\eta T[\psi F]\|_H \leq \left( \frac{\|\eta\|_1}{\sqrt{L}} A^{1/2} B^{1/2} C \kappa(\delta) + B^{1/2} \right) \frac{\|\psi\|_1}{\sqrt{K}} \|F\|_2 \kappa(\delta) + \frac{\|\eta\|_1}{\sqrt{L}} A^{1/2} B^{1/2} C \|T[\psi F]\|_2 \kappa(\delta).$$

Since $\|F\|_2 \leq \|F\|_2 \|F\|_2$, we have

$$\|[V_f^*TF]^{\eta,L;\psi,K} - V_f^*\eta T[\psi F]\|_H \leq \frac{\|\psi\|_1}{\sqrt{K}} B^{1/2} D \|F\|_2 \kappa(\delta) + \frac{\|\eta\|_1}{\sqrt{L}} A^{1/2} B^{1/2} C \sqrt{\|\psi\|_1} \|F\|_2 \kappa(\delta)^2 + \frac{\|\eta\|_1}{\sqrt{L}} A^{1/2} B^{1/2} C \|T[\psi F]\|_2 \kappa(\delta).$$

□
F.4 Proofs of Subsection 4.6

We start with two propositions.

**Proposition 68** (Stochastic phase space signal processing 1). Consider a bounded continuous frame $f$ with frame bounds $A, B$ and $\|f_\|_H \leq C$. Let $T : L^2(G) \to L^2(G)$ be a bounded linear operator. Let $r : C \to \mathbb{C}$ satisfy $|r(x)| \leq E |x|$ for some $E \geq 0$ and every $x \in C$. Consider the signal processing pipeline $\mathcal{H} \ni s \mapsto T s$, where

$$T s = V_\eta' \psi T r \circ V_f [S_f^{-1} s] \quad \text{or} \quad T s = S_f^{-1} V_\eta' \psi T r \circ V_f [S_f^{-1} s],$$

and

$$[T s]^{\psi, K}_f = V_\eta' \psi T r \circ V_f [S_f^{-1} s] \quad \text{or} \quad [T s]^{\psi, K}_f = S_f^{-1} V_\eta' \psi T r \circ V_f$$

respectively. Then

1. We have

$$E\left( \| [T s]^{\psi, K}_f - T s \|_H^2 \right) \leq \frac{\| \psi \|_1}{K} A^{-1} B^2 C^2 E^2 \| S_f^{-1} \|_H^2 \| T \|_2^2 \| s \|_H^2.$$

2. With probability more than $1 - \delta$, we have

$$\| [T s]^{\psi, K}_f - T s \|_H \leq \frac{\| \psi \|_1}{K} A^{-1/2} B C E \| S_f^{-1} \|_H \| T \|_2 \| s \|_H \kappa(\delta),$$

where $\kappa(\delta)$ can be chosen as one of the following two options.

- Markov type error bound: $\kappa(\delta) = \delta^{-1/2}$.
- Bernstein type error bound: $\kappa(\delta) = 4 \sqrt{\ln \left( \frac{1}{\delta} \right) + \frac{1}{4}}$ in case $T$ maps $L^\infty(G)$ to itself, and $K$ large enough, namely,

$$K \geq \| \psi \|_1 A B^{-1} C^{-2} \| T r \circ V_f [s'] \|_2^2 16 \left( \ln \left( \frac{1}{\delta} \right) + \frac{1}{4} \right) E^2,$$

where $E = A^{1/2} B^{-1/2} C^{-1} \| T r \circ V_f [s'] \|_\infty + \frac{1}{\| \psi \|_1} B^2 \| T r \circ V_f [s'] \|_2$ and $s' = S_f^{-1} s$ or $s' = s$ depending on the pipeline.

**Proposition 69** (Stochastic phase space signal processing 2). Consider a bounded continuous frame $f$ with frame bounds $A, B$ and $\|f_\|_H \leq C$. Let $T$ be a square integrable phase space operator with bound $D$. Let $r : C \to \mathbb{C}$ satisfy $|r(x)| \leq E |x|$ for some $E \geq 0$ and every $x \in C$. Consider the signal processing pipeline $\mathcal{H} \ni s \mapsto T s$, where

$$T s = V_\eta' \eta T (\psi r \circ V_f [S_f^{-1} s]) \quad \text{or} \quad T s = S_f^{-1} V_\eta' \eta T (\psi r \circ V_f [S_f^{-1} s]),$$

and

$$[T s]^{\psi, L, \eta, K}_f = [V_\eta' \eta T r \circ V_f]^{\psi, L, \eta, K}_f S_f^{-1} s \quad \text{or} \quad [T s]^{\psi, L, \eta, K}_f = S_f^{-1} [V_\eta' \eta T r \circ V_f]^{\psi, L, \eta, K}$$

respectively. Then

1. \[ E\left( \| [T s]^{\psi, K, \eta, L, \psi}_f - T s \|_H^2 \right) \]

$$\leq 4 \frac{\| \psi \|_1}{K} D^2 B^2 E^2 \| S_f^{-1} \|_H^2 \| s \|_H^2 + 16 \frac{\| \eta \|_1}{L} \| \psi \|_1 A^{-1} B^2 C^2 D^2 E^2 \| S_f^{-1} \|_H^2 \| s \|_H^2$$

$$+ 16 \frac{\| \eta \|_1}{L} A^{-1} B^2 C^2 E^2 \| T \|_2^2 \| S_f^{-1} \|_H^2 \| s \|_H^2$$

$$= O \left( \frac{\| \psi \|_1}{K} + \frac{\| \eta \|_1}{L} + \frac{\| \psi \|_1}{L K} \right) \| s \|_H^2.$$
2. With probability at least \((1 - \delta)^2\), and large enough \(K\),

\[
\left\| \left[ T_s \right]^{\eta,K} \cdot L - T_s \right\|_{\mathcal{H}} 
\leq \frac{\sqrt{\|\psi\|_1}}{K} BDE \| S_f^{-1} \|_{\mathcal{H}} \| s \|_{\mathcal{H}} \kappa(\delta) + \frac{\sqrt{\|\eta\|_1}}{\sqrt{L}} A^{-1/2} BCE \| T \|_2 \| S_f^{-1} \|_{\mathcal{H}} \| s \|_{\mathcal{H}} \kappa(\delta)^2
\]

\[+ \frac{\sqrt{\|\eta\|_1}}{\sqrt{L}} \frac{\sqrt{\|\psi\|_1}}{\sqrt{K}} A^{-1/2} BCD E \| S_f^{-1} \|_{\mathcal{H}} \| s \|_{\mathcal{H}} \kappa(\delta)^2 \]

\[= O \left( \frac{\sqrt{\|\psi\|_1}}{\sqrt{K}} \kappa(\delta) + \frac{\sqrt{\|\eta\|_1}}{\sqrt{L}} \frac{\sqrt{\|\psi\|_1}}{\sqrt{K}} \kappa(\delta)^2 + \frac{\sqrt{\|\eta\|_1}}{\sqrt{L}} \kappa(\delta) \right) \| s \|_{\mathcal{H}}, \]

where \(\kappa(\delta)\) can be chosen as one of the following two options.

- Markov type error bound: \(\kappa(\delta) = \delta^{-\frac{1}{2}}\).
- Bernstein type error bound: \(\kappa(\delta) = 4\sqrt{\ln(\frac{1}{\delta})} + \frac{1}{6}\) if \(K\) large enough, and the kernel \(R\) of \(T\) is in \(L^\infty(G^2)\).

Note that by Lemma 7, Item 5, \(\| S_f^{-1} \|_{\mathcal{H}} \leq \| V_f^* \| \cdot \| V_f^* \|\), and by \(\| s \|_{\mathcal{H}} \leq A^{-1/2} \| V_f[s] \|_2\) we have \(\| V_f^* \| \leq A^{-1/2}\). Thus, \(\| S_f^{-1} \|_{\mathcal{H}} \leq A\).

