#### Abstract

We study the statistical properties of stationary, isotropic and homogeneous turbulence in twodimensional (2D) flows, focusing on the direct cascade, that is on wave-numbers large compared to the integral scale, where both energy and enstrophy are provided to the fluid. Our starting point is the 2D Navier-Stokes equation in the presence of a stochastic forcing, or more precisely the associated field theory. We unveil two extended symmetries of the Navier-Stokes (NS) action which were not identified yet, one related to time-dependent (or time-gauged) shifts of the response fields and existing in both 2D and 3D, and the other to time-gauged rotations and specific to 2D flows. We derive the corresponding Ward identities, and exploit them within the non-perturbative renormalization group formalism, and the large wave-number expansion scheme developed in [Phys. Fluids 30, 055102 (2018)]. We consider the flow equation for a generalized $n$-point correlation function, and calculate its leading order term in the large wave-number expansion. At this order, the resulting flow equation can be closed exactly. We solve the fixed point equation for the 2-point function, which yields its explicit time dependence, for both small and large time delays in the stationary turbulent state. On the other hand, at equal times, the leading order term vanishes, so we compute the next-to-leading order term. We find that the flow equations for simultaneous $n$ point correlation functions are not fully constrained by the set of extended symmetries, and discuss the consequences.

[^0]
## I. INTRODUCTION

The 2D Navier-Stokes equation is a relevant description for large scale atmospheric and oceanic flows, rotating fluids, or magnetically forced stratified turbulence [1, 2]. In 2D, not only the energy, but also the enstrophy (squared vorticity) is conserved, which yields the existence of a double cascade, spreading on two distinct inertial ranges, as early predicted by Kraichnan [3], Leith [4] and Batchelor [5]. The energy flows from the integral scale $L$, where both energy and enstrophy are injected, towards the large scales where it is dissipated by some mechanism, such as an Eckman friction at scale $L_{0}$, while the enstrophy flows towards the small scales, where it is dissipated by viscosity at the Kolmogorov scale $\eta$. In the forceddissipative stationary regime, the inverse cascade of energy is characterized by Kolmogorov scalings with a $k^{-5 / 3}$ decay of the energy spectrum. In the direct cascade of enstrophy, the scalings can also be deduced from Kolmogorov types of arguments, which yield a $k^{-3}$ decay of the energy spectrum [3, 4]. This scaling was later corrected by Kraichnan himself, who suggested the presence of logarithmic corrections to the energy spectrum of the form $k^{-3} \ln (L k)^{-1 / 3}$ to ensure the constancy of the enstrophy flux [6]. Moreover, exact relations for the equal-time three-point correlations, analogous to the $-4 / 5$ law in three-dimensional (3D) turbulence, can also be derived in 2D, exploiting the conservation of both energy and enstrophy in their respective inertial ranges [7, 8].

In many respects, the understanding of 2D turbulence appears more advanced than its 3D counterpart. For instance, exact bounds on the exponents of the structure functions are known [8]. The small-scales statistics of the vorticity in the direct cascade was investigated by Falkovich and Lebedev [9, 10]. They found that the Kolmogorov-like exponents of the $2 n$ point structure functions of the vorticity are not modified by intermittency effects, but that the power-laws are corrected by logarithms, following $\left\langle\omega^{n}\left(\vec{r}_{1}\right) \omega^{n}\left(\vec{r}_{2}\right)\right\rangle \propto \ln \left(L /\left|\vec{r}_{1}-\vec{r}_{2}\right|\right)^{2 n / 3}$. This result received support from experimental measurements in electromagnetically forced conducting fluid layers turbulence [11] and in flowing soap films [12]. These works all indicate that there is no substancial intermittency in the small-scale statistics of 2D turbulence, at least in the absence of an Ekman friction. In the presence of such a term, the exponents of the structure functions are changed by intermittency corrections, which depend on the friction coefficient [13-15]. Let us also mention that perturbative Renormalisation Group (RG) techniques have been applied to study 2D turbulence in the presence of a power-law
forcing [16-18]. We refer the reader to reviews on 2D turbulence for a more exhaustive account [1, 2, 8, 19].

However, the complete characterization of the statistical properties of 2D turbulence remains a fundamental quest. In particular, the previous results concentrate on the structure functions, which are equal-time quantities, but the time dependence of velocity or vorticity correlations is also of fundamental interest. In this respect, recent theoretical works have shown that the time dependence of correlation (and response) functions could be calculated within the Non-Perturbative (also named functional) Renormalisation Group (NPRG) formalism [20, 21]. This framework allows one to compute statistical properties of turbulence from "first principles", in the sense that it is based on the forced NS equation and does not require phenomenological inputs [22]. It was exploited in 3D to obtain the exact time dependence of $n$-point generalized velocity correlation functions at leading order at large wave-numbers at non-equal times [21]. The case of equal times is much more involved and its complete analysis in 3D is still lacking.

The purpose of this paper is to use the NPRG formalism to investigate 2D turbulence. The outcome is three-fold. We identify two new extended symmetries of the 2D NS action and derive the associated Ward identities. At leading order in wave-numbers, we show that the flow equation for a generic $n$-point correlation function in the stream formulation can be closed exactly as in the velocity formulation in 3D, and we derive the fixed-point solution for the 2-point correlation. The corresponding predictions can be tested in experiments or numerical simulations. Moreover, we present a first step in the analysis of equal-time correlations in 2D. We compute the next-to-leading order (NLO) term in the large wavenumber expansion, in order to probe the presence of intermittency corrections at equal times. Interestingly, almost all the terms are controlled by the (extended) symmetries. These controlled terms turn out to vanish at equal times, which means that, as the leading terms, they cannot generate intermittency effects for simultaneous correlations. However, the symmetries do not seem to be sufficient to completly constrain the flow equation at NLO, and the only remaining term could be non-zero and be responsible for intermittency. Our analysis suggests that the corresponding effects are anyhow weaker than in 3D, since almost all the terms are controlled and vanish in 2D because of the specific time-gauged rotation symmetry, which does not occur in 3D. This is in accordance with standard observations, which support weak or no intermittency in the direct cascade in 2D turbulence.

The remainder of the paper is organized as follows. The field theory associated with the 2 D NS equation in the presence of a stochastic forcing is revisited in Sec. II, where its extended symmetries are analyzed in details. The NPRG formalism to study this field theory, developed in [21, 23, 24], is briefly presented in Sec. III, and the Ward identities related to the extended symmetries are derived in this framework. We then consider the flow equation for a generalized $n$-point correlation function in the stream formulation, and explain the principles of the large wave-number expansion. In Sec. IV, the leading order term in this expansion is calculated exactly, and the corresponding fixed-point solution is obtained for the two-point function, yielding the general form of its time dependence. The leading order term vanishes at equal time, as in 3D. In Sec. V, we calculate the NLO term in the large wave-number expansion, focusing on coinciding times, and discuss the results.

## II. FIELD THEORY FOR THE STREAM FUNCTION AND ITS SYMMETRIES

We consider the NS equation in the presence of an external stirring force $f_{\alpha}^{\text {inj }}$ and of an energy damping force $f_{\alpha}^{\text {damp }}$, in order to sustain a stationary turbulent regime

$$
\begin{equation*}
\partial_{t} v_{\alpha}+v_{\beta} \partial_{\beta} v_{\alpha}=\nu \partial^{2} v_{\alpha}-\partial_{\alpha} p+f_{\alpha}^{\text {damp }}+f_{\alpha}^{\text {inj }} \tag{1}
\end{equation*}
$$

where $\nu$ is the kinematic viscosity and $p$ is the pressure divided by the density of the fluid, and where the velocity, pressure and force fields depend on the space-time coordinate $(t, \vec{x})$. This equation is supplemented by the incompressibility constraint

$$
\begin{equation*}
\partial_{\alpha} v_{\alpha}=0 . \tag{2}
\end{equation*}
$$

Since in 2D the energy is transferred towards the large scales, the energy damping force is necessary to provide a dissipation mechanism at the largest scales. This damping can be achieved by a linear Ekman friction, $\vec{f}^{\text {damp }}=-\alpha \vec{v}$, which models the friction exerted on the bulk by the surrounding layers in which the 2D flow is embedded. In this work, we consider a non-local generalization of this term with a characteristic length scale $L_{0}$

$$
\begin{equation*}
\vec{f}^{\mathrm{damp}}(t, \vec{x})=-\int_{\vec{x}^{\prime}} R_{L_{0}^{-1}}\left(\left|\vec{x}-\vec{x}^{\prime}\right|\right) \vec{v}\left(t, \vec{x}^{\prime}\right) . \tag{3}
\end{equation*}
$$

The function $R_{L_{0}^{-1}}$ is chosen such that its Fourier transform vanishes exponentially at large wave-numbers $k \gg L_{0}^{-1}$. This term can be interpreted as an effective friction acting only
at the boundaries of the fluid, while not affecting the small scales, contrary to the Eckman friction.

For the derivation of the associated field theory and since universality is expected with respect to the precise form of the stirring force (as long as its characteristic distance scale $L$ is $L \gg \eta$ ), one usually chooses a stochastic forcing with Gaussian distribution of variance

$$
\begin{equation*}
\left\langle f_{\alpha}^{\mathrm{inj}}(t, \vec{x}) f_{\beta}^{\mathrm{inj}}\left(t^{\prime}, \vec{x}^{\prime}\right)\right\rangle=D_{\alpha \beta}\left(t-t^{\prime}, \vec{x}-\vec{x}^{\prime}\right)=2 \delta_{\alpha \beta} \delta\left(t-t^{\prime}\right) N_{L^{-1}}\left(\left|\vec{x}-\vec{x}^{\prime}\right|\right) \tag{4}
\end{equation*}
$$

The mapping to a field theory is then achieved using the Martin-Siggia-Rose-Janssen-de Dominicis (MSRJD) response-field formalism, developed in [25-27]. Whereas in most derivations in the context of turbulence, the profile $N$ has to be a power-law [16, 28-31], it can within the NPRG be shaped as a realistic large distance-scale forcing. The function $N_{L^{-1}}$ is hence chosen such that its Fourier transform is smooth, is peaked at the scale $L^{-1}$, is zero at vanishing wave-number and decays exponentially at large wave-number [32]. The MSRJD formalism with the non-local terms (3) and (4) is presented in [21, 23, 24]. It yields the partition function for the velocity, pressure, response fields, under the form

$$
\begin{equation*}
\mathcal{Z}[\vec{J}, \vec{J}, K, \bar{K}]=\int \mathcal{D}[\vec{v}, \vec{v}, p, \bar{p}] e^{-\mathcal{S}_{v}[\vec{v}, \vec{v}, p, \vec{p}]-\Delta \mathcal{S}_{v}[\vec{v}, \vec{v}]} e^{\int_{\mathbf{x}}\{\vec{J} \cdot \vec{v}+\vec{J} \cdot \vec{v}+K p+\bar{K} \bar{p}\}} \tag{5}
\end{equation*}
$$

with the notation $\mathbf{x} \equiv(t, \vec{x})$ and $\int_{\mathbf{x}}=\int d^{d} \vec{x} d t$, and similarly in the following $\mathbf{p} \equiv(\omega, \vec{p})$ and $\int_{\mathbf{p}} \equiv \int \frac{d^{d} \vec{p}}{(2 \pi)^{d}} \frac{d \omega}{2 \pi}$. In the MSRJD formalism, the response velocity $\vec{v}$ and response pressure $\bar{p}$ are introduced as the Lagrange multipliers of the equation of motion and of the incompressibility constraint respectively, and $\vec{J}, \vec{J}, K$, and $\bar{K}$ are the sources for the four fields [34]. The NS action for the velocity is obtained as

$$
\begin{align*}
\mathcal{S}_{v}[\vec{v}, \vec{v}, p, \bar{p}] & =\int_{\mathbf{x}}\left\{\bar{v}_{\alpha}(\mathbf{x})\left[\partial_{t} v_{\alpha}(\mathbf{x})-\nu \nabla^{2} v_{\alpha}(\mathbf{x})+v_{\beta}(\mathbf{x}) \partial_{\beta} v_{\alpha}(\mathbf{x})+\frac{1}{\rho} \partial_{\alpha} p(\mathbf{x})\right]+\bar{p}(\mathbf{x}) \partial_{\alpha} v_{\alpha}(\mathbf{x})\right\} \\
\Delta \mathcal{S}_{v}[\vec{v}, \vec{v}] & =\int_{t, \vec{x}, \vec{x}^{\prime}}\left\{\bar{v}_{\alpha}(t, \vec{x}) R_{L_{0}^{-1}}\left(\left|\vec{x}-\vec{x}^{\prime}\right|\right) v_{\alpha}\left(t, \vec{x}^{\prime}\right)-\bar{v}_{\alpha}(t, \vec{x}) N_{L^{-1}}\left(\left|\vec{x}-\vec{x}^{\prime}\right|\right) \bar{v}_{\alpha}\left(t, \vec{x}^{\prime}\right)\right\}, \tag{6}
\end{align*}
$$

where the quadratic non-local part has been separated for latter purposes. These expressions hold in a generic dimension $d$. We now specialize to two dimensions, and introduce the stream function formulation.

## A. Action for the stream function

In 2D, the incompressibility constraint allows one to express the velocity as

$$
\begin{equation*}
v_{\alpha}=\epsilon_{\alpha \beta} \partial_{\beta} \psi \tag{7}
\end{equation*}
$$

where $\psi$ is a pseudo-scalar field, called the stream function, and $\epsilon_{\alpha \beta}$ are the components of the antisymmetric tensor with two indices and with $\epsilon_{12}=1$, which satisfies the 2D identity

$$
\begin{equation*}
\epsilon_{\alpha \gamma} \epsilon_{\beta \gamma}=\delta_{\alpha \beta} . \tag{8}
\end{equation*}
$$

The stream function is related to the vorticity field through a Laplacian:

$$
\begin{equation*}
\omega=\epsilon_{\alpha \beta} \partial_{\alpha} v_{\beta}=\epsilon_{\alpha \beta} \epsilon_{\beta \gamma} \partial_{\alpha} \partial_{\gamma} \psi=-\partial^{2} \psi . \tag{9}
\end{equation*}
$$

From the field theory (5) and (6), setting the sources $K$ and $\bar{K}$ to zero, integrating over the pressure fields $p$ and $\bar{p}$, and using the resulting incompressibility contraints for $\vec{v}$ and $\overline{\vec{v}}$, the NS action for the velocity can be expressed as an action for the stream function, as

$$
\begin{align*}
\mathcal{S}_{\psi}[\psi, \bar{\psi}] & =\int_{\mathbf{x}} \partial_{\alpha} \bar{\psi}(\mathbf{x})\left[\partial_{t} \partial_{\alpha} \psi(\mathbf{x})-\nu \nabla^{2} \partial_{\alpha} \psi(\mathbf{x})+\epsilon_{\beta \gamma} \partial_{\gamma} \psi(\mathbf{x}) \partial_{\beta} \partial_{\alpha} \psi(\mathbf{x})\right] \\
\Delta \mathcal{S}_{\psi}[\psi, \bar{\psi}] & =\int_{t, \vec{x}, \vec{x}^{\prime}}\left\{\partial_{\alpha} \bar{\psi}(t, \vec{x}) R_{L_{0}^{-1}}\left(\left|\vec{x}-\vec{x}^{\prime}\right|\right) \partial_{\alpha}^{\prime} \psi\left(t, \vec{x}^{\prime}\right)-\partial_{\alpha} \bar{\psi}(t, \vec{x}) N_{L^{-1}}\left(\left|\vec{x}-\vec{x}^{\prime}\right|\right) \partial_{\alpha}^{\prime} \bar{\psi}\left(t, \vec{x}^{\prime}\right)\right\}, \tag{10}
\end{align*}
$$

where the response stream is related to the response velocity through

$$
\begin{equation*}
\bar{v}_{\alpha}=\epsilon_{\alpha \beta} \partial_{\beta} \bar{\psi} . \tag{11}
\end{equation*}
$$

One can then introduce a source for the stream function (resp. for the response stream) $J=-\epsilon_{\alpha \beta} \partial_{\beta} J_{\alpha}$ (resp. $\bar{J}=-\epsilon_{\alpha \beta} \partial_{\beta} \bar{J}_{\alpha}$ ) in the partition function, to obtain the moments of $\psi$ (resp. $\bar{\psi}$ ) as functional derivatives with respect to $J$ (resp. $\bar{J}$ ). Let us point out that this action is often obtained by taking the curl of the NS equation before casting it into a functional integral [16, 17]. Here, this operation comes as the consequence of the incompressibility constraint for $\overline{\vec{v}}$. This shows that in 2D, the velocity field action (6) and the stream function one (10) are equivalent.

## B. Symmetries and extended symmetries

The action (10) possesses several symmetries. In this work, we consider not only the exact symmetries of this action, but also its extended symmetries. We define an extended symmetry as a change of variables in the partition function which does not leave the action strictly invariant, but which induces a variation of the action linear in the fields. The
key point is that one can derive from these extended symmetries Ward identities which are more general than their non-extended versions. The Ward identities are exact relations between different correlation (or vertex) functions in specific configurations. Typically, the extended symmetries considered below are time-dependent generalizations of the original exact symmetries. As a consequence, the corresponding Ward identities are valid for arbitrary frequency instead of holding only at zero frequency. These identities are very useful in general within a field-theoretical framework, and in particular within the NPRG. Let us list all the symmetries and extended symmetries of the action (10), denoting generically $\eta$ or $\bar{\eta}$ their (scalar or vectorial) parameter:
a) $\delta \psi=\eta(t)$,
$\bar{a}) \quad \delta \bar{\psi}=\bar{\eta}(t)$
b) $\delta \psi=0$,

$$
\delta \bar{\psi}=x_{\alpha} \bar{\eta}_{\alpha}(t)
$$

c) $\delta \psi=0$,

$$
\begin{equation*}
\delta \bar{\psi}=\frac{x^{2}}{2} \bar{\eta}(t) \tag{12}
\end{equation*}
$$

$$
\text { d) } \quad \delta \psi=\epsilon_{\alpha \beta} x_{\alpha} \dot{\eta}_{\beta}(t)+\eta_{\alpha}(t) \partial_{\alpha} \psi, \quad \delta \bar{\psi}=\eta_{\alpha}(t) \partial_{\alpha} \bar{\psi}
$$

$$
e) \quad \delta \psi=-\dot{\eta}(t) \frac{x^{2}}{2}+\eta(t) \epsilon_{\alpha \beta} x_{\beta} \partial_{\alpha} \psi, \quad \delta \bar{\psi}=\eta(t) \epsilon_{\alpha \beta} x_{\beta} \partial_{\alpha} \bar{\psi}
$$

The symmetries $a$ ) and $\bar{a}$ ) are exact symmetries which just follow from the definitions (7) and (11). Indeed, the stream function and response stream are defined up to a constant function of time, and the functional integral does not fix this gauge invariance. The symmetries $b$ ) and $d$ ) correspond to known extended symmetries of the velocity action: $d$ ) is the timegauged (or time-dependent) Galilean symmetry [30, 35-37], and b) is a time-gauged shift of the response fields, first unveiled in [23]. On the other hand, the symmetries $c$ ) and $e$ ) are extended symmetries that were not, to the best of our knowledge, identified yet. The symmetry d) corresponds to a different time-gauged shift of the response field, which is also an extended symmetry of the 3D NS action (see below), while the symmetry e) can be interpreted as a time-gauged rotation, which is only realized in 2 D .

Let us expound in more details these extended symmetries, starting with the well-known time-gauged Galilean symmetry $d$ ). Since the action (10) is invariant under global Galilean transformation, the only non-zero variations stem from the time derivative. One can check that under this transformation,

$$
\begin{equation*}
\delta\left(\mathcal{S}_{\psi}+\Delta \mathcal{S}_{\psi}\right)=\int_{\mathbf{x}} \partial_{\alpha} \bar{\psi}\left[\epsilon_{\alpha \beta} \ddot{\eta}_{\beta}(t)+\dot{\eta}_{\beta}(t) \partial_{\beta} \partial_{\alpha} \psi+\epsilon_{\alpha \beta} \epsilon_{\beta \gamma} \dot{\eta}_{\gamma}(t) \partial_{\beta} \partial_{\alpha} \psi\right]=0 \tag{13}
\end{equation*}
$$

using the identity (8). Interestingly, the time-gauged Galilean symmetry is an exact symmetry in the stream formulation, whereas it is an extended one for the velocity action, because
the gauge degree of freedom is fixed in the latter.
Let us now consider the symmetries $b$ ) and $c$ ). A general space-time shift of the response field $\bar{\psi}(t, \vec{x}) \rightarrow \bar{\psi}(t, \vec{x})+\bar{\eta}(t, \vec{x})$ yields the first order variation of the action

$$
\begin{align*}
\delta\left(\mathcal{S}_{\psi}+\Delta \mathcal{S}_{\psi}\right)= & -\int_{\mathbf{x}} \bar{\eta}(\mathbf{x})\left\{\partial^{2}\left(\partial_{t}-\nu \partial^{2}\right) \psi+\partial_{\alpha} \partial_{\beta}\left(\epsilon_{\beta \gamma} \partial_{\gamma} \psi \partial_{\alpha} \psi\right)\right. \\
& \left.+\int_{\vec{x}^{\prime}}\left[R_{L_{0}^{-1}}\left(\left|\vec{x}-\vec{x}^{\prime}\right|\right) \partial^{\prime 2} \psi\left(t, \vec{x}^{\prime}\right)-2 N_{L^{-1}}\left(\left|\vec{x}-\vec{x}^{\prime}\right|\right) \partial^{\prime 2} \bar{\psi}\left(t, \vec{x}^{\prime}\right)\right]\right\} . \tag{14}
\end{align*}
$$

As in the velocity formulation, the non-linear term of this variation, stemming from the interaction, may vanish for some particular space dependence of $\bar{\eta}$. The choice $\bar{\eta}(\mathbf{x})=\bar{\eta}(t)$ is simply the gauge-invariance $\bar{a})$ for which $\delta\left(\mathcal{S}_{\psi}+\Delta \mathcal{S}_{\psi}\right)=0$. The choice $\bar{\eta}(\mathbf{x})=x_{\alpha} \bar{\eta}_{\alpha}(t)$ corresponds to the known time-gauged shift of the response fields (velocity and pressure) in the velocity formulation [23]. For this choice $\delta\left(\mathcal{S}_{\psi}+\Delta \mathcal{S}_{\psi}\right)$ also vanishes, which means that the time-gauged shift is an exact symmetry in the stream formulation, while it is an extended one in the velocity formulation, as for the time-gauged Galilean symmetry.

We here uncover another transformation which leads to the new extended symmetry $c$ ): $\bar{\eta}(t, \vec{x})=\frac{x^{2}}{2} \bar{\eta}(t)$. For this choice, the variation stemming from the interaction cancels by antisymmetry of $\epsilon_{\alpha \beta}$. Let us emphasize that this symmetry is not specific to 2 D , and can be expressed also in 3D in the velocity formulation, where it corresponds to a shift linear in space:

$$
\begin{equation*}
\delta \bar{v}_{\alpha}=\epsilon_{\alpha \beta \gamma} x_{\beta} \eta_{\gamma}(t), \quad \delta \bar{p}=v_{\alpha} \epsilon_{\alpha \beta \gamma} x_{\beta} \eta_{\gamma}(t), \tag{15}
\end{equation*}
$$

where the $\epsilon_{\alpha \beta \gamma}$ are the components of the fully antisymmetric tensor with three indices. One can indeed check, by performing this change of variables in the velocity action (6), and after some integration by parts and use of the anti-symmetry of $\epsilon_{\alpha \beta \gamma}$, that the corresponding variation reads
$\delta\left(\mathcal{S}_{v}+\Delta \mathcal{S}_{v}\right)=\int_{\mathbf{x}} \epsilon_{\alpha \beta \gamma} x_{\beta} \eta_{\gamma}(t)\left\{\partial_{t} v_{\alpha}(\mathbf{x})+\int_{\vec{x}^{\prime}} R_{L_{0}^{-1}}\left(\left|\vec{x}-\vec{x}^{\prime}\right|\right) v_{\alpha}\left(t, \vec{x}^{\prime}\right)-2 N_{L^{-1}}\left(\left|\vec{x}-\vec{x}^{\prime}\right|\right) \bar{v}_{\alpha}\left(t, \vec{x}^{\prime}\right)\right\}$,
and is linear in the fields. The transformation (15) is thus an extended symmetry of the NS velocity action in both 2D and 3D. This new symmetry yields Ward identities, given below in the 2D stream formulation, that could be useful in the study of the 3D NS turbulence as well. We did not find higher order space dependence of $\bar{\eta}(t, \vec{x})$ which induces a linear variation of the action in the fields.

Finally, we now consider the extended symmetry $e$ ), which is specific to 2D. This new symmetry can be interpreted as a time-gauged rotation in the same way as extended Galilean symmetry is a time-gauged translation in space. Using the anti-symmetry of $\epsilon_{\alpha \beta}$, one can check that the variation under the transformation $e$ ) is indeed linear is the field

$$
\begin{equation*}
\delta\left(\mathcal{S}_{\psi}+\Delta \mathcal{S}_{\psi}\right)=2 \int_{\mathbf{x}} \eta(t)\left[\partial_{t}^{2} \bar{\psi}-\partial_{t} \bar{\psi} \int_{\vec{x}^{\prime}} R_{L_{0}^{-1}}\left(\left|\vec{x}-\vec{x}^{\prime}\right|\right)\right] \tag{16}
\end{equation*}
$$

This symmetry can be expressed in the velocity formulation as well, at the cost of introducing a non-local shift of the pressure.

These extended symmetries can be translated into Ward identities. As they are exploited in the present work within the NPRG framework, we derive them in terms of the Effective Average Action (EAA) $\Gamma_{\kappa}$ defined in the next section. They essentially coincide with the Ward identities for the standard effective action $\Gamma$ usually defined in field theory, but for the terms associated with the variation of the non-local quadratic parts of the action. These terms are subtracted in the NPRG formalism (see Appendix A 1), but they can be straightforwardly included to deduce the Ward identities in terms of $\Gamma$ [23]. Let us now briefly introduce the EAA, and then establish these Ward identities.

## III. NPRG FORMALISM AND WARD IDENTITIES

## A. Formulation of the NPRG

The NPRG is a modern implementation of Wilson's original idea of the RG [38], conceived to efficiently average over fluctuations, even when they develop at all scales, as in standard critical phenomena [39-41]. It is a powerful method to compute the properties of strongly correlated systems, which can reach high precision levels [42, 43] and yield fully non-perturbative results, at equilibrium [44-46] and also out of equilibrium [47-51], restricting to a few classical statistical physics applications. The NS field theory was first studied using NPRG methods in $[24,52,53]$, and we here follow the formalism developed in [21, 24].

The core idea of the NPRG is to organize the integration of the fluctuations by adding to the action a non-local quadratic term, called the regulator and noted $\Delta \mathcal{S}_{\kappa}$. The role of the regulator is to freeze the degrees of freedom of the field with wave-number below the renormalization scale $\kappa$ to their mean-field value, while not affecting the degrees of freedom with wave-number above $\kappa$, with the additional requirement that the transition between
these two regimes is sufficiently smooth. By varying $\kappa$ from the ultraviolet (UV) cutoff of the theory, where the regulator ensure that mean-field is exact, to its infrared (IR) cutoff, one smoothly integrates over the fluctuations of the fields. If the starting action is at a critical point, the resulting flow reaches a fixed point, from which universal properties of the field theory can be calculated.

It turns out that in the Navier-Stokes action (10), terms which can play the role of regulators are already present for physical reasons. Indeed, the functions $N_{L^{-1}}$ and $R_{L_{0}^{-1}}$ associated with forcing and large-scale dissipation satisfy all the requirements to act as regulators of the theory. Their Fourier transform are smooth functions, which vanish exponentially for wave-numbers large compared to $L_{0}^{-1}$ or $L^{-1}$, and which regularize the fluctuating fields for small wave-numbers (see $[24,39]$ ). Thus, identifying their typical scale, $L_{0}^{-1}$ and $L^{-1}$, with the RG scale $\kappa$ yields a regulator $\Delta \mathcal{S}_{\kappa}$ for the NS field theory. Since we are interested in the direct cascade where wave-numbers are larger than both $L^{-1}$ and $L_{0}^{-1}$, we simply set $L^{-1}=L_{0}^{-1}=\kappa$. To study the inverse cascade, which corresponds to wave-numbers between $L_{0}^{-1}$ and $L^{-1}$, the scale $L$ should be kept fixed while setting $L_{0}^{-1}=\kappa$ (this is left for future work).

In the presence of the regulator $\Delta \mathcal{S}_{\kappa}$, the generating functional $\mathcal{Z}$ of the correlation functions becomes scale dependent

$$
\begin{equation*}
\mathcal{Z}_{\kappa}[J, \bar{J}]=\int \mathcal{D} \psi \mathcal{D} \bar{\psi} e^{-\mathcal{S}_{\psi}-\Delta \mathcal{S}_{\psi}} e^{\int_{\mathbf{x}}\{J \psi+\bar{J} \bar{\psi}\}} \tag{17}
\end{equation*}
$$

The average of the stream function (and response stream) can be obtained through functional derivatives of $\mathcal{W}_{\kappa}=\ln \mathcal{Z}_{\kappa}$ with respect to the sources as

$$
\begin{equation*}
\Psi(\mathbf{x})=\langle\psi(\mathbf{x})\rangle=\frac{\delta \mathcal{W}_{\kappa}}{\delta J(\mathbf{x})}, \bar{\Psi}(\mathbf{x})=\langle\bar{\psi}(\mathbf{x})\rangle=\frac{\delta \mathcal{W}_{\kappa}}{\delta \bar{J}(\mathbf{x})} . \tag{18}
\end{equation*}
$$

When the renormalization scale $\kappa$ varies, $\mathcal{W}_{\kappa}$ evolves according to the following exact flow equation (which is similar to the Polchinski equation [54]):

$$
\begin{equation*}
\partial_{\kappa} \mathcal{W}_{\kappa}=-\frac{1}{2} \int_{\mathbf{x}, \mathbf{y}} \partial_{\kappa}\left[\mathcal{R}_{\kappa}\right]_{i j}(\mathbf{x}-\mathbf{y})\left\{\frac{\delta^{2} \mathcal{W}_{\kappa}}{\delta \mathrm{j}_{i}(\mathbf{x}) \delta \mathrm{j}_{j}(\mathbf{y})}+\frac{\delta \mathcal{W}_{\kappa}}{\delta \mathrm{j}_{i}(\mathbf{x})} \frac{\delta \mathcal{W}_{\kappa}}{\delta \mathrm{j}_{j}(\mathbf{y})}\right\} \tag{19}
\end{equation*}
$$

where $i, j \in\{1,2\}$ with $\mathrm{j}_{1}=J$ and $\mathrm{j}_{2}=\bar{J}$. The EAA $\Gamma_{\kappa}$ (which is the generating functional of one particle-irreducible (1-PI) correlation functions [55, 56]) is defined as the Legendre transform of $\mathcal{W}_{\kappa}$, up to the regulator term:

$$
\begin{equation*}
\Gamma_{\kappa}[\Psi, \bar{\Psi}]+\mathcal{W}_{\kappa}[J, \bar{J}]=\int_{\mathbf{x}}\{J \Psi+\bar{J} \bar{\Psi}\}-\Delta \mathcal{S}_{\kappa}[\Psi, \bar{\Psi}] \tag{20}
\end{equation*}
$$

The flow of $\Gamma_{\kappa}$ with the RG scale $\kappa$ is given by the Wetterich equation [57]

$$
\begin{equation*}
\partial_{\kappa} \Gamma_{\kappa}=\frac{1}{2} \int_{\mathbf{x}, \mathbf{y}} \partial_{\kappa}\left[\mathcal{R}_{\kappa}\right]_{i j}(|\mathbf{x}-\mathbf{y}|)\left[\Gamma_{\kappa}^{(2)}+\mathcal{R}_{\kappa}\right]_{j i}^{-1}(\mathbf{y}, \mathbf{x}), \tag{21}
\end{equation*}
$$

where $\Gamma_{\kappa}^{(2)}$ is the Hessian of $\Gamma_{\kappa}$ and the regulator matrix $\left[\mathcal{R}_{\kappa}\right]$ is defined as

$$
\begin{equation*}
\left[\mathcal{R}_{\kappa}\right]_{i j}(\mathbf{x}-\mathbf{y})=\frac{\delta^{2} \Delta \mathcal{S}_{\kappa}}{\delta \varphi_{i}(\mathbf{x}) \delta \varphi_{j}(\mathbf{y})} \tag{22}
\end{equation*}
$$

with $i, j \in\{1,2\}$ and $\varphi_{1}=\Psi, \varphi_{2}=\bar{\Psi}$. The RG flow equation (21) is also exact. Its initial condition corresponds to the 'microscopic' model, which is $\mathcal{S}_{\psi}$ in (10). The flow is hence initiated at a very large wave-number $\Lambda$ at which the continuous description of the fluid dynamics in terms of NS equation starts to be valid. At this scale, one can show that $\Gamma_{\Lambda}$ identifies with the bare action $\Gamma_{\Lambda}=\mathcal{S}_{\psi}$, since no fluctuation is yet incorporated. When $\kappa \rightarrow L^{-1}$, the regulator reaches its original value and one obtains the actual properties of the model, when all fluctuations up to the physical IR cutoff have been integrated over. Eq. (21) provides the exact interpolation between these two scales.

