(Dated: October 24, 2018)

We propose a novel mechanism for a nonequilibrium phase transition within a $U(1)$-broken phase of an electron-hole-photon system, from a Bose-Einstein condensate of polaritons to a photon laser, induced by the non-Hermitian nature of the condensate. We show that a (uniform) steady state of the condensate can always be classified into two types, namely, arising either from lower or upper-branch polaritons. We prove (for a general model) and demonstrate (for a particular model of polaritons) that an exceptional point where the two types coalesce marks the endpoint of a first-order-like phase boundary between the two types, similar to a critical point in a liquid-gas phase transition. Since the phase transition found in this paper is not in general triggered by population inversion, our result implies that the second threshold observed in experiments is not necessarily a strong-to-weak-coupling transition, contrary to the widely-believed understanding. Although our calculation mainly aims to clarify polariton physics, our discussion applies to general driven-dissipative condensates composed of two complex fields.

PACS numbers:

The phenomenon of macroscopic condensation has been one of the principal topics in modern condensed matter physics and optics [1]. The central example is, of course, Bose-Einstein condensation (BEC), which has been observed in various systems, ranging from atomic gases [2, 3], liquid $^4$He [4], exciton-polaritons [5–8], magnons [9–11], photons [12], to plasmonic-lattice-atomic gases [2, 3], liquid [1], to plasmonic-lattice-atomic gases [2, 3], liquid [1]. The central example is, of course, Bose-Einstein condensation (BEC), which has been observed in various systems, ranging from atomic gases [2, 3], liquid $^4$He [4], exciton-polaritons [5–8], magnons [9–11], photons [12], to plasmonic-lattice-atomic gases [2, 3], liquid [1]. In these systems, thermalization plays a crucial role in achieving macroscopic occupation of the lowest energy level. A photon laser [14, 15], in contrast, is a nonequilibrium condensate, where the population inversion in an optical gain medium induces macroscopic coherence.

The semiconductor microcavity system [3–5] provides a unique opportunity to study similarities and differences of these two classes of condensation phenomena [16], since it can exhibit both [17], by tuning the pump power. At low pump power, where the strong light-matter coupling enables hybrid light-matter quasiparticles called polaritons to form, thermalization of polaritons is efficient due to relaxation processes such as stimulated scattering. This makes it possible, once the pump power exceeds a certain threshold, for the system to exhibit macroscopic coherence among polaritons to turn into a polariton-BEC [3]. At even higher power, in contrast, the system operates in the weak light-matter coupling regime as a vertical-cavity surface-emitting laser (VCSEL), a type of a photon laser, with electrons and holes acting as a gain medium. Interestingly, a number of experiments [18–28] have observed a second threshold between the former and latter regimes, which has been traditionally interpreted as suggesting a strong-to-weak coupling phase transition.

This two-threshold-behavior presents a theoretical challenge, however. The phase transition to photon lasing is associated with breaking a $U(1)$ symmetry, but the polariton-BEC, which arises after the first threshold, is already in a $U(1)$-broken phase. Thus, there seems to be no good reason to expect a second phase transition. Indeed, to our knowledge, all theories to date predict a crossover [2, 3, 29, 30].

In this paper, we propose a novel mechanism for a phase transition within the $U(1)$-broken phase, triggered by the non-Hermitian nature of the out-of-equilibrium condensate. Using an exact equations of motion approach, we clarify that the steady states of a two-component condensate of electron-hole pairs and photons can be classified into two types of solutions, corresponding to condensation to different branches of the polariton...
FIG. 2: (Color online) Model driven-dissipative electron-hole-photon gas. The system is attached to an electron-hole bath and a photon vacuum. Electrons (holes) are incoherently supplied to the system with the rate $\gamma_{e(h)}$. In the system, the injected electrons (“e”) and holes (“h”) repulsively (e-e, h-h) and attractively (e-h) interact with the Coulomb potential $V_{k-k'} = e^2/(2|\mathbf{k} - \mathbf{k}'|)$. The electrons and holes pair-annihilate (create) to create (annihilate) cavity-photons (“ph”) via the dipole coupling $g$ between the electron-hole carriers and the cavity-photons. The created photons in the cavity leak out to the vacuum with the decay rate $\kappa$.

The phase transition found in this paper is ultimately caused by the non-orthogonality of the eigenmodes of the coupled electron-hole with photon coherent fields. Thus, our discussion is applicable to any driven-dissipative condensate composed of two complex fields with balanced gain-and-loss, e.g., a driven-dissipative BEC of atoms in a double-well potential, a supersolid realized in a double-cavity, and a plasmonic-lattice-polariton BEC. Because the transition is insensitive to details of the system such as the presence of population inversion, our finding implies that it may happen in the strong-coupling regime as well, contrary to the ordinary understanding.