Formula (122) can be plugged in the bounds of Propositions 68 and 69.

**Remark 70.** In case \(\psi = \eta\) and \(K = L\), the error in the stochastic method is controlled by \(O(\sqrt{\frac{\|s\|_{\mathcal{H}}}{\sqrt{K}}})\). Thus, choosing \(K = Z \|\psi\|_1\) results in error \(O(\frac{1}{\sqrt{Z}})\).

Next, we prove Proposition 69 and note that Proposition 68 is similar.

**Proof of Proposition 69**

1. By Proposition 26,

\[
\mathbb{E} \left( \left\| \left[ V_f^* T_r \circ V_f \right]^{\eta,L,K} - V_f^* \eta T(\psi_r \circ V_f[s]) \right\|_{\mathcal{H}} \right)
\leq 4 \frac{\|\psi\|_1}{K} D^2 B \| r \circ V_f[s] \|_2^2 + 16 \frac{\|\eta\|_1 \|\psi\|_1}{LK} A^{-1} BC^2 D^2 \| r \circ V_f[s] \|_2^2
\]

\[+ 16 \frac{\|\eta\|_1}{L} A^{-1} BC^2 \| T \|_2 \| r \circ V_f[s] \|_2^2 \]

so the claim follows from \(\| r \circ V_f[s] \|_2 \leq E^2 B \| s \|_{\mathcal{H}}\) and bounding the vector norm \(\| S_f^{-1} z \|_{\mathcal{H}}\) by \(\| S_f^{-1} \|_{\mathcal{H}} || z ||_{\mathcal{H}}\) where \(z\) is the vector on which \(S_f^{-1}\) is applied in the pipeline.

2. By Proposition 28 With probability at least \((1 - \delta)^2\), and large enough \(K\),

\[
\left\| \left[ V_f^* T_r \circ V_f \right]^{\eta,L,K} - V_f^* \eta T(\psi_r \circ V_f[s]) \right\|_{\mathcal{H}} \leq B^{1/2} D \| r \circ V_f[s] \|_2 \frac{\|\psi\|_1}{\sqrt{K}} \kappa(\delta) + A^{-1/2} B^{1/2} C \| T \|_2 \| r \circ V_f[s] \|_2 \frac{\sqrt{\|\eta\|_1}}{\sqrt{L}} \kappa(\delta)^2
\]

\[+ A^{-1/2} B^{1/2} CD \| r \circ V_f[s] \|_2 \frac{\sqrt{\|\eta\|_1 \sqrt{\|\psi\|_1 \sqrt{K}}}}{\sqrt{L}} \kappa(\delta)^2 \]

where \(\kappa(\delta)\) is either the Markov or Bernstein type error bounds. In the Bernstein bound case, note that \(r \circ V_f[s'] \in L^\infty(G)\), where \(s' = S_f^1 s\) or \(s\), depending on the pipeline. Indeed,

\[
\left| r(V_f[s'](g)) \right| \leq E \| f_g \|_{\mathcal{H}} \| s' \|_{\mathcal{H}} \leq EC \max \{ \| s \|_{\mathcal{H}}, \left| S_f^{-1} \right| \| s \|_{\mathcal{H}} \}. \]

The claim now follows as before.
Proof of Theorem 52. We study the signal processing pipeline \( V_f^* \eta T (\psi r \circ V_f[s]) \) and note that to get the two pipelines \( (55) \) we either multiply from the right or from the left by the bounded operator \( S_f^{-1} \). In both cases, this multiplies the resulting bound by \( \|S_f^{-1}\|_\mathcal{H} \).

Denote by \( \mathcal{E} \) the error in either of the cases of Assumption 31; Namely, either

\[
\mathcal{E} = \| V_f^* \eta T V_f[s] - V_f^* K Tr \circ V_f[s] \|_\mathcal{H} \tag{123}
\]

or

\[
\mathcal{E} = \| V_f^* Tr \circ V_f[s] - [V_f^* Tr \circ V_f]^\eta K,\psi, K[s] \|_\mathcal{H} \tag{124}
\]

For the first case of Assumption 31 we have

\[
\mathcal{E} = \| V_f^* Tr \circ V_f[s] - V_f^* K Tr \circ V_f[s] \|_\mathcal{H}
\]

\[
\leq \| V_f^* Tr \circ V_f[s] - \psi T \psi r \circ V_f[s] \|_\mathcal{H} + \| V_f^* \eta T \psi r \circ V_f[s] - V_f^* K Tr \circ V_f[s] \|_\mathcal{H} \tag{125}
\]

and in this case we denote

\[
\mathcal{E}_0 = \| V_f^* \eta T \psi r \circ V_f[s] - V_f^* K Tr \circ V_f[s] \|_\mathcal{H} \tag{126}
\]

For the second case of Assumption 31 we have

\[
\mathcal{E} = \| V_f^* Tr \circ V_f[s] - [V_f^* Tr \circ V_f]^\eta K,\psi, K[s] \|_\mathcal{H}
\]

\[
\leq \| V_f^* Tr \circ V_f[s] - \psi T \psi r \circ V_f[s] \|_\mathcal{H} + \| V_f^* \eta T \psi r \circ V_f[s] - [V_f^* Tr \circ V_f]^\eta K,\psi, K[s] \|_\mathcal{H} \tag{127}
\]

and in this case we denote

\[
\mathcal{E}_0 = \| V_f^* \eta T \psi r \circ V_f[s] - [V_f^* Tr \circ V_f]^\eta K,\psi, K[s] \|_\mathcal{H} \tag{128}
\]

Let us bound the first term of the last line of \( (125) \) and \( (127) \). We have

\[
\| V_f^* Tr \circ V_f[s] - \psi T \psi r \circ V_f[s] \|_\mathcal{H} \leq B^{1/2} \| Tr \circ V_f[s] - \psi T \psi r \circ V_f[s] \|_2.
\]

Now, by \( (52) \) and \( (54) \),

\[
\| Tr \circ V_f[s] - \psi T \psi r \circ V_f[s] \|_2 \leq \| Tr \circ V_f[s] - T \psi r \circ V_f[s] \|_2 + \| T \psi r \circ V_f[s] - \psi T \psi r \circ V_f[s] \|_2 \leq \| T \|_2 \| r \circ V_f[s] - \psi r \circ V_f[s] \|_2 + \| T \psi - \psi T \psi r \|_2 \| r \circ V_f[s] \|_2 \leq \| T \|_2 \| (1 - \psi) r \circ V_f[s] \|_2 + \epsilon E \| V_f[s] \|_2.
\]

To analyze the first term of the last line of \( (125) \), observe

\[
\| (1 - \psi) r \circ V_f[s] \|_2^2 = \int |1 - \psi(g)|^2 |r(V_f[s](g))|^2 \, dg \leq \int |1 - \psi(g)|^2 E^2 |V_f[s](g)|^2 \, dg \leq E^2 \| \psi V_f[s] - V_f[s] \|_2^2 \leq \epsilon^2 E^2 \| V_f[s] \|_2^2.
\]

Thus, the first term of the last line of \( (125) \) and \( (127) \) satisfies

\[
\| V_f^* Tr \circ V_f[s] - V_f^* \eta T \psi r \circ V_f[s] \|_\mathcal{H} = O(\epsilon) \| V_f[s] \|_2 = O(\epsilon) \| s \|_\mathcal{H} \tag{130}
\]

As a result, by the property \((a + b)^2 \leq 4 \max(a^2, b^2)\) for every \( a, b \in \mathbb{R} \), both \( (125) \) and \( (127) \) lead to

\[
\mathcal{E}^2 \leq 4 \max \{ O(\epsilon^2) \| s \|_\mathcal{H}^2, \, \mathcal{E}_0^2 \}.
\]

By Lemma 63,

\[
\mathbb{E} \left( \mathcal{E}^2 \right) \leq 4 O(\epsilon^2) \| s \|_\mathcal{H}^2 + 4 \mathbb{E} \left( \mathcal{E}_0^2 \right),
\]

which gives \( (59) \) by Proposition 68 or \( (59) \) depending on the case of Assumption 31.