## B. Definition of generalized correlation functions

The functional $\mathcal{W}_{\kappa}$ is the generating functional of connected correlation functions, which correspond to the cumulants for a field theory [55, 56]. The $n$-point generalized connected correlation functions can be obtained as functional derivatives of $\mathcal{W}_{\kappa}$ with respect to the sources

$$
\begin{equation*}
G_{i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{x}_{\ell}\right\}_{1 \leq \ell \leq n} ; \mathbf{j}\right]=\frac{\delta^{n} \mathcal{W}_{\kappa}}{\delta \mathrm{j}_{i_{1}}\left(\mathbf{x}_{1}\right) \ldots \delta \mathrm{j}_{i_{n}}\left(\mathbf{x}_{n}\right)}, \tag{23}
\end{equation*}
$$

where $i_{k}=1,2$ with $\mathrm{j}_{1}=J$ and $\mathrm{j}_{2}=\bar{J}$ as before. They are called generalized because they include derivatives with respect to response fields, which are related to correlations with the forcing [24]. Note that in this definition, $G_{i_{1} \ldots i_{n}}^{(n)}$ is still a functional of the sources, which is materialized by the square brackets and the explicit j dependency. Let us also introduce the notation $G^{(m, \bar{m})}\left[\mathbf{x}_{1}, \ldots, \mathbf{x}_{m+\bar{m}} ; \mathbf{j}\right]$ where the $m$ first derivatives are with respect to $J$ and the $\bar{m}$ last with respect to $\bar{J}$. We indicate that a correlation function is evaluated at zero sources using the notation

$$
\begin{equation*}
G_{i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{x}_{\ell}\right\}_{1 \leq \ell \leq n}\right) \equiv G_{i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{x}_{\ell}\right\} ; \mathrm{j}=0\right] \tag{24}
\end{equation*}
$$

(and accordingly for $G^{(m, \bar{m})}$ ). The Fourier transforms of these functions are defined as:

$$
\begin{equation*}
\tilde{G}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right)=\int_{\left\{\mathbf{x}_{\ell}\right\}} G^{(n)}\left(\left\{\mathbf{x}_{\ell}\right\}_{1 \leq \ell \leq n}\right) e^{-i \sum_{k=1}^{n}\left(\vec{p}_{k} \cdot \vec{x}_{k}-\omega_{k} t_{k}\right)} \tag{25}
\end{equation*}
$$

or similarly extracting the delta function of conservation of the total wave-vector and frequency

$$
\begin{equation*}
\tilde{G}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right)=(2 \pi)^{d+1} \delta^{d}\left(\sum_{k=1}^{n} \vec{p}_{k}\right) \delta\left(\sum_{k=1}^{n} \omega_{k}\right) \bar{G}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n-1}\right) . \tag{26}
\end{equation*}
$$

The EAA is the generating functionals of 1-PI correlation functions, also called vertex functions. This means that any vertex functions can be obtained by taking functional derivatives of $\Gamma_{\kappa}$ with respect to the average fields $\Psi$ and $\bar{\Psi}$. The $n$-point vertex (1-PI) functions are defined using the same conventions as for the connected correlation functions:

$$
\begin{equation*}
\Gamma_{i_{1} \ldots i_{n}}^{(n)}\left[\mathbf{x}_{1}, \ldots, \mathbf{x}_{n} ; \varphi\right]=\frac{\delta^{n} \Gamma_{\kappa}}{\delta \varphi_{i_{1}}\left(\mathbf{x}_{1}\right) \ldots \delta \varphi_{i_{n}}\left(\mathbf{x}_{n}\right)} \tag{27}
\end{equation*}
$$

where $i_{k}=1,2$ with $\varphi_{1}=\Psi$ and $\varphi_{1}=\bar{\Psi}$, or alternatively $\Gamma^{(m, \bar{m})}\left[\mathbf{x}_{1}, \ldots, \mathbf{x}_{m+\bar{m}} ; \varphi\right]$. Accordingly, we define $\Gamma_{i_{1} \ldots i_{n}}^{(n)}\left(\mathbf{x}_{1}, \ldots, \mathbf{x}_{n}\right)$ and $\Gamma^{(m, \bar{m})}\left(\mathbf{x}_{1}, \ldots, \mathbf{x}_{m+\bar{m}}\right)$ as the previous vertex functions evaluated at zero fields. Finally we define the Fourier transforms before and after extracting the delta function of conservation of wave-vector and frequency, $\tilde{\Gamma}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right)$ and $\bar{\Gamma}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n-1}\right)$, respectively. The knowledge of the set of connected correlation functions or of the set of vertex functions is equivalent. Indeed, they are inter-related: any $n$-point connected correlation function $G^{(n)}$ can be constructed as a sum of tree diagrams whose vertices are the 1-PI functions $\Gamma^{(k)}, 2<k \leq n$ and whose edges are the propagators $G^{(2)}$ [55, 56].

## C. Ward identities for the vertex functions in the stream formulation

In Sec. IV and Sec. V, we present calculations within the large wave-number expansion. As explained in Appendix B 1, a key ingredient in these calculations in the existence of Ward identities for the vertex functions. We hence give below the Ward identities associated with the extended symmetries of the NS action in terms of the vertex functions, and within the NPRG framework. Ward identities for the connected correlation functions can be derived in the same way.

The list (12) of the extended symmetries in the stream function formulation only contains continuous changes of variables which are at most linear in the field, and so are the
corresponding variations of the action. In this case, they can be translated readily into Ward identities that the EAA must verify along the RG flow. These identities simply express that the EAA possesses the same symmetry as $\mathcal{S}_{\psi}$, except for the non-invariant terms which are not renormalized. The general derivation was presented in [23] and is summarized in Appendix A 1. It is shown in particular that in the NPRG framework, the regulator terms do not enter these identities when the change of variable is a shift of the fields or when it leaves the regulators invariant, which is the case for all the symmetries presented in Sec. IIB.

The functional Ward identities for the EAA associated with the extended symmetries (12) are:
a) $\int_{\vec{x}} \frac{\delta \Gamma_{\kappa}}{\delta \Psi(\mathbf{x})}=0$,
$\bar{a}) \int_{\vec{x}} \frac{\delta \Gamma_{\kappa}}{\delta \bar{\Psi}(\mathbf{x})}=0$
b) $\int_{\vec{x}} x_{\alpha} \frac{\delta \Gamma_{\kappa}}{\delta \bar{\Psi}(\mathbf{x})}=0$
c) $\int_{\vec{x}} \frac{x^{2}}{2} \frac{\delta \Gamma_{\kappa}}{\delta \bar{\Psi}(\mathbf{x})}=-2 \int_{\vec{x}} \partial_{t} \Psi$
d) $\int_{\vec{x}}\left\{\left(-\epsilon_{\beta \alpha} x_{\beta} \partial_{t}+\partial_{\alpha} \Psi\right) \frac{\delta \Gamma_{\kappa}}{\delta \Psi(\mathbf{x})}+\partial_{\alpha} \bar{\Psi} \frac{\delta \Gamma_{\kappa}}{\delta \bar{\Psi}(\mathbf{x})}\right\}=0$
e) $\int_{\vec{x}}\left\{\left(\frac{x^{2}}{2} \partial_{t}+\epsilon_{\alpha \beta} x_{\beta} \partial_{\alpha} \Psi\right) \frac{\delta \Gamma_{\kappa}}{\delta \Psi(\mathbf{x})}+\epsilon_{\alpha \beta} x_{\beta} \partial_{\alpha} \bar{\Psi} \frac{\delta \Gamma_{\kappa}}{\delta \bar{\Psi}(\mathbf{x})}\right\}=2 \int_{\vec{x}} \partial_{t}^{2} \bar{\Psi}$.

From these functional identities, one can derive a hierarchy of identities for the vertex functions $\Gamma^{(m, \bar{m})}$, by taking the corresponding functional derivatives and evaluating them at zero fields. In the Fourier space, they read:

$$
\begin{align*}
& \text { a), } \bar{a})\left.\quad \bar{\Gamma}_{\kappa}^{(m, \bar{m})}(\ldots, \varpi, \vec{q}, \ldots)\right|_{\vec{q}=0}=0 \\
& \text { b) }\left.\frac{\partial}{\partial q^{i}} \bar{\Gamma}_{\kappa}^{(m, \bar{m}+1)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq m}, \varpi, \vec{q},\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq \bar{m}-1}\right)\right|_{\vec{q}=0}=0 \\
& \text { c) }\left.\frac{\partial^{2}}{\partial q^{2}} \bar{\Gamma}_{\kappa}^{(m, \bar{m}+1)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq m}, \varpi, \vec{q},\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq \bar{m}-1}\right)\right|_{\vec{q}=0}=0 \\
& \quad \text { except }\left.\frac{\partial^{2}}{\partial q^{2}} \bar{\Gamma}_{\kappa}^{(1,1)}(\varpi, \vec{q})\right|_{\vec{q}=0}=-4 i \varpi \\
& \text { d) }\left.\frac{\partial}{\partial q^{i}} \bar{\Gamma}_{\kappa}^{(m+1, \bar{m})}\left(\varpi, \vec{q},\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq m+\bar{m}-1}\right)\right|_{\vec{q}=0}=i \epsilon_{\alpha \beta} \tilde{\mathcal{D}}_{\beta}(\varpi) \bar{\Gamma}_{\kappa}^{(m, \bar{m})}\left(\left\{\mathbf{p}_{\ell}\right\}\right) \\
& \text { e) }\left.\frac{\partial^{2}}{\partial q^{2}} \bar{\Gamma}_{\kappa}^{(m+1, \bar{m})}\left(\varpi, \vec{q},\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq m+\bar{m}-1}\right)\right|_{\vec{q}=0}=\tilde{\mathcal{R}}(\varpi) \bar{\Gamma}_{\kappa}^{(m, \bar{m})}\left(\left\{\mathbf{p}_{\ell}\right\}\right), \tag{29}
\end{align*}
$$

where we have introduced the two operators $\tilde{\mathcal{D}}_{\alpha}(\varpi)$ and $\tilde{\mathcal{R}}(\varpi)$ defined as:

$$
\begin{align*}
& \tilde{\mathcal{D}}_{\alpha}(\varpi) F\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right) \equiv-\sum_{k=1}^{n} p_{k}^{\alpha}\left[\frac{F\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq k-1}, \omega_{k}+\varpi, \vec{p}_{k},\left\{\mathbf{p}_{\ell}\right\}_{k+1 \leq \ell \leq n}\right)-F\left(\left\{\mathbf{p}_{\ell}\right\}\right)}{\varpi}\right] \\
& \tilde{\mathcal{R}}(\varpi) F\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right) \equiv 2 i \epsilon_{\alpha \beta} \sum_{k=1}^{n} p_{k}^{\alpha} \frac{\partial}{\partial p_{k}^{\beta}}\left[\frac{F\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq k-1}, \omega_{k}+\varpi, \vec{p}_{k},\left\{\mathbf{p}_{\ell}\right\}_{k+1 \leq \ell \leq n}\right)-F\left(\left\{\mathbf{p}_{\ell}\right\}\right)}{\varpi}\right] . \tag{30}
\end{align*}
$$

The derivation of the identities $d$ ) and $e$ ) is reported in Appendix A 2 and Appendix A 3 respectively.

## D. Large wave-number expansion of the flow equations

Let us explain the principles of the large wave-number expansion. The flow equation (21) is exact, but it is not closed. Indeed, the flow equation for a generic $n$-point function $\Gamma_{\kappa}^{(n)}$ can be deduced by taking the corresponding functional derivatives of (21), and it involves $(n+1)$ and $(n+2)$ vertex functions. As such, one has to consider an infinite hierarchy of flow equations. For example, the flow equation for the two-point function is given in the Fourier space by

$$
\begin{align*}
\partial_{s} \bar{\Gamma}_{m n}^{(2)}(\mathbf{p}) & =\int_{\mathbf{q}} \partial_{s} \mathcal{R}_{i j}(\mathbf{q}) \bar{G}_{j k}^{(2)}(\mathbf{q})\left[-\frac{1}{2} \bar{\Gamma}_{k l m n}^{(4)}(\mathbf{q},-\mathbf{q}, \mathbf{p})\right. \\
& \left.+\bar{\Gamma}_{k m s}^{(3)}(\mathbf{q}, \mathbf{p}) \bar{G}_{s t}^{(2)}(\mathbf{q}+\mathbf{p}) \bar{\Gamma}_{t n l}^{(3)}(\mathbf{q}+\mathbf{p},-\mathbf{p})\right] \bar{G}_{l i}^{(2)}(\mathbf{q}) \tag{31}
\end{align*}
$$

which depends on the 3- and 4-point vertices. The right-hand side (r.h.s.) is represented diagrammatically in Fig. 1, where the dashed circles are the vertex functions, the thick lines are propagators and the cross is the derivative of the regulator. The r.h.s. involves

FIG. 1. Diagrammatic representation of the flow of $\Gamma_{\kappa}^{(2)}$.
the integrated, or internal, wave-vector and frequency $\mathbf{q}$ circulating in the loops besides the
external wave-vector and frequency $\mathbf{p}$ at which the vertex function on the left-hand side (l.h.s.) is evaluated.

In most applications, this hierarchy is closed by simply truncating higher-order vertices, or proposing an ansatz for $\Gamma_{\kappa}$ [39]. An alternative strategy, pioneered in [43, 58] and called the BMW approximation scheme, consists in expanding these vertices in the internal wavevector $\vec{q}$. This approximation relies on the two following properties of the regulator: on the one hand, its insertion in the integration loop on the r.h.s. of (21) cuts off the internal wavenumber $|\vec{q}|$ to values $|\vec{q}| \lesssim \kappa$. As a consequence, if the system is probed at a wave-number scale $|\vec{p}|$ much larger than the renormalization scale, $p \gg \kappa$, there is a clear separation of scales in the flow equations: $q / p \ll 1$. On the other hand, the presence of the regulator ensures that the vertex functions are smooth at any finite scale $\kappa>0$, which allows one to perform a Taylor expansion in powers of $\vec{q}$. The underlying idea is that, close to a fixed point, the vertex functions are expected to depend on the internal wave-number only through ratio of the type $q / p$, which means that the expansion at $q \simeq 0$ is expected to be equivalent to an expansion at $p \rightarrow \infty$. This expansion becomes exact in the limit of infinite wave-numbers, and the error at finite but large $p$ is small. In fact, this expansion was found to be a reliable approximation for arbitrary momenta [43, 58].

The BMW strategy has turned out to be very successful in the context of turbulence, since the expanded flow equations can be closed at zero fields thanks to the Ward identities, whereas it generically requires to keep a whole dependence in background fields. This was first noticed in [24] for the two-point function, and generalized in [21] where the exact leading order term in the large wave-number expansion of the flow equation of an arbitrary $n$-point correlation function was obtained in 3D. The striking feature of these flow equations is that they do not exhibit the decoupling property usually expected for flow equations, e.g. in standard critical phenomena. The decoupling property ensures that the existence of a fixed point entails standard scale invariance for $\kappa$ much smaller than any non-exceptional wave-number (see [21]). In 3D turbulence, the violation of the decoupling property yields a breaking of standard scale invariance, which is manifest in the time dependence of generic correlation functions. This breaking was related in [20, 21], at least for small time delays, to the sweeping effect. The latter is the random advection of small-scale velocities by large-scale structures in the turbulent flow, and is well-known phenomenologically [59, 60].

In the following, we calculate the flow equation of a generalized $n$-point correlation func-
tion in the stream formulation within the large wave-number expansion. In Sec. IV, we derive the leading order, and derive the general form of the time dependence of the twopoint function. We show that a similar breaking of standard scale invariance occurs in 2D turbulence, but its explicit expression is different. However, the (leading order) nondecoupling term of the flow equation turns out to vanish at equal time, as in 3D, such that standard scale invariance, which means Kolmogorov-Kraichnan scaling, is recovered at this order for equal-time quantities. Hence, in Sec. V, we calculate the NLO term in the large wave-number expansion of the flow equation, focusing on equal times, in order to seek for possible intermittency corrections to simultaneous quantities, such as structure functions. This calculation is specific to 2 D since it exploits the new extended symmetry related to time-gauged rotations.

## IV. TIME DEPENDENCE OF GENERIC CORRELATION FUNCTIONS

In this section, we express the flow equation for a generic generalized $n$-point correlation function in the stream formulation, and we compute its exact leading term in the large wavenumber expansion for non-equal time delays. We then derive the corresponding fixed-point solutions for the two-point function, and show that its time dependence explicitly breaks scale invariance.

## A. Flow equation for generic correlation functions at leading order

The flow equation for a generic connected correlation function of the stream and response stream functions $G_{\psi}^{(n)}$ is obtained by taking $n$ functional derivatives of (19) with respect to the sources $\mathrm{j}_{i_{k}}, 1 \leq k \leq n$, which yields

$$
\begin{align*}
\partial_{\kappa} G_{\psi, i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{x}_{\ell}\right\}_{1 \leq \ell \leq n} ; \mathbf{j}\right] & =-\frac{1}{2} \int_{\mathbf{y}_{1}, \mathbf{y}_{2}} \partial_{\kappa}\left[\mathcal{R}_{\kappa}\right]_{i j}\left(\mathbf{y}_{1}-\mathbf{y}_{2}\right)\left\{G_{\psi, i j i_{1} \ldots i_{n}}^{(n+2)}\left[\mathbf{y}_{1}, \mathbf{y}_{2},\left\{\mathbf{x}_{\ell}\right\} ; \mathbf{j}\right]\right. \\
& \left.+\sum_{\substack{\left.\left\{i_{\ell}\right\}_{1},\left\{i_{\ell}\right\}_{2}\right) \\
\#++\# 2=n}} G_{\psi, i\left\{i_{\ell}\right\} 1}^{(\# 1+1)}\left[\mathbf{y}_{1},\left\{\mathbf{x}_{\ell}\right\}_{1} ; \mathbf{j}\right] G_{\psi, j\left\{i_{\ell}\right\}_{2}}^{(\# 2+1)}\left[\mathbf{y}_{2},\left\{\mathbf{x}_{\ell}\right\}_{2} ; \mathbf{j}\right]\right\} . \tag{32}
\end{align*}
$$

where the indices $i_{\ell} \in\{1,2\}$ stand for the sources $J$ or $\bar{J}$, and $\left(\left\{i_{\ell}\right\}_{1},\left\{i_{\ell}\right\}_{2}\right)$ indicates all the possible bipartitions of the $n$ indices $\left\{i_{\ell}\right\}_{1 \leq \ell \leq n}$, and $\left(\left\{\mathbf{x}_{\ell}\right\}_{1},\left\{\mathbf{x}_{\ell}\right\}_{2}\right)$ the corresponding bipartition in coordinates. Finally, $\# 1$ and $\# 2$ are the cardinals of $\left\{i_{\ell}\right\}_{1}$ (resp. $\left\{i_{\ell}\right\}_{2}$ ).

We now consider the large wave-number expansion of (32). The calculation of the leading order term is formally the same as in 3D in the velocity formulation [21]. Nevertheless, the derivation in the stream formulation is reported in Appendix B 1 for completeness. We first show that in the limit of large wave-numbers, that is when all the $\vec{p}_{\ell}, 1 \leq \ell \leq n$ are large compared to $\kappa$, as well as all their partial sums, the flow equation (32) reduces to

$$
\begin{equation*}
\partial_{\kappa} \tilde{G}_{\psi, i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right)=\frac{1}{2} \int_{\mathbf{q}_{1}, \mathbf{q}_{2}} \tilde{\partial}_{\kappa} \tilde{G}_{\psi, i j}^{(2)}\left(-\mathbf{q}_{1},-\mathbf{q}_{2}\right)\left[\frac{\delta^{2}}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right) \delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{G}_{\psi, i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\} ; j\right]\right]_{\varphi=0}, \tag{33}
\end{equation*}
$$

up to terms tending to zero faster than any power of the $p_{\ell}$. In the velocity formulation, the leading order term is obtained by setting $q_{1}, q_{2}$ to zero in the equivalent terms in bracket. In the stream formulation, because of the gauge symmetry $a$ ) in (12), there is no information at this order. Indeed, the symmetry $a$ ) implies that the vertex functions are zero if one of the wave-numbers is set to zero, according to (29), and thus

$$
\begin{equation*}
\left.\left[\frac{\delta^{2}}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right) \delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{G}_{\psi, i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n} ; \mathbf{j}\right]\right]_{\varphi=0}\right|_{\vec{q}_{1}=\vec{q}_{2}=0}=0 \tag{34}
\end{equation*}
$$

As a consequence, the first non-zero contribution comes from the second order term in the $q_{1}, q_{2}$ expansion (since the odd terms of this expansion vanishes by parity of $\left.\tilde{\partial}_{\kappa} \tilde{G}_{\psi, i j}^{(2)}\left(-\mathbf{q}_{1},-\mathbf{q}_{2}\right)\right)$. It reads

$$
\begin{align*}
\partial_{\kappa} \tilde{G}_{\psi, i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right) & =\frac{1}{2} \int_{\mathbf{q}_{1}, \mathbf{q}_{2}} \tilde{\partial}_{\kappa} \tilde{G}_{\psi, i j}^{(2)}\left(-\mathbf{q}_{1},-\mathbf{q}_{2}\right) \\
& \times\left.\frac{q_{a}^{\alpha} q_{b}^{\beta}}{2} \frac{\partial^{2}}{\partial q_{a}^{\alpha} \partial q_{b}^{\beta}}\left[\frac{\delta^{2}}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right) \delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{G}_{\psi, i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\} ; j\right]\right]_{\varphi=0}\right|_{\vec{q}_{1}=\vec{q}_{2}=0} \tag{35}
\end{align*}
$$

where $a, b$ take value in $\{1,2\}$. As in the velocity formulation, one can then show that this flow equation can be closed using the Ward identities (see Appendix B1), which yields

$$
\begin{equation*}
\partial_{\kappa} \tilde{G}_{\psi, i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right)=\frac{1}{2} \int_{\mathbf{q}_{1}, \mathbf{q}_{2}} \tilde{\partial}_{\kappa} \tilde{G}_{v_{\mu} v_{\nu}}^{(2)}\left(-\mathbf{q}_{1},-\mathbf{q}_{2}\right) \tilde{\mathcal{D}}_{\mu}\left(\varpi_{1}\right) \tilde{\mathcal{D}}_{\nu}\left(\varpi_{2}\right) \tilde{G}_{\psi, i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}\right) . \tag{36}
\end{equation*}
$$

One can check, using the correspondence

$$
\begin{equation*}
\tilde{G}_{v, k_{1} \cdots k_{n}}^{(n)}\left(\left\{\omega_{k}, \vec{p}_{k}\right\}\right)=(i)^{n} \epsilon_{k_{1} \ell_{1}} p_{1}^{\ell_{1}} \cdots \epsilon_{k_{n} \ell_{n}} p_{n}^{\ell_{n}} \tilde{G}_{\psi, i_{1} \ldots i_{n}}^{(n)}\left(\left\{\omega_{k}, \vec{p}_{k}\right\}\right) \tag{37}
\end{equation*}
$$

that the same result as in the velocity formulation, obtained in [21], is recovered.

## B. Fixed-point and conservation of enstrophy in the direct cascade

Our goal is to describe the universal properties of the direct enstrophy cascade in the forced-dissipative stationary regime. This regime, characterized by some form of scale invariance, corresponds to a fixed point in the RG framework (see [21] for details). In order to study the fixed point, it is convenient to work with dimensionless variables, denoted with a hat symbol, using the RG scale $\kappa$ as unit of wave-numbers. We introduce the dimensionless forcing profile through

$$
\begin{equation*}
N_{\kappa}(\vec{q})=D_{\kappa}(|\vec{q}| / \kappa)^{2} \hat{n}(|\vec{q}| / \kappa), \tag{38}
\end{equation*}
$$

where $D_{\kappa}$ is a scale dependent forcing amplitude, and $\hat{n}$ is the specific forcing profile, which fulfills the requirements stated in Sec. III (smoothness and fast decay at large wave-numbers). Similarly, the dimensionless effective friction can be defined through

$$
\begin{equation*}
R_{\kappa}(\vec{q})=\nu_{\kappa} \vec{q}^{2} \hat{r}(|\vec{q}| / \kappa), \tag{39}
\end{equation*}
$$

with $\nu_{\kappa}$ a scale dependent coefficient and $\hat{r}$ is also a smooth and fastly decaying function. As the action (10) is dimensionless, one deduces that $\psi \bar{\psi}$ is also dimensionless, and that dimensionless frequencies can be defined according to $\omega=\kappa^{2} \nu_{\kappa} \hat{\omega}$. One then obtains that the dimensionless response stream is given by $\bar{\psi}=\kappa\left(D_{\kappa}^{-1} \nu_{\kappa}\right)^{1 / 2} \hat{\bar{\psi}}$, and the dimensionless stream function by $\psi=\kappa^{-1}\left(D_{\kappa} \nu_{\kappa}^{-1}\right)^{1 / 2} \hat{\psi}$. At the fixed point, the coefficients $D_{\kappa}$ and $\nu_{\kappa}$ are generically expected to behave as power-laws $D_{\kappa} \sim \kappa^{-\eta_{D}^{*}}$ and $\nu_{\kappa} \sim \kappa^{-\eta_{\nu}^{*}}$, where the exponents are the fixed-point values of the functions

$$
\begin{equation*}
\eta_{D}(\kappa)=-\kappa \partial_{\kappa} \ln D_{\kappa},, \quad \eta_{\nu}(\kappa)=-\kappa \partial_{\kappa} \ln \nu_{\kappa} . \tag{40}
\end{equation*}
$$

One deduces that the dynamical critical exponent $z$, which characterizes the scaling between space and time as $\omega \sim|\vec{p}|^{z}$, is given by $z=2-\eta_{\nu}^{*}$. The two exponents $\eta_{D}^{*}$ and $\eta_{\nu}^{*}$ are not independent. Their relation follows from the Galilean invariance. Let us temporarily introduce a coupling $\lambda$ in front of the non-linear advection term in the action (10). The Galilean invariance entails that this coupling is not renormalized, that is $\partial_{\kappa} \lambda=0$, or equivalently, the flow equation for the dimensionless coupling, defined through $\lambda=k D_{\kappa}^{-1 / 2} \nu_{\kappa}^{3 / 2} \hat{\lambda}_{\kappa}$, is exactly

$$
\begin{equation*}
\kappa \partial_{\kappa} \hat{\lambda}_{\kappa}=-\frac{1}{2} \hat{\lambda}_{\kappa}\left(2+\eta_{D}(\kappa)-3 \eta_{\nu}(\kappa)\right) . \tag{41}
\end{equation*}
$$

This implies that at any non-Gaussian fixed point $\left(\hat{\lambda}_{*} \neq 0\right)$, the exponent $\eta_{\nu}^{*}$ is given by

$$
\begin{equation*}
\eta_{\nu}^{*}=-\left(2+\eta_{D}^{*}\right) / 3 . \tag{42}
\end{equation*}
$$

In 3 D , the value of the exponent $\eta_{D}^{*}$ is fixed by requiring that the mean rate of energy injection (and dissipation) $\varepsilon$ is constant [24]. In 2D, this constraint only gives some bounds on the exponent, and one is led to also analyze the mean rate of enstrophy injection $\varepsilon_{\omega}$ (and dissipation) [24]. The latter can be expressed as [19]

$$
\begin{align*}
\varepsilon_{\omega} & =\langle(\vec{\nabla} \times \vec{f})(t, \vec{x}) \cdot \vec{\omega}(t, \vec{x})\rangle=\lim _{\delta t \rightarrow 0^{+}} \int_{\omega, \vec{q}} q^{4} N(\vec{q}) G_{\psi}^{(1,1)}(\omega, \vec{q}) e^{-i \omega \delta t} \\
& =D_{\kappa} \kappa^{4} \lim _{\delta t \rightarrow 0^{+}} \int_{\hat{\omega}, \hat{\vec{q}}} \hat{q}^{6} \hat{n}(\hat{q}) \hat{G}_{\psi}^{(1,1)}(\hat{\omega}, \hat{\vec{q}}) e^{-i \hat{\omega} \delta t} \tag{43}
\end{align*}
$$

The properties of $\hat{n}$ ensures that the integral is both UV and IR finite, and we denote $\Omega^{-1}$ the value of this integral, which is non-universal. To obtain a constant ( $\kappa$ independent) mean enstrophy injection rate thus imposes $\eta_{D}^{*}=4$. The identity (42) then yields $\eta_{\nu}^{*}=2$. As a consequence, the leading scaling between space and time vanishes, that is $z=0$, which is very peculiar and occurs only in $d=2$. This scaling is thus governed by sub-leading logarithms, as $\omega \sim(\ln (|\vec{p}| / \Lambda))^{\delta}$, where $\Lambda$ is for instance the UV scale, and $\delta$ an exponent to be determined. In order to account for this sub-leading behavior, one is led to include logarithmic corrections in the scale-dependent coefficients, such that they behave at a fixed point as

$$
\begin{equation*}
\nu_{\kappa} \sim \kappa^{-\eta_{\nu}^{*}}(\ln (\kappa / \Lambda))^{\gamma_{\nu}^{*}}, \quad D_{\kappa} \sim \kappa^{-\eta_{D}^{*}}(\ln (\kappa / \Lambda))^{\gamma_{D}^{*}} . \tag{44}
\end{equation*}
$$

This sub-leading behavior modifies the flow equation (41) as follows

$$
\begin{equation*}
\kappa \partial_{\kappa} \hat{\lambda}_{\kappa}=-\frac{1}{2} \hat{\lambda}_{\kappa}\left(2+\eta_{D}-3 \eta_{\nu}\right)+\frac{1}{2}\left(\gamma_{D}-3 \gamma_{\nu}\right)(\ln (\kappa / \Lambda))^{-1} \hat{\lambda}_{\kappa} . \tag{45}
\end{equation*}
$$

Since the corrections to the fixed point are expected to decay faster than a logarithmic, we require that $\gamma_{D}-3 \gamma_{\nu}=0$ at a non-Gaussian fixed point, which yields $\gamma_{D}=3 \gamma_{\nu} \equiv 3 \gamma$. The value of $\gamma$ is a priori not fixed, and should be computed by integrating the flow equations. In fact, if one assumes that there is no intermittency correction, that is that dimensional scalings are not modified, then $\gamma$ can be determined by consistency, following Kraichnan's argument. This is done in Sec. VA. In the following, we make no assumptions on the presence or not of intermittency, and keep an undetermined exponent $\gamma$.

In order to define dimensionless correlation functions, let us first express the forcing amplitude at the integral scale $D_{L^{-1}}$ as a function of the enstrophy rate using (43) evaluated at $\kappa=L^{-1}: \varepsilon_{\omega}=D_{L^{-1}} L^{-4} \Omega^{-1}$. Assuming the log-corrected power-law behavior (44) on the
whole inertial range, one can relate the coefficient $D_{\kappa}$ to its value at the integral scale as

$$
\begin{equation*}
D_{\kappa}=D_{L^{-1}}(\kappa L)^{-4}\left(\frac{\ln (\kappa / \Lambda)}{\ln \left(L^{-1} / \Lambda\right)}\right)^{3 \gamma} \simeq \varepsilon_{\omega} \Omega \kappa^{-4}\left|\frac{\ln (\kappa / \Lambda)}{\ln (L \Lambda)}\right|^{3 \gamma} \equiv D_{0} \varepsilon_{\omega} \kappa^{-4} s^{3 \gamma} \tag{46}
\end{equation*}
$$

where we have introduced the "RG time" $s=\ln (\kappa / \Lambda)$ and the non-universal constant $D_{0}=$ $\Omega|\ln (L \Lambda)|^{-3 \gamma}$. The coefficient $\nu_{\kappa}$ can be related in the same way to its value at the dissipative scale $\eta=\left(\nu^{3} / \varepsilon_{\omega}\right)^{1 / 6}$ as

$$
\begin{equation*}
\nu_{\kappa}=\nu_{\eta^{-1}}(\kappa \eta)^{-2}\left(\frac{\ln (\kappa / \Lambda)}{\ln \left(\eta^{-1} / \Lambda\right)}\right)^{\gamma} \simeq \varepsilon_{\omega}^{1 / 3} \kappa^{-2}\left|\frac{\ln (\kappa / \Lambda)}{\ln (\eta \Lambda)}\right|^{\gamma} \equiv \nu_{0} \varepsilon_{\omega}^{1 / 3} \kappa^{-2} s^{\gamma} \tag{47}
\end{equation*}
$$

where we have identified $\nu \simeq \nu_{\eta^{-1}}$, i.e. neglected its evolution between the microscopic scale $\Lambda$ and the dissipative one $\eta^{-1}$, and defined $\nu_{0}=|\ln (\eta \Lambda)|^{-\gamma}$.