We use a microscopic model schematically shown in Fig. 2, which has been shown to capture both the essential physics of the BEC state and the VCSEL, as well as to give a semiquantitative agreement with photoluminescence experiments. The system is composed of electrons, holes, and cavity-photons, and they are coupled to an electron-hole bath and a photon vacuum. Electrons (holes) are incoherently pumped to the system from the bath at a rate $\gamma_{e(h)}$. The injected electrons and holes Coulomb-interact with each other and create (annihilate) photons by pair-annihilation (creation). The photons leak out to the vacuum with the decay rate $\kappa$, driving the system into a non-equilibrium steady state. The explicit expression for the Hamiltonian $H$ is given in the Supplemental Material.

We apply the Keldysh Green’s function method to the model. As shown in Ref. 51 in a formally exact way, the dynamics of the electron-hole dipole polarization $p_k(r,t)$ and the electron (hole) density $n_{k,e(h)}(r,t)$ obeys the generalized Boltzmann equation:

$$i\hbar \partial_t p_k(r,t) = \left[ \epsilon_{k,e} + \epsilon_{k,h} - \frac{\hbar^2 \nabla^2}{2m_{cav}} - 2i\gamma \right] p_k(r,t) - \sum_{k'} L_{k,k'}(r,t) \Delta_{k'}(r,t),$$

$$\partial_t n_{k,\sigma}(r,t) + v_{k,\sigma} \cdot \nabla n_{k,\sigma}(r,t) = -2\gamma \frac{\hbar}{\kappa} n_{k,\sigma}(r,t) + I_{k,\sigma}(r,t).$$

Here, $\epsilon_{k,e(h)} = \hbar^2 k^2/(2m_{cav}) + E_k/2$ is the dispersion of the electron (hole) in the conduction (valence) band, where $m_{cav}$ is the effective mass of electrons (holes). $E_k$ is the energy gap of the semiconductor material. $m_{eh} = 2m_em_h/(m_e + m_h)$ is twice the reduced mass of an electron and a hole, and $v_{k,e(h)} = \hbar k/m_{cav}$. We have introduced the order parameter $\Delta_{k}(r,t) = \sum_k V_{k-k'} p_k(r,t) - g\lambda_{cav}(r,t)\lambda_{cav}(r,t)$ describing the condensed phase, where $\lambda_{cav}(r,t) = \langle a(r,t) \rangle$ is the coherent cavity-photon amplitude (where $a(r,t)$ is the annihilation operator of a cavity-photon), $V_k = e^2/(2|\mathbf{k}|)$ is the two-dimensional Coulomb interaction ($e$ is the dielectric constant), and $g$ is a dipole coupling between carriers (electrons and holes) and photons. The coupling of the system to the bath causes the dephasing/decay of $p_k(r,t)$ with the rate $2\gamma \gamma_{e(h)}/2$. $L_{k,k'}(r,t)$ and $I_{k,\sigma}(r,t)$ in Eqs. 1 and 2, determined microscopically from the self-energy $\Sigma$ and the Green’s function $G$ in the Nambu-Keldysh formalism (see the Supplemental Material for their explicit form), describe many-body effects, such as band renormalization and collision, as well as the electron-hole pumping and its thermalization.

The electron-hole dynamics is coupled to the dynamics of the coherent cavity-photon amplitude, given by the Heisenberg equation:

$$i\hbar \partial_t \lambda_{cav}(r,t) = \langle \{ a(r,t), H \} \rangle = \left[ \hbar \omega_{cav} - \frac{\hbar^2 \nabla^2}{2m_{cav}} - i\kappa \right] \lambda_{cav}(r,t) + g \sum_k p_k(r,t),$$

where $\hbar\omega_{cav}$ is the cavity-photon energy, and $m_{cav}$ is a cavity-photon mass.

We consider a uniform steady state given by the ansatz $p_k(r,t) = p_k^0 e^{-iEt/\hbar}$, $\lambda_{cav}(t) = \lambda_{cav}^0 e^{-iEt/\hbar}$, $p_k(t) = p_k^0 e^{-iEt/\hbar}$, where $E$ is the condensate emission energy.
Our discussion assumes that Eqs. (11)-(13) are solved self-consistently for a given parameter set [50]. Defining a complex quantity \( \lambda_{{\text{ch}}} \) by \( \lambda_{{\text{ch}}} = \phi_k \), with \( \sum_k |\phi_k|^2 = 1 \) and \( \text{Arg} \sum_k \phi_k = 0 \), to quantify the electron-hole pair amplitude, we arrive at an eigenvalue problem,