Equation \( (77) \) follows from the inequality

\[
\mathcal{E} \leq O(\epsilon) \| s \|_\mathcal{H}^2 + \mathcal{E}_0 \tag{133}
\]

and from Proposition 68 or \( (59) \) depending on the case of Assumption 31.
F.5 Proofs of Subsection 5.3.1

Proof of Claim 73. Let $\delta$. Given $q \in \mathcal{R}_C$, we can approximate $q$ by a smooth function $p \in L^2([-1/2, 1/2])$ that vanishes in a neighborhood of $-1/2$ and $1/2$, up to the small errors

$$\|q - p\|_2 < \delta, \quad \|q\|_\infty - \|p\|_\infty < \delta, \quad \|\xi^{-1}q\|_\infty - \|\xi^{-1}p\|_\infty < \delta. \quad (134)$$

Since $p$ and $\xi^{-1}p$ have continuously differentiable periodic extensions, their Fourier series converge to $p$ and $\xi^{-1}p$ respectively in both $L^2(-1/2, 1/2)$ and $L^\infty(-1/2, 1/2)$. We denote by $v_M$ the truncation of the Fourier series of $\xi^{-1}p$ up to the frequency $M$, multiplied by $\xi$. There is thus a large enough $M$, such that $v_M \in V_M$ satisfies

$$\|v_M - p\|_2 < \delta, \quad \|v_M - p\|_\infty < \delta, \quad \|\xi^{-1}v_M - \xi^{-1}p\|_\infty < \delta. \quad (135)$$

Given any $\delta' > 0$, by choosing $\delta$ small enough, and $M$ large enough, equations (134) and (135) guarantee that $v_M \in V_M \cap \mathcal{R}_C$ and $\|v_M - q\|_2 < \delta'$.

We prove Proposition 43 in a sequence of claims. Consider the phase space domain $G_M$ of [14]. Recall that $[-S, S]$ is the support of the mother wavelet $f$. Thus, $[-S/\omega, S\omega]$ is the support of the dilated wavelet $\omega^{1/2}f(\omega z)$. Since the signal $q$ is supported in time in $[-1/2, 1/2]$, $V_f[q](x, \omega)$ is zero for any $x \in (-1/2 - S/\omega, 1/2 + S/\omega)$. As a result, restricting $V_f[q]$ to the phase space domain

$$G_M' = \{(x, \omega) \mid W^{-1}M^{-1} < \omega < WM\}$$

is equivalent to restricting $V_f[q]$ to $G_M$. We thus consider without loss of generality the domain $G_M'$ instead of $G_M$ in this section.

We define the following inner product that corresponds to enveloping by $\xi$.

**Definition 71.** For any two measurable $q, p : [-1/2, 1/2] \to \mathbb{C}$

$$\langle q, p \rangle_\xi = \langle \xi^{-1}q, \xi^{-1}p \rangle = \int_{-1/2}^{1/2} \frac{1}{\xi'(x)}q(x)p(x)dx$$

where $\langle \xi^{-1}q, \xi^{-1}p \rangle$ is the $L^2[-1/2, 1/2]$ inner product. Denote

$$\|q\|_\xi = \sqrt{\langle q, q \rangle_\xi}.$$

Denote by $L_{2,\xi}(-1/2, 1/2)$ the Hilbert space of signals with $\|q\|_\xi < \infty$.

The following lemma characterizes the behavior of admissible wavelets about the zero frequency.

**Lemma 72.** Let $f \in L_2(\mathbb{R})$ be an admissible wavelet supported in $[-S, S]$. Then

$$|\hat{f}(z)| \leq 2\pi S \|f\|_1 |z| \leq 2^{3/2}\pi S^{3/2} \|f\|_2 |z|.$$

**Proof.** First note that by the fact that $f$ is supported in $(-S, S)$, it is also in $L^1(\mathbb{R})$ by the Cauchy-Schwarz inequality, with

$$\|f\|_1 \leq \sqrt{2S} \|f\|_2.$$

By the wavelet admissibility condition $\hat{f}(0) = 0$. Moreover, since $f$ is compactly supported, $\hat{f}$ is smooth. Thus, for $z > 0$,

$$\hat{f}(z) = \int_0^z \hat{f}'(y)dy.$$

As a result

$$|\hat{f}(z)| \leq \int_0^z |\hat{f}'(y)|dy \leq \|\hat{f}'\|_\infty z \leq 2\pi \|f\|_1 z \leq 2S\pi \|f\|_1 z \leq 2^{3/2}\pi S^{3/2} \|f\|_2 |z|.$$

For $z < 0$ the proof is similar.
Note that the basis \( \{ e^{2\pi i m \xi(x)} \}_{m=-M}^{M} \) of \( V_M \) is an orthonormal basis in \( L_2(\xi(-1/2,1/2)) \). By Parseval's identity, for \( q \in V_M \) satisfying

\[
q(x) = \sum_{m=-M}^{M} c_m e^{2\pi i m \xi(x)},
\]

we have

\[
\|q\|_\xi = \sqrt{\sum_{m=-M}^{M} |c_m|^2} = \| \{ c_m \}_{m=-M}^{M} \|_2.
\]

We prove Proposition 40 by embedding the signal class \( \mathcal{R}_C \) in a richer space, and proving linear volume discretization for the richer space. Consider the signal space \( \mathcal{S}_E \) of signals \( q \in L^2(-1/2,1/2) \) satisfying

\[
\|q\|_\xi \leq E \|q\|_2
\]

for some fixed \( E > 0 \).

**Claim 73.** \( \mathcal{R}_C \subset \mathcal{S}_E \) for any \( E \geq C^2 \).

**Proof.** Let \( q = \xi s \in \mathcal{R}_C \). By Cauchy Schwartz inequality

\[
\|q\|_\xi = \|s\|_2 \leq \|s\|_\infty = \|\xi^{-1} q\|_\infty \leq C \|q\|_\infty \leq C^2 \|q\|_2
\]

so

\[
\|q\|_\xi \leq C^2 \|q\|_2 \leq E \|q\|_2.
\]

\( \square \)

**Claim 74.** Under the above construction, with \( \xi \) satisfying (77) with \( k > 2 \), we have \( \mu(G_M) \leq 5WM \), and for every \( q_M \in V_M \cap \mathcal{S}_E \) we have

\[
\frac{\|I - \psi_M \mathcal{V}_f[q_M]\|_2}{\|\mathcal{V}_f[q_M]\|_2} = O(W^{-1}) + o_M(1).
\]

(137)

By Claim 73, Proposition 40 is now a corollary of Claim 74, where for every \( \varepsilon \) we choose \( W \) and \( M_0 \) large enough, so that for every \( M > M_0 \)

\[
\frac{\|I - \psi_M \mathcal{V}_f[q_M]\|_2}{\|\mathcal{V}_f[q_M]\|_2} < \varepsilon.
\]

(138)

**Proof of Claim 74.** Since \( \{ e^{2\pi i m \xi(x)} \}_{m=-M}^{M} \) is an orthonormal basis of \( V_M \subset L_2(\xi(-1/2,1/2)) \), in the frequency domain signals in \( V_M \) are spanned by \( \{ \hat{b}_m(z) = \xi(z-m) \}_{m=-M}^{M} \) (see Lemma 61). We bound \( \hat{b}_m(z) \) by

\[
|\hat{b}_m(z)| = |\hat{\xi}(z-m)| \leq \begin{cases} 
D, & |z-m| \leq 1 \\
D|z-m|^{-k}, & |z-m| > 1.
\end{cases}
\]