## C. Solution at the fixed point for the two-point function

In this section, we derive the expression of the two-point correlation function in the stream formulation $C_{\psi} \equiv G_{\psi}^{(2,0)}$, obtained as the solution of the leading order flow equation at the fixed point. The flow equation at leading order for the mixed time-wavevector two-point correlation function can be deduced from the general flow (36) by performing the inverse Fourier transform on the frequency. It reads

$$
\begin{equation*}
\kappa \partial_{\kappa} C_{\psi}(t, \vec{p})=-\frac{1}{2} p^{2} C_{\psi}(t, \vec{p}) \int_{\varpi} \frac{\cos (\varpi t)-1}{\varpi^{2}} J_{\kappa}(\varpi), \tag{48}
\end{equation*}
$$

where $J_{\kappa}(\varpi)$ can be expressed as

$$
\begin{equation*}
J_{\kappa}(\varpi)=-\int_{\vec{q}} \tilde{\partial}_{\kappa} \bar{C}(\varpi, \vec{q})=-2 \int_{\vec{q}}\left\{\kappa \partial_{\kappa} N_{\kappa}(\vec{q})|\bar{G}(\varpi, \vec{q})|^{2}-\kappa \partial_{\kappa} R_{\kappa}(\vec{q}) \bar{C}(\varpi, \vec{q}) \Re[\bar{G}(\varpi, \vec{q})]\right\} \tag{49}
\end{equation*}
$$

with $\bar{C}$ and $\bar{G}$ the transverse parts of the two-point correlation and response function of the velocity, $\bar{G}_{v, \mu \nu}^{(2,0)}(\mathbf{p})=P_{\mu \nu}^{\perp}(\vec{p}) \bar{C}(\mathbf{p})$ and $\bar{G}_{v, \mu \nu}^{(1,1)}(\mathbf{p})=P_{\mu \nu}^{\perp}(\vec{p}) \bar{G}(\mathbf{p})$. The remarkable feature of this equation is that $\kappa \partial_{\kappa} C_{\psi} / C_{\psi}$ does not vanish at large wave-numbers, which means that there is no decoupling of the large wave-numbers. As shown in [21, 24], this leads to a violation of standard scale invariance, which is manifest in the solutions derived below.

This flow equation can be simplified in both the regime of large and small time delays as [21]

$$
\kappa \partial_{\kappa} C_{\psi}(t, \vec{p})=C_{\psi}(t, \vec{p}) \times\left\{\begin{array}{lll}
\frac{I_{\kappa}^{0}}{4} t^{2} p^{2}+\mathcal{O}\left(p_{\max }\right) & I_{\kappa}^{0}=\int_{\varpi} J_{\kappa}(\varpi) & t \ll 1 \\
\frac{I_{\kappa}^{\infty}}{4}|t| p^{2}+\mathcal{O}\left(p_{\max }\right) & I_{\kappa}^{\infty}=J_{\kappa}(0) & t \gg 1
\end{array}\right.
$$

where the $\mathcal{O}\left(p_{\max }\right)$ explicitly indicates the contributions beyond the leading order neglected in this flow equation. In order to study the fixed point, and using the dimensional analysis of Sec. IV B, we define the dimensionless correlation function

$$
\begin{equation*}
C_{\psi}(t, \vec{p})=\frac{D_{0}}{\nu_{0}} \frac{\varepsilon_{\omega}^{2 / 3}}{\kappa^{6}} s^{2 \gamma} \hat{C}_{s}\left(\hat{t}=\nu_{0} \varepsilon_{\omega}^{1 / 3} s^{\gamma} t, \hat{p}=p / \kappa\right), \tag{50}
\end{equation*}
$$

such that one obtains the dimensionless flow equation

$$
\left[\partial_{s}-6+\frac{2 \gamma}{s}-\hat{p} \partial_{\hat{p}}+\frac{\gamma}{s} \hat{t} \partial_{\hat{t}}\right] \hat{C}_{s}(\hat{t}, \hat{\vec{p}})=\hat{C}_{s}(\hat{t}, \hat{\vec{p}}) \times \begin{cases}\hat{\alpha}_{s}^{0} \hat{p}^{2} \hat{t}^{2}+\mathcal{O}\left(\hat{p}_{\max }\right) & t \ll 1  \tag{51}\\ \hat{\alpha}_{s}^{\infty} \hat{p}^{2}|\hat{t}|+\mathcal{O}\left(\hat{p}_{\max }\right) & t \gg 1\end{cases}
$$

where $\hat{\alpha}_{s}^{0, \infty}=D_{0} \nu_{0}^{-3} \hat{I}_{s}^{0, \infty} / 4$, with the dimensionless integrals $\hat{I}_{s}^{0} \equiv D_{\kappa}^{-1} \nu_{\kappa} I_{\kappa}^{0}$ and $\hat{I}_{s}^{\infty} \equiv$ $\kappa^{2} D_{\kappa}^{-1} \nu_{\kappa}^{2} I_{\kappa}^{\infty}$. In order to simplify the flow equation, we search for a solution of the form

$$
\begin{equation*}
\hat{C}_{s}(\hat{t}, \hat{\vec{p}})=\frac{1}{\hat{p}^{6}} \ln (\hat{p})^{-2 \gamma} \tilde{C}_{s}\left(\tilde{t}=\ln (\hat{p})^{-\gamma} \hat{t}, \hat{\vec{p}}\right) \tag{52}
\end{equation*}
$$

which satisfies the flow equation

$$
\begin{array}{r}
{\left[\partial_{s}+2 \gamma\left(\frac{1}{s}+\frac{1}{\ln (p / \Lambda)-s}\right)-\hat{p} \partial_{\hat{p}}+\gamma\left(\frac{1}{s}+\frac{1}{\ln (p / \Lambda)-s}\right) \tilde{t} \partial_{\hat{t}}\right] \tilde{C}_{s}(\tilde{t}, \hat{\vec{p}})=} \\
\tilde{C}_{s}(\tilde{t}, \hat{\vec{p}}) \times\left\{\begin{array}{l}
\hat{\alpha}_{s}^{0} \hat{p}^{2} \tilde{t}^{2} \ln (\hat{p})^{2 \gamma}+\mathcal{O}\left(\hat{p}_{\max }\right) \\
\hat{\alpha}_{s}^{\infty} \hat{p}^{2}|\tilde{t}| \ln (\hat{p})^{\gamma}+\mathcal{O}\left(\hat{p}_{\max }\right)
\end{array}\right. \tag{53}
\end{array}
$$

When approaching the fixed point, in the limit $s \rightarrow-\infty$, the term $\ln (p / \Lambda)$ is negligible compared to $s$ for any given external wave-number $p$, such that the terms proportional to $\gamma$ vanish. Moreover, the fixed point corresponds by definition to $\partial_{s} \hat{C}_{s}=0$, and dimensionless quantities reaching a constant value $\hat{\alpha}_{s}^{0} \rightarrow \hat{\alpha}_{*}^{0}$ and $\tilde{\alpha}_{s}^{\infty} \rightarrow \hat{\alpha}_{*}^{\infty}$. The fixed-point solution can be obtained by integrating the resulting fixed-point equation as

$$
\ln \left(\tilde{C}_{*}(\tilde{t}, \hat{\vec{p}})\right)= \begin{cases}-\tilde{t}^{2} \hat{\alpha}_{*}^{0} \int_{0}^{\hat{p}} x \ln (x)^{2 \gamma} d x+\hat{F}_{0}(\tilde{t})+\mathcal{O}\left(\hat{p}_{\max }\right) & t \ll 1  \tag{54}\\ -|\tilde{t}| \hat{\alpha}_{*}^{\infty} \int_{0}^{\hat{p}} x \ln (x)^{\gamma} d x+\hat{F}_{\infty}(\tilde{t})+\mathcal{O}\left(\hat{p}_{\max }\right) & t \gg 1\end{cases}
$$

where $\hat{F}_{0, \infty}$ are universal scaling functions, that can not be computed from the large wavenumber regime alone, but which can be determined by (numerical) integration of the complete flow equation. One then deduces the dimensionful physical two-point correlation function

$$
\begin{align*}
C_{\psi}(t, \vec{p})= & C_{0} \frac{\varepsilon_{\omega}^{2 / 3}}{p^{6}} \ln (p L)^{-2 \gamma} \hat{\mathcal{F}}_{0, \infty}\left(\bar{\nu}_{0} \varepsilon_{\omega}^{1 / 3} t \ln (p L)^{-\gamma}\right) \\
& \times\left\{\begin{aligned}
\exp \left(-\beta_{L}^{0} t^{2} \int_{0}^{p L} x \ln (x)^{2 \gamma} d x+\mathcal{O}\left(p_{\max } L\right)\right) & t \ll 1 \\
\exp \left(-\beta_{L}^{\infty}|t| \int_{0}^{p L} x \ln (x)^{\gamma} d x+\mathcal{O}\left(p_{\max } L\right)\right) & t \gg 1
\end{aligned}\right. \tag{55}
\end{align*}
$$

with $C_{0}=D_{0} \nu_{0}^{-1}|\ln (L \Lambda)|^{2 \gamma}, \bar{\nu}_{0}=\nu_{0}|\ln (L \Lambda)|^{\gamma}, \beta_{L}^{0}=\varepsilon_{\omega}^{2 / 3} L^{2} \bar{\nu}_{0}^{2} \hat{\alpha}_{*}^{0}, \beta_{L}^{\infty}=\varepsilon_{\omega}^{1 / 3} \bar{\nu}_{0} L^{2} \hat{\alpha}_{*}^{\infty}$, and $\hat{\mathcal{F}}_{0, \infty}=\exp \left(\hat{F}_{0, \infty}\right)$. The leading order term in the exponential, typically of order $p^{2}$, is exact. It provides the decorrelation time of the two-point function in the two regimes of small and large time-delays. This term involves an explicit dependence in the integral scale $L$, and thus breaks standard scale invariance. In 3D, one obtains a Gaussian dependence in $t p$ for large $p$ and small $t$ (no logarithms), which is usually interpreted as a consequence of the sweeping effect [21]. It was early predicted by Kraichnan within the DIA approximation [59], and later confirmed by RG approaches under some assumptions on the effective viscosity [61]. It has been observed in many numerical simulations of the NS equation [20, 62-65] as well as in experiments [66] in 3D. The solution (55) shows that the effect of sweeping takes a modified form in 2D, where it is corrected by a logarithm. Moreover, it indicates that a crossover to a $|t|$ dependence occurs at long time delays, as predicted in 3D [21].

The term $\hat{\mathcal{F}}_{0, \infty} / p^{6}$ in (55) corresponds to the solution that would be obtained assuming standard scale invariance (corrected by the sub-leading logarithm in 2D). As clear in Eq. (55), it is not exact in this calculation, since the contribution $\mathcal{O}\left(p_{\max } L\right)$ of the neglected subleading terms in the flow equation could modify this scaling solution, and possibly generate intermittency corrections. This has to be assessed by computing the NLO term in the flow equation, which is the purpose of Sec. V. We first briefly discuss the generalization to $n$-point correlations.

## D. Time-dependence of $n$-point function at the fixed point

The flow equation (35) for a $n$-point function at leading order in the large wave-number expansion can be expressed in a time-wavevector representation as

$$
\begin{align*}
\partial_{\kappa} G_{\psi, i_{1} \ldots i_{n}}^{(n)}\left(t_{1}, \vec{p}_{1}, \cdots, t_{n-1}, \vec{p}_{n-1}\right) & =\frac{1}{2} G_{\psi, i_{1} \ldots i_{n}}^{(n)}\left(t_{1}, \vec{p}_{1}, \cdots, t_{n-1}, \vec{p}_{n-1}\right) \\
& \times \sum_{k, \ell} \vec{p}_{k} \cdot \vec{p}_{\ell} \int_{\varpi} J_{\kappa}(\varpi) \frac{e^{i \varpi\left(t_{k}-t_{\ell}\right)}-e^{i \varpi t_{k}}-e^{-i \varpi t_{\ell}}+1}{\varpi^{2}} . \tag{56}
\end{align*}
$$

This equation can be simplified in both the limits of small and large time delays, as [21]

$$
\begin{array}{rlr}
\partial_{\kappa} G_{\psi, i_{1} \ldots i_{n}}^{(n)}\left(\left\{t_{i}, \vec{p}_{i}\right\}\right) & =G_{\psi, i_{1} \ldots i_{n}}^{(n)}\left(\left\{t_{i}, \vec{p}_{i}\right\}\right) \\
& \times \begin{cases}\frac{I_{\kappa}^{0}}{4}\left|\sum_{\ell} t_{\ell} p_{\ell}\right|^{2}+\mathcal{O}\left(p_{\max }\right) & t_{k} \ll 1 \\
\frac{I_{\kappa}^{\infty}}{4} \sum_{k, \ell} \vec{p}_{k} \cdot \vec{p}_{\ell}\left(\left|t_{k}\right|+\left|t_{\ell}\right|-\left|t_{k}-t_{\ell}\right|\right)+\mathcal{O}\left(p_{\max }\right) & t_{k} \gg 1\end{cases} \tag{57}
\end{array}
$$

In order to find the fixed point solution, one introduces the dimensionless $n$-point function, specifying the number $m$ of $\psi$ and $\bar{m}$ of $\bar{\psi}$ fields, as

$$
\begin{equation*}
G_{\psi, i_{1} \ldots i_{m+\bar{m}}}^{(m, \bar{m})}\left(\left\{t_{i}, \vec{p}_{i}\right\}\right)=\left(\frac{D_{0}}{\nu_{0}}\right)^{\frac{m-\bar{m}}{2}} \varepsilon_{\omega}^{\frac{m-\bar{m}}{3}} \frac{s^{\gamma(m-\bar{m})}}{\kappa^{4 m-2}} \hat{G}_{\psi, i_{1} \ldots i_{m+\bar{m}}}^{(m, \bar{m})}\left(\left\{\hat{t}_{i}=\nu_{0} \varepsilon_{\omega}^{1 / 3} s^{\gamma} t_{i}, \hat{\vec{p}}_{i}=\vec{p}_{i} / \kappa\right\}\right) . \tag{58}
\end{equation*}
$$

The dimensionless function hence satisfies the flow equation

$$
\begin{align*}
& {\left[\partial_{s}-4 m+2+(m-\bar{m}) \frac{\gamma}{s}-\sum_{k=1}^{m+\bar{m}-1} \hat{p}_{k} \partial_{\hat{p}_{k}}+\frac{\gamma}{s} \sum_{k=1}^{m+\bar{m}-1} \hat{t}_{k} \partial_{\hat{t}_{k}}\right] \hat{G}_{\psi, i_{1} \ldots i_{n}}^{(m, \bar{m})}=} \\
& \quad \hat{G}_{\psi, i_{1} \ldots i_{m+\bar{m}}}^{(m, \bar{m})} \times\left\{\begin{array}{ll}
\hat{\alpha}_{\kappa}^{0}\left|\sum_{\ell} \hat{t}_{\ell} \hat{\vec{p}}_{\ell}\right|^{2}+\mathcal{O}\left(\hat{p}_{\max }\right) \\
\hat{\alpha}_{\kappa}^{\infty} \sum_{k, \ell} \hat{\vec{p}}_{k} \cdot \hat{\vec{p}}_{\ell}\left(\left|\hat{t}_{k}\right|+\left|\hat{t}_{\ell}\right|-\left|\hat{t}_{k}-\hat{t}_{\ell}\right|\right)+\mathcal{O}\left(\hat{p}_{\max }\right) & t_{k} \gg 1
\end{array},\right. \tag{59}
\end{align*}
$$

As for the two-point function, the explicit $s$ dependence can be removed by searching for a solution of a particular form. The corresponding fixed-point solutions, at un-equal times, will have a similar behavior as the solutions obtained in 3D in [21], modified by the logarithmic corrections. We leave for future work their explicit derivation, and rather focus on the simultaneous functions in the following.

## V. $N$-POINT CORRELATION FUNCTION AT EQUAL TIMES

The NLO term in the large wave-number expansion of the flow equation (35) is calculated in Sec. VB. Before studying this term, let us assume that it decouples at equal-time, which means that the $\mathcal{O}\left(p_{\max } L\right)$ term in (57) is also zero at equal time, and expound the consequences for the two-point function.

## A. Logarithmic corrections assuming no intermittency

In this section, we hence focus on the two-point function $C_{\psi}$, and assume decoupling at equal time, which means that there is no intermittency, and the exponent of the power-law
in (55) (corresponding to Kolmogorov-Kraichnan scaling) is exact. In this case, as suggested by Kraichnan [6], logarithmic corrections are needed in order to ensure consistency with the hypothesis of a constant enstrophy flux in the inertial range. Let us unfold Kraichnan's argument within the present formalism, which will fix the value of the exponent $\gamma$ of the logarithm. We then give explicitly the logarithmic corrections in the time-dependence of the two-point function and in the equal-time $n$-point functions.

For this, we first compute the energy spectrum, assuming that the (connected) equal-time two-point function $C_{\psi}(0, \vec{x})=\langle\psi(t, \vec{x}) \psi(t, 0)\rangle_{c}$ has no intermittency correction. Using the previous scaling analysis, one deduces that

$$
\begin{equation*}
C_{\psi}(0, \vec{p}) \sim|\vec{p}|^{-6}(\ln (|\vec{p}| L))^{-2 \gamma} . \tag{60}
\end{equation*}
$$

and obtains for the energy spectrum

$$
\begin{equation*}
E(p)=2 \pi p^{3} C_{\psi}(0, \vec{p}) \sim p^{-3}(\ln (p L))^{-2 \gamma} . \tag{61}
\end{equation*}
$$

We now establish the expression of the flux of enstrophy. Let $T(p)$ be the rate of energy transfer owing to the nonlinear interactions in NS equation. The nonlinear transfer of enstrophy is then given by $p^{2} T(p)$. The flux of enstrophy $Z(p)$ is defined as the nonlinear transfer accross a scale $p$ as $Z(p)=\int_{p}^{\infty} p^{\prime 2} T\left(p^{\prime}\right) d p^{\prime}$. In the direct-cascade range of wavenumbers, the enstrophy flux is estimated to be $[2,6,19]$

$$
\begin{equation*}
Z(p) \sim \varpi_{p} p^{3} E(p) \quad \text { with } \quad \varpi_{p}^{2} \sim \int_{p_{\min }}^{p} d p^{\prime} p^{\prime 2} E\left(p^{\prime}\right) \tag{62}
\end{equation*}
$$

where $\varpi_{p}$ is the characteristic frequency of the distortion of eddies at scale $1 / p$ and $p_{\min } \sim 1 / L$ is the lowest turbulent wave-number. In our framework, one obtains $\varpi_{p}^{2} \sim$ $(\ln (p L))^{-2 \gamma+1}$, which then yields $Z(p) \sim(\ln (p L))^{-3 \gamma+\frac{1}{2}}$. Requiring a constant enstrophy flux $Z(p) \equiv \varepsilon_{\omega}$ for wave-numbers in the direct cascade thus fixes $\gamma=1 / 6$. As expected, this value corresponds to the log-corrected spectrum predicted by Kraichnan

$$
\begin{equation*}
E(p) \sim p^{-3}(\ln (p L))^{-1 / 3} . \tag{63}
\end{equation*}
$$

Let us emphasize that this reasoning does not prove the existence of the log-corrections, but simply deduce their form under the assumption of absence of intermittency. With this value of the exponent, the integral $\int_{0}^{p L} x(\ln x)^{\mu_{0, \infty}} d x$, with $\mu_{0} \equiv 2 \gamma$ and $\mu_{\infty} \equiv \gamma$, in Eq. (55)
behaves at large $p$ as $(p L)^{2} \ln (p L)^{\mu_{0, \infty}}$, with possible superimposed oscillations. Hence one obtains in the exponential

$$
C_{\psi}(t, \vec{p}) \sim \begin{cases}\exp \left(-\bar{\beta}_{L}^{0} t^{2} p^{2} \ln (p L)^{-1 / 3}\right) & t \ll 1  \tag{64}\\ \exp \left(-\bar{\beta}_{L}^{\infty}|t| p^{2} \ln (p L)^{-1 / 6}\right) & t \gg 1\end{cases}
$$

where numerical constants and a factor $L^{2}$ has been absorbed in the $\bar{\beta}_{L}^{0, \infty}$. It would be very interesting to test this prediction in numerical simulations or experiments. If the exponent of the logarithm in the time dependence can be precisely determined (which is certainly difficult), this would constitute another test of the existence of intermittency in the 2D direct cascade.

To make connection with other existing results, let us express the equal-time two-point correlation function of the vorticity

$$
\begin{equation*}
C_{\omega}(0, \vec{p})=p^{4} C_{\psi}(0, \vec{p}) \sim p^{-2} \ln (p L)^{-1 / 3} . \tag{65}
\end{equation*}
$$

In real space, one obtains

$$
\begin{equation*}
C_{\omega}(0, \vec{r})=\int_{0}^{\pi} d \theta \int d p \frac{1}{p} \ln (p L)^{-1 / 3} \exp (i|\vec{p}| \vec{r} \mid \cos \theta)=\int d p \frac{1}{p} \ln (p L)^{-1 / 3} J_{0}(p r) \tag{66}
\end{equation*}
$$

where $J_{0}$ is a Bessel function. The integral on $p$ is cut in the IR by $1 / L$. In the UV, the Bessel function is dominated by values $p \lesssim 1 / r$ since it rapidly oscillates around 0 at large $p$, which suppresses the integrand. One thus obtains $C_{\omega}^{(2,0)}(0, \vec{x}) \sim \ln (L /|\vec{x}|)^{2 / 3}$, which corresponds to the Falkovich and Lebedev prediction [9, 10].

Extending this comparison to higher-order simultaneous $n$-point correlations of the vorticity requires further work. Let us just give the result in the Fourier space. The flow equation (59) reduces at the fixed point, for equal times $t_{\ell}=0$, and expressed for the $m=2 n(\bar{m}=0)$ vorticity correlation as

$$
\begin{equation*}
\left[-4 n+2+\frac{n}{3 s}-\sum_{k=1}^{2 n-1} \hat{p}_{k} \partial_{\hat{p}_{k}}\right] \hat{G}_{\omega, i_{1} \ldots i_{n}}^{(2 n, 0)}=0 . \tag{67}
\end{equation*}
$$

One deduces the general solution of this equation as

$$
\begin{equation*}
\hat{G}_{\omega, i_{1} \ldots i_{2 n}}^{(2 n, 0)}\left(0, \hat{\vec{p}}_{1}, \cdots, 0, \hat{\vec{p}}_{2 n-1}\right)=\left(\prod_{k=1}^{2 n-1} \hat{p}_{k}^{-2}\left(\ln \hat{p}_{k}\right)^{-1 / 6}\right) \ln \left|\hat{\vec{p}}_{1}+\cdots+\hat{\vec{p}}_{2 n-1}\right|^{-1 / 6} \hat{F}^{(2 n)}, \tag{68}
\end{equation*}
$$

where $\hat{F}^{(2 n)}$ is a scaling function. The obtained logarithmic corrections have an overall behavior compatible with Falkovich-Lebedev prediction in real space $\left\langle\omega^{n}\left(\vec{r}_{1}\right) \omega^{n}\left(\vec{r}_{2}\right)\right\rangle \propto$
$\ln \left(L /\left|\vec{r}_{1}-\vec{r}_{2}\right|\right)^{2 n / 3}$. However, in order to make the statement precise, one needs to perform the multi-dimensional inverse Fourier transforms of (68). This requires to take into account the different integration sectors with great care. We leave the corresponding analysis for further work.

## B. $N$-point correlation function at equal times

At equal time, the exact leading term at large wave-number of the flow equation for a generic $n$-point correlation function, given by the r.h.s. of Eq. (35), vanishes. This can be read off directly from (32), or equivalently in the frequency space from (36). Indeed, the equal-time correlation function is obtained by integrating over all the external frequencies

$$
\begin{equation*}
\tilde{G}_{\psi, i_{1} \ldots i_{n}}^{(n)}\left(\left\{t=0, \vec{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right)=\int_{\omega_{1}, \ldots \omega_{n}} \tilde{G}_{\psi, i_{1} \ldots i_{n}}^{(n)}\left(\left\{\omega_{\ell}, \vec{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right) . \tag{69}
\end{equation*}
$$

Since the operator $\tilde{\mathcal{D}}(\varpi)$ in (36) acts as a finite difference, the integrated r.h.s. vanishes upon absorbing the related shifts by a change of variable in the external frequencies. At equal times, the first non-trivial contribution hence comes from the NLO term in the large-wave number expansion, which is the fourth order term in the $q_{1}, q_{2}$ expansion

$$
\begin{align*}
& \partial_{\kappa} \int_{\left\{\omega_{\ell}\right\}} \tilde{G}_{\psi, i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right)=\frac{1}{2} \int_{\mathbf{q}_{1}, \mathbf{q}_{2}} \tilde{\partial}_{\kappa} \tilde{G}_{\psi, i j}^{(2)}\left(-\mathbf{q}_{1},-\mathbf{q}_{2}\right) \\
& \times\left.\int_{\left\{\omega_{\ell}\right\}} \frac{q_{a}^{\mu} q_{b}^{\nu} q_{c}^{\rho} q_{d}^{\sigma}}{4!} \frac{\partial^{4}}{\partial q_{a}^{\mu} \partial q_{b}^{\nu} \partial q_{c}^{\rho} \partial q_{d}^{\sigma}}\left[\frac{\delta^{2}}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right) \delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{G}_{\psi, i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\} ; j\right]\right]_{\varphi=0}\right|_{\vec{q}_{1}=\vec{q}_{2}=0} \tag{70}
\end{align*}
$$

where as before $a, b, c, d$ take value in $\{1,2\}$. The detailed calculation of this term is reported in Appendix B 2, we summarize below the main steps.

First, one can show that among all the different combinations of $\vec{q}_{1}$ and $\vec{q}_{2}$ derivatives, only the ones with two $\vec{q}_{1}$ and two $\vec{q}_{2}$ survive after the integration over the external frequencies. The terms with four derivatives with respect to $\vec{q}_{1}$ vanish when evaluating at $\vec{q}_{2}=0$ because of the identity $a$ ) in (29) related to the gauge symmetry, (and similarly for $\vec{q}_{2}$ ). The terms with only one $\vec{q}_{1}$ derivative (and similarly only one $\vec{q}_{2}$ ) vanish as well. The reason is that this derivative yields an overall $\tilde{\mathcal{D}}$ operator as at leading order, and this contribution vanishes when integrating over the external frequencies (see Appendix B 2). Only the terms with two derivatives of $\vec{q}_{1}$ and $\vec{q}_{2}$ remain, and they can be written, using space translations and
rotations invariance of $\tilde{\partial}_{\kappa} \tilde{G}_{\psi}^{(2)}$, as

$$
\begin{align*}
& \partial_{\kappa} \int_{\left\{\omega_{\ell}\right\}} \tilde{G}_{\psi, i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right)=\frac{1}{2} \int_{\varpi_{1}, \varpi_{2}} \tilde{K}_{i j}\left(\varpi_{1}, \varpi_{2}\right) \\
& \times\left.\int_{\left\{\omega_{\ell}\right\}}\left(\frac{\partial^{4}}{\partial q_{1}^{\mu} \partial q_{1}^{\mu} \partial q_{2}^{\nu} \partial q_{2}^{\nu}}+2 \frac{\partial^{4}}{\partial q_{1}^{\mu} \partial q_{2}^{\mu} \partial q_{1}^{\nu} \partial q_{2}^{\nu}}\right)\left[\frac{\delta^{2}}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right) \delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{G}_{\psi, i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\} ; j\right]\right]_{\varphi=0}\right|_{\vec{q}_{1}=\vec{q}_{2}=0} . \tag{71}
\end{align*}
$$

with

$$
\begin{equation*}
\tilde{K}_{i j}\left(\varpi_{1}, \varpi_{2}\right) \equiv \frac{1}{32} \int_{\vec{q}} \tilde{\partial}_{\kappa} \tilde{G}_{\psi, i j}^{(2)}\left(-\varpi_{1},-\varpi_{2}, q^{2}\right)\left(q^{2}\right)^{2} . \tag{72}
\end{equation*}
$$

The last two parts of Appendix B 2 are devoted to show that

$$
\begin{align*}
\frac{\partial^{4}}{\partial q_{1}^{\mu} \partial q_{1}^{\mu} \partial q_{2}^{\nu} \partial q_{2}^{\nu}} & {\left.\left[\frac{\delta^{2}}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right) \delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{G}_{\psi, i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n} ; \mathbf{j}\right]\right]_{\varphi=0}\right|_{\vec{q}_{1}=\vec{q}_{2}=0} } \\
& =\delta_{i \psi} \delta_{j \psi} \tilde{\mathcal{R}}\left(\varpi_{1}\right) \tilde{\mathcal{R}}\left(\varpi_{2}\right) \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}\right) \tag{73}
\end{align*}
$$

which means that the contribution with the uncrossed derivatives is completly controlled by the extended symmetries and can be closed exactly using the corresponding Ward identities. It turns out that this term vanishes after integration over frequencies by conservation of angular momentum.

$$
\begin{align*}
& \int_{\left\{\omega_{\ell}\right\}} \tilde{\mathcal{R}}\left(\varpi_{1}\right) \frac{2 i \epsilon_{\alpha \beta}}{\varpi_{2}} \sum_{k=1}^{n} p_{k}^{a} \frac{\partial}{\partial p_{k}^{b}} \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left(\ldots, \omega_{k}+\varpi_{2}, \vec{p}_{k}, \ldots\right) \\
& =\int_{\left\{\omega_{\ell}\right\}} \tilde{\mathcal{R}}\left(\varpi_{1}\right) \frac{2 i \epsilon_{\alpha \beta}}{\varpi_{2}} \sum_{k=1}^{n-1} p_{k}^{a} \frac{\partial}{\partial p_{k}^{b}}\left[\tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left(\ldots, \omega_{k}+\varpi_{2}, \vec{p}_{k}, \ldots\right)-\tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left(\ldots, \omega_{n}+\varpi_{2}, \vec{p}_{n}\right)\right] \\
& =0 \tag{74}
\end{align*}
$$

and thus, it gives no contribution at equal times.
To summarize, beyond the technical details, one finds that all the terms which are controlled by the extended symmetries of the NS action vanish after integration over external frequencies. The only remaining term, which is not controlled by symmetries is the one with the crossed derivatives

$$
\begin{align*}
& \partial_{\kappa} \int_{\left\{\omega_{\ell}\right\}} \tilde{G}_{\psi, i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right) \\
& \quad=\left.\int_{\varpi_{1}, \varpi_{2}} \tilde{K}_{i j}\left(\varpi_{1}, \varpi_{2}\right) \int_{\left\{\omega_{\ell}\right\}} \frac{\partial^{4}}{\partial q_{1}^{\mu} \partial q_{2}^{\mu} \partial q_{1}^{\nu} \partial q_{2}^{\nu}}\left[\frac{\delta^{2}}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right) \delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{G}_{\psi, i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\} ; j\right]\right]_{\varphi=0}\right|_{\vec{q}_{1}=\vec{q}_{2}=0} . \tag{75}
\end{align*}
$$

This term is a priori non zero, and could be a source of intermittency. However, the effect can be expected to be much weaker than in 3D, since the time-gauged rotation does not hold in 3D and the corresponding terms do not vanish a priori.