For \( \hat{q} = \sum_{m=-M}^{M} c_m \hat{b}_m \), with \( \|q\|_\xi = \| \{ c_m \}_{m=1}^{N} \|_2 \), we have \( |c_m| \leq \|q\|_\xi \) for all \( m \). Thus

\[
|\hat{q}(z)| \leq \sum_{m=-M}^{M} |c_m| \hat{b}_m(z) \leq \sum_{m=-M}^{M} \|q\|_\xi \begin{cases} 
D, & |z-m| \leq 1 \\
D|z-m|^{-k}, & |z-m| > 1.
\end{cases}
\]

(139)

For \( |z| \leq M + 2 \), (139) leads to the bound

\[
|\hat{q}(z)| \leq 2D \|q\|_\xi + \sum_{-M \leq m \leq M, \text{and } |z|} D|z-m|^{-k},
\]

(140)
and (140) is maximized by taking \( z = 0 \). We extend the sum to \( m \) between \(-\infty\) and \( \infty \), and without loss of generality increase the value of the sum by choosing \( z = 0 \). Thus, since \( k > 2 \),

\[
|q(\omega)| \leq 2D \|q\|_\xi + 2 \|q\|_\xi D \sum_{m=1}^{\infty} m^{-k} \leq 2D \|q\|_\xi + 2 \|q\|_\xi D \left( 1 + \int_1^{\infty} m^{-k} dm \right)
\]

\[
\leq 4 \|q\|_\xi D + 2 \|q\|_\xi D(k-1)^{-1} \leq 6D \|q\|_\xi.
\]

Now, for \( |z| > M + 2 \), without loss of generality consider \( z > 0 \). By (139) we have

\[
|\hat{q}(z)| \leq \|q\|_\xi \sum_{m=-M}^{M} (z-m)^{-k} \leq \|q\|_\xi \int_{-\infty}^{M+1} (z-m)^{-k} dm
\]

\[
\leq \|q\|_\xi D(z-M-1)^{-k+1}(k-1)^{-1}.
\]

Overall,

\[
\frac{|\hat{q}(z)|}{\|q\|_\xi} \leq \hat{E}(z) := \begin{cases} 
\frac{6D}{|z|}, & |z| \leq M + 2 \\
\frac{6D}{(|z|-M-1)^{-k+1}}, & |z| > M + 2
\end{cases}.
\] (141)

We consider the domain \( G'_M = \{ (x,\omega) : W^{-1}M^{-1} < \omega < AM \} \). Recall that restricting to \( G'_M \) is equivalent to restricting to \( \hat{G}_M \). Let \( \psi_M \) denote by abuse of notation the projection in phase space that restricts functions to the domain \( G'_M \). Next, we bound the error \( \| (I-\psi_M)V_f [q] \|_2 \) for signals in \( V_M \). Note that for every \( \omega \in \mathbb{R} \)

\[
\int_{\mathbb{R}} |V_f [q](\omega, x)|^2 dx = \int_{\mathbb{R}} |\hat{q}(z)|^2 \omega^{-1} |\hat{f}(\omega^{-1} z)|^2 dz.
\] (142)

Indeed, by Lemma 61

\[
V_f [q](x, \omega) = \int_{\mathbb{R}} \hat{q}(z) \omega^{-1/2} \hat{f}(\omega^{-1} z) e^{-2\pi i x z} dz
\]

\[
= \mathcal{F}^{-1} \left( \hat{q}\omega^{-1/2} \hat{f}(\omega^{-1} \cdot) \right)(x),
\]

so by Plancherel’s identity

\[
\int_{\mathbb{R}} |V_f [q](\omega, x)|^2 dx = \int_{\mathbb{R}} |\hat{q}(z)\omega^{-1/2} \hat{f}(\omega^{-1} z)|^2 dz.
\] (143)

Let us now bound the right-hand-side of (143) for \( \omega \) such that \((x,\omega) \notin G'_M \). We then integrate the result for \( \omega \in (W M, \infty) \), and for \( \omega \in (0, W^{-1} M^{-1}) \), to bound the error in phase space truncation by \( \psi_M \). Negative \( \omega \) are treated similarly.

We start with \( \omega > W M \). Here, we decompose the integral along \( z \) into two integrals with boundaries in \( 0, M + 2 + (0.5(\omega - M - 2))^{1/2} \). For each segment of the integral along \( z \), by additivity of the integral, we integrate \( \omega \) along \((W M, \infty) \) and show that the resulting value is small. The first segment gives

\[
\int_0^{M+2 + (0.5(\omega - M - 2))^{1/2}} |\hat{q}(z)|^2 d z \omega^{-1/2} \hat{f}(\omega^{-1} z)^2 d z
\]

\[
\leq \int_0^{M+2 + (0.5(\omega - M - 2))^{1/2}} |\hat{q}(z)|^2 d z \max_{0 \leq z < M+2 + (0.5(\omega - M - 2))^{1/2}} \omega^{-1/2} \hat{f}(\omega^{-1} z)^2.
\]

By Lemma 72, the dilated mother wavelet satisfies

\[
\omega^{-1/2} \hat{f}(\omega^{-1} z) \leq 2\pi S \| f \|_1 |z| \omega^{-1.5},
\] (144)
Thus \(k\) since for \(w\), the bound (147) gives so

\[
\int_0^{M+2+\left(0.5(\omega-M-2)\right)^{1/2}} |q(z)|^2 |\omega^{-1/2} \tilde{f}(\omega^{-1} z)|^2 \, dz
\]

\[
\leq \|q\|^2 \frac{4\pi^2 S^2}{\|f\|_1^2} (M + 2 + \left(0.5(\omega-M-2)\right)^{1/2})^2 \omega^{-3} = 4\pi^2 S^2 \|q\|^2 \|f\|_1^2 G(\omega)
\]

for \(G(\omega) = \left(M + 2 + \left(0.5(\omega-M-2)\right)^{1/2}\right)^2 \omega^{-3}\). We study \(G(\omega)\) for different values of \(\omega\). When \(\omega > M^2\), the value \(\left(M + 2 + \left(0.5(\omega-M-2)\right)^{1/2}\right)^2\) is bounded by \(4\omega\) for large enough \(M\), so

\[
G(\omega) \leq 4\omega^{-2}. \quad (146)
\]

When \(\omega < M^2\), \(\left(M + 2 + \left(0.5(\omega-M-2)\right)^{1/2}\right)^2\) is bounded by \(4M^2\) for large enough \(M\), so

\[
G(\omega) \leq 4M^2 \omega^{-3}. \quad (147)
\]

For \(\omega > M^2\), integrating via the bound (146) gives

\[
\int_{M^2}^{\infty} \int_0^{M+2+\left(0.5(\omega-M-2)\right)^{1/2}} |q(z)|^2 |\omega^{-1/2} \tilde{f}(\omega^{-1} z)|^2 \, dz \, d\omega = o_M(1) \|q\|^2_2, \quad (148)
\]

where \(o_M(1)\) is a function that converges to zero as \(M \to \infty\). For \(WM < \omega < M^2\), integrating via the bound (147) gives

\[
\int_{WM}^{M^2} \int_0^{M+2+\left(0.5(\omega-M-2)\right)^{1/2}} |q(z)|^2 |\omega^{-1/2} \tilde{f}(\omega^{-1} z)|^2 \, dz \, d\omega = O(W^{-2}) \|q\|^2_2 \quad (149)
\]

Overall, (149) and (148) give

\[
\int_{WN}^{\infty} \int_0^{M+2+\left(0.5(\omega-M-2)\right)^{1/2}} |q(z)|^2 |\omega^{-1/2} \tilde{f}(\omega^{-1} z)|^2 \, dz \, d\omega = (O(W^{-2}) + o_M(1)) \|q\|^2_2. \quad (150)
\]

Next, we study \(z \in \left(M + 2 + \left(0.5(\omega-M-2)\right)^{1/2}, \infty\right)\). Here, we take the maximum of the signal squared, and take the 2 norm of the window. By (141) we obtain for large enough \(M\)

\[
\int_{M+2+\left(0.5(\omega-M-2)\right)^{1/2}}^{\infty} |q(z)|^2 |\omega^{-1/2} \tilde{f}(\omega^{-1} z)|^2 \, dz \leq \|f\|^2_2 36D^2 \left(M + 2 + \left(0.5(\omega-M-2)\right)^{1/2} - M - 1\right)^{-2k+2} \|\bar{q}\|^2_2 < \|f\|^2_2 36D^2(\omega-M)^{-k+1} \|\bar{q}\|^2_2 \quad (151)
\]

Integrating the bound (151) along \(w \in (WM, \infty)\) gives

\[
\int_{WM}^{\infty} \int_{M+2+\left(0.5(\omega-M-2)\right)^{1/2}}^{\infty} |q(z)|^2 |\omega^{-1/2} \tilde{f}(\omega^{-1} z)|^2 \, dz \, d\omega = o_M(1) \|q\|^2_2 = o_M(1) \|q\|^2_2, \quad (152)
\]

since \(k > 2\) and \(|\bar{q}|_\xi \leq E \|\bar{q}\|_2\).

Last, we integrate \(\omega \in (0, W^{-1}M^{-1})\). By (141)

\[
\|\bar{q}\|_\infty \leq 6D \|\bar{q}\|_\xi.
\]

Thus

\[
\int_{-\infty}^{\infty} |q(z)|^2 |\omega^{-1/2} \tilde{f}(\omega^{-1} z)|^2 \, dz \leq \|\bar{q}\|^2_\infty \|\bar{f}\|^2_2 \leq 36D^2 \|f\|^2_2 \|\bar{q}\|^2_\xi = O(1) \|q\|^2_2. \quad (153)
\]
Thus, the integration of the bound (153) for $\omega \in (0, W^{-1} M^{-1})$ gives
\[
\int_0^{W^{-1} M^{-1}} \int_{-\infty}^{\infty} |\tilde{q}(z)|^2 |\omega^{-1/2} \hat{f}(\omega^{-1} z)|^2 \, dz = O(M^{-1}) \|q\|_2^2.
\] (154)

Summarizing the estimates (150), (152) and (154), together with the analogue bounds for $\omega < 0$, we obtain
\[
\|(I - \psi_M) V_f[q]\|_2 = O(W^{-1}) + o_M(1) \|q\|_2.
\]
Last, since by the frame assumption $\|q\|_2^2 \leq A^{-1} \|V_f(q)\|_2^2$, we have
\[
\frac{\|(I - \psi_M) V_f[q]\|_2}{\|V_f[q]\|_2} = J(W, M) = O(W^{-1}) + o_M(1).
\]

This means that given $\epsilon > 0$, we may choose $W$ large enough to guarantee $J(W, M) < \epsilon$ up from some large enough $M_0$, and also guarantee for every $M \in \mathbb{N}$
\[
\|\psi_M\|_1 \leq C^\nu M
\]
with $C^\nu = 3W$ by (159).

\[\square\]

### F.6 Proofs of Subsection 5.3.2

**Proof of Proposition 7** Consider $W > 1$. Similarly to formula (152) of the CWT, for the STFT we have
\[
\int_{\mathbb{R}} |V_f[q]|^2 \, dx = \int_{\mathbb{R}} |\tilde{q}(z)|^2 |\hat{f}(z - \omega)|^2 \, dz.
\] (155)

We consider $\omega > 0$ and $z > 0$, and note that the other cases are similar. For each value of $\omega > MW$, we decompose the integral (155) along $z$ into two the integrals in $z \in (0, (M + \omega)/2)$ and $z \in ((M + \omega)/2, \infty)$.

For $z \in (0, (M + \omega)/2)$, we have
\[
z - M - \omega/2 \leq -M(W/2 - 1) < 0,
\]
so $|z - \omega|^{-2\kappa}$ obtains its maximum at $z = (M + \omega)/2$. Thus, by (78),
\[
\int_0^{(M+\omega)/2} |\tilde{q}(z)|^2 |\hat{f}(z - \omega)|^2 \, dz \leq \|q\|_2^2 \max_{0 \leq z \leq (M+\omega)/2} C^{2\kappa} |z - \omega|^{-2\kappa}
\]
\[
= \|q\|_2^2 C^{2\kappa} (M + \omega)/2 - \omega|^{-2\kappa} = \|q\|_2^2 C^{2\kappa} (M - \omega)/2|^{-2\kappa}.
\] (156)

Integrating the bound (156) for $\omega \in (WM, \infty)$ gives
\[
\int_{WM}^{\infty} (M+\omega)/2 |\tilde{q}(z)|^2 |\hat{f}(z - \omega)|^2 \, dz \, d\omega = (W - 1)^{-2\kappa+1} M^{-2\kappa+1} \|q\|_2^2 O(1) = o_W(1) o_M(1) \|q\|_2^2.
\] (157)

For $z \in ((M + \omega)/2, \infty)$, $\tilde{q}$ decays like $M^{1/2} (z - M)^{-1}$. Indeed, since $z > M$
\[
\sum_{n=-M}^{M} c_n \text{sinc} (z - n) \leq \|\{c_n\}\|_2 \sqrt{\sum_{n=-M}^{M} \frac{1}{(z - n)^2}} \leq \|q\|_2 \sqrt{\sum_{n=-M}^{M} \frac{1}{(z - M)^2}} \leq 2 \|q\|_2 \sqrt{M(z - M)^{-1}}.
\] (158)

Now, by (156) and (158),
\[
\int_{(M+\omega)/2}^{M} |\tilde{q}(z)|^2 |\hat{f}(z - \omega)|^2 \, dz \leq 2 \|f\|_2^2 \max_{M+\omega/2 \leq \omega} M(z - M)^{-2}
\]
\[
= \|f\|_2^2 \max_{M+\omega/2 \leq \omega} M((\omega - M)/2)^{-2}.
\] (159)
Integrating the bound \(159\) for \(\omega \in (WM, \infty)\) gives
\[
\int_{WM}^{\infty} \int_{(\omega + \omega)/2}^{\infty} |q(z)|^2 \left|\hat{f}(z - \omega)\right|^2 dzd\omega = (W - 1)^{-1} \|q\|^2 \Omega(1).
\] (160)

Last, the bounds \(157\) and \(160\) are combined similarly to the proof of Claim \(74\). □

**F.7 The localizing time-frequency transform: proofs of Subsection 3.6.1 and 3.6.2**

Since \((x, \omega, \tau) \mapsto f_{x, \omega, \tau}\) is continuous, \(V_f[s] : G \to \mathbb{C}\) is a continuous function for every \(s \in L^2(\mathbb{R})\), and thus measurable. To show that \(f\) is continuous frame, it is left to show the existence of frames bounds \(0 < A \leq B < \infty\) satisfying \(11\). Equivalently we show that \(V_f\) is injective and
\[
\|V_f\| \leq B^{1/2}, \quad \|V_f^*\| \leq A^{-1/2}
\] (161)
where \(V_f^* : L^2(G) \to L^2(\mathbb{R})\) is the pseudo inverse of \(V_f\) as defined in Subsection 3.1.

We start by deriving some basic formulas for the LTFT system. For convenience, we recall equation \(55\) here.

\[
f_{x, \omega, \tau}(t) = \begin{cases} \sqrt{\frac{\tau}{\omega}}h\left(\frac{\omega}{\omega}(t - x)\right)e^{2\pi i \omega(t - x)} & \text{if } |\omega| < a_{\tau} \\ \sqrt{\frac{\tau}{b_{\tau}}h\left(\frac{\omega}{b_{\tau}}(z - \omega)\right)e^{2\pi i \omega z} & \text{if } a_{\tau} \leq |\omega| \leq b_{\tau} \\ \sqrt{\frac{\tau}{b_{\tau}}h\left(\frac{\omega}{b_{\tau}}(z - \omega)\right)e^{2\pi i \omega z} & \text{if } b_{\tau} < |\omega|. \end{cases}
\] (162)

Next, we derive a formula for the LTFT atoms \(\hat{f}_{x, \omega, \tau}\) in the frequency domain.