It is possible that the crossed contribution (75) turns out to be proportional to the uncrossed one (73), and thus vanishes, at least in some specific wave-vector configurations, but we have not been able to prove it. If this were case, this would imply that there is no intermittency in the direct cascade of 2 D turbulence at equal times. It is instructive to consider the flow of the two-point function to further comment on this. The function appearing in square bracket in the r.h.s. of the flow equation (71) for $n=2$ is a function of $\vec{p}, \vec{q}_{1}$, and $\vec{q}_{2}$, and the corresponding frequencies:

$$
\begin{equation*}
\left[\frac{\delta^{2}}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right) \delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{G}_{\psi, i_{1}, i_{2}}^{(2)}[\mathbf{p} ; j]\right]_{\varphi=0} \equiv F\left(\omega, \vec{p}, \varpi_{1}, \vec{q}_{1}, \varpi_{2}, \vec{q}_{2}\right) \tag{76}
\end{equation*}
$$

The wave-vector part of $F$ involves only five independent scalars in 2D, which, considering the symmetry of exchange $\vec{q}_{1} \longleftrightarrow \vec{q}_{2}$ can be chosen as

$$
\begin{equation*}
F\left(\vec{p}, \vec{q}_{1}, \vec{q}_{2}\right)=\mathcal{F}\left(p^{2}, q_{1}^{2}+q_{2}^{2},\left(q_{1}^{2}+q_{2}^{2}\right)^{2}, \vec{q}_{1} \cdot \vec{q}_{2}, \vec{p} \cdot\left(\vec{q}_{1}+\vec{q}_{2}\right)\right), \tag{77}
\end{equation*}
$$

omitting the frequencies, which play no rôle for evaluating the $q$ derivatives. One obtains that

$$
\begin{align*}
\left.\frac{\partial^{4}}{\partial q_{1}^{\mu} \partial q_{1}^{\nu} \partial q_{2}^{\rho} \partial q_{2}^{\sigma}} F\left(\vec{p}, \vec{q}_{1}, \vec{q}_{2}\right)\right|_{\vec{q}_{1}=\vec{q}_{2}=0} & =\delta_{\mu \nu} \delta_{\rho \sigma} f_{1}\left(p^{2}\right)+\left(\delta_{\mu \rho} \delta_{\nu \sigma}+\delta_{\mu \sigma} \delta_{\nu \rho}\right) f_{2}\left(p^{2}\right) \\
& +p_{\mu} p_{\nu} p_{\rho} p_{\sigma} f_{3}\left(p^{2}\right)+\left(\delta_{\mu \nu} p_{\rho} p_{\sigma}+\delta_{\rho \sigma} p_{\mu} p_{\nu}\right) f_{4}\left(p^{2}\right) \\
& +\left(\delta_{\mu \rho} p_{\nu} p_{\sigma}+\delta_{\mu \sigma} p_{\nu} p_{\rho}+\delta_{\nu \rho} p_{\mu} p_{\sigma}+\delta_{\nu \sigma} p_{\mu} p_{\rho}\right) f_{5}\left(p^{2}\right) \tag{78}
\end{align*}
$$

with $f_{1}=4 \mathcal{F}^{(0,2,0,0,0)}-8 \mathcal{F}^{(0,0,1,0,0)}, f_{2}=\mathcal{F}^{(0,0,0,2,0)}, f_{3}=\mathcal{F}^{(0,0,0,0,4)}, f_{4}=2 \mathcal{F}^{(0,1,0,0,2)}$ and $f_{5}=\mathcal{F}^{(0,0,0,1,2)}$. One hence deduces that

$$
\begin{align*}
\left.\frac{\partial^{4}}{\partial q_{1}^{\mu} \partial q_{1}^{\mu} \partial q_{2}^{\nu} \partial q_{2}^{\nu}} F\left(\vec{p}, \vec{q}_{1}, \vec{q}_{2}\right)\right|_{\vec{q}_{1}=\vec{q}_{2}=0} & =4 f_{1}+4 f_{2}+p^{4} f_{3}+p^{2}\left(8 f_{4}+4 f_{5}\right) \\
\left.2 \frac{\partial^{4}}{\partial q_{1}^{\mu} \partial q_{1}^{\nu} \partial q_{2}^{\mu} \partial q_{2}^{\nu}} F\left(\vec{p}, \vec{q}_{1}, \vec{q}_{2}\right)\right|_{\vec{q}_{1}=\vec{q}_{2}=0} & =4 f_{1}+12 f_{2}+2 p^{4} f_{3}+p^{2}\left(8 f_{4}+12 f_{5}\right) \tag{79}
\end{align*}
$$

The crossed and uncrossed terms seem not to be proportional in general. They would be so for instance if the function $\mathcal{F}$ depends only on the moduli of the wave-vectors, but not on their relative angles. For the structure functions, which involve only two space points, it is not clear which configurations of wave-vectors dominate, and whether this relation could be fulfilled. The detailed analysis of structure functions is left for future investigations.

## VI. CONCLUSION AND PERSPECTIVES

In this paper, we investigated 2D forced turbulence, using field theoretical techniques. We unveiled two extended symmetries of the NS field theory that were not identified yet. One, related to time-gauged shift of the response field, exists in both 3 D and 2 D , while the other one, related to time-gauged rotations, is only realized in 2D. These symmetries bring new exact relations between the correlation functions of the theory through Ward identities, which can be useful in general.

We then exploited these Ward identities in the framework of the NPRG, within the largewave number expansion scheme developed in [21, 24], to compute some properties of the correlation functions of 2D isotropic and homogeneous turbulence. The leading order term of this expansion can be closed exactly, and allowed us to obtain the time dependence of the 2point correlation function in the stream formulation at both small and large time delays. This prediction could be tested in numerical simulations or in experiments. The generalization for $n$-point function is left for future work. This exact leading order contribution explicitly breaks standard scale invariance.

At equal times, the leading order term vanishes, and one is left with log-corrected powerlaws. If one assumes that there is no intermittency, then one recovers Kraichnan's logarithms, by unrolling a similar argument within the NPRG formalism. To assess the presence or not of intermittency in equal-time quantities, we calculated the NLO term in the large-wave number expansion. We found that almost all the terms are controlled by the symmetries, and that these terms vanish at equal times, and hence cannot generate intermittency. Nevertheless, there remains one contribution, which is not constrained by the symmetries. This contribution could lead to intermittency correction. However, this correction can be reasonably expected to be much weaker than in 3D, since in 3D many other contributions remain. Moreover, the unconstrained contribution could turn out to vanish is some specific wave-vector configurations, as the ones involved in the calculation of structure functions. Further works are in progress to approximate this contribution and estimate the related intermittency correction. Let us also emphasize that the techniques developed in the present work could be useful to study other hydrodynamical systems, such as passively advected quantities [67-73], which is underway [74].

## Appendix A: Extended symmetries and Ward identities

In this appendix, we explain the general derivation of Ward identities within the NPRG framework, and then give details on the derivation of the ones associated to the time-gauged Galilean and rotation symmetries in the stream formulation.

## 1. Ward identities in the NPRG framework

Let us illustrate the derivation of a Ward identity on a generic field theory for a field $\phi$ which can possess multiple components. Within the NPRG framework, in the presence of the infrared regulator $\Delta \mathcal{S}_{\kappa}$, the associated partition function is

$$
\begin{equation*}
\mathcal{Z}_{\kappa}[\mathrm{j}]=\int D[\phi] e^{-\mathcal{S}[\phi]-\Delta \mathcal{S}_{\kappa}[\phi]+\mathrm{j} \cdot \phi} \tag{A1}
\end{equation*}
$$

Let us consider a change of variable $\phi \rightarrow \phi^{\prime}$ in $\mathcal{Z}_{\kappa}$ which leaves the functional measure invariant. Denoting $\delta \mathcal{X}[\phi]=\mathcal{X}\left[\phi^{\prime}\right]-\mathcal{X}[\phi]$, where $\mathcal{X}$ is a generic functional, one has

$$
\begin{align*}
\mathcal{Z}_{\kappa}[\mathrm{j}] & =\int D\left[\phi^{\prime}\right] e^{-\mathcal{S}\left[\phi^{\prime}\right]-\Delta \mathcal{S}_{\kappa}\left[\phi^{\prime}\right]+\mathrm{j} \cdot \phi^{\prime}} \\
& =\int D[\phi] e^{-\mathcal{S}[\phi+\delta \phi]-\Delta \mathcal{S}_{\kappa}[\phi+\delta \phi]+\mathrm{j} \cdot \phi+\mathrm{j} \cdot \delta \phi} \\
& =\int D[\phi] e^{-\mathcal{S}[\phi]-\Delta \mathcal{S}_{\kappa}[\phi]+\mathrm{j} \cdot \phi} e^{-\delta\left(\mathcal{S}+\Delta \mathcal{S}_{\kappa}\right)[\phi]+\mathrm{j} \cdot \delta \phi} \\
& =\mathcal{Z}_{\kappa}[\mathrm{j}]\left\langle e^{-\delta\left(\mathcal{S}+\Delta \mathcal{S}_{\kappa}\right)[\phi]+\mathrm{j} \cdot \delta \phi}\right\rangle_{\mathrm{j}} \tag{A2}
\end{align*}
$$

where $\langle\cdot\rangle_{\mathrm{j}}$ is the mean value in presence of the sources. Since $\phi \rightarrow \phi^{\prime}$ is just a change of variables, the partition function is unchanged, which implies the Ward identity

$$
\begin{equation*}
\left\langle e^{-\delta\left(\mathcal{S}+\Delta \mathcal{S}_{k}\right)[\phi]+\mathrm{j} \cdot \delta \phi}\right\rangle_{\mathrm{j}}=1 \tag{A3}
\end{equation*}
$$

We focus on infinitesimal transformations, $\delta \phi=\delta_{\epsilon} \phi=O(\epsilon)$, which are at most linear in the fields

$$
\begin{equation*}
\phi_{i}(\mathbf{x}) \rightarrow \phi_{i}^{\prime}(\mathbf{x})=\phi_{i}(\mathbf{x})+\delta_{\epsilon} \phi_{i}(\mathbf{x}), \quad \delta_{\epsilon} \phi_{i}(\mathbf{x})=\epsilon\left[\int_{\mathbf{y}} A_{i j}(\mathbf{x}, \mathbf{y}) \phi_{j}(\mathbf{y})+B_{i}(\mathbf{x})\right] \tag{A4}
\end{equation*}
$$

where $A$ is an operator acting on $\phi$. It follows that $\left\langle\delta_{\epsilon} \phi\right\rangle=\delta_{\epsilon} \Phi$, with $\Phi \equiv\langle\phi\rangle_{\mathrm{j}}$. At linear order in $\epsilon$, one obtains from Eq. (A3)

$$
\begin{equation*}
\left\langle\delta_{\epsilon} \mathcal{S}\right\rangle_{\mathrm{j}}+\left\langle\delta_{\epsilon} \Delta \mathcal{S}_{\kappa}\right\rangle_{\mathrm{j}}+\mathrm{j} \cdot \delta_{\epsilon} \Phi=0 \tag{A5}
\end{equation*}
$$

where $\delta_{\epsilon} \mathcal{X}$ is the part of $\delta \mathcal{X}$ linear in $\epsilon$. Defining $\mathcal{R}_{\kappa}^{i j}(\mathbf{x}, \mathbf{y}) \equiv \frac{\delta^{2} \Delta \mathcal{S}_{\kappa}}{\delta \phi_{i}(\mathbf{x}) \delta \phi_{j}(\mathbf{y})}$, one has

$$
\begin{equation*}
\delta_{\epsilon} \Delta \mathcal{S}_{\kappa}=\int_{\mathbf{x}, \mathbf{y}} \mathcal{R}_{\kappa}^{i j}(\mathbf{x}, \mathbf{y}) \delta_{\epsilon} \phi_{i}(\mathbf{x}) \phi_{j}(\mathbf{y}), \tag{A6}
\end{equation*}
$$

since $\Delta \mathcal{S}_{\kappa}$ is quadratic in the fields and

$$
\begin{equation*}
\mathrm{j}_{i}(\mathbf{x})=\frac{\delta \Gamma_{\kappa}}{\delta \phi_{i}(\mathbf{x})}+\int_{\mathbf{y}} \mathcal{R}_{\kappa}^{i j}(\mathbf{x}, \mathbf{y}) \Phi_{j}(\mathbf{y}) \tag{A7}
\end{equation*}
$$

which follows from the definition of $\Gamma_{\kappa}$ (20). Using these relations and (A4), one deduces from (A5) the Ward identity

$$
\begin{equation*}
\delta_{\epsilon} \Gamma_{\kappa}[\Phi]=\left\langle\delta_{\epsilon} \mathcal{S}\right\rangle_{\mathbf{j}}+\epsilon \int_{\mathbf{x}, \mathbf{y}, \mathbf{z}} \mathcal{R}_{\kappa}^{i j}(\mathbf{x}, \mathbf{y}) A_{i k}(\mathbf{x}, \mathbf{z}) G_{j k}(\mathbf{y}, \mathbf{z}), \tag{A8}
\end{equation*}
$$

where $\delta_{\epsilon} \Gamma_{\kappa}[\Phi]=\int_{\mathbf{x}} \frac{\delta \Gamma_{\kappa}}{\delta \Phi_{i}(\mathbf{x})} \delta_{\epsilon} \Phi_{i}(\mathbf{x})$. The second term vanishes if the regulator term is invariant under the transformation. Let us notice that, because of the definition of the Legendre transform, the variation of the regulator under the shift part of the change of variable (A4) never enters the Ward identity in this formalism.

For exact symmetries of the action and of the regulator, Eq. (A8) simply translates into $\delta_{\epsilon} \Gamma_{\kappa}[\Phi]=0$, which means that $\Gamma_{\kappa}$ also possesses these symmetries. For extended symmetries, where the variations of the action and of the regulator are non-zero but linear in the fields, the mean and the variation commute and the Ward identity reads $\delta_{\epsilon} \Gamma_{\kappa}[\Phi]=\delta_{\epsilon} \mathcal{S}[\Phi]$, which means that the variation of the EAA $\Gamma_{\kappa}$ is equal to the mean of the variation of $\mathcal{S}$. This provides non-renormalisation theorems which fix a sector of $\Gamma_{\kappa}$ to its bare value. The transformations considered in this paper are all pure shifts of the fields, except the extended Galilean symmetry and the extended rotations. However, as the regulator is invariant under space translations, rotations, and is instantaneous (delta-correlated in time), it is invariant as well under time-gauged translations and time-gauged rotations, and thus it does not enter the corresponding Ward identities.

## 2. Ward identity for the time-gauged Galilean symmetry

The set of Ward identities related to the time-gauged Galilean symmetry for generic vertex functions are derived in $[21,24]$ in the velocity formulation. We present in this appendix their derivation in the stream formulation. The functional Ward identity for time-gauged Galilean transformation, Eq. (28) d), reads

$$
\begin{equation*}
\int_{\vec{x}}\left\{\left(-\epsilon_{\gamma \beta} x_{\gamma} \partial_{t}+\partial_{\beta} \Psi\right) \frac{\delta \Gamma_{\kappa}}{\delta \Psi(\mathbf{x})}+\partial_{\beta} \bar{\Psi} \frac{\delta \Gamma_{\kappa}}{\delta \bar{\Psi}(\mathbf{x})}\right\}=0 \tag{A9}
\end{equation*}
$$

To deduce the Ward identity for a generic vertex function $\Gamma_{\kappa}^{(m, n)}$, one takes $m$ functional derivatives of (A9) with respect to the stream function $\Psi\left(\mathbf{x}_{i}\right)$ and $n$ with respect to response response stream $\bar{\Psi}\left(\mathbf{x}_{j}\right)$, and then set the fields to zero, which yields, after multiplying by $\epsilon_{\alpha \beta}$,

$$
\begin{align*}
& \int_{\vec{x}}\left\{-x_{\alpha} \partial_{t} \Gamma_{\kappa}^{(m+1, n)}\left(\mathbf{x},\left\{\mathbf{x}_{\ell}\right\}_{1 \leq \ell \leq m+n}\right)\right. \\
& \left.-\epsilon_{\alpha \beta} \sum_{k=1}^{m+n} \delta\left(t-t_{k}\right) \delta^{d}\left(\vec{x}-\vec{x}_{k}\right) \partial_{\beta} \Gamma_{\kappa}^{(m, n)}\left(\left\{\mathbf{x}_{\ell}\right\}_{1 \leq \ell \leq k-1}, \mathbf{x},\left\{\mathbf{x}_{\ell}\right\}_{k+1 \leq \ell \leq m+n}\right)\right\}=0 . \tag{A10}
\end{align*}
$$

This identity reads in the Fourier space:

$$
\begin{align*}
& \left.\frac{\partial}{\partial q^{\alpha}} \tilde{\Gamma}_{\kappa}^{(m+1, n)}\left(\varpi, \vec{q},\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq m+n}\right)\right|_{\vec{q}=0} \\
& \quad=-i \epsilon_{\alpha \beta} \sum_{k=1}^{m+n} \frac{p_{k}^{\beta}}{\varpi} \tilde{\Gamma}_{\kappa}^{(m, n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq k-1}, \omega_{k}+\varpi, \vec{p}_{k},\left\{\mathbf{p}_{\ell}\right\}_{k+1 \leq \ell \leq m+n}\right) \\
& \quad \equiv i \epsilon_{\alpha \beta} \tilde{\mathcal{D}}_{\beta}(\varpi) \tilde{\Gamma}_{\kappa}^{(m, n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq m+n}\right) \tag{A11}
\end{align*}
$$

The corresponding expression for $\bar{\Gamma}_{\kappa}^{(m+1, n)}$, which is defined as in (26) by extracting the delta functions associated to the conservation of wave-vector and frequency, i.e. the invariance under global translations, can be deduced from (A11) and reads

$$
\begin{equation*}
\left.\frac{\partial}{\partial q^{\alpha}} \bar{\Gamma}_{\kappa}^{(m+1, n)}\left(\varpi, \vec{q},\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq m+n-1}\right)\right|_{\vec{q}=0}=i \epsilon_{\alpha \beta} \mathcal{D}_{\beta}(\varpi) \bar{\Gamma}_{\kappa}^{(m, n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq m+n-1}\right) \tag{A12}
\end{equation*}
$$

where the operator $\mathcal{D}_{\beta}(\varpi)$ is now defined by

$$
\begin{align*}
\mathcal{D}_{\alpha}(\varpi) & F\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right) \\
& \equiv-\sum_{k=1}^{n} p_{k}^{\alpha}\left[\frac{F\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq k-1}, \omega_{k}+\varpi, \vec{p}_{k},\left\{\mathbf{p}_{\ell}\right\}_{k+1 \leq \ell \leq n}\right)-F\left(\left\{\mathbf{p}_{\ell}\right\}\right)}{\varpi}\right] \tag{A13}
\end{align*}
$$

The expression shows explicitly the regularity of the limit $\varpi \rightarrow 0$.

## 3. Ward identity for the time-gauged rotation symmetries

The functional Ward identity associated with the time-gauged rotation, Eq. (28) e), is given by

$$
\begin{equation*}
\int_{\vec{x}}\left\{\left(\frac{x^{2}}{2} \partial_{t}+\epsilon_{\alpha \beta} x_{\beta} \partial_{\alpha} \Psi\right) \frac{\delta \Gamma_{\kappa}}{\delta \Psi(\mathbf{x})}+\epsilon_{\alpha \beta} x_{\beta} \partial_{\alpha} \bar{\Psi} \frac{\delta \Gamma_{\kappa}}{\delta \bar{\Psi}(\mathbf{x})}\right\}=2 \int_{\vec{x}} \partial_{t}^{2} \bar{\Psi} \tag{A14}
\end{equation*}
$$

Let us first derive an identity for $\Gamma^{(1,1)}$. Taking one derivative with respect to $\bar{\Psi}\left(\mathbf{x}^{\prime}\right)$, setting the fields to zero, and noting that $\partial_{\alpha} \Gamma_{\kappa}^{(0,1)}(\mathbf{x})=0$ by translational invariance, one obtains in the Fourier space

$$
\begin{equation*}
\left.\frac{\partial^{2}}{\partial p^{2}} \tilde{\Gamma}_{\kappa}^{(1,1)}\left(\mathbf{p}, \mathbf{p}^{\prime}\right)\right|_{\vec{p}=0}=-4 i \omega \delta^{d}\left(\vec{p}^{\prime}\right) \delta\left(\omega+\omega^{\prime}\right) \tag{A15}
\end{equation*}
$$

This result can be interpreted as the non-renormalisation of the kinetic term in the bare action.

We now derive the identity for a generic vertex function. Taking $m$ functional derivatives of (A14) with respect to $\Psi$ and $n$ with respect to $\bar{\psi}$, one obtains

$$
\begin{align*}
& \int_{\vec{x}}\left\{\frac{x^{2}}{2} \partial_{t} \Gamma_{\kappa}^{(m+1, n)}\left(\mathbf{x},\left\{\mathbf{x}_{\ell}\right\}_{1 \leq \ell \leq m+n}\right)\right. \\
& \left.-\sum_{k=1}^{m+n} \delta\left(t-t_{k}\right) \delta^{d}\left(\vec{x}-\vec{x}_{k}\right) \epsilon_{\alpha \beta} x_{\beta} \partial_{\alpha} \Gamma_{\kappa}^{(m, n)}\left(\left\{\mathbf{x}_{\ell}\right\}_{1 \leq \ell \leq k-1}, \mathbf{x},\left\{\mathbf{x}_{\ell}\right\}_{k+1 \leq \ell \leq m+n}\right)\right\}=0 \tag{A16}
\end{align*}
$$

One then deduces the general identity in the Fourier space:

$$
\begin{align*}
\frac{\partial^{2}}{\partial q^{2}} & \left.\tilde{\Gamma}_{\kappa}^{(m+1, n)}\left(\mathbf{q},\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq m+n}\right)\right|_{\vec{q}=0} \\
& =\frac{2 i \epsilon_{\alpha \beta}}{\varpi} \sum_{k=1}^{m+n} p_{k}^{\alpha} \frac{\partial}{\partial p_{k}^{\beta}} \tilde{\Gamma}_{\kappa}^{(m, n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq k-1}, \omega_{k}+\varpi, \mathbf{p}_{k},\left\{\mathbf{p}_{\ell}\right\}_{k+1 \leq \ell \leq m+n}\right) \\
& \equiv \tilde{\mathcal{R}}(\varpi) \tilde{\Gamma}_{\kappa}^{(m, n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq m+n}\right) \tag{A17}
\end{align*}
$$

This identity can be expressed in terms of the $\bar{\Gamma}_{\kappa}^{(m, n)}$, i.e. extracting the delta of conservation, as

$$
\begin{equation*}
\left.\frac{\partial^{2}}{\partial q^{2}} \bar{\Gamma}_{\kappa}^{(m+1, n)}\left(\varpi, \vec{q},\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq m+n-1}\right)\right|_{\vec{q}=0}=\tilde{\mathcal{R}}(\varpi) \bar{\Gamma}_{\kappa}^{(m, n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq m+n-1}\right) \tag{A18}
\end{equation*}
$$

where the identities $a$ ) and $d$ ) of Eq. (29) have been used. In contrast with the case of Galilean symmetry, this expression does not explicitly show that the limit $\varpi \rightarrow 0$ is welldefined. Indeed, extended Galilean symmetry corresponds to time-gauged space translation and the zero frequency limit is equivalent to time-independent space translation, which are
implicitly used when passing from the $\tilde{\Gamma}_{\kappa}^{(m, n)}$ to the $\bar{\Gamma}_{\kappa}^{(m, n)}$. For time-gauged rotations, the zero frequency limit, i.e. time-independent rotations, are needed. The corresponding Ward identity reads

$$
\begin{equation*}
\epsilon_{\alpha \beta} \sum_{k=1}^{m+n-1} p_{k}^{\alpha} \frac{\partial}{\partial p_{k}^{\beta}} \bar{\Gamma}_{\kappa}^{(m, n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq m+n-1}\right)=0 . \tag{A19}
\end{equation*}
$$

Substracting it from (A18), one finally obtains an expression in terms of finite differences as for the time-gauged Galilean identity:

$$
\begin{equation*}
\left.\frac{\partial^{2}}{\partial q^{2}} \bar{\Gamma}_{\kappa}^{(m+1, n)}\left(\varpi, \vec{q},\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq m+n-1}\right)\right|_{\vec{q}=0}=\mathcal{R}(\varpi) \bar{\Gamma}_{\kappa}^{(m, n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq m+n-1}\right) \tag{A20}
\end{equation*}
$$

with

$$
\begin{align*}
\mathcal{R}(\varpi) & F\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right) \\
& \equiv 2 i \epsilon_{\alpha \beta} \sum_{k=1}^{n} p_{k}^{\alpha} \frac{\partial}{\partial p_{k}^{\beta}}\left[\frac{F\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq k-1}, \omega_{k}+\varpi, \vec{p}_{k},\left\{\mathbf{p}_{\ell}\right\}_{k+1 \leq \ell \leq n}\right)-F\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right)}{\varpi}\right] \tag{A21}
\end{align*}
$$

where the regularity of the limit $\varpi \rightarrow 0$ is now manifest.
Let us note that similar subtleties arise when passing from the $\tilde{\Gamma}_{\kappa}^{(m, n)}$ to the $\bar{\Gamma}_{\kappa}^{(m, n)}$ for the symmetries $b$ ) and $c$ ) of Eq. (28), but the derivation of the corresponding identities is straightforward since the r.h.s. is always zero. We finally recapitulate the list of Ward identities for the vertex function $\tilde{\Gamma}^{(m, n)}$, which are the ones used in Appendix B
a) $\left.\quad \tilde{\Gamma}_{\kappa}^{(m, n)}(\ldots, \varpi, \vec{q}, \ldots)\right|_{\vec{q}=0}=0$
b) $\left.\frac{\partial}{\partial q^{i}} \tilde{\Gamma}_{\kappa}^{(m, n+1)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq m}, \varpi, \vec{q},\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right)\right|_{\vec{q}=0}=0$
c) $\left.\frac{\partial^{2}}{\partial q^{2}} \tilde{\Gamma}_{\kappa}^{(m, n+1)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq m}, \varpi, \vec{q},\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right)\right|_{\vec{q}=0}=0$

$$
\text { except }\left.\frac{\partial^{2}}{\partial q^{2}} \tilde{\Gamma}_{\kappa}^{(1,1)}\left(\varpi^{\prime}, \vec{q}^{\prime}, \varpi, \vec{q}\right)\right|_{\vec{q}=0}=4 i \varpi \delta^{d}\left(\vec{q}^{\prime}\right) \delta\left(\varpi+\varpi^{\prime}\right)
$$

d) $\left.\frac{\partial}{\partial q^{i}} \tilde{\Gamma}_{\kappa}^{(m+1, n)}\left(\varpi, \vec{q},\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq m+n}\right)\right|_{\vec{q}=0}=i \epsilon_{\alpha \beta} \tilde{\mathcal{D}}_{\beta}(\varpi) \tilde{\Gamma}_{\kappa}^{(m, n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq m+n}\right)$
e) $\left.\frac{\partial^{2}}{\partial q^{2}} \tilde{\Gamma}_{\kappa}^{(m+1, n)}\left(\varpi, \vec{q},\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq m+n}\right)\right|_{\vec{q}=0}=\tilde{\mathcal{R}}(\varpi) \tilde{\Gamma}_{\kappa}^{(m, n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq m+n}\right)$

$$
\begin{equation*}
\text { except }\left.\frac{\partial^{2}}{\partial q^{2}} \tilde{\Gamma}_{\kappa}^{(1,1)}\left(\varpi, \vec{q}, \varpi^{\prime}, \vec{q}^{\prime}\right)\right|_{\vec{q}=0}=-4 i \varpi \delta^{d}\left(\vec{q}^{\prime}\right) \delta\left(\varpi+\varpi^{\prime}\right) \tag{A22}
\end{equation*}
$$

with the two following definitions for the operator $\tilde{\mathcal{D}}_{\alpha}(\varpi)$ and $\tilde{\mathcal{R}}(\varpi)$ :

$$
\begin{align*}
& \tilde{\mathcal{D}}_{\alpha}(\varpi) F\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right) \equiv-\sum_{k=1}^{n} \frac{p_{k}^{\alpha}}{\varpi} F\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq k-1}, \omega_{k}+\varpi, \vec{p}_{k},\left\{\mathbf{p}_{\ell}\right\}_{k+1 \leq \ell \leq n}\right) \\
& \tilde{\mathcal{R}}(\varpi) F\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right) \equiv \frac{2 i \epsilon_{\alpha \beta}}{\varpi} \sum_{k=1}^{n} p_{k}^{\alpha} \frac{\partial}{\partial p_{k}^{\beta}} F\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq k-1}, \omega_{k}+\varpi, \mathbf{p}_{k},\left\{\mathbf{p}_{\ell}\right\}_{k+1 \leq \ell \leq n}\right) . \tag{A23}
\end{align*}
$$

## Appendix B: Large wave-number expansion in the stream formulation

Let us derive the expression (33) of the flow equation for a generic generalized $n$-point connected correlation function $\tilde{G}_{\psi}^{(n)}$ in the regime of large wave-numbers. This derivation is the same as the one given in the velocity formulation in [21], but we repeat it in the stream formulation for completeness. The flow equation for a generic $G_{\psi}^{(n)}$ is obtained by taking $n$ functional derivatives of (19) with respect to the sources $\mathrm{j}_{i_{k}}, 1 \leq k \leq n$, which yields

$$
\begin{align*}
\partial_{\kappa} G_{\psi, i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{x}_{\ell}\right\}_{1 \leq \ell \leq n} ; \mathbf{j}\right] & =-\frac{1}{2} \int_{\mathbf{y}_{1}, \mathbf{y}_{2}} \partial_{\kappa}\left[\mathcal{R}_{\kappa}\right]_{i j}\left(\mathbf{y}_{1}-\mathbf{y}_{2}\right)\left\{G_{\psi, i j i_{1} \ldots i_{n}}^{(n+2)}\left[\mathbf{y}_{1}, \mathbf{y}_{2},\left\{\mathbf{x}_{\ell}\right\} ; \mathbf{j}\right]\right. \\
& \left.+\sum_{\substack{\left(\left\{i_{\ell} \ell_{1},\left\{i_{\ell}\right\}_{2}\right) \\
\# 1+\# 2=n\right.}} G_{\psi, i\left\{i_{\ell}\right\} 1}^{(\# 1+1)}\left[\mathbf{y}_{1},\left\{\mathbf{x}_{\ell}\right\}_{1} ; \mathbf{j}\right] G_{\psi, j\left\{i_{\ell}\right\}_{2}}^{(\# 2+1)}\left[\mathbf{y}_{2},\left\{\mathbf{x}_{\ell}\right\}_{2} ; \mathbf{j}\right]\right\}, \tag{B1}
\end{align*}
$$

with the indices $i_{\ell} \in\{1,2\}$ standing for the source $J$ or $\bar{J}$, as in the main text, and $\left(\left\{i_{\ell}\right\}_{1},\left\{i_{\ell}\right\}_{2}\right)$ indicating all the possible bipartitions of the $n$ indices $\left\{i_{\ell}\right\}_{1 \leq \ell \leq n}$, and $\left(\left\{\mathbf{x}_{\ell}\right\}_{1},\left\{\mathbf{x}_{\ell}\right\}_{2}\right)$ the corresponding bipartition in coordinates. Finally, \#1 and \#2 are the cardinals of $\left\{i_{\ell}\right\}_{1}$ (resp. $\left\{i_{\ell}\right\}_{2}$ ). Focusing on the first line of (B1), one can write

$$
\begin{align*}
& \int_{\mathbf{y}_{1}, \mathbf{y}_{2}} \partial_{\kappa}\left[\mathcal{R}_{\kappa}\right]_{i j}\left(\mathbf{y}_{1}-\mathbf{y}_{2}\right) G_{\psi, i j i_{1} \ldots i_{n}}^{(n+2)}\left[\mathbf{y}_{1}, \mathbf{y}_{2},\left\{\mathbf{x}_{\ell}\right\} ; \mathbf{j}\right]=\int_{\mathbf{y}_{1}, \mathbf{y}_{2}} \partial_{\kappa}\left[\mathcal{R}_{\kappa}\right]_{i j}\left(\mathbf{y}_{1}-\mathbf{y}_{2}\right) \\
& \times\left[\int_{\mathbf{z}_{1}, \mathbf{z}_{2}} G_{\psi, k i}^{(2)}\left[\mathbf{z}_{1}, \mathbf{y}_{1} ; \mathbf{j}\right] G_{\psi, \ell j}^{(2)}\left[\mathbf{z}_{2}, \mathbf{y}_{2} ; \mathbf{j}\right] \frac{\delta^{2}}{\delta \varphi_{k}\left(\mathbf{z}_{1}\right) \delta \varphi_{\ell}\left(\mathbf{z}_{2}\right)}\right. \\
& \left.+\int_{\mathbf{z}} G_{\psi, \ell i j}^{(3)}\left[\mathbf{z}, \mathbf{y}_{1}, \mathbf{y}_{2} ; \mathbf{j}\right] \frac{\delta}{\delta \varphi_{\ell}(\mathbf{z})}\right] G_{\psi, i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{x}_{\ell}\right\} ; \mathbf{j}\right] . \tag{B2}
\end{align*}
$$