**Lemma 75.** LTFT atoms take the following form in the frequency domain.

\[
\hat{f}_{x, \omega, \tau}(z) = \begin{cases} \sqrt{\frac{\tau}{\omega}}h\left(\frac{\omega}{\omega}(z - \omega)\right)e^{-2\pi i \omega z} & \text{if } |\omega| < a_{\tau} \\ \sqrt{\frac{\tau}{b_{\tau}}h\left(\frac{\omega}{b_{\tau}}(z - \omega)\right)e^{-2\pi i \omega z} & \text{if } a_{\tau} \leq |\omega| \leq b_{\tau} \\ \sqrt{\frac{\tau}{b_{\tau}}h\left(\frac{\omega}{b_{\tau}}(z - \omega)\right)e^{-2\pi i \omega z} & \text{if } b_{\tau} < |\omega|. \end{cases}
\] (163)

For \(f_{\tau}(t) = \tau^{-1/2}h(t^{-1} t)e^{2\pi i t}\) we have
\[
\hat{f}_{\tau}(z) = \tau^{1/2}h(\tau(z - 1)),
\] (164)
and another formula in case \(a_{\tau} \leq |\omega| \leq b_{\tau}\) is
\[
\hat{f}_{x, \omega, \tau}(z) = \omega^{-1/2} \hat{f}_{\tau}(\omega^{-1} z)e^{-2\pi i \omega z}.
\]

**Proof.** We consider the transform formulas of \(13\)

\[
f_{x, \omega, \tau}(t) = \begin{cases} \mathcal{T}(x)\mathcal{M}(\omega)\mathcal{D}(a_{\tau} t)h & \text{if } |\omega| < a_{\tau} \\ \mathcal{T}(x)\mathcal{M}(\omega)\mathcal{D}(\omega/\tau)h & \text{if } a_{\tau} \leq |\omega| \leq b_{\tau} \\ \mathcal{T}(x)\mathcal{M}(\omega)\mathcal{D}(b_{\tau} t)h & \text{if } b_{\tau} < |\omega|. \end{cases}
\] (165)

Thus, by Lemma \(61\)

\[
\hat{f}_{x, \omega, \tau}(z) = \begin{cases} \mathcal{M}(-x)\mathcal{T}(\omega)\mathcal{D}(\tau/a_{\tau})h & \text{if } |\omega| < a_{\tau} \\ \mathcal{M}(-x)\mathcal{T}(\omega)\mathcal{D}(\omega/\tau)h & \text{if } a_{\tau} \leq |\omega| \leq b_{\tau} \\ \mathcal{M}(-x)\mathcal{T}(\omega)\mathcal{D}(b_{\tau} t)h & \text{if } b_{\tau} < |\omega|, \end{cases}
\] (166)
which gives \(163\).
We can write \( f_\tau = M(1)D(\tau^{-1})h \). Another formula in case \( a_\tau \leq |\omega| \leq b_\tau \) is
\[
{f_\tau}_\omega = T(x)D(\omega)\hat{f}_\tau,
\]
so
\[
\hat{f}_\tau,\omega,\tau = M(-\omega)D(\omega^{-1})\hat{f}_\tau.
\]
We can also write
\[
\hat{f}_\tau,\omega,\tau = M(-\omega)D(\omega^{-1})T(1)D(\tau)\hat{f}_\tau.
\]

For convenience, we repeat here Definition \([15]\). The sub-frame filters \( \tilde{S}_f^{\text{low}}, \tilde{S}_f^{\text{mid}}, \text{and } \tilde{S}_f^{\text{high}} \) are the functions \( \mathbb{R} \rightarrow \mathbb{C} \) defined by
\[
\tilde{S}_f^{\text{band}}(z) = \int_{\tau_1}^{\tau_2} \int_{\mathbb{R}} |\hat{h}^{\text{band}}(\tau, \omega; z - \omega)|^2 \, d\omega d\tau.
\]
(167)
The frame filter \( \tilde{S}_f : \mathbb{R} \rightarrow \mathbb{C} \) is defined by
\[
\tilde{S}_f = \tilde{S}_f^{\text{low}} + \tilde{S}_f^{\text{mid}} + \tilde{S}_f^{\text{high}}.
\]
Let \( \text{band} \in \{\text{low, mid, high} \} \), and recall that \( \mathcal{J}_\text{band} \) denotes the integration domain of \( \omega \) corresponding to the band. For convenience, we recall equation \([169]\)
\[
\hat{h}^{\text{band}}(\tau, \omega; z - \omega) = \begin{cases} 
\sqrt{\frac{\pi}{\tau}} h\left(\frac{\pi}{\tau}(z - \omega)\right) & \text{if } |\omega| < a_\tau \\
\sqrt{\frac{\pi}{\tau}} h\left(\frac{\pi}{\tau}(z - \omega)\right) & \text{if } a_\tau \leq |\omega| \leq b_\tau \\
\sqrt{\frac{\pi}{\tau}} h\left(\frac{\pi}{\tau}(z - \omega)\right) & \text{if } b_\tau \leq |\omega|.
\end{cases}
\]
(168)
Thus, by \([165]\),
\[
\hat{f}_\tau,\omega,\tau(z) = \hat{h}^{\text{band}}(\tau, \omega; z - \omega)e^{-2\pi i x z},
\]
for the band corresponding to \( \omega \). We can now derive an Proof Proposition \([16]\).

**Proof of Proposition \([16]\)** For any band \( \text{band} \in \{\text{low, mid, high} \} \)
\[
S_f^{\text{band}}s = \int_{\tau_1}^{\tau_2} \int_{\mathcal{J}_\text{band}} \int_{\mathbb{R}} V_f[s](x, \omega, \tau) \, dx \, d\omega d\tau,
\]
and observe that
\[
S_f = S_f^{\text{low}} + S_f^{\text{mid}} + S_f^{\text{high}}.
\]
We show that for any band \( \text{band} \in \{\text{low, mid, high} \} \), and any \( s \in L^2(\mathbb{R}) \),
\[
\mathcal{F}S_f^{\text{band}}s(z) = \tilde{S}_f^{\text{band}}(z)s(z).
\]
(169)
We offer the following informal computation.
\[
\mathcal{F}S_f^{\text{band}}s(z) = \int_{\tau_1}^{\tau_2} \int_{\mathcal{J}_\text{band}} \int_{\mathbb{R}} V_f[s](x, \omega, \tau) \hat{f}_\tau,\omega,\tau(z) \, dx \, d\omega d\tau
\]
\[
= \int_{\tau_1}^{\tau_2} \int_{\mathcal{J}_\text{band}} \int_{\mathbb{R}} \hat{s}(y) \hat{f}_\tau,\omega,\tau(y) \, dy \, dx \, d\omega d\tau
\]
\[
= \int_{\tau_1}^{\tau_2} \int_{\mathcal{J}_\text{band}} \int_{\mathbb{R}} \hat{s}(y) \hat{h}^{\text{band}}(\tau, \omega; y - \omega)e^{-2\pi i x z} dy \, \hat{h}^{\text{band}}(\tau, \omega; z - \omega)e^{-2\pi i x z} \, dx \, d\omega d\tau
\]
\[
= \int_{\tau_1}^{\tau_2} \int_{\mathcal{J}_\text{band}} \int_{\mathbb{R}} \left( \int_{\mathbb{R}} e^{-2\pi i x (z - y)} dx \right) \hat{s}(y) \hat{h}^{\text{band}}(\tau, \omega; y - \omega) \, d\omega d\tau
\]
\[
= \int_{\tau_1}^{\tau_2} \int_{\mathcal{J}_\text{band}} \hat{s}(z - y) \hat{h}^{\text{band}}(\tau, \omega; y - \omega) \, d\omega d\tau
\]
\[
= \int_{\tau_1}^{\tau_2} \int_{\mathcal{J}_\text{band}} \hat{s}(z) \hat{h}^{\text{band}}(\tau, \omega; z - \omega) \, d\omega d\tau
\]
\[
= \hat{s}(z) \int_{\tau_1}^{\tau_2} \int_{\mathcal{J}_\text{band}} |\hat{h}^{\text{band}}(\tau, \omega; z - \omega)|^2 \, d\omega d\tau.
\]
Here, $\delta$ is the delta functional, and the informal computation with the delta functional can be formulated appropriately similarly to the usual Calderns reproducing formula in continuous wavelet analysis (see, e.g., [10 Proposition 2.1 and 2.4.1], [8 Theorem 1], and [15 Theorem 2.5]).