The derivatives of $G^{(n)}$ with respect to $\varphi$ must be understood as acting on $G^{(n)}$ expressed as a diagram constructed from $\Gamma_{\kappa}$ vertices. More precisely, $G^{(n)}$ is the sum of all tree diagrams with vertices the $\Gamma^{(k)}, k \leq n$ and with edges the propagator $G^{(2)}$, the latter satisfying

$$
\begin{equation*}
G_{\psi, k \ell}^{(2)}[\mathbf{x}, \mathbf{y} ; \mathbf{j}]=\frac{\delta \varphi_{k}(\mathbf{x})}{\delta \mathrm{j}_{\ell}(\mathbf{y})}=\left(\frac{\delta \mathbf{j}}{\delta \varphi}\right)_{k \ell}^{-1}(\mathbf{x}, \mathbf{y})=\left[\Gamma^{(2)}+\mathcal{R}_{\kappa}\right]_{k \ell}^{-1}[\mathbf{x}, \mathbf{y} ; \varphi] . \tag{B3}
\end{equation*}
$$

Furthermore, introducing the differential operator

$$
\begin{equation*}
\tilde{\partial}_{\kappa} \equiv \partial_{\kappa} R_{\kappa} \frac{\delta}{\delta R_{\kappa}}+\partial_{\kappa} N_{\kappa} \frac{\delta}{\delta N_{\kappa}} \tag{B4}
\end{equation*}
$$

and using the expression (B3), one has

$$
\begin{equation*}
\tilde{\partial}_{\kappa} G_{\psi, k \ell}^{(2)}\left[\mathbf{z}_{1}, \mathbf{z}_{2} ; \mathbf{j}\right]=-\int_{\mathbf{y}_{1}, \mathbf{y}_{2}} \partial_{\kappa}\left[\mathcal{R}_{\kappa}\right]_{i j}\left(\mathbf{y}_{1}-\mathbf{y}_{2}\right) G_{\psi, k i}^{(2)}\left[\mathbf{z}_{1}, \mathbf{y}_{1} ; \mathbf{j}\right] G_{\psi, \ell j}^{(2)}\left[\mathbf{z}_{2}, \mathbf{y}_{2} ; \mathbf{j}\right] \tag{B5}
\end{equation*}
$$

which appears in the first term of the r.h.s. of (B2). The second term in the r.h.s. of (B2) vanishes when the sources are set to zero, since it is proportional to the flow of the average stream function or the average response stream function. Indeed, the functions $G_{\psi, i}^{(1)}(\mathbf{x})$ are the expectation values of the stream function and response stream function. The expression of their flow can be deduced by taking one derivative of (19) with respect to a source and setting the sources to zero, which yields

$$
\begin{equation*}
\partial_{\kappa} G_{\psi, \ell}^{(1)}(\mathbf{z})=-\frac{1}{2} \int_{\mathbf{y}_{1}, \mathbf{y}_{2}} \partial_{\kappa}\left[\mathcal{R}_{\kappa}\right]_{i j}\left(\mathbf{y}_{1}-\mathbf{y}_{2}\right) G_{\psi, \ell i j}^{(3)}\left(\mathbf{z}, \mathbf{y}_{1}, \mathbf{y}_{2}\right), \tag{B6}
\end{equation*}
$$

omitting additional contribution proportional to $G^{(1)}$. As the average fields $G_{\psi, \ell}^{(1)}(\mathbf{z})$ are constant in space coordinates when the sources are set to zero, one can work in the comoving frame where they are identically zero, and so is their flow $\partial_{\kappa} G_{\psi, \ell}^{(1)}(\mathbf{z})$. By identification, one concludes that the second term in the r.h.s. of Eq. (B2) vanishes when evaluated at zero fields. Gathering the previous expressions and setting the fields to zero, the flow equation for $G^{(n)}$ can be rewritten as

$$
\begin{align*}
\partial_{\kappa} G_{\psi, i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{x}_{\ell}\right\}_{1 \leq \ell \leq n}\right) & =\frac{1}{2} \int_{\mathbf{y}_{1}, \mathbf{y}_{2}}\left\{\tilde{\partial}_{\kappa} G_{\psi, k l}^{(2)}\left(\mathbf{y}_{1}, \mathbf{y}_{2}\right)\left[\frac{\delta^{2}}{\delta \varphi_{k}\left(\mathbf{y}_{1}\right) \delta \varphi_{\ell}\left(\mathbf{y}_{2}\right)} G_{\psi, i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{x}_{\ell}\right\}_{1 \leq \ell \leq n} ; \mathbf{j}\right]\right]_{\varphi=0}\right. \\
& \left.-\sum_{\substack{\left\{\begin{array}{c}
\left.\{i\}_{1},\left\{i_{\ell}\right\}_{2}\right) \\
\# 1+\# 2=n
\end{array}\right.}} G_{\psi, i\left\{i_{\ell}\right\}_{1}}^{(\# 1+1)}\left(\mathbf{y}_{1},\left\{\mathbf{x}_{\ell}\right\}_{1}\right) \partial_{\kappa}\left[\mathcal{R}_{\kappa}\right]_{i j}\left(\mathbf{y}_{1}-\mathbf{y}_{2}\right) G_{\psi, j\left\{i_{\ell}\right\}_{2}}^{(\# 2+1)}\left(\mathbf{y}_{2},\left\{\mathbf{x}_{\ell}\right\}_{2}\right)\right\} . \tag{B7}
\end{align*}
$$

This yields in the Fourier space

$$
\begin{align*}
\partial_{\kappa} \tilde{G}_{\psi, i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right) & =\frac{1}{2} \int_{\mathbf{q}_{1}, \mathbf{q}_{2}}\left\{\tilde{\partial}_{\kappa} \tilde{G}_{\psi, k l}^{(2)}\left(-\mathbf{q}_{1},-\mathbf{q}_{2}\right)\left[\frac{\delta^{2}}{\delta \varphi_{k}\left(\mathbf{q}_{1}\right) \delta \varphi_{\ell}\left(\mathbf{q}_{2}\right)} \tilde{G}_{\psi, i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\} ; j\right]\right]_{\varphi=0}\right. \\
& \left.-\sum_{\substack{\left(\{i \ell\}_{1},\left\{i_{\ell}\right\}_{2}\right) \\
\# 1+\# 2=n}} \tilde{G}_{\psi, i\left\{i_{\ell}\right\}_{1}}^{(\# 1+1)}\left(\mathbf{q}_{1},\left\{\mathbf{p}_{\ell}\right\}_{1}\right) \partial_{\kappa}\left[\mathcal{R}_{\kappa}\right]_{i j}\left(-\mathbf{q}_{1},-\mathbf{q}_{2}\right) \tilde{G}_{\psi, j\left\{i_{\ell}\right\}_{2}}^{(\# 2+1)}\left(\mathbf{q}_{2},\left\{\mathbf{p}_{\ell}\right\}_{2}\right)\right\}, \tag{B8}
\end{align*}
$$

where in the first line the Fourier transform is meant after the functional derivatives

$$
\begin{equation*}
\left[\frac{\delta^{2}}{\delta \varphi_{k}\left(\mathbf{q}_{1}\right) \delta \varphi_{\ell}\left(\mathbf{q}_{2}\right)} \tilde{G}_{\psi, i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\} ; \mathbf{j}\right]\right]_{\varphi=0} \equiv \mathrm{FT}\left(\left.\frac{\delta^{2}}{\delta \varphi_{k}\left(\mathbf{z}_{1}\right) \delta \varphi_{\ell}\left(\mathbf{z}_{2}\right)} G_{\psi, i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{x}_{\ell}\right\} ; \mathbf{j}\right]\right|_{\varphi=0}\right)\left(\mathbf{q}_{1}, \mathbf{q}_{2},\left\{\mathbf{p}_{\ell}\right\}\right) \tag{B9}
\end{equation*}
$$

with $\mathrm{FT}(\ldots$. . ) denoting the Fourier transform.
We focus on the flow equation (B8), and now consider the limit of large wave-numbers, which we define as all external wave-numbers being large compared to the RG scale $\left|\vec{p}_{\ell}\right| \gg \kappa$ for $1 \leq \ell \leq n$, as well as all possible partial sums being large $\left|\sum_{\ell \in I} \vec{p}_{\ell}\right| \gg \kappa$, for $I$ a subset of $\{1, \ldots n\}$, which means that we exclude exceptional configurations where a partial sum vanishes. The following proof relies on the presence of the derivative of the regulator term $\partial_{\kappa}\left[\mathcal{R}_{\kappa}\right]$ in the flow equation (B8). The key properties of this term are that, on the one hand, it rapidly tends to zero for wave-numbers greater that the RG scale, and on the other hand, it ensures the analyticity of all vertex functions at any finite $\kappa$. Let us examine the second terms of the r.h.s. of (B8) in this limit. Using invariance under space-time translation, it can be rewritten as

$$
\begin{align*}
& \int_{\mathbf{q}_{1}, \mathbf{q}_{2}} \sum_{\substack{\left.\left\{i i_{\ell}\right\}_{1},\left\{i_{\ell}\right\}_{2}\right) \\
\# 1+\# 2=n}} G_{\psi, i\left\{i_{\ell}\right\}_{1}}^{(\# 1+1)}\left(\mathbf{q}_{1},\left\{\mathbf{p}_{\ell}\right\}_{1}\right) \partial_{\kappa}\left[\mathcal{R}_{\kappa}\right]_{i j}\left(-\mathbf{q}_{1},-\mathbf{q}_{2}\right) G_{\psi, j\left\{\ell_{\ell}\right\}_{2}}^{(\# 2+1)}\left(\mathbf{q}_{2},,\left\{\mathbf{p}_{\ell}\right\}_{2}\right) \\
& =(2 \pi)^{3} \delta\left(\sum_{k=1}^{n} \omega_{k}\right) \delta^{2}\left(\sum_{k=1}^{n} \vec{p}_{k}\right) \int_{\substack{\mathbf{q}}} \sum_{\substack{\left\{\left\{i_{2}\right\}_{1},\left\{i i^{\prime}\right\}_{2}\right) \\
\# 1+\# 2=n}} \bar{G}_{\psi,\left\{i_{\ell}\right\}_{1 i} i}^{(\# 1+1)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1}\right) \partial_{\kappa}\left[\mathcal{R}_{k}\right]_{i j}\left(\sum\left\{\vec{p}_{k}\right\}_{1}\right) \bar{G}_{\psi, j\left\{i_{\ell}\right\}_{2}}^{(\# 2+1)}\left(\left\{\mathbf{p}_{\ell}\right\}_{2}\right), \tag{B10}
\end{align*}
$$

where $\sum\left\{\vec{p}_{k}\right\}_{1}$ is the sum of all the wave-numbers in $\left\{\vec{p}_{k}\right\}_{1}$. Thus this term is proportional to the derivative of the regulator evaluated at a sum of external wave-numbers which is large $\sum\left\{\vec{p}_{k}\right\}_{1} \gg \kappa$. Hence it is suppressed at least exponentially in the limit of large wavenumbers and can be neglected safely. Finally, only the first term of (B8) survives in this limit and one obtains Eq. (33) of the main text.

## 1. Flow equation at leading order at unequal times

Let us now calculate the leading order term (at unequal times) of the flow equation of a generic correlation function $G^{(n)}$ in the large wave-number expansion, and show that the result obtained in the velocity formulation [21] is recovered. This calculation is again analogous to the one in the velocity formulation, but we propose here a slightly more condensed
derivation. As we work exclusively in the stream formulation in this appendix, we drop the $\psi$ index on the correlation function $G_{\psi,\left\{i_{\ell}\right\}}^{(n)}$. The $\psi$ index is used instead to explicitly indicate a $i_{\ell}=1$ index, i.e. a $\psi$ leg. We first perform the explicit calculation for the two-point function, and then establish the general expression for a $n$-point function.

## a. Two-point function

As explained in the main text, the first term of the large wave-number expansion is zero and the leading order term involves two $q$ derivatives and reads for the two-point function

$$
\begin{align*}
& \left.\partial_{\kappa} \tilde{G}_{\psi \psi}^{(2)}\left(\mathbf{p}_{1}, \mathbf{p}_{2}\right)\right|_{\text {leading }}=\frac{1}{2} \int_{\mathbf{q}_{1}, \mathbf{q}_{2}} \tilde{\partial}_{\kappa} \tilde{G}_{i j}^{(2)}\left(-\mathbf{q}_{1},-\mathbf{q}_{2}\right) \\
& \quad \times \frac{q_{a}^{\alpha} q_{b}^{\beta}}{2} \frac{\partial^{2}}{\partial q_{a}^{\alpha} \partial q_{b}^{\beta}} \int_{\mathbf{k}_{1}, \mathbf{k}_{2}} \tilde{G}_{\psi m}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) \tilde{G}_{\psi n}^{(2)}\left(\mathbf{p}_{2},-\mathbf{k}_{2}\right)\left[-\tilde{\Gamma}_{i j m n}^{(4)}\left(\mathbf{q}_{1}, \mathbf{q}_{2}, \mathbf{k}_{1}, \mathbf{k}_{2}\right)\right. \\
& \left.\quad+\int_{\mathbf{k}_{3}, \mathbf{k}_{4}} \tilde{\Gamma}_{i m s}^{(3)}\left(\mathbf{q}_{1}, \mathbf{k}_{1}, \mathbf{k}_{3}\right) \tilde{G}_{s t}^{(2)}\left(-\mathbf{k}_{3},-\mathbf{k}_{4}\right) \tilde{\Gamma}_{j n t}^{(3)}\left(\mathbf{q}_{2}, \mathbf{k}_{2}, \mathbf{k}_{4}\right)+\left(i, \mathbf{q}_{1}\right) \leftrightarrow\left(j, \mathbf{q}_{2}\right)\right]_{\vec{q}_{1}=\vec{q}_{2}=0} \tag{B11}
\end{align*}
$$

where the double arrow means the permutation of the preceeding term. We focus on the stream-stream correlation, but the following derivation holds for generic indices. The derivatives acting on $\tilde{\Gamma}^{(4)}$ can be expressed as

$$
\begin{align*}
\frac{q_{a}^{\alpha} q_{b}^{\beta}}{2} & \left.\frac{\partial^{2}}{\partial q_{a}^{\alpha} \partial q_{b}^{\beta}} \tilde{\Gamma}_{i j m n}^{(4)}\left(\mathbf{q}_{1}, \mathbf{q}_{2}, \mathbf{k}_{1}, \mathbf{k}_{2}\right)\right|_{\vec{q}_{1}=\vec{q}_{2}=0} \\
= & \left.\frac{q_{1}^{\alpha} q_{1}^{\beta}}{2} \frac{\partial^{2}}{\partial q_{1}^{\alpha} \partial q_{1}^{\beta}} \tilde{\Gamma}_{i j m n}^{(4)}\left(\mathbf{q}_{1}, \omega_{2}, \overrightarrow{0}, \mathbf{k}_{1}, \mathbf{k}_{2}\right)\right|_{\vec{q}_{1}=0}+\left.q_{1}^{\alpha} q_{2}^{\beta} \frac{\partial^{2}}{\partial q_{1}^{\alpha} \partial q_{2}^{\beta}} \tilde{\Gamma}_{i j m n}^{(4)}\left(\mathbf{q}_{1}, \mathbf{q}_{2}, \mathbf{k}_{1}, \mathbf{k}_{2}\right)\right|_{\vec{q}_{1}=\vec{q}_{2}=0} \\
& \quad+\left.\frac{q_{2}^{\alpha} q_{2}^{\beta}}{2} \frac{\partial^{2}}{\partial q_{2}^{\alpha} \partial q_{2}^{\beta}} \tilde{\Gamma}_{i j m n}^{(4)}\left(\omega_{1}, \overrightarrow{0}, \mathbf{q}_{2}, \mathbf{k}_{1}, \mathbf{k}_{2}\right)\right|_{\vec{q}_{2}=0} \\
= & \left.q_{1}^{\alpha} q_{2}^{\beta} \frac{\partial^{2}}{\partial q_{1}^{\alpha} \partial q_{2}^{\beta}} \tilde{\Gamma}_{i j m n}^{(4)}\left(\mathbf{q}_{1}, \mathbf{q}_{2}, \mathbf{k}_{1}, \mathbf{k}_{2}\right)\right|_{\vec{q}_{1}=\vec{q}_{2}=0} \\
= & \delta_{\psi k} \delta_{\psi \ell} i^{2} q_{1}^{\alpha} q_{2}^{\beta} \epsilon_{\alpha \mu} \epsilon_{\beta \nu} \tilde{\mathcal{D}}_{\mu}\left(\omega_{1}\right) \tilde{\mathcal{D}}_{\nu}\left(\omega_{2}\right) \tilde{\Gamma}_{m n}^{(2)}\left(\mathbf{k}_{1}, \mathbf{k}_{2}\right) \tag{B12}
\end{align*}
$$

where in the second equality, Eq. (A22) a) -which states that the vertex functions are proportional to the product of their wave-numbers- is used, and in the third equality, Eq. (A22) $b$ ) and $d$ ) are used. Thus, among the different combinations of $\vec{q}_{1}$ and $\vec{q}_{2}$, only one survives due to the space-independent gauge invariance.

The derivatives acting on the one particle-reducible (1-PR) term read

$$
\begin{align*}
\frac{q_{a}^{\alpha} q_{b}^{\beta}}{2} & \frac{\partial^{2}}{\partial q_{a}^{\alpha} \partial q_{b}^{\beta}}\left[\tilde{\Gamma}_{k m s}^{(3)}\left(\mathbf{q}_{1}, \mathbf{k}_{1}, \mathbf{k}_{3}\right) \tilde{G}_{s t}^{(2)}\left(-\mathbf{k}_{3},-\mathbf{k}_{4}\right) \tilde{\Gamma}_{\ell n t}^{(3)}\left(\mathbf{q}_{2}, \mathbf{k}_{2}, \mathbf{k}_{4}\right)\right]_{\vec{q}_{1}=\vec{q}_{2}=0} \\
= & \left.\frac{q_{1}^{\alpha} q_{1}^{\beta}}{2} \frac{\partial^{2}}{\partial q_{1}^{\alpha} \partial q_{1}^{\beta}} \tilde{\Gamma}_{k m s}^{(3)}\left(\mathbf{q}_{1}, \mathbf{k}_{1}, \mathbf{k}_{3}\right)\right|_{\vec{q}_{1}=0} \tilde{G}_{s t}^{(2)}\left(-\mathbf{k}_{3},-\mathbf{k}_{4}\right) \tilde{\Gamma}_{\ell n t}^{(3)}\left(\omega_{2}, \overrightarrow{0}, \mathbf{k}_{2}, \mathbf{k}_{4}\right) \\
& +\left.\left.q_{1}^{\alpha} q_{2}^{\beta} \frac{\partial}{\partial q_{1}^{\alpha}} \tilde{\Gamma}_{k m s}^{(3)}\left(\mathbf{q}_{1}, \mathbf{k}_{1}, \mathbf{k}_{3}\right)\right|_{\vec{q}_{1}=0} \tilde{G}_{s t}^{(2)}\left(-\mathbf{k}_{3},-\mathbf{k}_{4}\right) \frac{\partial}{\partial q_{2}^{\beta}} \tilde{\Gamma}_{\ell n t}^{(3)}\left(\mathbf{q}_{2}, \mathbf{k}_{2}, \mathbf{k}_{4}\right)\right|_{\vec{q}_{2}=0} \\
& +\left.\frac{q_{2}^{\alpha} q_{2}^{\beta}}{2} \tilde{\Gamma}_{k m s}^{(3)}\left(\omega_{1}, \overrightarrow{0}, \mathbf{k}_{1}, \mathbf{k}_{3}\right) \tilde{G}_{s t}^{(2)}\left(-\mathbf{k}_{3},-\mathbf{k}_{4}\right) \frac{\partial^{2}}{\partial q_{2}^{\alpha} \partial q_{2}^{\beta}} \tilde{\Gamma}_{\ell n t}^{(3)}\left(\mathbf{q}_{2}, \mathbf{k}_{2}, \mathbf{k}_{4}\right)\right|_{\vec{q}_{2}=0} \\
= & \left.\left.q_{1}^{\alpha} q_{2}^{\beta} \frac{\partial}{\partial q_{1}^{\alpha}} \tilde{\Gamma}_{k m s}^{(3)}\left(\mathbf{q}_{1}, \mathbf{k}_{1}, \mathbf{k}_{3}\right)\right|_{\vec{q}_{1}=0} \tilde{G}_{s t}^{(2)}\left(-\mathbf{k}_{3},-\mathbf{k}_{4}\right) \frac{\partial}{\partial q_{2}^{\beta}} \tilde{\Gamma}_{\ell n t}^{(3)}\left(\mathbf{q}_{2}, \mathbf{k}_{2}, \mathbf{k}_{4}\right)\right|_{\vec{q}_{2}=0} \\
= & \delta_{\psi k} \delta_{\psi \ell} i^{2} q_{1}^{\alpha} q_{2}^{\beta} \epsilon_{\alpha \mu} \epsilon_{\beta \nu} \tilde{\mathcal{D}}_{\mu}\left(\omega_{1}\right) \tilde{\Gamma}_{m s}^{(2)}\left(\mathbf{k}_{1}, \mathbf{k}_{3}\right) \tilde{G}_{s t}^{(2)}\left(-\mathbf{k}_{3},-\mathbf{k}_{4}\right) \tilde{\mathcal{D}}_{\nu}\left(\omega_{2}\right) \tilde{\Gamma}_{n t}^{(2)}\left(\mathbf{k}_{2}, \mathbf{k}_{4}\right) . \tag{B13}
\end{align*}
$$

Inserting both expressions in (B11) leads to

$$
\begin{align*}
& \left.\partial_{\kappa} \tilde{G}_{\psi \psi}^{(2)}\left(\mathbf{p}_{1}, \mathbf{p}_{2}\right)\right|_{\text {leading }}=\frac{1}{2} \int_{\mathbf{q}_{1}, \mathbf{q}_{2}} \tilde{\partial}_{\kappa} \tilde{G}_{\psi \psi}^{(2)}\left(-\mathbf{q}_{1},-\mathbf{q}_{2}\right) i^{2} q_{1}^{\alpha} q_{2}^{\beta} \epsilon_{\alpha \mu} \epsilon_{\beta \nu} \\
& \quad \int_{\mathbf{k}_{1}, \mathbf{k}_{2}} \tilde{G}_{\psi m}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) \tilde{G}_{\psi n}^{(2)}\left(\mathbf{p}_{2},-\mathbf{k}_{2}\right)\left[-\tilde{\mathcal{D}}_{\mu}\left(\varpi_{1}\right) \tilde{\mathcal{D}}_{\nu}\left(\varpi_{2}\right) \tilde{\Gamma}_{m n}^{(2)}\left(\mathbf{k}_{1}, \mathbf{k}_{2}\right)\right. \\
& \left.\quad+\int_{\mathbf{k}_{3}, \mathbf{k}_{4}} \tilde{\mathcal{D}}_{\mu}\left(\varpi_{1}\right) \tilde{\Gamma}_{m s}^{(2)}\left(\mathbf{k}_{1}, \mathbf{k}_{3}\right) \tilde{G}_{s t}^{(2)}\left(-\mathbf{k}_{3},-\mathbf{k}_{4}\right) \tilde{\mathcal{D}}_{\nu}\left(\varpi_{2}\right) \tilde{\Gamma}_{n t}^{(2)}\left(\mathbf{k}_{2}, \mathbf{k}_{4}\right)+\left(\mu, \omega_{1}\right) \leftrightarrow\left(\nu, \omega_{2}\right)\right] . \tag{B14}
\end{align*}
$$

To further simplify the second term, on can insert the following relation

$$
\begin{equation*}
\tilde{G}_{s t}^{(2)}\left(-\mathbf{k}_{3},-\mathbf{k}_{4}\right)=\int_{\mathbf{k}_{5}, \mathbf{k}_{6}} \tilde{G}_{s u}^{(2)}\left(-\mathbf{k}_{3},-\mathbf{k}_{5}\right) \tilde{\Gamma}_{u v}^{(2)}\left(\mathbf{k}_{5}, \mathbf{k}_{6}\right) \tilde{G}_{v t}^{(2)}\left(-\mathbf{k}_{6},-\mathbf{k}_{4}\right) \tag{B15}
\end{equation*}
$$

such that each $\tilde{\mathcal{D}}(\varpi) \tilde{\Gamma}^{(2)}$ is enclosed between two $\tilde{G}^{(2)}$. This combination can then be rewritten, making explicit the operator $\tilde{\mathcal{D}}$, as

$$
\begin{align*}
\int_{\mathbf{k}_{1}, \mathbf{k}_{3}} & \tilde{G}_{\psi m}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) \tilde{\mathcal{D}}_{\mu}\left(\varpi_{1}\right) \tilde{\Gamma}_{m s}^{(2)}\left(\mathbf{k}_{1}, \mathbf{k}_{3}\right) \tilde{G}_{s u}^{(2)}\left(-\mathbf{k}_{3},-\mathbf{k}_{5}\right) \\
= & -\int_{\mathbf{k}_{1}, \mathbf{k}_{3}} \tilde{G}_{\psi m}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right)\left[\frac{k_{1}^{\mu}}{\varpi_{1}} \tilde{\Gamma}_{m s}^{(2)}\left(\nu_{1}+\varpi_{1}, \vec{k}_{1}, \mathbf{k}_{3}\right)+\frac{k_{3}^{\mu}}{\varpi_{1}} \tilde{\Gamma}_{m s}^{(2)}\left(\mathbf{k}_{1}, \nu_{3}+\varpi_{1}, \vec{k}_{3}\right)\right] \tilde{G}_{s u}^{(2)}\left(-\mathbf{k}_{3},-\mathbf{k}_{5}\right) \\
= & -\int_{\mathbf{k}_{1}} \frac{k_{1}^{\mu}}{\varpi} \tilde{G}_{\psi m}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) \delta_{m u} \delta\left(\varpi_{1}+\nu_{1}-\nu_{5}\right) \delta^{2}\left(\vec{k}_{1}-\vec{k}_{5}\right) \\
& +\int_{\mathbf{k}_{3}} \frac{k_{3}^{\mu}}{\varpi} \delta_{\psi s} \delta\left(\omega_{1}+\varpi+\nu_{3}\right) \delta^{2}\left(\vec{p}_{1}+\vec{k}_{3}\right) \tilde{G}_{s u}^{(2)}\left(-\mathbf{k}_{3},-\mathbf{k}_{5}\right) \\
= & -\frac{k_{5}^{\mu}}{\varpi_{1}} \tilde{G}_{\psi u}^{(2)}\left(\mathbf{p}_{1},-\nu_{5}+\varpi_{1},-\vec{k}_{5}\right)+\frac{p_{1}^{\mu}}{\varpi_{1}} \tilde{G}_{\psi u}^{(2)}\left(\omega_{1}+\varpi_{1}, \vec{p}_{1},-\vec{k}_{5}\right) \\
= & -\tilde{\mathcal{D}}_{\mu}\left(\varpi_{1}\right) \tilde{G}_{\psi u}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{5}\right), \tag{B16}
\end{align*}
$$

where the second equality is simplified using that $\tilde{G}^{(2)}$ and $\tilde{\Gamma}^{(2)}$ are the inverse of each other

$$
\begin{equation*}
\int_{\mathbf{p}_{2}} \tilde{G}_{i j}\left(\mathbf{p}_{1},-\mathbf{p}_{2}\right) \tilde{\Gamma}_{j k}\left(\mathbf{p}_{2},-\mathbf{p}_{3}\right)=\delta_{i k} \delta\left(\nu_{1}-\nu_{3}\right) \delta^{d}\left(\vec{p}_{1}-\vec{p}_{3}\right) . \tag{B17}
\end{equation*}
$$

In fact, this calculation proves the general property

$$
\begin{align*}
\frac{\partial}{\partial q_{\alpha}} \frac{\delta}{\delta \varphi_{k}(\mathbf{q})} & \left.\tilde{G}_{i j}^{(2)}\left[\mathbf{p}_{1}, \mathbf{p}_{2} ; j\right]_{\varphi=0}\right|_{\vec{q}=0} \\
& =-\left.\int_{\mathbf{k}_{1}, \mathbf{k}_{2}} \tilde{G}_{i m}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) \frac{\partial}{\partial q_{\alpha}} \tilde{\Gamma}_{k m n}^{3)}\left(\mathbf{q}, \mathbf{k}_{1}, \mathbf{k}_{2}\right)\right|_{\vec{q}=0} \tilde{G}_{n j}^{(2)}\left(-\mathbf{k}_{2}, \mathbf{p}_{2}\right) \\
& =-\int_{\mathbf{k}_{1}, \mathbf{k}_{2}} \tilde{G}_{i m}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) i \epsilon_{\alpha \mu} \tilde{\mathcal{D}}_{\mu}(\varpi) \tilde{\Gamma}_{m n}^{(2)}\left(\mathbf{k}_{1}, \mathbf{k}_{2}\right) \tilde{G}_{n j}^{(2)}\left(-\mathbf{k}_{2}, \mathbf{p}_{2}\right) \\
& =i \epsilon_{\alpha \mu} \tilde{\mathcal{D}}_{\mu}(\varpi) \tilde{G}_{i j}^{(2)}\left(\mathbf{p}_{1}, \mathbf{p}_{2}\right) \tag{B18}
\end{align*}
$$

which will be useful in the general case. For the flow of the two point function, this allows one to write - relabelling the integration and summation variables for convenience-

$$
\begin{align*}
& \left.\partial_{\kappa} \tilde{G}_{\psi \psi}^{(2)}\left(\mathbf{p}_{1}, \mathbf{p}_{2}\right)\right|_{\text {leading }}=\frac{1}{2} \int_{\mathbf{q}_{1}, \mathbf{q}_{2}} \tilde{\partial}_{\kappa} \tilde{G}_{\psi \psi}^{(2)}\left(-\mathbf{q}_{1},-\mathbf{q}_{2}\right) i^{2} q_{1}^{\alpha} q_{2}^{\beta} \epsilon_{\alpha \mu} \epsilon_{\beta \nu} \\
& \quad \int_{\mathbf{k}_{1}, \mathbf{k}_{2}}\left[-\tilde{G}_{\psi m}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) \tilde{G}_{\psi n}^{(2)}\left(\mathbf{p}_{2},-\mathbf{k}_{2}\right) \tilde{\mathcal{D}}_{\mu}\left(\varpi_{1}\right) \tilde{\mathcal{D}}_{\nu}\left(\varpi_{2}\right) \tilde{\Gamma}_{m n}^{(2)}\left(\mathbf{k}_{1}, \mathbf{k}_{2}\right)\right. \\
& \left.\quad+\tilde{\mathcal{D}}_{\mu}\left(\varpi_{1}\right) \tilde{G}_{\psi m}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) \Gamma_{m n}^{(2)}\left(\mathbf{k}_{1}, \mathbf{k}_{2}\right) \tilde{\mathcal{D}}_{\nu}\left(\varpi_{2}\right) \tilde{G}_{\psi n}^{(2)}\left(\mathbf{p}_{2},-\mathbf{k}_{2}\right)+\left(\mu, \omega_{1}\right) \leftrightarrow\left(\nu, \omega_{2}\right)\right] . \tag{B19}
\end{align*}
$$