**Proof of Theorem 12** We offer the following informal computation, analogues to the proof of Proposition 19

$$
\|V_f^\text{band}_s\|_2^2 = \int_{\tau_1}^{\tau_2} \int_{\mathcal{J}_B^\text{band}} \int_{R} |V_f[s](x, \omega, \tau)|^2 \, dx \, d\omega \, d\tau
$$

$$
= \int_{\tau_1}^{\tau_2} \int_{\mathcal{J}_B^\text{band}} \int_{R} \hat{s}(y) \overline{f_{x, \omega, \tau}}(y) \, dy \int_{z \in R} \hat{s}(z) f_{x, \omega, \tau}(z) \, dz \, dx \, d\omega \, d\tau
$$

$$
= \int_{\tau_1}^{\tau_2} \int_{\mathcal{J}_B^\text{band}} \int_{R} \hat{s}(y) \overline{h^\text{band}(\tau, \omega; y - \omega)} e^{-2\pi i \tau z} \, dy \ldots
$$

$$
\ldots \hat{h}(\tau, \omega; z - \omega) e^{-2\pi i \tau z} \, dz \, dx \, d\omega \, d\tau
$$

$$
= \int_{\tau_1}^{\tau_2} \int_{\mathcal{J}_B^\text{band}} \int_{\tau, \omega} \hat{s}(z) \overline{h^\text{band}(\tau, \omega; z - \omega)} \, dz \, d\omega \, d\tau
$$

$$
= \int_{\tau_1}^{\tau_2} \int_{\mathcal{J}_B^\text{band}} |\hat{s}(z)|^2 \int_{\tau_1}^{\tau_2} \int_{\mathcal{J}_B^\text{band}} |h^\text{band}(\tau, \omega; z - \omega)|^2 \, d\omega \, d\tau. \tag{170}
$$

Here, $\delta$ is the delta functional, and the formal computation with the delta functional can be formulated appropriately as explained in the proof of Proposition 19.

Repeating (10), we denote for each band

$$
\hat{S}_f^\text{band}_s(z) = \int_{\tau_1}^{\tau_2} \int_{\mathcal{J}_B^\text{band}} |h^\text{band}(\tau, \omega; z - \omega)|^2 \, d\omega \, d\tau
$$

and

$$
\hat{S}_f = \hat{S}_f^\text{low} + \hat{S}_f^\text{mid} + \hat{S}_f^\text{high}. \tag{171}
$$

Now note that by the fact the three $\mathcal{J}_B^\text{band}$ domains are disjoint, so

$$
\|V_f[s]\|_2^2 = \|V_f^\text{low}_s]\|_2^2 + \|V_f^\text{mid}_s]\|_2^2 + \|V_f^\text{high}_s]\|_2^2.
$$

Thus, by (170) and (172),

$$
\|V_f[s]\|_2^2 = \int_{z \in R} |\hat{s}(z)|^2 \hat{S}_f(z) \, dz.
$$

Our goal now is to show that for every $z \in R$, $\hat{S}_f(z)$ is bounded from below by some $A > 0$, and from above by some $B > 0$. The constants $A, B$ are the frame bounds. In the following we construct implicit upper and lower bounds for $\hat{S}_f(z)$, without any effort to make these bound realistic estimates of $\|V_f\|^2$ and $\|V_f^*_s\|^2$. The goal is to prove that $f$ is a continuous frame, rather than to obtain good frame bound. In Subsection 3.6.2 we explain separately that numerically estimating $\hat{S}_f$ and $\hat{S}_f^*$ give good estimates for the frame bounds.

Next, we show that there is some $A > 0$ such that for every $z \in R$, $\hat{S}_f(z) \geq A$. For simplicity, we consider the case where $a_\tau = a$ and $b_\tau = b$ are constants. The general case is shown similarly with the appropriate modifications. Let $z \geq 0$, and note that the case $z \leq 0$ is shown symmetrically. By the fact that $h$ is a non-negative function,

$$
\hat{h}(0) = \|h\|_1 > 0. \tag{173}
$$
Since \( h \) is compactly supported, \( \hat{h} \) is smooth, so there is some \( \nu > 0 \) such that for every \( z \in (-\nu, \nu) \)

\[
\hat{h}(z) \geq \frac{1}{2} \|h\|_1 = C_0. \tag{174}
\]

If \( z \in [0, a] \),

\[
\hat{h}^{\mathrm{band}}(\tau, \omega; z - \omega) = \sqrt{\frac{\tau}{a}} \hat{h}(\frac{\tau}{a}(z - \omega)).
\]

By (174), for any \( \omega \)

we have

\[
|\hat{h}^{\mathrm{band}}(\tau, \omega; z - \omega)| \geq \sqrt{\frac{\tau}{a}} C_0. \tag{175}
\]

Let \( I_z \) denote the interval \( (z - \nu \frac{\tau_2}{\tau}, z + \nu \frac{\tau_2}{\tau}) \cap (-a, a) \), and note that the length of \( I_z \) is bounded from below by

\[
\mu(I_z) \geq \frac{\nu}{\tau_2}. \tag{176}
\]

Thus, by the fact that the integrand of (40) is non-negative, the fact that \( \mu(I([\tau_1, \tau_s]) = 1, (175) \)

\[
\int_{\tau_1}^{\tau_2} \int_{I_z} \frac{|\hat{h}^{\mathrm{band}}(\tau, \omega; z - \omega)|^2}{\omega} \, d\omega \, d\tau \geq \int_{\tau_1}^{\tau_2} \int_{I_z} \frac{|\hat{h}^{\mathrm{band}}(\tau, \omega; z - \omega)|^2}{\omega} \, d\omega \, d\tau \geq \nu \frac{\tau_1}{\tau_2} C_0^2 = C_1. \tag{177}
\]

If \( z \in (a, b] \),

\[
\hat{h}^{\mathrm{band}}(\tau, \omega; z - \omega) = \sqrt{\frac{\omega}{\tau}} \hat{h}(\frac{\omega}{\tau}(z - \omega)).
\]

By (174), for any \( \omega \)

we have

\[
|\hat{h}^{\mathrm{band}}(\tau, \omega; z - \omega)| \geq \sqrt{\frac{\tau}{b}} C_0. \tag{178}
\]

Let \( I_z \) denote the interval \( (z - \nu \frac{\tau_2}{\tau}, z + \nu \frac{\tau_2}{\tau}) \cap (a, b) \), and note that the length of \( I_z \) is bounded from below by

\[
\mu(I_z) \geq \frac{\nu}{\tau_2}. \tag{179}
\]

Thus, by the fact that the integrand of (40) is non-negative, by \( \mu(I([\tau_1, \tau_s]) = 1, (178) \)

\[
\int_{\tau_1}^{\tau_2} \int_{I_z} \frac{|\hat{h}^{\mathrm{band}}(\tau, \omega; z - \omega)|^2}{\omega} \, d\omega \, d\tau \geq \int_{\tau_1}^{\tau_2} \int_{I_z} \frac{|\hat{h}^{\mathrm{band}}(\tau, \omega; z - \omega)|^2}{\omega} \, d\omega \, d\tau \geq \nu \frac{\tau_1}{\tau_2} C_0^2 = C_2. \tag{180}
\]