This expression can be further simplified by making explicit the $\tilde{\mathcal{D}}$ operator, since some terms cancel out between the two terms in brackets. Indeed, the first one reads

$$
\begin{align*}
& \int_{\mathbf{k}_{1}, \mathbf{k}_{2}} \tilde{G}_{\psi m}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) \tilde{G}_{\psi n}^{(2)}\left(\mathbf{p}_{2},-\mathbf{k}_{2}\right) \tilde{\mathcal{D}}_{\mu}\left(\varpi_{1}\right) \tilde{\mathcal{D}}_{\nu}\left(\varpi_{2}\right) \tilde{\Gamma}_{m n}^{(2)}\left(\mathbf{k}_{1}, \mathbf{k}_{2}\right) \\
& =\int_{\mathbf{k}_{1}, \mathbf{k}_{2}} \tilde{G}_{\psi m}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) \tilde{G}_{\psi n}^{(2)}\left(\mathbf{p}_{2},-\mathbf{k}_{2}\right)\left[\frac{k_{1}^{\mu} k_{1}^{\nu} \varpi_{1} \varpi_{2}}{\varpi_{m n}^{(2)}\left(\nu_{1}+\varpi_{1}+\varpi_{2}, \vec{k}_{1}, \mathbf{k}_{2}\right)}\right. \\
& \left.+\frac{k_{1}^{\mu} k_{2}^{\nu}}{\varpi_{1} \varpi_{2}} \tilde{\Gamma}_{m n}^{(2)}\left(\nu_{1}+\varpi_{1}, \vec{k}_{1}, \nu_{2}+\varpi_{2}, \vec{k}_{2}\right)+\left(\mu, \varpi_{1}\right) \leftrightarrow\left(\nu, \varpi_{2}\right)+\frac{k_{2}^{\mu} k_{2}^{\nu}}{\varpi_{1} \varpi_{2}} \tilde{\Gamma}_{m n}^{(2)}\left(\mathbf{k}_{1}, \nu_{2}+\varpi_{1}+\varpi_{2}, \vec{k}_{2}\right)\right] \\
& =\int_{\mathbf{k}_{1}} \frac{k_{1}^{\mu} k_{1}^{\nu}}{\varpi_{1} \varpi_{2}} \tilde{G}_{\psi m}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) \delta_{\psi m} \delta\left(\omega_{2}+\nu_{1}+\varpi_{1}+\varpi_{2}\right) \delta^{2}\left(\vec{p}_{2}+\vec{k}_{1}\right) \\
& +\int_{\mathbf{k}_{2}} \frac{k_{2}^{\mu} k_{2}^{\nu}}{\varpi_{1} \varpi_{2}} \tilde{G}_{\psi n}^{(2)}\left(\mathbf{p}_{2},-\mathbf{k}_{2}\right) \delta_{\psi n} \delta\left(\omega_{1}+\nu_{2}+\varpi_{1}+\varpi_{2}\right) \delta^{2}\left(\vec{p}_{1}+\vec{k}_{2}\right) \\
& +\int_{\mathbf{k}_{1}, \mathbf{k}_{2}} \tilde{G}_{\psi m}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) \tilde{G}_{\psi n}^{(2)}\left(\mathbf{p}_{2},-\mathbf{k}_{2}\right) \frac{k_{1}^{\mu} k_{2}^{\nu}}{\varpi_{1} \varpi_{2}} \tilde{\Gamma}_{m n}^{(2)}\left(\nu_{1}+\varpi_{1}, \vec{k}_{1}, \nu_{2}+\varpi_{2}, \vec{k}_{2}\right)+\left(\mu, \varpi_{1}\right) \leftrightarrow\left(\nu, \varpi_{2}\right) \\
& =\frac{p_{2}^{\mu} p_{2}^{\nu}}{\varpi_{1} \varpi_{2}} \tilde{G}_{\psi \psi}^{(2)}\left(\mathbf{p}_{1}, \omega_{2}+\nu_{1}+\varpi_{1}+\varpi_{2}, \vec{k}_{2}\right)+\frac{p_{1}^{\mu} p_{1}^{\nu}}{\varpi_{1} \varpi_{2}} \tilde{G}_{\psi \psi}^{(2)}\left(\omega_{1}+\nu_{1}+\varpi_{1}+\varpi_{2}, \vec{k}_{1}, \mathbf{p}_{2}\right) \\
& +\int_{\mathbf{k}_{1}, \mathbf{k}_{2}} \tilde{G}_{\psi m}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) \tilde{G}_{\psi n}^{(2)}\left(\mathbf{p}_{2},-\mathbf{k}_{2}\right) \frac{k_{1}^{\mu} k_{2}^{\nu} \tilde{\Gamma}_{1} \varpi_{2}}{\varpi_{m n}^{(2)}\left(\nu_{1}+\varpi_{1}, \vec{k}_{1}, \nu_{2}+\varpi_{2}, \vec{k}_{2}\right)+\left(\mu, \varpi_{1}\right) \leftrightarrow\left(\nu, \varpi_{2}\right),} \tag{B20}
\end{align*}
$$

and the second term is

$$
\begin{align*}
& \int_{\mathbf{k}_{1}, \mathbf{k}_{2}} \tilde{\mathcal{D}}_{\mu}\left(\varpi_{1}\right) \tilde{G}_{\psi m}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) \Gamma_{m n}^{(2)}\left(\mathbf{k}_{1}, \mathbf{k}_{2}\right) \tilde{\mathcal{D}}_{\nu}\left(\varpi_{2}\right) \tilde{G}_{\psi n}^{(2)}\left(\mathbf{p}_{2},-\mathbf{k}_{2}\right) \\
& =\int_{\mathbf{k}_{1}, \mathbf{k}_{2}}\left[\frac{p_{1}^{\mu}}{\varpi_{1}} \tilde{G}_{\psi m}^{(2)}\left(\omega_{1}+\varpi_{1}, \vec{p}_{1},-\mathbf{k}_{1}\right)-\frac{k_{1}^{\mu}}{\varpi_{1}} \tilde{G}_{\psi m}^{(2)}\left(\mathbf{p}_{1},-\nu_{1}+\varpi_{1},-\vec{k}_{1}\right)\right] \\
& \times \Gamma_{m n}^{(2)}\left(\mathbf{k}_{1}, \mathbf{k}_{2}\right)\left[\frac{p_{2}^{\nu}}{\varpi_{2}} \tilde{G}_{\psi n}^{(2)}\left(\omega_{2}+\varpi_{2}, \vec{p}_{2},-\mathbf{k}_{2}\right)-\frac{k_{2}^{\nu}}{\varpi_{2}} \tilde{G}_{\psi n}^{(2)}\left(\mathbf{p}_{2},-\nu_{2}+\varpi_{2},-\vec{k}_{2}\right)\right] \\
& =\frac{p_{1}^{\mu} p_{2}^{\nu}}{\varpi_{1} \varpi_{2}} \tilde{G}_{\psi \psi}^{(2)}\left(\omega_{1}+\varpi_{1}, \vec{p}_{1}, \omega_{2}+\varpi_{2}, \vec{p}_{2}\right) \\
& +\frac{p_{2}^{\mu} p_{2}^{\nu}}{\varpi_{1} \varpi_{2}} \tilde{G}_{\psi \psi}^{(2)}\left(\mathbf{p}_{1}, \omega_{2}+\nu_{1}+\varpi_{1}+\varpi_{2}, \vec{k}_{2}\right)+\frac{p_{1}^{\mu} p_{1}^{\nu}}{\varpi_{1} \varpi_{2}} \tilde{G}_{\psi \psi}^{(2)}\left(\omega_{1}+\nu_{1}+\varpi_{1}+\varpi_{2}, \vec{k}_{1}, \mathbf{p}_{2}\right) \\
& +\int_{\mathbf{k}_{1}, \mathbf{k}_{2}} \tilde{G}_{\psi m}^{(2)}\left(\mathbf{p}_{1},-\nu_{1}+\varpi_{1},-\vec{k}_{1}\right) \tilde{G}_{\psi n}^{(2)}\left(\mathbf{p}_{2},-\nu_{2}+\varpi_{2},-\vec{k}_{2}\right) \frac{k_{1}^{\mu} k_{2}^{\nu}}{\varpi_{1} \varpi_{2}} \tilde{\Gamma}_{m n}^{(2)}\left(\mathbf{k}_{1}, \mathbf{k}_{2}\right) . \tag{B21}
\end{align*}
$$

The last lines cancel out by shifting the frequencies $\nu_{1}$ and $\nu_{2}$ and one is left with

$$
\begin{align*}
& \left.\partial_{\kappa} \tilde{G}_{\psi \psi}^{(2)}\left(\mathbf{p}_{1}, \mathbf{p}_{2}\right)\right|_{\text {leading }}=\frac{1}{2} \int_{\mathbf{q}_{1}, \mathbf{q}_{2}} \tilde{\partial}_{\kappa} \tilde{G}_{\psi \psi}^{(2)}\left(-\mathbf{q}_{1},-\mathbf{q}_{2}\right) i^{2} q_{1}^{\alpha} q_{2}^{\beta} \epsilon_{\alpha \mu} \epsilon_{\beta \nu} \\
& \quad \times\left[\frac{p_{2}^{\mu} p_{2}^{\nu}}{\varpi_{1} \varpi_{2}} \tilde{G}_{\psi \psi}^{(2)}\left(\mathbf{p}_{1}, \omega_{2}+\nu_{1}+\varpi_{1}+\varpi_{2}, \vec{k}_{2}\right)+\frac{p_{1}^{\mu} p_{1}^{\nu}}{\varpi_{1} \varpi_{2}} \tilde{G}_{\psi \psi}^{(2)}\left(\omega_{1}+\nu_{1}+\varpi_{1}+\varpi_{2}, \vec{k}_{1}, \mathbf{p}_{2}\right)\right. \\
& \left.\quad+\frac{p_{2}^{\mu} p_{2}^{\nu}}{\varpi_{1} \varpi_{2}} \tilde{G}_{\psi \psi}^{(2)}\left(\mathbf{p}_{1}, \omega_{2}+\nu_{1}+\varpi_{1}+\varpi_{2}, \vec{k}_{2}\right)+\frac{p_{1}^{\mu} p_{1}^{\nu}}{\varpi_{1} \varpi_{2}} \tilde{G}_{\psi \psi}^{(2)}\left(\omega_{1}+\nu_{1}+\varpi_{1}+\varpi_{2}, \vec{k}_{1}, \mathbf{p}_{2}\right)\right] \\
& \quad=\frac{1}{2} \int_{\mathbf{q}_{1}, \mathbf{q}_{2}} \tilde{\partial}_{\kappa} \tilde{G}_{v_{\mu} v_{\nu}}^{(2)}\left(-\mathbf{q}_{1},-\mathbf{q}_{2}\right) \mathcal{D}_{\mu}\left(\omega_{1}\right) \mathcal{D}_{\nu}\left(\omega_{2}\right) \tilde{G}_{\psi \psi}^{(2)}\left(\mathbf{p}_{1}, \mathbf{p}_{2}\right), \tag{B22}
\end{align*}
$$

where the definition of the stream function in Fourier space: $\tilde{v}_{\mu}(\mathbf{q})=i \epsilon_{\mu \alpha} q_{\alpha}$ has been used in the last equality. This concludes the proof, and shows that the leading order result obtained in the velocity formulation is recovered in the stream function one for the two-point function.

## b. n-point function

Let us now consider a generic $n$-point correlation function. The leading order term of its flow equation reads

$$
\begin{align*}
\left.\partial_{\kappa} \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left(\mathbf{p}_{1}, \ldots, \mathbf{p}_{n}\right)\right|_{\text {leading }} & =\frac{1}{2} \int_{\mathbf{q}_{1}, \mathbf{q}_{2}} \tilde{\partial}_{\kappa} \tilde{G}_{i j}^{(2)}\left(-\mathbf{q}_{1},-\mathbf{q}_{2}\right) \\
& \times\left.\frac{q_{a}^{\alpha} q_{b}^{\beta}}{2} \frac{\partial^{2}}{\partial q_{a}^{\alpha} \partial q_{b}^{\beta}}\left[\frac{\delta^{2}}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right) \delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left[\mathbf{p}_{1}, \ldots, \mathbf{p}_{n} ; \mathbf{j}\right]\right]_{\varphi=0}\right|_{\vec{q}_{1}=\vec{q}_{2}=0} . \tag{B23}
\end{align*}
$$

The generalized correlation functions $\tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}\right)$ can be expressed as the sum over all trees whose edges are the propagators $\tilde{G}^{(2)}$, whose vertices are the vertex functions $\tilde{\Gamma}^{(k)}$ and with
external legs carrying momenta (i.e. wave-vectors and frequencies) and indices matching the indices of the correlation function: $\left\{\left(i_{\ell}, \mathbf{p}_{\ell}\right)\right\}$. Symbolically,

$$
\begin{align*}
\tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n} ; j\right] & =\sum_{\text {trees }} \alpha_{\mathcal{T}} \tilde{\mathcal{T}}_{i_{1} \cdots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\}\right] \\
\tilde{\mathcal{T}}_{i_{1} \cdots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\}\right] & =\int_{\mathbf{k}_{i}} \prod_{i=1}^{m} \mathcal{E}_{i}^{\mathcal{T}}\left[\left\{\mathbf{p}_{\ell}\right\}_{i},\left\{\mathbf{k}_{\ell}\right\}_{i}\right] \tag{B24}
\end{align*}
$$

where $\alpha_{\mathcal{T}}$ is a combinatorial factor, the $\mathcal{E}_{i}^{\mathcal{T}}$ are the vertex functions and propagators entering the composition of the tree $\tilde{\mathcal{T}}$ and the integration is done over all the internal momenta of the diagram. The $\left\{\mathbf{p}_{\ell}\right\}_{i}$ which are not empty form a partition of the external momenta $\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}$, and the internal momenta $\left\{\mathbf{k}_{\ell}\right\}_{i}$ are chosen such that when a propagator is attached to a vertex function, the sum of the momenta of the propagator and of the vertex function at the link is zero. Finally, the internal indices of the theory - here $i_{\ell} \in\{\psi, \bar{\psi}\}$ - have been omitted on $\mathcal{E}_{i}^{\mathcal{T}}$ to alleviate notations but follow straightforwardly from the partition of momenta. The term in square bracket in the flow equation (B23) is a sum of tree diagrams where the two functional derivatives have been distributed

$$
\begin{align*}
& \left.\frac{\delta^{2}}{\delta \varphi_{k}\left(\mathbf{q}_{1}\right) \delta \varphi_{\ell}\left(\mathbf{q}_{2}\right)} \tilde{\mathcal{T}}_{i_{1} \cdots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\}\right]_{\varphi=0}\right|_{\vec{q}_{1}=\vec{q}_{2}=0} \\
& =\left\{\int_{\mathbf{k}_{\text {intern }}} \sum_{\substack{i, j \\
i \neq j}}\left(\prod_{m \neq i, j} \mathcal{E}_{m}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{m},\left\{\mathbf{k}_{\ell}\right\}_{m}\right)\right)\right. \\
& \times\left.\left.\frac{\delta}{\delta \varphi_{k}\left(\mathbf{q}_{1}\right)} \mathcal{E}_{i}^{\mathcal{T}}\left[\left\{\mathbf{p}_{\ell}\right\}_{i},\left\{\mathbf{k}_{\ell}\right\}_{i}\right]\right|_{\varphi=0} \frac{\delta}{\delta \varphi_{\ell}\left(\mathbf{q}_{2}\right)} \mathcal{E}_{j}^{\mathcal{T}}\left[\left\{\mathbf{p}_{\ell}\right\}_{j},\left\{\mathbf{k}_{\ell}\right\}_{j}\right]\right|_{\varphi=0} \\
& \left.+\left.\int_{\mathbf{k}_{\text {intern }}} \sum_{i}\left(\prod_{j \neq i} \mathcal{E}_{j}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{j},\left\{\mathbf{k}_{\ell}\right\}_{j}\right)\right) \frac{\delta^{2}}{\delta \varphi_{k}\left(\mathbf{q}_{1}\right) \delta \varphi_{\ell}\left(\mathbf{q}_{2}\right)} \mathcal{E}_{i}^{\mathcal{T}}\left[\left\{\mathbf{p}_{\ell}\right\}_{i},\left\{\mathbf{k}_{\ell}\right\}_{i}\right]\right|_{\varphi=0}\right\}\left.\right|_{\vec{q}_{1}=\vec{q}_{2}=0} \tag{B25}
\end{align*}
$$

When acting with a field functional derivative, either the derivative hits on a vertex function, giving

$$
\begin{equation*}
\frac{\delta}{\delta \varphi_{i}\left(\mathbf{q}_{a}\right)} \tilde{\Gamma}_{i_{1} \ldots i_{k}}^{(k)}\left[\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq k} ; \varphi\right]_{\varphi=0}=\tilde{\Gamma}_{i i_{1} \ldots i_{k}}^{(k+1)}\left(\mathbf{q}_{a},\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq k}\right) \tag{B26}
\end{equation*}
$$

or the derivative hits on a propagator, giving

$$
\begin{equation*}
\frac{\delta}{\delta \varphi_{i}\left(\mathbf{q}_{a}\right)} G_{m n}^{(2)}\left[\mathbf{p}_{1}, \mathbf{p}_{2} ; \mathbf{j}\right]_{\varphi=0}=-\int_{\mathbf{k}_{1}, \mathbf{k}_{2}} G_{m u}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) \tilde{\Gamma}_{i u v}^{(3)}\left(\mathbf{q}_{a}, \mathbf{k}_{1}, \mathbf{k}_{2}\right) G_{v n}^{(2)}\left(-\mathbf{k}_{2}, \mathbf{p}_{2}\right), \tag{B27}
\end{equation*}
$$

with $a \in\{1,2\}$. Distributing the two $\vec{q}$-derivatives in the flow equation (B23), the terms with $a=b$, which correspond to two $\vec{q}$-derivatives acting on the same leg of the diagram,
are zero, because a vertex function with a wave-number set to zero vanishes. Thus one is left with one derivative hitting on each leg:

$$
\begin{align*}
\left.\partial_{\kappa} \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right)\right|_{\text {leading }} & =\frac{1}{2} \int_{\mathbf{q}_{1}, \mathbf{q}_{2}} \tilde{\partial}_{\kappa} \tilde{G}_{i j}^{(2)}\left(-\mathbf{q}_{1},-\mathbf{q}_{2}\right) \\
& \times\left. q_{1}^{\alpha} q_{2}^{\beta} \frac{\partial^{2}}{\partial q_{1}^{\alpha} \partial q_{2}^{\beta}}\left[\frac{\delta^{2}}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right) \delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\} ; j\right]\right]_{\varphi=0}\right|_{\vec{q}_{1}=\vec{q}_{2}=0} . \tag{B28}
\end{align*}
$$

Next, we need to prove the following property

$$
\begin{align*}
\frac{\partial^{2}}{\partial q_{1}^{\alpha} \partial q_{2}^{\beta}} & {\left.\left[\frac{\delta^{2}}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right) \delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n} ; \mathbf{j}\right]\right]_{\varphi=0}\right|_{\vec{q}_{1}=\vec{q}_{2}=0} } \\
& =\delta_{i \psi} \delta_{j \psi} i^{2} \epsilon_{\alpha \mu} \epsilon_{\beta \nu} \tilde{\mathcal{D}}_{\mu}\left(\varpi_{1}\right) \tilde{\mathcal{D}}_{\nu}\left(\varpi_{2}\right) \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}\right) . \tag{B29}
\end{align*}
$$

For this, let us examine the case of only one functional derivative and subsequent wavenumber derivative applied to a generic tree $\tilde{\mathcal{T}}^{(n)}$, which reads

$$
\begin{align*}
\frac{\partial}{\partial q_{a}^{\alpha}} \frac{\delta}{\delta \varphi_{i}\left(\mathbf{q}_{a}\right)} & \left.\tilde{\mathcal{T}}_{i_{1} \cdots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\}\right]_{\varphi=0}\right|_{\vec{q}_{a}=0} \\
& =\int_{\mathbf{k}_{\text {intern }}} \sum_{i=1}^{m}\left(\prod_{\substack{j=1 \\
j \neq i}}^{m} \mathcal{E}_{j}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{j},\left\{\mathbf{k}_{\ell}\right\}_{j}\right)\right) \frac{\partial}{\partial q_{a}^{\alpha}} \frac{\delta}{\delta \varphi_{i}\left(\mathbf{q}_{a}\right)} \mathcal{E}_{i}^{\mathcal{T}}\left[\left\{\mathbf{p}_{\ell}\right\}_{i},\left\{\mathbf{k}_{\ell}\right\}_{i}\right] \tag{B30}
\end{align*}
$$

giving either

$$
\begin{equation*}
\left.\frac{\partial}{\partial q_{a}^{\alpha}} \frac{\delta}{\delta \varphi_{i}\left(\mathbf{q}_{a}\right)} \tilde{\Gamma}_{i_{1} \ldots i_{k}}^{(k)}\left[\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq k} ; \varphi\right]_{\varphi=0}\right|_{\vec{q}_{a}=0}=\delta_{i \psi} i \epsilon_{\alpha \mu} \tilde{\mathcal{D}}_{\mu}\left(\varpi_{a}\right) \tilde{\Gamma}_{i_{1} \ldots i_{k}}^{(k)}\left(\left\{\mathbf{p}_{\ell}\right\}\right), \tag{B31}
\end{equation*}
$$

if $\mathcal{E}_{i}^{\mathcal{T}}$ is a vertex function, or

$$
\begin{equation*}
\left.\frac{\partial}{\partial q_{a}^{\alpha}} \frac{\delta}{\delta \varphi_{i}\left(\mathbf{q}_{a}\right)} G_{m n}^{(2)}\left[\mathbf{p}_{1}, \mathbf{p}_{2} ; \mathbf{j}\right]_{\varphi=0}\right|_{\vec{q}_{a}=0}=\delta_{i \psi} i \epsilon_{\alpha \mu} \tilde{\mathcal{D}}_{\mu}\left(\varpi_{a}\right) \tilde{G}_{m n}^{(2)}\left(\mathbf{p}_{1}, \mathbf{p}_{2}\right), \tag{B32}
\end{equation*}
$$

if it is a propagator, using the property (B18). This shows that

$$
\begin{align*}
\frac{\partial}{\partial q_{a}^{\alpha}} \frac{\delta}{\delta \varphi_{i}\left(\mathbf{q}_{a}\right)} & \left.\tilde{\mathcal{T}}_{i_{1} \cdots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\}\right]_{\varphi=0}\right|_{\vec{q}_{a}=0} \\
& =\delta_{i \psi} i \epsilon_{\alpha \mu} \int_{\mathbf{k}_{\text {intern }}} \sum_{i=1}^{m}\left(\prod_{\substack{j=1 \\
j \neq i}}^{m} \mathcal{E}_{j}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{j},\left\{\mathbf{k}_{\ell}\right\}_{j}\right)\right) \tilde{\mathcal{D}}_{\mu}\left(\varpi_{a}\right) \mathcal{E}_{i}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{i},\left\{\mathbf{k}_{\ell}\right\}_{i}\right), \tag{B33}
\end{align*}
$$

which means that the operator $\tilde{\mathcal{D}}_{\mu}\left(\varpi_{a}\right)$ is distributed on the elements of the tree according to the Leibniz rule. Furthermore, because of conservation of momenta, the r.h.s. is equivalent
to the operator $\tilde{\mathcal{D}}_{\mu}$ acting on the tree $\tilde{\mathcal{T}}^{(n)}$, that is only on the external legs $\left\{\mathbf{p}_{\ell}\right\}$, i.e.

$$
\begin{align*}
\tilde{\mathcal{D}}_{\mu}\left(\varpi_{a}\right) \int_{\mathbf{k}} \mathcal{E}_{1}^{\mathcal{T}}\left(\left\{\mathbf{k}_{\ell}\right\}_{1},-\mathbf{k}\right) \mathcal{E}_{2}^{\mathcal{T}}\left(\mathbf{k},\left\{\mathbf{k}_{\ell}\right\}_{2}\right) & =\int_{\mathbf{k}}\left[\tilde{\mathcal{D}}_{\mu}\left(\varpi_{a}\right) \mathcal{E}_{1}^{\mathcal{T}}\left(\left\{\mathbf{k}_{\ell}\right\}_{1},-\mathbf{k}\right) \mathcal{E}_{2}^{\mathcal{T}}\left(\mathbf{k},\left\{\mathbf{k}_{\ell}\right\}_{2}\right)\right. \\
& \left.+\mathcal{E}_{1}^{\mathcal{T}}\left(\left\{\mathbf{k}_{\ell}\right\}_{1},-\mathbf{k}\right) \tilde{\mathcal{D}}_{\mu}\left(\varpi_{a}\right) \mathcal{E}_{2}^{\mathcal{T}}\left(\mathbf{k},\left\{\mathbf{k}_{\ell}\right\}_{2}\right)\right] . \tag{B34}
\end{align*}
$$

This relation can be simply established by expanding the r.h.s.,

$$
\begin{align*}
\int_{\mathbf{k}} & {\left[\tilde{\mathcal{D}}_{\mu}\left(\varpi_{a}\right) \mathcal{E}_{i}^{\mathcal{T}}\left(\left\{\mathbf{k}_{\ell}\right\}_{\ell \in I},-\mathbf{k}\right) \mathcal{E}_{j}^{\mathcal{T}}\left(\mathbf{k},\left\{\mathbf{k}_{\ell}\right\}_{\ell \in J}\right)+\mathcal{E}_{i}^{\mathcal{T}}\left(\left\{\mathbf{k}_{\ell}\right\}_{\ell \in I},-\mathbf{k}\right) \tilde{\mathcal{D}}_{\mu}\left(\varpi_{a}\right) \mathcal{E}_{j}^{\mathcal{T}}\left(\mathbf{k},\left\{\mathbf{k}_{\ell}\right\}_{\ell \in J}\right)\right] } \\
& =-\int_{\mathbf{k}}\left[\sum_{i \in I} \frac{k_{i}^{\mu}}{\varpi_{a}} \mathcal{E}_{i}^{\mathcal{T}}\left(\varpi_{i}+\omega_{a}, \vec{k}_{i},\left\{\mathbf{k}_{\ell}\right\}_{\ell \in I \backslash i},-\mathbf{k}\right) \mathcal{E}_{j}^{\mathcal{T}}\left(\mathbf{k},\left\{\mathbf{k}_{\ell}\right\}_{\ell \in J}\right)\right. \\
& +\sum_{j \in J} \frac{k_{j}^{\mu}}{\varpi_{a}} \mathcal{E}_{i}^{\mathcal{T}}\left(\left\{\mathbf{k}_{\ell}\right\}_{\ell \in I},-\mathbf{k}\right) \mathcal{E}_{j}^{\mathcal{T}}\left(\mathbf{k}, \varpi_{j}+\omega_{a}, \vec{k}_{j},\left\{\mathbf{k}_{\ell}\right\}_{\ell \in J \backslash j}\right) \\
& +\frac{k^{\mu}}{\varpi_{a}} \mathcal{E}_{i}^{\mathcal{T}}\left(\left\{\mathbf{k}_{\ell}\right\}_{\ell \in I},-\varpi+\omega_{a},-\vec{k}\right) \mathcal{E}_{j}^{\mathcal{T}}\left(\mathbf{k},\left\{\mathbf{k}_{\ell}\right\}_{\ell \in J}\right) \\
& \left.-\mathcal{E}_{i}^{\mathcal{T}}\left(\left\{\mathbf{k}_{\ell}\right\}_{\ell \in I},-\mathbf{k}\right) \frac{k^{\mu}}{\varpi_{a}} \mathcal{E}_{j}^{\mathcal{T}}\left(\varpi+\omega_{a}, \vec{k},\left\{\mathbf{k}_{\ell}\right\}_{\ell \in J}\right)\right], \tag{B35}
\end{align*}
$$

and shifting the appropriate frequency to show that the two last terms cancel out, which proves (B34). One hence obtains

$$
\begin{align*}
\left.\frac{\partial}{\partial q_{a}^{\alpha}} \frac{\delta}{\delta \varphi_{i}\left(\mathbf{q}_{a}\right)} \tilde{\mathcal{T}}_{i_{1} \cdots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\}\right]_{\varphi=0}\right|_{\vec{q}_{a}=0} & =\delta_{i \psi} i \epsilon_{\alpha \mu} \tilde{\mathcal{D}}_{\mu}\left(\varpi_{a}\right) \int_{\mathbf{k}_{\text {intern }}} \prod_{i=1}^{m} \mathcal{E}_{i}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{i},\left\{\mathbf{k}_{\ell}\right\}_{i}\right) \\
& =\delta_{i \psi} i \epsilon_{\alpha \mu} \tilde{\mathcal{D}}_{\mu}\left(\varpi_{a}\right) \tilde{\mathcal{T}}_{i_{1} \cdots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}\right) \tag{B36}
\end{align*}
$$

To prove (B29), one still needs to check that the same property holds for two functional derivatives and their subsequent wave-number derivatives. Let us examine this contribution

$$
\begin{align*}
& \left.\frac{\partial^{2}}{\partial q_{1}^{\alpha} \partial q_{2}^{\beta}} \frac{\delta^{2}}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right) \delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{\mathcal{T}}_{i_{1} \cdots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\}\right]_{\varphi=0}\right|_{\vec{q}_{1}=\vec{q}_{2}=0} \\
& =\frac{\partial^{2}}{\partial q_{1}^{\alpha} \partial q_{2}^{\beta}}\left\{\int_{\mathbf{k}_{\text {intern }}} \sum_{\substack{k, k^{\prime} \\
k \neq k^{\prime}}}\left(\prod_{m \neq k, k^{\prime}} \mathcal{E}_{m}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{m},\left\{\mathbf{k}_{\ell}\right\}_{m}\right)\right)\right. \\
& \times\left.\left.\frac{\delta}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right)} \mathcal{E}_{k}^{\mathcal{T}}\left[\left\{\mathbf{p}_{\ell}\right\}_{k},\left\{\mathbf{k}_{\ell}\right\}_{k}\right]\right|_{\varphi=0} \frac{\delta}{\delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \mathcal{E}_{k^{\prime}}^{\mathcal{T}}\left[\left\{\mathbf{p}_{\ell}\right\}_{k^{\prime}},\left\{\mathbf{k}_{\ell}\right\}_{k^{\prime}}\right]\right|_{\varphi=0} \\
& \left.+\left.\int_{\mathbf{k}_{\text {intern }}} \sum_{k}\left(\prod_{k^{\prime} \neq k} \mathcal{E}_{k^{\prime}}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{k^{\prime}},\left\{\mathbf{k}_{\ell}\right\}_{k^{\prime}}\right)\right) \frac{\delta^{2}}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right) \delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \mathcal{E}_{k}^{\mathcal{T}}\left[\left\{\mathbf{p}_{\ell}\right\}_{k},\left\{\mathbf{k}_{\ell}\right\}_{k}\right]\right|_{\varphi=0}\right\}\left.\right|_{\vec{q}_{1}=\vec{q}_{2}=0} \tag{B37}
\end{align*}
$$

First applying one of the wave-number derivative - say $\vec{q}_{2}{ }^{-}$, the $\varphi_{j}\left(\mathbf{q}_{2}\right)$ functional derivatives can be replaced by $\delta_{j \psi} i \epsilon_{\beta \nu} \tilde{\mathcal{D}}_{\nu}\left(\varpi_{2}\right)$. This is possible for the second term in curly brackets
as well because the object to which the derivative is applied, $\left.\frac{\delta}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right)} \mathcal{E}_{k}^{\mathcal{T}}\left[\left\{\mathbf{p}_{\ell}\right\}_{k},\left\{\mathbf{k}_{\ell}\right\}_{k}\right]\right|_{\varphi=0}$ is a tree with the $\vec{q}_{1}$ leg amputated, for which the derivative property of $\tilde{\mathcal{D}}_{\mu}\left(\varpi_{a}\right)$ (B34) holds. Thus, one obtains

$$
\begin{align*}
& \left.\frac{\partial^{2}}{\partial q_{1}^{\alpha} \partial q_{2}^{\beta}} \frac{\delta^{2}}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right) \delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{\mathcal{T}}_{i_{1} \cdots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\}\right]_{\varphi=0}\right|_{\vec{q}_{1}=\vec{q}_{2}=0} \\
& =\delta_{j \psi} i \epsilon_{\beta \nu} \frac{\partial}{\partial q_{1}^{\alpha}}\left\{\int_{\mathbf{k}_{\text {intern }}} \sum_{\substack{k, k^{\prime} \\
k \not k^{\prime}}}\left(\prod_{m \neq k, k^{\prime}} \mathcal{E}_{m}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{m},\left\{\mathbf{k}_{\ell}\right\}_{m}\right)\right)\right. \\
& \times\left.\frac{\delta}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right)} \mathcal{E}_{k}^{\mathcal{T}}\left[\left\{\mathbf{p}_{\ell}\right\}_{k},\left\{\mathbf{k}_{\ell}\right\}_{k}\right]\right|_{\varphi=0} \tilde{\mathcal{D}}_{\nu}\left(\varpi_{2}\right) \mathcal{E}_{k^{\prime}}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{k^{\prime}},\left\{\mathbf{k}_{\ell}\right\}_{k^{\prime}}\right) \\
& \left.+\int_{\mathbf{k}_{\text {intern }}} \sum_{k}\left(\prod_{k^{\prime} \neq k} \mathcal{E}_{k^{\prime}}^{\mathcal{T}}\left\{\left\{\mathbf{p}_{\ell}\right\}_{k^{\prime}},\left\{\mathbf{k}_{\ell}\right\}_{k^{\prime}}\right)\right) \tilde{\mathcal{D}}_{\nu}\left(\varpi_{2}\right)\left[\left.\frac{\delta}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right)} \mathcal{E}_{k}^{\mathcal{T}}\left[\left\{\mathbf{p}_{\ell}\right\}_{k},\left\{\mathbf{k}_{\ell}\right\}_{k}\right]\right|_{\varphi=0}\right]\right\}\left.\right|_{\vec{q}_{1}=0} \\
& =\left.\delta_{j \psi} i \epsilon_{\beta \nu} \frac{\partial}{\partial q_{1}^{\alpha}}\left\{\tilde{\mathcal{D}}_{\nu}\left(\varpi_{2}\right)\left[\left.\int_{\mathbf{k}_{\text {intern }}} \sum_{k}\left(\prod_{k^{\prime} \neq k} \mathcal{E}_{k^{\prime}}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{k^{\prime}},\left\{\mathbf{k}_{\ell}\right\}_{k^{\prime}}\right)\right) \frac{\delta}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right)} \mathcal{E}_{k}^{\mathcal{T}}\left[\left\{\mathbf{p}_{\ell}\right\}_{k},\left\{\mathbf{k}_{\ell}\right\}_{k}\right]\right|_{\varphi=0}\right]\right\}\right|_{\vec{q}_{1}=0} . \tag{B38}
\end{align*}
$$

Making explicit the operator $\tilde{\mathcal{D}}_{\nu}\left(\varpi_{2}\right)$ yields

$$
\begin{align*}
& \left.\frac{\partial^{2}}{\partial q_{1}^{\alpha} \partial q_{2}^{\beta}} \frac{\delta^{2}}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right) \delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{\mathcal{T}}_{i_{1} \cdots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\}\right]_{\varphi=0}\right|_{\vec{q}_{1}=\vec{q}_{2}=0} \\
& =-\delta_{j \psi} i \epsilon_{\beta \mu} \frac{\partial}{\partial q_{1}^{\alpha}}\left\{\frac{q_{1}^{\nu}}{\varpi_{2}}\left[\left.\int_{\mathbf{k}_{\text {intern }}} \sum_{k}\left(\prod_{k^{\prime} \neq k} \mathcal{E}_{k^{\prime}}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{k^{\prime}},\left\{\mathbf{k}_{\ell}\right\}_{k^{\prime}}\right)\right) \frac{\delta}{\delta \varphi_{i}\left(\varpi_{1}+\varpi_{2}, \vec{q}_{1}\right)} \mathcal{E}_{k}^{\mathcal{T}}\left[\left\{\mathbf{p}_{\ell}\right\}_{k},\left\{\mathbf{k}_{\ell}\right\}_{k}\right]\right|_{\varphi=0}\right]\right. \\
& \left.+\sum_{k=1}^{n} \frac{p_{k}^{\nu}}{\varpi_{2}}\left[\left.\int_{\mathbf{k}_{\text {intern }}} \sum_{m}\left(\prod_{m^{\prime} \neq m} \mathcal{E}_{m^{\prime}}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{m^{\prime}} \backslash k_{+},\left\{\mathbf{k}_{\ell}\right\}_{m^{\prime}}\right)\right) \frac{\delta}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right)} \mathcal{E}_{m}^{\mathcal{T}}\left[\left\{\mathbf{p}_{\ell}\right\}_{m} \backslash k_{+},\left\{\mathbf{k}_{\ell}\right\}_{m}\right]\right|_{\varphi=0}\right]\right\}\left.\right|_{\vec{q}_{1}=0} \tag{B39}
\end{align*}
$$

with the shorthand notation $\left\{\mathbf{p}_{\ell}\right\}_{m} \backslash k_{+}=\left\{\nu_{k}+\omega_{2}, \vec{p}_{k}, \mathbf{p}_{\ell \neq k}\right\}_{m}$ if $\mathbf{p}_{k} \in\left\{\mathbf{p}_{\ell}\right\}_{m}$ and else $\left\{\mathbf{p}_{\ell}\right\}_{m} \backslash k_{+}=\left\{\mathbf{p}_{\ell}\right\}_{m}$. Distributing the $\vec{q}_{1}$ derivative gives
$\left.\frac{\partial^{2}}{\partial q_{1}^{\alpha} \partial q_{2}^{\beta}} \frac{\delta^{2}}{\delta \varphi_{k}\left(\mathbf{q}_{1}\right) \delta \varphi_{\ell}\left(\mathbf{q}_{2}\right)} \tilde{\mathcal{T}}_{i_{1} \cdots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\}\right]_{\varphi=0}\right|_{\vec{q}_{1}=\vec{q}_{2}=0}$
$=-\delta_{j \psi} i \epsilon_{\beta \nu}\left\{\frac{\delta_{\alpha \nu}}{\varpi_{2}}\left[\left.\int_{\mathbf{k}_{\text {intern }}} \sum_{k}\left(\prod_{k^{\prime} \neq k} \mathcal{E}_{k^{\prime}}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{k^{\prime}},\left\{\mathbf{k}_{\ell}\right\}_{k^{\prime}}\right)\right) \frac{\delta}{\delta \varphi_{i}\left(\varpi_{1}+\varpi_{2}, \overrightarrow{0}\right)} \mathcal{E}_{k}^{\mathcal{T}}\left[\left\{\mathbf{p}_{\ell}\right\}_{k},\left\{\mathbf{k}_{\ell}\right\}_{k}\right]\right|_{\varphi=0}\right]_{\vec{q}_{1}=0}\right.$
$\left.+\delta_{i \psi} i \epsilon_{\alpha \mu} \sum_{k=1}^{n} \frac{p_{k}^{\nu}}{\varpi_{2}}\left[\int_{\mathbf{k}_{\text {intern }}} \sum_{m}\left(\prod_{m^{\prime} \neq m} \mathcal{E}_{m^{\prime}}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{m^{\prime}} \backslash k_{+},\left\{\mathbf{k}_{\ell}\right\}_{m^{\prime}}\right)\right) \tilde{\mathcal{D}}_{\mu}\left(\varpi_{1}\right) \mathcal{E}_{m}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{m} \backslash k_{+},\left\{\mathbf{k}_{\ell}\right\}_{m}\right)\right]\right\}$
$=-\delta_{i \psi} \delta_{j \psi} i^{2} \epsilon_{\alpha \mu} \epsilon_{\beta \nu} \sum_{k=1}^{n} \frac{p_{k}^{\nu}}{\varpi_{2}}\left[\tilde{\mathcal{D}}_{\mu}\left(\varpi_{1}\right) \int_{\mathbf{k}_{\text {intern }}} \prod_{m} \mathcal{E}_{m}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{m} \backslash k_{+},\left\{\mathbf{k}_{\ell}\right\}_{m}\right)\right]$
$=\delta_{i \psi} \delta_{j \psi} i^{2} \epsilon_{\alpha \mu} \epsilon_{\beta \nu} \tilde{\mathcal{D}}_{\nu}\left(\varpi_{2}\right) \tilde{\mathcal{D}}_{\mu}\left(\varpi_{1}\right) \tilde{\mathcal{T}}_{i_{1} \cdots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}\right)$,
which proves the property (B29). The flow equation (B23) for the two-point function at leading order is finally given by

$$
\begin{align*}
\left.\partial_{\kappa} \tilde{G}_{\psi, i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right)\right|_{\text {leading }} & =\frac{1}{2} \int_{\mathbf{q}_{1}, \mathbf{q}_{2}} \tilde{\partial}_{\kappa} \tilde{G}_{\psi \psi}^{(2)}\left(-\mathbf{q}_{1},-\mathbf{q}_{2}\right) i^{2} q_{1}^{\alpha} q_{2}^{\beta} \epsilon_{\alpha \mu} \epsilon_{\beta \nu} \tilde{\mathcal{D}}_{\mu}\left(\omega_{1}\right) \tilde{\mathcal{D}}_{\nu}\left(\omega_{2}\right) \tilde{G}_{\psi, i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}\right) \\
& =\frac{1}{2} \int_{\mathbf{q}_{1}, \mathbf{q}_{2}} \tilde{\partial}_{\kappa} \tilde{G}_{v_{\mu} v_{\nu}}^{(2)}\left(-\mathbf{q}_{1},-\mathbf{q}_{2}\right) \tilde{\mathcal{D}}_{\mu}\left(\omega_{1}\right) \tilde{\mathcal{D}}_{\nu}\left(\omega_{2}\right) \tilde{G}_{\psi, i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}\right), \tag{B41}
\end{align*}
$$

which is closed, i.e. it does not involve higher-order correlation functions. This closure has been achieved without any approximation apart from the large wave-number limit.

## 2. Flow equation at NLO at equal times

As presented in the main text, the leading order term in the flow equation vanishes when all times are equal (i.e. when integrated over all the external frequencies). In this appendix, we hence calculate the NLO term, focusing on equal-times correlations, and show that all the terms which are controlled by the extended symmetries vanish.

The NLO term of the flow equation for the generalized correlation function reads

$$
\begin{align*}
\partial_{\kappa} \int_{\left\{\omega_{\ell}\right\}} & \left.\tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right)\right|_{N L O}=\frac{1}{2} \int_{\mathbf{q}_{1}, \mathbf{q}_{2}} \tilde{\partial}_{\kappa} \tilde{G}_{i j}^{(2)}\left(-\mathbf{q}_{1},-\mathbf{q}_{2}\right) \\
& \times\left.\int_{\left\{\omega_{\ell}\right\}} \frac{q_{a}^{\mu} q_{b}^{\nu} q_{c}^{\rho} q_{d}^{\sigma}}{4!} \frac{\partial^{4}}{\partial q_{a}^{\mu} \partial q_{b}^{\nu} \partial q_{c}^{\rho} \partial q_{d}^{\sigma}}\left[\frac{\delta^{2}}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right) \delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\} ; \mathbf{j}\right]\right]_{\varphi=0}\right|_{\vec{q}_{1}=\vec{q}_{2}=0} \tag{B42}
\end{align*}
$$

where as before $a, b, c, d$ take value in $\{1,2\}$. As in the previous calculation Appendix B 1, the four wave-number derivatives can be classified according to the respective number of $\vec{q}_{1}$ and $\vec{q}_{2}$ derivatives. Using the same argument as in Sec. VB, if the four derivatives are $\vec{q}_{1}$ (resp. four $\vec{q}_{2}$ ), this contribution is zero because the vertex function with the wave-number $\vec{q}_{2}$ (resp. $\vec{q}_{1}$ ) vanishes when this wave-number is set to zero. Thus we consider below separately the two remaining cases: three $\vec{q}_{1}$ and one $\vec{q}_{2}$ (and equivalently one $\vec{q}_{1}$ and three $\vec{q}_{2}$ ), and finally two $\vec{q}_{1}$ and two $\overrightarrow{q_{2}}$.

## a. Contributions 1-3 and 3-1

Although no Ward identity exists for the third wave-number derivative of a vertex function, the time-gauged Galilean Ward identity can still be used on the leg with one $q$ derivative
and the proof of Appendix B1 for one $\psi$ derivative can be carried through to show that one obtains an operator $\tilde{\mathcal{D}}$ acting on the external legs of the whole diagram

$$
\begin{align*}
\partial_{\kappa} \int_{\left\{\omega_{\ell}\right\}} & \left.\tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right)\right|_{N L O, 1-3}=\frac{1}{2} \int_{\mathbf{q}_{1}, \mathbf{q}_{2}} \tilde{\partial}_{\kappa} \tilde{G}_{\psi j}^{(2)}\left(-\mathbf{q}_{1},-\mathbf{q}_{2}\right) \\
& \times \int_{\left\{\omega_{\ell}\right\}} \frac{q_{1}^{\mu} q_{2}^{\nu} q_{2}^{\rho} q_{2}^{\sigma}}{3!} \frac{\partial^{3}}{\partial q_{2}^{\nu} \partial q_{2}^{\rho} \partial q_{2}^{\sigma}}\left\{i \epsilon_{\mu \alpha} \tilde{\mathcal{D}}_{\alpha}\left(\varpi_{1}\right)\left[\frac{\delta}{\delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\} ; j\right]\right]_{\varphi=0}\right\}_{\vec{q}_{2}=0} \tag{B43}
\end{align*}
$$

Distributing the $\vec{q}_{2}$ derivatives, one obtains two types of terms: either all $\vec{q}_{2}$ derivatives act on the term in square bracket or one of them acts on the operator $\tilde{\mathcal{D}}$

$$
\begin{align*}
& \int_{\left\{\omega_{\ell}\right\}} \frac{q_{1}^{\mu} q_{2}^{\nu} q_{2}^{\rho} q_{2}^{\sigma}}{3!} \frac{\partial^{3}}{\partial q_{2}^{\nu} \partial q_{2}^{\rho} \partial q_{2}^{\sigma}}\left\{i \epsilon_{\mu \alpha} \tilde{\mathcal{D}}_{\alpha}\left(\varpi_{1}\right)\left[\frac{\delta}{\delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\} ; j\right]\right]_{\varphi=0}\right\}_{\vec{q}_{2}=0} \\
& =\left.\left.\int_{\left\{\omega_{\ell}\right\}} \frac{q_{1}^{\mu} q_{2}^{\nu} q_{2}^{\rho} q_{2}^{\sigma}}{3!} i \epsilon_{\mu \alpha} \tilde{\mathcal{D}}_{\alpha}\left(\omega_{1}\right)\right|_{\vec{q}_{2}=0} \frac{\partial^{3}}{\partial q_{2}^{\nu} \partial q_{2}^{\rho} \partial q_{2}^{\sigma}}\left[\frac{\delta}{\delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left[\mathbf{p}_{1}, \ldots, \mathbf{p}_{n} ; j\right]\right]_{\varphi=0}\right|_{\vec{q}_{2}=0} \\
& \quad+\left.\left.\int_{\left\{\omega_{e}\right\}} \frac{q_{1}^{\mu} q_{2}^{\nu} q_{2}^{\rho} q_{2}^{\sigma}}{2} i \epsilon_{\mu \alpha} \frac{\partial}{\partial q_{2}^{\nu}} \tilde{\mathcal{D}}_{\alpha}\left(\omega_{1}\right)\right|_{\vec{q}_{2}=0} \frac{\partial^{2}}{\partial q_{2}^{\rho} \partial q_{2}^{\sigma}}\left[\frac{\delta}{\delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\} ; j\right]\right]_{\varphi=0}\right|_{\vec{q}_{2}=0} \\
& =\left.\int_{\left\{\omega_{\ell}\right\}} \frac{q_{1}^{\mu} q_{2}^{\nu} q_{2}^{\rho} q_{2}^{\sigma}}{2} i \epsilon_{\mu \alpha} \delta_{\nu \alpha} \frac{1}{\omega_{1}} \frac{\partial^{2}}{\partial q_{2}^{\rho} \partial q_{2}^{\sigma}}\left[\frac{\delta}{\delta \varphi_{j}\left(\varpi_{2}+\varpi_{1}, \vec{q}_{2}\right)} \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\} ; j\right]\right]_{\varphi=0}\right|_{\vec{q}_{2}=0} . \tag{B44}
\end{align*}
$$

In the first term of the first equality, $\left.\tilde{\mathcal{D}}\right|_{\vec{q}_{2}=0}$ shifts only the frequencies associated to $\vec{p}_{1}$ and $\overrightarrow{p_{2}}$, thus this term is zero due to the conservation of wave-number of the object in square bracket and the integration in frequency. The $\vec{q}_{2}$ derivative on $\tilde{\mathcal{D}}$ selects the frequency shift on the $\mathbf{q}_{2}$ leg, which does not vanishes. However, this term is proportional to $\epsilon_{\mu \nu} q_{1}^{\mu} q_{2}^{\nu}$. Hence, within Eq. (B43), the conservation of wave-number of $G_{i j}^{(2)}\left(-\mathbf{q}_{1},-\mathbf{q}_{2}\right)$ gives $\vec{q}_{1}+\vec{q}_{2}=0$, and thus $\epsilon_{\mu \nu} q_{1}^{\mu} q_{2}^{\nu}=-\epsilon_{\mu \nu} q_{2}^{\mu} q_{1}^{\nu}=0$, and this term gives no contribution either to the flow equation. Hence, all the contributions with three $q_{1}$ derivatives and one $q_{2}$, or three $q_{2}$ derivatives and one $q_{1}$ vanish

$$
\begin{equation*}
\left.\partial_{\kappa} \int_{\left\{\omega_{\ell}\right\}} \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right)\right|_{N L O, 1-3}=0 \tag{B45}
\end{equation*}
$$

## b. Contributions 2-2

The only remaining contribution in the NLO term of the flow equation involves an equal number of $q_{1}$ and $q_{2}$ derivatives

$$
\begin{align*}
& \left.\partial_{\kappa} \int_{\left\{\omega_{\ell}\right\}} \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right)\right|_{N L O}=\left.\partial_{\kappa} \int_{\left\{\omega_{\ell}\right\}} \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right)\right|_{N L O, 2-2} \\
& =\frac{1}{2} \int_{\mathbf{q}_{1}, \mathbf{q}_{2}} \tilde{\partial}_{\kappa} \tilde{G}_{i j}^{(2)}\left(-\mathbf{q}_{1},-\mathbf{q}_{2}\right) \\
& \quad \times\left.\int_{\left\{\omega_{\ell}\right\}} \frac{q_{1}^{\mu} q_{1}^{\nu} q_{2}^{\rho} q_{2}^{\sigma}}{4} \frac{\partial^{4}}{\partial q_{1}^{\mu} \partial q_{1}^{\nu} \partial q_{2}^{\rho} \partial q_{2}^{\sigma}}\left[\frac{\delta^{2}}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right) \delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\} ; j\right]\right]_{\varphi=0}\right|_{\vec{q}_{1}=\vec{q}_{2}=0} \tag{B46}
\end{align*}
$$

Using the invariance under space translation and rotation in the $\vec{q}_{1}, \vec{q}_{2}$ integrals, one can write

$$
\begin{align*}
\int_{\vec{q}_{1}, \vec{q}_{2}} \tilde{\partial}_{\kappa} \tilde{G}_{i j}^{(2)}\left(-\mathbf{q}_{1},-\mathbf{q}_{2}\right) \frac{q_{1}^{\mu} q_{1}^{\nu} q_{2}^{\rho} q_{2}^{\sigma}}{4} & =\frac{1}{4} \int_{\vec{q}} \tilde{\partial}_{\kappa} \tilde{\tilde{G}}_{i j}^{(2)}\left(-\omega_{1},-\omega_{2}, q^{2}\right) q^{\mu} q^{\nu} q^{\rho} q^{\sigma} \\
& =\left(\delta_{\mu \nu} \delta_{\rho \sigma}+\delta_{\mu \rho} \delta_{\nu \sigma}+\delta_{\mu \sigma} \delta_{\nu \rho}\right) \tilde{K}_{i j}\left(\omega_{1}, \omega_{2}\right), \tag{B47}
\end{align*}
$$

with

$$
\begin{equation*}
\tilde{K}_{i j}\left(\omega_{1}, \omega_{2}\right) \equiv \frac{1}{32} \int_{\vec{q}} \tilde{\partial}_{\kappa} \overline{\tilde{G}}_{i j}^{(2)}\left(-\omega_{1},-\omega_{2}, q^{2}\right)\left(q^{2}\right)^{2} \tag{B48}
\end{equation*}
$$

where the notation $\overline{\tilde{G}}$ indicates that the delta of conservation has been extracted for the wave-numbers only, and not for the frequencies. The expression (B46) hence comprises two contributions

$$
\begin{align*}
& \left.\partial_{\kappa} \int_{\left\{\omega_{\ell}\right\}} \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right)\right|_{N L O}=\frac{1}{2} \int_{\varpi_{1}, \varpi_{2}} \tilde{K}_{i j}\left(\varpi_{1}, \varpi_{2}\right) \\
& \quad \times\left.\int_{\left\{\omega_{\ell}\right\}}\left(\frac{\partial^{4}}{\partial q_{1}^{\mu} \partial q_{1}^{\mu} \partial q_{2}^{\nu} \partial q_{2}^{\nu}}+2 \frac{\partial^{4}}{\partial q_{1}^{\mu} \partial q_{2}^{\mu} \partial q_{1}^{\nu} \partial q_{2}^{\nu}}\right)\left[\frac{\delta^{2}}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right) \delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\} ; \mathbf{j}\right]\right]_{\varphi=0}\right|_{\vec{q}_{1}=\vec{q}_{2}=0} \tag{B49}
\end{align*}
$$

referred to as the uncrossed and the crossed ones, according to whether the $\vec{q}_{1}$ derivative is contracted with the other $\vec{q}_{1}$ derivative or with the $\vec{q}_{2}$ derivative.

We show in the next sections, first on the example of the two-point function, and then for a generic $n$-point function, that the uncrossed contribution can be closed exactly using
the Ward identities associated with the new symmetries

$$
\begin{align*}
\partial_{\kappa} & \left.\tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n}\right)\right|_{\text {uncrossed }} \\
& =\left.\frac{1}{2} \int_{\varpi_{1}, \varpi_{2}} \tilde{K}_{i j}\left(\varpi_{1}, \varpi_{2}\right) \frac{\partial^{4}}{\partial q_{1}^{\mu} \partial q_{1}^{\mu} \partial q_{2}^{\nu} \partial q_{2}^{\nu}}\left[\frac{\delta^{2}}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right) \delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\} ; j\right]\right]_{\varphi=0}\right|_{\vec{q}_{1}=\vec{q}_{2}=0} \\
& =\frac{1}{2} \int_{\varpi_{1}, \varpi_{2}} \tilde{K}_{\psi \psi}\left(\varpi_{1}, \varpi_{2}\right) \tilde{\mathcal{R}}\left(\varpi_{1}\right) \tilde{\mathcal{R}}\left(\varpi_{2}\right) \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}\right), \tag{B50}
\end{align*}
$$

where $\tilde{\mathcal{R}}$ is defined in Eq. (A23). It follows that this contribution also vanishes when integrated over the external frequencies. However, the crossed contribution is not controlled by these Ward identities, and we have not been able to further constrain this last remaining term.

## c. Uncrossed derivatives contribution for the flow of the two-point function

In this section, we show that the uncrossed contribution to the flow of $G_{\psi \psi}^{(2)}\left(\mathbf{p}_{1}, \mathbf{p}_{2}\right)$ can be closed exactly. Distributing the $\vec{q}$-derivatives, this contribution reads

$$
\begin{align*}
& \left.\partial_{\kappa} \int_{\omega_{1}, \omega_{2}} \tilde{G}_{\psi \psi}^{(2)}\left(\mathbf{p}_{1}, \mathbf{p}_{2}\right)\right|_{\text {uncrossed }}=\frac{1}{2} \int_{\varpi_{1}, \varpi_{2}} \tilde{K}_{i j}\left(\varpi_{1}, \varpi_{2}\right) \int_{\omega_{1}, \omega_{2}} \frac{\partial^{4}}{\partial q_{1}^{\mu} \partial q_{1}^{\mu} \partial q_{2}^{\nu} \partial q_{2}^{\nu}} \\
& \quad \int_{\mathbf{k}_{1}, \mathbf{k}_{2}} \tilde{G}_{\psi m}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) \tilde{G}_{\psi n}^{(2)}\left(\mathbf{p}_{2},-\mathbf{k}_{2}\right)\left[-\tilde{\Gamma}_{i j m n}^{(4)}\left(\mathbf{q}_{1}, \mathbf{q}_{2}, \mathbf{k}_{1}, \mathbf{k}_{2}\right)\right. \\
& \left.\quad+\int_{\mathbf{k}_{3}, \mathbf{k}_{4}} \tilde{\Gamma}_{i m s}^{(3)}\left(\mathbf{q}_{1}, \mathbf{k}_{1}, \mathbf{k}_{3}\right) \tilde{G}_{s t}^{(2)}\left(-\mathbf{k}_{3},-\mathbf{k}_{4}\right) \tilde{\Gamma}_{j n t}^{(3)}\left(\mathbf{q}_{2}, \mathbf{k}_{2}, \mathbf{k}_{4}\right)+\left(i, \mathbf{q}_{1}\right) \leftrightarrow\left(j, \mathbf{q}_{2}\right)\right]_{\vec{q}_{1}=\vec{q}_{2}=0} \\
& \quad=\frac{1}{2} \int_{\varpi_{1}, \varpi_{2}} \tilde{K}_{i j}\left(\varpi_{1}, \varpi_{2}\right) \int_{\omega_{1}, \omega_{2}} \\
& \quad \int_{\mathbf{k}_{1}, \mathbf{k}_{2}} \tilde{G}_{\psi m}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) \tilde{G}_{\psi n}^{(2)}\left(\mathbf{p}_{2},-\mathbf{k}_{2}\right)\left[-\frac{\partial^{4}}{\partial q_{1}^{\mu} \partial q_{1}^{\mu} \partial q_{2}^{\nu} \partial q_{2}^{\nu}} \tilde{\Gamma}_{i j m n}^{(4)}\left(\mathbf{q}_{1}, \mathbf{q}_{2}, \mathbf{k}_{1}, \mathbf{k}_{2}\right)\right. \\
& \left.\quad+\int_{\mathbf{k}_{3}, \mathbf{k}_{4}} \frac{\partial^{2}}{\partial q_{1}^{\mu} \partial q_{1}^{\mu}} \tilde{\Gamma}_{i m s}^{(3)}\left(\mathbf{q}_{1}, \mathbf{k}_{1}, \mathbf{k}_{3}\right) \tilde{G}_{s t}^{(2)}\left(-\mathbf{k}_{3},-\mathbf{k}_{4}\right) \frac{\partial^{2}}{\partial q_{2}^{\nu} \partial q_{2}^{\nu}} \tilde{\Gamma}_{j n t}^{(3)}\left(\mathbf{q}_{2}, \mathbf{k}_{2}, \mathbf{k}_{4}\right)+\left(i, \mathbf{q}_{1}\right) \leftrightarrow\left(j, \mathbf{q}_{2}\right)\right]_{\vec{q}_{1}=\vec{q}_{2}=0} \\
& \quad=\frac{1}{2} \int_{\varpi_{1}, \varpi_{2}} \tilde{K}_{\psi \psi}\left(\varpi_{1}, \varpi_{2}\right) \int_{\omega_{1}, \omega_{2}} \\
& \quad \int_{\mathbf{k}_{1}, \mathbf{k}_{2}} \tilde{G}_{\psi m}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) \tilde{G}_{\psi n}^{(2)}\left(\mathbf{p}_{2},-\mathbf{k}_{2}\right)\left[-\tilde{\mathcal{R}}\left(\varpi_{1}\right) \tilde{\mathcal{R}}\left(\varpi_{2}\right) \tilde{\Gamma}_{m n}^{(2)}\left(\mathbf{k}_{1}, \mathbf{k}_{2}\right)\right. \\
& \left.\quad+\int_{\mathbf{k}_{3}, \mathbf{k}_{4}} \tilde{\mathcal{R}}\left(\varpi_{1}\right) \tilde{\Gamma}_{m s}^{(2)}\left(\mathbf{k}_{1}, \mathbf{k}_{3}\right) \tilde{G}_{s t}^{(2)}\left(-\mathbf{k}_{3},-\mathbf{k}_{4}\right) \tilde{\mathcal{R}}\left(\varpi_{2}\right) \tilde{\Gamma}_{n t}^{(2)}\left(\mathbf{k}_{2}, \mathbf{k}_{4}\right)+\left(\varpi_{1}\right) \leftrightarrow\left(\varpi_{2}\right)\right] . \tag{B51}
\end{align*}
$$

Following the same lines as for the operator $\tilde{\mathcal{D}}$, one can show that the terms in square bracket can be expressed as the operator $\tilde{\mathcal{R}}$ acting on the external legs of the original diagram. Using that $\tilde{G}^{(2)}$ and $\tilde{\Gamma}^{(2)}$ are inverse of each other, the second term of (B51) can be rewritten as two combinations of $\tilde{G}^{(2)} \tilde{\mathcal{R}}\left(\varpi_{a}\right) \tilde{\Gamma}^{(2)} \tilde{G}^{(2)}$ attached by a $\tilde{\Gamma}^{(2)}$. For each of them, one has

$$
\begin{align*}
& \int_{\mathbf{k}_{1}, \mathbf{k}_{3}} \tilde{G}_{\psi m}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) \tilde{\mathcal{R}}\left(\varpi_{1}\right) \tilde{\Gamma}_{m s}^{(2)}\left(\mathbf{k}_{1}, \mathbf{k}_{3}\right) \tilde{G}_{s u}^{(2)}\left(-\mathbf{k}_{3},-\mathbf{k}_{5}\right) \\
&= \frac{2 i \epsilon_{\alpha \beta}}{\varpi_{1}} \int_{\mathbf{k}_{1}, \mathbf{k}_{3}} \tilde{G}_{\psi m}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right)\left[k_{1}^{\alpha} \frac{\partial}{\partial k_{1}^{\beta}} \tilde{\Gamma}_{m s}^{(2)}\left(\nu_{1}+\varpi_{1}, \vec{k}_{1}, \mathbf{k}_{3}\right)\right. \\
&\left.+k_{3}^{\alpha} \frac{\partial}{\partial k_{3}^{\beta}} \tilde{\Gamma}_{m s}^{(2)}\left(\mathbf{k}_{1}, \nu_{3}+\varpi_{1}, \vec{k}_{3}\right)\right] \tilde{G}_{s u}^{(2)}\left(-\mathbf{k}_{3},-\mathbf{k}_{5}\right) \\
&= \frac{2 i \epsilon_{\alpha \beta}}{\varpi_{1}}\left[\int_{\mathbf{k}_{1}} \tilde{G}_{\psi m}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) k_{1}^{\alpha} \frac{\partial}{\partial k_{1}^{\beta}} \delta_{m u} \delta\left(\varpi_{1}+\nu_{1}-\nu_{5}\right) \delta^{2}\left(\vec{k}_{1}-\vec{k}_{5}\right)\right. \\
&\left.+\int_{\mathbf{k}_{3}} \tilde{G}_{s u}^{(2)}\left(-\mathbf{k}_{3},-\mathbf{k}_{5}\right) k_{3}^{\alpha} \frac{\partial}{\partial k_{3}^{\beta}} \delta_{\psi s} \delta\left(\omega_{1}+\varpi+\nu_{3}\right) \delta^{2}\left(\vec{p}_{1}+\vec{k}_{3}\right)\right] \\
&=-k_{5}^{\alpha} \frac{\partial}{\partial k_{5}^{\beta}} \tilde{G}_{\psi u}^{(2)}\left(\mathbf{p}_{1},-\nu_{5}+\varpi_{1},-\vec{k}_{5}\right)-p_{1}^{\alpha} \frac{\partial}{\partial p_{1}^{\beta}} \tilde{G}_{\psi u}^{(2)}\left(\omega_{1}+\varpi_{1}, \vec{p}_{1},-\vec{k}_{5}\right) \\
&=-\tilde{\mathcal{R}}\left(\varpi_{1}\right) \tilde{G}_{\psi u}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{5}\right), \tag{B52}
\end{align*}
$$

where in the second equality, $\tilde{G}^{(2)}$ and $\tilde{\Gamma}^{(2)}$ have been contracted, and in the third, an integration by part is performed. We have thereby established the equivalent property (B18) of $\tilde{\mathcal{D}}$ for $\tilde{\mathcal{R}}$ :

$$
\begin{equation*}
\left.\frac{\partial^{2}}{\partial q_{\mu} \partial q_{\mu}} \frac{\delta}{\delta \varphi_{k}(\mathbf{q})} \tilde{G}_{i j}^{(2)}\left[\mathbf{p}_{1}, \mathbf{p}_{2} ; \mathbf{j}\right]_{\varphi=0}\right|_{\vec{q}=0}=\tilde{\mathcal{R}}(\varpi) \tilde{G}_{i j}^{(2)}\left(\mathbf{p}_{1}, \mathbf{p}_{2}\right) \tag{B53}
\end{equation*}
$$