Last, if \( z \in [b, \infty) \),

\[
\hat{h}^{\mathrm{band}}(\tau, \omega; z - \omega) = \sqrt{\frac{\tau}{b}} h(\frac{\tau}{b}(z - \omega)).
\]

By (174), for any \( \omega \)

we have

\[
|\hat{h}^{\mathrm{band}}(\tau, \omega; z - \omega)| \geq \sqrt{\frac{\tau}{b}} C_0. \tag{181}
\]
Let $\mathcal{I}_z$ denote the interval $(z - \nu, z + \nu)$, and note that the length of $\mathcal{I}_z$ is bounded from below by
\[
\mu(\mathcal{I}_z) \geq \nu.
\]
(182)

Thus, by the fact that the integrand of (180) is non-negative, by $\mu(\mathcal{I}_z) = 1$, (181) and (182),
\[
\hat{S}_f^{\text{band}}(z) = \int_{\tau_1}^{\tau_2} \int_{\mathcal{J}_z} \hat{h}^{\text{band}}(\tau, \omega; z - \omega) \, d\omega d\tau \geq \int_{\tau_1}^{\tau_2} \int_{\mathcal{I}_z} \left| \hat{h}^{\text{band}}(\tau, \omega; z - \omega) \right|^2 d\omega d\tau \geq \frac{b}{\tau_2} \int_{\mathcal{I}_z} \left| \hat{h}^{\text{band}}(\tau, \omega; 0) \right|^2 d\omega d\tau \geq \frac{b}{\tau_2} C_0^2 = C_3.
\]
(183)

By taking $A = \min\{C_1, C_2, C_3\}$, for every $z \geq 0$
\[
\hat{S}_f^{\text{band}}(z) \geq A,
\]
and thus
\[
\left\| V_f(s) \right\|_2^2 \geq A \left\| s \right\|_2.
\]

Next, we bound $\left\| V_f \right\|^2$ from above. Note that
\[
\left\| V_f \right\|^2 = \left\| V_{f^{\text{low}}} \right\|^2 + \left\| V_{f^{\text{mid}}} \right\|^2 + \left\| V_{f^{\text{high}}} \right\|^2,
\]
where $V_{f^{\text{band}}}$ is $V_f$ restricted to $(x, \omega, \tau)$ with $\omega \in \mathcal{J}_x$, for any bad $\mathcal{J}_x \in \{\text{low, mid, high}\}$. The systems $f^{\text{low}}$ and $f^{\text{high}}$ are both STFT systems restricted in phase space to a sub-domain of frequencies, and integrated along $\tau \in (\tau_1, \tau_2)$. By extending $f^{\text{low}}$ and $f^{\text{high}}$ to the whole frequency axis $\mathbb{R}$, and by Subsection 4.8 we increase $\| V_{f^{\text{low}}} \|$ and $\| V_{f^{\text{high}}} \|$ to the frame bound of the STFT which is 1. This shows that
\[
\left\| V_{f^{\text{low}}} \right\|, \left\| V_{f^{\text{high}}} \right\| \leq 1.
\]

It is left to bound $\| V_{f^{\text{mid}}} \|^2$ from above.

Recall the pseudo mother wavelet defined in (37),
\[
f_\tau(t) = \tau^{-1/2} h(\tau^{-1} t) e^{2\pi i t}.
\]

In the following we use the bound
\[
\left\| \hat{f}_{\tau} \right\|_\infty \leq \| f \|_1 = \tau^{1/2} \int |h(\tau^{-1} t)| \tau^{-1} dt = \tau^{1/2} \| h \|_1 \leq \tau_2^{1/2} \| h \|_2 \leq \tau_2^{1/2} \| h \|_2 = C_0.
\]
(184)

By (170)
\[
\left\| V_{f^{\text{mid}}} \right\|^2 = \int_z |\hat{h}(z)|^2 \hat{S}_f^{\text{mid}}(z) dz,
\]
and by Lemma 75
\[
\hat{S}_f^{\text{mid}}(z) = \int_{\tau_1}^{\tau_2} \int_{\mathcal{J}_z} \omega^{-1} |f_\tau(\omega^{-1} z)|^2 \, d\omega d\tau.
\]
(185)

Let us change variable in (185), and consider the interval $\omega \in \mathcal{J}_x = [a, b]$. By $\omega^{-1} z = y$, we have $\omega = y^{-1} \, dy$, and $\omega = a \iff y = a^{-1} z$, $\omega = b \iff y = b^{-1} z$.

Thus
\[
\hat{S}_f^{\text{mid}}(z) = \int_{\tau_1}^{\tau_2} \int_{y^{-1} \mathcal{J}_x} \omega^{-1} |f_\tau(\omega^{-1} z)|^2 \omega^{-1} \, dy \, d\tau = \int_{\tau_1}^{\tau_2} \int_{y^{-1} \mathcal{J}_x} |f_\tau(y)|^2 y^{-1} \, dy \, d\tau.
\]

Therefore, by (184),
\[
\hat{S}_f^{\text{mid}}(z) = \int_{\tau_1}^{\tau_2} \int_{y^{-1} \mathcal{J}_x} \omega^{-1} |f_\tau(y)|^2 y^{-1} \, dy \, d\tau \leq \int_{\tau_1}^{\tau_2} C_0 \int_{y^{-1} \mathcal{J}_x} y^{-1} \, dy \, d\tau = \int_{\tau_1}^{\tau_2} C_0 \ln \left( \frac{b}{a} \right) d\tau = (\tau_2 - \tau_1) C_0 \ln \left( \frac{b}{a} \right) = C'.
\]

To conclude,
\[ \|V_f\| \leq \|V_{f_{\text{low}}}\| + \|V_{f_{\text{mid}}}\| + \|V_{f_{\text{high}}}\| \leq 2 + \sqrt{C'} = \sqrt{B}. \]

### F.8 Proofs of Subsection 6.3

**Proof of Proposition 43.** We sketch the proof of Proposition 43 in two steps.

The first step is to treat the LTFT as an integration of continuous frames along the $\tau$ axis. For each fixed $\tau \in [\tau_1, \tau_2]$, consider the two-dimensional time-frequency system \( \{f_{x,\omega,\tau}\}_{(x,\omega) \in \mathbb{R}^2} \). Similarly to the proof of Theorem 14 we can show that \( \{f_{x,\omega,\tau}\}_{(x,\omega) \in \mathbb{R}^2} \) is a continuous frame for each $\tau$. Indeed, the only adjustment required in the proof of Theorem 14 is to take $\tau$ as a constant instead of integrating it along $\tau \in [\tau_1, \tau_2]$. We obtain a family of continuous frames with global frame bounds $A, B$. For each fixed $\tau$, \( \{f_{x,\omega,\tau}\}_{(x,\omega) \in \mathbb{R}^2} \) is a CWT-STFT hybrid time-frequency transform, where low and high frequency atoms are STFT atoms, and middle frequency atoms are pseudo-CWT atoms. To show linear volume of the CWT-STFT hybrid transform with respect to $V_R^n$ and $\psi_R^n$, we truncate from phase space any frequency above $WR$ or below $-WR$. Since we take $W > 1$, and the high transition frequency $b_\tau$ is less than $R$, we actually only truncate STFT atoms. Now, the error entailed by truncating STFT atoms was derived in the proof of Proposition 41, which shows that the CWT-STFT hybrid transform is linear volume discretizable.

In the second step, we consider the LTFT transform as the integration of the CWT-STFT hybrid transforms along $\tau \in [\tau_1, \tau_2]$, all sharing the same envelope. Thus, by Remark 36 the LTFT is linear volume discretizable with respect to the class $\text{PW}_R$, the discretization \( \{V_R^n\}_{M \in \mathbb{N}} \), and the envelopes $\psi_R^n$.