Inserting this result in the last line of (B51) yields

$$
\begin{align*}
& \left.\partial_{\kappa} \int_{\omega_{1}, \omega_{2}} \tilde{G}_{\psi \psi}^{(2)}\left(\mathbf{p}_{1}, \mathbf{p}_{2}\right)\right|_{\text {uncrossed }}=\frac{1}{2} \int_{\varpi_{1}, \varpi_{2}} \tilde{K}_{\psi \psi}\left(\varpi_{1}, \varpi_{2}\right) \int_{\omega_{1}, \omega_{2}} \int_{\mathbf{k}_{1}, \mathbf{k}_{2}} \\
& \quad\left[-G_{\psi u}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) G_{\psi v}^{(2)}\left(\mathbf{p}_{2},-\mathbf{k}_{2}\right) \tilde{\mathcal{R}}\left(\varpi_{1}\right) \tilde{\mathcal{R}}\left(\varpi_{2}\right) \tilde{\Gamma}_{u v}^{(2)}\left(\mathbf{k}_{1}, \mathbf{k}_{2}\right)\right. \\
& \left.\quad+\tilde{\mathcal{R}}\left(\varpi_{1}\right) G_{\psi u}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) \Gamma_{u v}^{(2)}\left(\mathbf{k}_{1}, \mathbf{k}_{2}\right) \tilde{\mathcal{R}}\left(\varpi_{2}\right) G_{\psi v}^{(2)}\left(\mathbf{p}_{2},-\mathbf{k}_{2}\right)+\left(\varpi_{1}\right) \leftrightarrow\left(\varpi_{2}\right)\right] . \tag{B54}
\end{align*}
$$

In fact, this structure is the same as the one appearing with the operator $\tilde{\mathcal{D}}$ for the leading order at unequal times. It generalizes as well for any correlation functions, as shown in the next section. Let us examine separately the two terms in square brackets. The first term
reads

$$
\begin{align*}
& \int_{\mathbf{k}_{1}, \mathbf{k}_{2}} G_{\psi \psi}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) G_{\psi v}^{(2)}\left(\mathbf{p}_{2},-\mathbf{k}_{2}\right) \tilde{\mathcal{R}}\left(\varpi_{1}\right) \tilde{\mathcal{R}}\left(\varpi_{2}\right) \tilde{\Gamma}_{u v}^{(2)}\left(\mathbf{k}_{1}, \mathbf{k}_{2}\right) \\
& =\frac{2 i \epsilon_{\alpha_{\beta}}}{\varpi_{2}} \int_{\mathbf{k}_{1}, \mathbf{k}_{2}} G_{\psi u}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) G_{\psi v}^{(2)}\left(\mathbf{p}_{2},-\mathbf{k}_{2}\right) \\
& \quad \times \tilde{\mathcal{R}}\left(\varpi_{1}\right)\left[k_{1}^{\alpha} \frac{\partial}{\partial k_{1}^{\beta}} \tilde{\Gamma}_{u v}^{(2)}\left(\nu_{1}+\varpi_{2}, \vec{k}_{1}, \mathbf{k}_{2}\right)+k_{2}^{\alpha} \frac{\partial}{\partial k_{2}^{\beta}} \tilde{\Gamma}_{u v}^{(2)}\left(\mathbf{k}_{1}, \nu_{2}+\varpi_{2}, \vec{k}_{2}\right)\right] \\
& =-\frac{4 \epsilon_{\alpha \beta} \epsilon_{\rho \sigma}}{\varpi_{1} \varpi_{2}} \int_{\mathbf{k}_{1}, \mathbf{k}_{2}} G_{\psi u}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) G_{\psi v}^{(2)}\left(\mathbf{p}_{2},-\mathbf{k}_{2}\right) \\
& \quad \times\left\{k_{1}^{\rho} \frac{\partial}{\partial k_{1}^{\sigma}}\left[k_{1}^{\alpha} \frac{\partial}{\partial k_{1}^{\beta}} \tilde{\Gamma}_{u v}^{(2)}\left(\nu_{1}+\varpi_{1}+\varpi_{2}, \vec{k}_{1}, \mathbf{k}_{2}\right)+k_{2}^{\alpha} \frac{\partial}{\partial k_{2}^{\beta}} \tilde{\Gamma}_{u v}^{(2)}\left(\nu_{1}+\varpi_{1}, \vec{k}_{1}, \nu_{2}+\varpi_{2}, \vec{k}_{2}\right)\right]\right. \\
& \left.+k_{2}^{\rho} \frac{\partial}{\partial k_{2}^{\sigma}}\left[k_{1}^{\alpha} \frac{\partial}{\partial k_{1}^{\beta}} \tilde{\beta}_{u v}^{(2)}\left(\nu_{1}+\varpi_{2}, \vec{k}_{1}, \nu_{2}+\varpi_{1}, \vec{k}_{2}\right)+k_{2}^{\alpha} \frac{\partial}{\partial k_{2}^{\beta}} \tilde{\Gamma}_{u v}^{(2)}\left(\mathbf{k}_{1}, \nu_{2}+\varpi_{1}+\varpi_{2}, \vec{k}_{2}\right)\right]\right\} \\
& =-\frac{4 \epsilon_{\alpha \beta} \epsilon_{\rho \sigma}}{\varpi_{1} \varpi_{2}}\left\{\int_{\vec{k}_{1}} G_{\psi \psi}^{(2)}\left(\mathbf{p}_{1}, \omega_{2}+\varpi_{1}+\varpi_{2},-\vec{k}_{1}\right) k_{1}^{\rho} \frac{\partial}{\partial k_{1}^{\sigma}}\left[k_{1}^{\alpha} \frac{\partial}{\partial k_{1}^{\beta}} \delta^{2}\left(\vec{p}_{2}+\vec{k}_{1}\right)\right]\right. \\
& \quad+\int_{\vec{k}_{2}} G_{\psi \psi}^{(2)}\left(\omega_{1}+\varpi_{1}+\varpi_{2},-\vec{k}_{2}, \mathbf{p}_{2}\right) k_{2}^{\rho} \frac{\partial}{\partial k_{2}^{\sigma}}\left[k_{2}^{\alpha} \frac{\partial}{\partial k_{2}^{\beta}} \delta^{2}\left(\vec{p}_{1}+\vec{k}_{2}\right)\right] \\
& +\int_{\mathbf{k}_{1}, \mathbf{k}_{2}} G_{\psi u}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) G_{\psi v}^{(2)}\left(\mathbf{p}_{2},-\mathbf{k}_{2}\right) k_{1}^{\alpha} k_{2}^{\rho} \frac{\partial^{2}}{\partial k_{1}^{\beta}} \partial \tilde{k}_{2}^{\sigma} \\
& \left.\tilde{\Gamma}_{u v}^{(2)}\left(\nu_{1}+\varpi_{2}, \vec{k}_{1}, \nu_{2}+\varpi_{1}, \vec{k}_{2}\right)+\left(\varpi_{1}\right) \leftrightarrow\left(\varpi_{2}\right)\right\} \\
& =  \tag{B55}\\
& =-\frac{4 \epsilon_{\alpha \beta} \epsilon_{\rho \sigma}}{\varpi_{1} \varpi_{2}}\left\{p_{2}^{\alpha} \frac{\partial}{\partial p_{2}^{\beta}}\left[p_{2}^{\rho} \frac{\partial}{\partial p_{2}^{\sigma}} G_{\psi \psi}^{(2)}\left(\mathbf{p}_{1}, \omega_{2}+\varpi_{1}+\varpi_{2}, \vec{p}_{2}\right)\right]+p_{1}^{\alpha} \frac{\partial}{\partial p_{1}^{\beta}}\left[p_{1}^{\rho} \frac{\partial}{\partial p_{1}^{\sigma}} \sigma_{\psi \psi}^{(2)}\left(\omega_{1}+\varpi_{1}+\varpi_{2}, \vec{p}_{1}, \mathbf{p}_{2}\right)\right]\right. \\
& \left.+\int_{\mathbf{k}_{1}, \mathbf{k}_{2}} G_{\psi u}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) G_{\psi v}^{(2)}\left(\mathbf{p}_{2},-\mathbf{k}_{2}\right) k_{1}^{\alpha} k_{2}^{\rho} \frac{\partial^{2}}{\partial k_{1}^{\beta} \partial k_{2}^{\sigma}} \tilde{\Gamma}_{u v}^{(2)}\left(\nu_{1}+\varpi_{2}, \vec{k}_{1}, \nu_{2}+\varpi_{1}, \vec{k}_{2}\right)+\left(\varpi_{1}\right) \leftrightarrow\left(\varpi_{2}\right)\right\},
\end{align*}
$$

using integration by part twice for the first two terms in the last equality. For the second term, one has

$$
\begin{align*}
& \int_{\mathbf{k}_{1}, \mathbf{k}_{2}} \tilde{\mathcal{R}}\left(\varpi_{1}\right) G_{\psi u}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) \Gamma_{u v}^{(2)}\left(\mathbf{k}_{1}, \mathbf{k}_{2}\right) \tilde{\mathcal{R}}\left(\varpi_{2}\right) G_{\psi v}^{(2)}\left(\mathbf{p}_{2},-\mathbf{k}_{2}\right) \\
& =-\frac{4 \epsilon_{\alpha \beta} \epsilon_{\rho \sigma}}{\varpi_{1} \varpi_{2}} \int_{\mathbf{k}_{1}, \mathbf{k}_{2}}\left[k_{1}^{\alpha} \frac{\partial}{\partial k_{1}^{\beta}} G_{\psi u}^{(2)}\left(\mathbf{p}_{1},-\nu_{1}+\varpi_{1},-\vec{k}_{1}\right)+p_{1}^{\alpha} \frac{\partial}{\partial p_{1}^{\beta}} G_{\psi u}^{(2)}\left(\vec{p}_{1}, \omega_{1}+\varpi_{1},-\mathbf{k}_{1}\right)\right] \tilde{\Gamma}_{u v}^{(2)}\left(\mathbf{k}_{1}, \mathbf{k}_{2}\right) \\
& \times\left[k_{2}^{\rho} \frac{\partial}{\partial k_{2}^{\sigma}} G_{\psi v}^{(2)}\left(\mathbf{p}_{2},-\nu_{2}+\varpi_{2},-\vec{k}_{2}\right)+p_{2}^{\rho} \frac{\partial}{\partial p_{2}^{\sigma}} G_{\psi v}^{(2)}\left(\omega_{2}+\varpi_{2}, \vec{p}_{2},-\mathbf{k}_{2}\right)\right] \\
& =-\frac{4 \epsilon_{\alpha \beta} \epsilon_{\rho \sigma}}{\varpi_{1} \varpi_{2}}\left\{\int_{\mathbf{k}_{1}, \mathbf{k}_{1}} k_{1}^{\alpha} \frac{\partial}{\partial k_{1}^{\beta}} G_{\psi u}^{(2)}\left(\mathbf{p}_{1},-\varpi_{1}+\varpi_{1},-\vec{k}_{1}\right) \tilde{\Gamma}_{u v}^{(2)}\left(\mathbf{k}_{1}, \mathbf{k}_{2}\right) k_{2}^{\rho} \frac{\partial}{\partial k_{2}^{\sigma}} G_{\psi v}^{(2)}\left(\mathbf{p}_{2},-\varpi_{2}+\varpi_{2},-\vec{k}_{2}\right)\right. \\
& +\int_{\vec{k}_{1}} p_{2}^{\rho} \frac{\partial}{\partial p_{2}^{\sigma}} \delta^{\sigma}\left(\vec{p}_{2}+\vec{k}_{1}\right) k_{1}^{\alpha} \frac{\partial}{\partial k_{1}^{\beta}} G_{\psi \psi}^{(2)}\left(\mathbf{p}_{1}, \omega_{2}+\varpi_{1}+\varpi_{2},-\vec{k}_{1}\right) \\
& \left.+\int_{\vec{k}_{2}} p_{1}^{\alpha} \frac{\partial}{\partial p_{1}^{\beta}} \delta^{\sigma}\left(\vec{p}_{1}+\vec{k}_{2}\right)\left[k_{2}^{\rho} \frac{\partial}{\partial k_{2}^{\sigma}} G_{\psi \psi}^{(2)}\left(\omega_{1}+\varpi_{1}+\varpi_{2},-\vec{k}_{2}, \mathbf{p}_{2}\right)+p_{2}^{\rho} \frac{\partial}{\partial p_{2}^{\sigma}} G_{\psi \psi}^{(2)}\left(\omega_{2}+\varpi_{2}, \vec{p}_{2}, \omega_{1}+\varpi_{1},-\vec{k}_{2}\right)\right]\right\} \tag{B56}
\end{align*}
$$

Integrating by part and shifting the frequencies in the first term in the curly bracket and exchanging the $\vec{k}_{1}$ (resp. $\vec{k}_{2}$ ) integral with the $\vec{p}_{2}$ (resp. $\vec{p}_{1}$ ) derivative in the two last terms, one obtains

$$
\begin{align*}
& \int_{\mathbf{k}_{1}, \mathbf{k}_{2}} \tilde{\mathcal{R}}\left(\varpi_{1}\right) G_{\psi u}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) \Gamma_{u v}^{(2)}\left(\mathbf{k}_{1}, \mathbf{k}_{2}\right) \tilde{\mathcal{R}}\left(\varpi_{2}\right) G_{\psi v}^{(2)}\left(\mathbf{p}_{2},-\mathbf{k}_{2}\right) \\
& =-\frac{4 \epsilon_{\alpha \beta} \epsilon_{\rho \sigma}}{\varpi_{1} \varpi_{2}}\left\{\int_{\mathbf{k}_{1}, \mathbf{k}_{1}} G_{\psi u}^{(2)}\left(\mathbf{p}_{1},-\mathbf{k}_{1}\right) k_{1}^{\alpha} k_{2}^{\rho} \frac{\partial^{2}}{\partial k_{1}^{\beta} \partial k_{2}^{\sigma}} \tilde{\Gamma}_{u v}^{(2)}\left(\varpi_{1}+\varpi_{1}, \vec{k}_{1}, \varpi_{2}+\varpi_{2}, \vec{k}_{2}\right) G_{\psi v}^{(2)}\left(\mathbf{p}_{2},-\mathbf{k}_{2}\right)\right. \\
& +p_{2}^{\rho} \frac{\partial}{\partial p_{2}^{\sigma}}\left[p_{2}^{\alpha} \frac{\partial}{\partial p_{2}^{\beta}} G_{\psi \psi}^{(2)}\left(\mathbf{p}_{1}, \omega_{2}+\varpi_{1}+\varpi_{2}, \vec{p}_{2}\right)\right] \\
& \left.+p_{1}^{\alpha} \frac{\partial}{\partial p_{1}^{\beta}}\left[p_{1}^{\rho} \frac{\partial}{\partial p_{1}^{\sigma}} G_{\psi \psi}^{(2)}\left(\omega_{1}+\varpi_{1}+\varpi_{2}, \vec{p}_{1}, \mathbf{p}_{2}\right)\right]+p_{1}^{\alpha} p_{2}^{\rho} \frac{\partial^{2}}{\partial p_{1}^{\beta} \partial p_{2}^{\sigma}} G_{\psi \psi}^{(2)}\left(\omega_{1}+\varpi_{2}, \vec{p}_{1}, \omega_{2}+\varpi_{1}, \vec{p}_{2}\right)\right\} \tag{B57}
\end{align*}
$$

Inserting the expressions (B55) and (B57) into (B54) finally leads to the expected result

$$
\begin{align*}
& \left.\partial_{\kappa} \tilde{G}_{\psi \psi}^{(2)}\left(\mathbf{p}_{1}, \mathbf{p}_{2}\right)\right|_{\text {uncrossed }}=\frac{1}{2} \int_{\varpi_{1}, \varpi_{2}} \tilde{K}_{\psi \psi}\left(\varpi_{1}, \varpi_{2}\right) \\
& \quad-\frac{4 \epsilon_{\alpha \beta} \epsilon_{\rho \sigma}}{\varpi_{1} \varpi_{2}}\left[p_{1}^{\alpha} \frac{\partial}{\partial p_{1}^{\beta}}\left[p_{1}^{\rho} \frac{\partial}{\partial p_{1}^{\sigma}} G_{\psi \psi}^{(2)}\left(\omega_{1}+\varpi_{1}+\varpi_{2}, \vec{p}_{1}, \mathbf{p}_{2}\right)\right]+p_{2}^{\rho} \frac{\partial}{\partial p_{2}^{\sigma}}\left[p_{2}^{\alpha} \frac{\partial}{\partial p_{2}^{\beta}} G_{\psi \psi}^{(2)}\left(\mathbf{p}_{1}, \omega_{2}+\varpi_{1}+\varpi_{2}, \vec{p}_{2}\right)\right]\right. \\
& \left.\quad+p_{1}^{\alpha} p_{2}^{\rho} \frac{\partial^{2}}{\partial p_{1}^{\beta} \partial p_{2}^{\sigma}} G_{\psi \psi}^{(2)}\left(\omega_{1}+\varpi_{2}, \vec{p}_{1}, \omega_{2}+\varpi_{1}, \vec{p}_{2}\right)+\left(\varpi_{1}\right) \leftrightarrow\left(\varpi_{2}\right)\right] \\
& \quad=\frac{1}{2} \int_{\varpi_{1}, \varpi_{2}} K_{\psi \psi}\left(\varpi_{1}, \varpi_{2}\right) \tilde{\mathcal{R}}\left(\varpi_{1}\right) \tilde{\mathcal{R}}\left(\varpi_{2}\right) G_{\psi \psi}^{(2)}\left(\mathbf{p}_{1}, \mathbf{p}_{2}\right) . \tag{B58}
\end{align*}
$$

## d. Uncrossed derivatives contribution for the flow of a generic n-point function

Let us show that the result of the previous section for $\tilde{G}_{\psi \psi}^{(2)}\left(\mathbf{p}_{1}, \mathbf{p}_{2}\right)$ can be generalized for any generic correlation function, i.e. that

$$
\begin{align*}
\frac{\partial^{4}}{\partial q_{1}^{\mu} \partial q_{1}^{\mu} \partial q_{2}^{\nu} \partial q_{2}^{\nu}} & {\left.\left[\frac{\delta^{2}}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right) \delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\}_{1 \leq \ell \leq n} ; j\right]\right]_{\varphi=0}\right|_{\vec{q}_{1}=\vec{q}_{2}=0} } \\
& =\delta_{i \psi} \delta_{j \psi} \tilde{\mathcal{R}}\left(\varpi_{1}\right) \tilde{\mathcal{R}}\left(\varpi_{2}\right) \tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}\right) \tag{B59}
\end{align*}
$$

Following the same procedure as for the leading order at unequal times, let us first examine the action of only one functional derivative and subsequent two wave-number derivatives applied to a tree $\tilde{\mathcal{T}}^{(n)}$ composing $\tilde{G}_{i_{1} \ldots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}\right)$. Using the property (B53) demonstrated in the previous section, one readily obtains

$$
\begin{align*}
\frac{\partial^{2}}{\partial q_{a}^{\mu} \partial q_{a}^{\mu}} \frac{\delta}{\delta \varphi_{i}\left(\mathbf{q}_{a}\right)} & \left.\tilde{\mathcal{T}}_{i_{1} \cdots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\}\right]_{\varphi=0}\right|_{\vec{q}_{a}=0} \\
& =\delta_{i \psi} \int_{\mathbf{k}_{\text {intern }}} \sum_{k=1}^{m}\left(\prod_{\substack{k^{\prime}=1 \\
k^{\prime} \neq k}}^{m} \mathcal{E}_{k^{\prime}}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{k^{\prime}},\left\{\mathbf{k}_{\ell}\right\}_{k^{\prime}}\right)\right) \tilde{\mathcal{R}}\left(\varpi_{a}\right) \mathcal{E}_{k}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{k},\left\{\mathbf{k}_{\ell}\right\}_{k}\right) \tag{B60}
\end{align*}
$$

Thus, one only needs to show that the operator $\tilde{\mathcal{R}}\left(\varpi_{a}\right)$ verifies as well the Leibniz rule.

$$
\begin{align*}
\tilde{\mathcal{R}}\left(\varpi_{a}\right) \int_{\mathbf{k}} \mathcal{E}_{1}^{\mathcal{T}}\left(\left\{\mathbf{k}_{\ell}\right\}_{1},-\mathbf{k}\right) \mathcal{E}_{2}^{\mathcal{T}}\left(\mathbf{k},\left\{\mathbf{k}_{\ell}\right\}_{2}\right) & =\int_{\mathbf{k}}\left[\tilde{\mathcal{R}}\left(\varpi_{a}\right) \mathcal{E}_{1}^{\mathcal{T}}\left(\left\{\mathbf{k}_{\ell}\right\}_{1},-\mathbf{k}\right) \mathcal{E}_{2}^{\mathcal{T}}\left(\mathbf{k},\left\{\mathbf{k}_{\ell}\right\}_{2}\right)\right. \\
& \left.+\mathcal{E}_{1}^{\mathcal{T}}\left(\left\{\mathbf{k}_{\ell}\right\}_{1},-\mathbf{k}\right) \tilde{\mathcal{R}}\left(\varpi_{a}\right) \mathcal{E}_{2}^{\mathcal{T}}\left(\mathbf{k},\left\{\mathbf{k}_{\ell}\right\}_{2}\right)\right] \tag{B61}
\end{align*}
$$

This can be checked by inspection of the r.h.s., which reads

$$
\begin{align*}
\int_{\mathbf{k}} & {\left[\tilde{\mathcal{R}}\left(\varpi_{a}\right) \mathcal{E}_{i}^{\mathcal{T}}\left(\left\{\mathbf{k}_{\ell}\right\}_{\ell \in I},-\mathbf{k}\right) \mathcal{E}_{j}^{\mathcal{T}}\left(\mathbf{k},\left\{\mathbf{k}_{\ell}\right\}_{\ell \in J}\right)+\mathcal{E}_{i}^{\mathcal{T}}\left(\left\{\mathbf{k}_{\ell}\right\}_{\ell \in I},-\mathbf{k}\right) \tilde{\mathcal{R}}\left(\varpi_{a}\right) \mathcal{E}_{j}^{\mathcal{T}}\left(\mathbf{k},\left\{\mathbf{k}_{\ell}\right\}_{\ell \in J}\right)\right] } \\
& =\frac{2 i \epsilon_{a b}}{\varpi_{a}} \int_{\mathbf{k}}\left[\sum_{i \in I} k_{i}^{a} \frac{\partial}{\partial k_{i}^{b}} \mathcal{E}_{i}^{\mathcal{T}}\left(\nu_{i}+\varpi_{a}, \vec{k}_{i},\left\{\mathbf{k}_{\ell}\right\}_{\ell \in I \backslash i},-\mathbf{k}\right) \mathcal{E}_{j}^{\mathcal{T}}\left(\mathbf{k},\left\{\mathbf{k}_{\ell}\right\}_{\ell \in J}\right)\right. \\
& +\sum_{j \in J} k_{j}^{a} \frac{\partial}{\partial k_{j}^{b}} \mathcal{E}_{i}^{\mathcal{T}}\left(\left\{\mathbf{k}_{\ell}\right\}_{\ell \in I},-\mathbf{k}\right) \mathcal{E}_{j}^{\mathcal{T}}\left(\mathbf{k}, \nu_{j}+\varpi_{a}, \vec{k}_{j},\left\{\mathbf{k}_{\ell}\right\}_{\ell \in J \backslash j}\right) \\
& +k^{a} \frac{\partial}{\partial k^{b}} \mathcal{E}_{i}^{\mathcal{T}}\left(\left\{\mathbf{k}_{\ell}\right\}_{\ell \in I},-\nu+\varpi_{a},-\vec{k}\right) \mathcal{E}_{j}^{\mathcal{T}}\left(\mathbf{k},\left\{\mathbf{k}_{\ell}\right\}_{\ell \in J}\right) \\
& \left.+\mathcal{E}_{i}^{\mathcal{T}}\left(\left\{\mathbf{k}_{\ell}\right\}_{\ell \in I},-\mathbf{k}\right) k^{a} \frac{\partial}{\partial k^{b}} \mathcal{E}_{j}^{\mathcal{T}}\left(\nu+\varpi_{a}, \vec{k},\left\{\mathbf{k}_{\ell}\right\}_{\ell \in J}\right)\right] \tag{B62}
\end{align*}
$$

Integrating by part in $\vec{k}$ and shifting the associated frequency, the two last terms cancel out, proving (B61). One concludes that

$$
\begin{equation*}
\left.\frac{\partial^{2}}{\partial q_{a}^{\mu} \partial q_{a}^{\mu}} \frac{\delta}{\delta \varphi_{i}\left(\mathbf{q}_{a}\right)} \tilde{\mathcal{T}}_{i_{1} \cdots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\}\right]_{\varphi=0}\right|_{\vec{q}_{a}=0}=\tilde{\mathcal{R}}\left(\omega_{a}\right) \tilde{\mathcal{T}}_{i_{1} \cdots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}\right) \tag{B63}
\end{equation*}
$$

The remaining task to prove (B59) is to show that the same property holds for two functional derivatives and their subsequent wave-number derivatives. As for the leading order at unequal time, distributing the two $\vec{q}_{2}$ derivatives and setting $\vec{q}_{2}$ to zero, one then applies the property (B61) to show that the resulting $\tilde{\mathcal{R}}\left(\varpi_{2}\right)$ can be pulled out of the remaining diagram

$$
\begin{align*}
& \left.\frac{\partial^{4}}{\partial q_{1}^{\mu} \partial q_{1}^{\mu} \partial q_{2}^{\nu} \partial q_{2}^{\nu}} \frac{\delta^{2}}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right) \delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{\mathcal{T}}_{i_{1} \cdots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\}\right]_{\varphi=0}\right|_{\vec{q}_{1}=\vec{q}_{2}=0} \\
& =\left.\delta_{j \psi} \frac{\partial^{2}}{\partial q_{1}^{\mu} \partial q_{1}^{\mu}}\left\{\tilde{\mathcal{R}}\left(\varpi_{2}\right)\left[\left.\int_{\mathbf{k}_{\text {intern }}} \sum_{k}\left(\prod_{k^{\prime} \neq k} \mathcal{E}_{k^{\prime}}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{k^{\prime}},\left\{\mathbf{k}_{\ell}\right\}_{k^{\prime}}\right)\right) \frac{\delta}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right)} \mathcal{E}_{k}^{\mathcal{T}}\left[\left\{\mathbf{p}_{\ell}\right\}_{k},\left\{\mathbf{k}_{\ell}\right\}_{k}\right]\right|_{\varphi=0}\right]\right\}\right|_{\vec{q}_{1}=0} \tag{B64}
\end{align*}
$$

Expressing $\tilde{\mathcal{R}}\left(\varpi_{2}\right)$ explicitly and distributing the $\vec{q}_{1}$ derivative gives

$$
\begin{align*}
& \left.\frac{\partial^{4}}{\partial q_{1}^{\mu} \partial q_{1}^{\mu} \partial q_{2}^{\nu} \partial q_{2}^{\nu}} \frac{\delta^{2}}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right) \delta \varphi_{j}\left(\mathbf{q}_{2}\right)} \tilde{\mathcal{T}}_{i_{1} \cdots i_{n}}^{(n)}\left[\left\{\mathbf{p}_{\ell}\right\}\right]_{\varphi=0}\right|_{\vec{q}_{1}=\vec{q}_{2}=0} \\
& =\delta_{j \psi} \frac{2 \epsilon_{\rho \sigma}}{\varpi_{2}} \frac{\partial^{2}}{\partial q_{1}^{\mu} \partial q_{1}^{\mu}}\left\{q_{1}^{\rho} \frac{\partial}{\partial q_{1}^{\sigma}}\left[\int_{\mathbf{k}_{\text {intern }}} \sum_{k}\left(\prod_{k^{\prime} \neq k} \mathcal{E}_{k^{\prime}}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{k^{\prime}},\left\{\mathbf{k}_{\ell}\right\}_{k^{\prime}}\right)\right) \frac{\delta}{\delta \varphi_{i}\left(\varpi_{1}+\varpi_{2}, \vec{q}_{1}\right)} \mathcal{E}_{k}^{\mathcal{T}}\left[\left\{\mathbf{p}_{\ell}\right\}_{k},\left\{\mathbf{k}_{\ell}\right\}_{k}\right]_{\varphi=0}\right]\right. \\
& \left.+\sum_{k=1}^{n} p_{k}^{\rho} \frac{\partial}{\partial p_{k}^{\sigma}}\left[\left.\int_{\mathbf{k}_{\text {intern }}} \sum_{m}\left(\prod_{m^{\prime} \neq m} \mathcal{E}_{m^{\prime}}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{m^{\prime}} \backslash k_{+},\left\{\mathbf{k}_{\ell}\right\}_{m^{\prime}}\right)\right) \frac{\delta}{\delta \varphi_{i}\left(\mathbf{q}_{1}\right)} \mathcal{E}_{m}^{\mathcal{T}}\left[\left\{\mathbf{p}_{\ell}\right\}_{m} \backslash k_{+},\left\{\mathbf{k}_{\ell}\right\}_{m}\right]\right|_{\varphi=0}\right]\right\}\left.\right|_{\vec{q}_{1}=0} \\
& =\delta_{j \psi} \frac{2 i \epsilon_{\rho \sigma}}{\varpi_{2}}\left\{2 \delta_{\mu \rho} \frac{\partial^{2}}{\partial q_{1}^{\mu} \partial q_{1}^{\sigma}}\left[\left.\int_{\mathbf{k}_{\text {intern }}} \sum_{k}\left(\prod_{k^{\prime} \neq k} \mathcal{E}_{k^{\prime}}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{k^{\prime}},\left\{\mathbf{k}_{\ell}\right\}_{k^{\prime}}\right)\right) \frac{\delta}{\delta \varphi_{i}\left(\varpi_{1}+\varpi_{2}, \vec{q}_{1}\right)} \mathcal{E}_{k}^{\mathcal{T}}\left[\left\{\mathbf{p}_{\ell}\right\}_{k},\left\{\mathbf{k}_{\ell}\right\}_{k}\right]\right|_{\varphi=0}\right]_{\vec{q}_{1}=0}\right. \\
& \left.+\delta_{i \psi} \sum_{k=1}^{n} p_{k}^{\rho} \frac{\partial}{\partial p_{k}^{\sigma}}\left[\int_{\mathbf{k}_{\text {intern }}} \sum_{m}\left(\prod_{m^{\prime} \neq m} \mathcal{E}_{m^{\prime}}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{m^{\prime}} \backslash k_{+},\left\{\mathbf{k}_{\ell}\right\}_{m^{\prime}}\right)\right) \tilde{\mathcal{R}}\left(\varpi_{1}\right) \mathcal{E}_{m}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{m} \backslash k_{+},\left\{\mathbf{k}_{\ell}\right\}_{m}\right)\right]\right\} \\
& =\delta_{i \psi} \delta_{j \psi} \frac{2 i \epsilon_{\rho \sigma}}{\varpi_{2}} \sum_{k=1}^{n} p_{k}^{\rho} \frac{\partial}{\partial p_{k}^{\sigma}}\left[\tilde{\mathcal{R}}\left(\varpi_{1}\right) \int_{\mathbf{k}_{\text {intern }}} \prod_{m} \mathcal{E}_{m}^{\mathcal{T}}\left(\left\{\mathbf{p}_{\ell}\right\}_{m} \backslash k_{+},\left\{\mathbf{k}_{\ell}\right\}_{m}\right)\right] \\
& =\delta_{i \psi} \delta_{j \psi} \tilde{\mathcal{R}}\left(\varpi_{2}\right) \tilde{\mathcal{R}}\left(\varpi_{1}\right) \tilde{\mathcal{T}}_{i_{1} \cdots i_{n}}^{(n)}\left(\left\{\mathbf{p}_{\ell}\right\}\right), \tag{B65}
\end{align*}
$$

where the first term in the second equality vanishes by antisymmetry of $\epsilon_{\rho \sigma}$. This proves the property (B59), and yields (B50).

[32] Note that one does not need to impose the forcing to be solenoidal, as the incompressibility is explicitly enforced along each realization of the flow. As a consequence, it can be chosen diagonal in component space without loss of generality.
[33] Tristan Buckmaster and Vlad Vicol, Nonuniqueness of weak solutions to the Navier-Stokes equation, arXiv:1709.10033 (2017).
[34] Note that the standard derivation of the MSRJD action for NS implicitly assumes existence and unicity of weak solutions of the Navier-Stokes equation, which is is a delicate issue from a mathematical point of view [33]. The assumption is actually a little weaker than strict uniqueness, since for a typical set of initial conditions, there may exist a set of velocity configurations spoiling unicity, as long as they are of zero measure with respect to the realizations of the forcing.