\[
\tilde{\mathcal{A}} \left( \begin{array}{c} \lambda_{{\text{cav}}} \\ \lambda_{{\text{ch}}} \end{array} \right) = \left( \begin{array}{c} h_{{\text{cav}}} g_0 \\ g_0 \end{array} \right) \left( \begin{array}{c} \lambda_{{\text{cav}}} \\ \lambda_{{\text{ch}}} \end{array} \right) = E \left( \begin{array}{c} \lambda_{{\text{cav}}} \\ \lambda_{{\text{ch}}} \end{array} \right),
\]

where \( h_{{\text{cav}}} = \hbar \omega_{{\text{cav}}} - i \kappa, \) \( g_0 = g \sum_k \phi_k = g \phi(r = 0), \) \( g_0 = g \sum_k \phi_k \), and \( \lambda_{{\text{cav}}} = \sum_k (\varepsilon_{k,e} + \varepsilon_{k,h} - 2i\gamma)|\phi_k|^2 - \sum_{p,k'} V_{k-p} \phi_k \phi_{k'} \). The first line in Eq. (11) is equivalent to Eq. (13) in the steady state, and the second line is obtained by multiplying \( \phi_k^* \) to both sides of Eq. (11) and integrating over \( k \).

The matrix \( \tilde{\mathcal{A}} \) can be diagonalized with eigenvectors \( u_- = \left( \frac{-\varepsilon_{\text{cav}}}{\sqrt{2}}, -g_0^* \right)^T \), \( u_+ = \left( g_0, \frac{-\varepsilon_{\text{cav}}}{\sqrt{2}} \right)^T \), and corresponding eigenvalues \( E_{\pm} = [h_{{\text{cav}}} + \pm \Omega/2]. \) Here, \( \Omega = \sqrt{\delta^2 + 4\text{Re}(g_0^* g_0)} \) is the exciton Rabi splitting, and we take \( \text{Re}\Omega \geq 0 \) (i.e. \( \text{Re}E_+ \geq \text{Re}E_- \)) without loss of generality. In the diagonal basis, Eq. (4) reads

\[
\left( \begin{array}{cc} E_- & 0 \\ 0 & E_+ \end{array} \right) \left( \begin{array}{c} \lambda_0 \\ \lambda_+ \end{array} \right) = E \left( \begin{array}{c} \lambda_0 \\ \lambda_+ \end{array} \right),
\]

where \( (\lambda_0, \lambda_+)^T = \tilde{U}(\lambda_{{\text{cav}}}, \lambda_{{\text{ch}}})^T \) with \( \tilde{U}^{-1} = (u_-, u_+) \).

Other than a trivial solution \( \lambda_0 = \lambda_+ = 0 \) that corresponds to the normal phase, Eq. (4) has two types of solutions. One type satisfies \( \lambda_0 \neq 0 \) and \( E = E_- \) with \( \lambda_0 = 0 \) automatically satisfied, as shown in Ref. [51]. The other type is a solution with \( \lambda_0 \neq 0 \) and \( E = E_+ \) with \( \lambda_0 = 0 \). From here on, we call the former (latter) the “-” (“+”) solution.

Now we show that a first-order-like phase transition between the two solutions occurs. We examine the exceptional point (EP), where \( \Omega = 0 \) and \( u_\pm \) coalesce such that \( \tilde{\mathcal{A}} \) has only a single eigenvector [58], and show that this marks the end of a phase boundary. The proof is presented in the Supplemental Material [51] and we sketch the argument here. Introducing the complex splitting parameter,

\[
\Lambda = \Omega^2 - \varphi^2 + 4g_0^* g_0,
\]

which characterizes the difference between \( E_- \) and \( E_+ \), we divide the complex \( \Lambda \)-plane into the regions I-IV, as shown in Fig. 3(a). Here, regions II and III (I and IV) are in the so-called weak- (strong-) coupling regime [59] with \( \delta^2 + 4\text{Re}(g_0^* g_0) < 4\kappa^2 \) where \( \delta = \text{Re}\varphi, \) and equality holds at the EP [60]. Due to the constraint of the balanced condensate-gain-and-loss giving real emission energy \( E \), only the “+” (“-”) solution can be realized in region II(III). When crossing the dotted line in Fig. 3(a) from region III to II, the solution type switch without discontinuity in the emission energy, leading to a smooth crossover. In contrast, sweeping parameters in a route that encircles the EP and crosses through the coexistence regions IV and I, the solution type must switch discontinuously, resulting in a phase transition, proving the theorem [61].

To make contact between the above general arguments and real physical systems, we explicitly solve for the polariton-BEC and VCSEL. In the dilute equilibrium limit \( \kappa = 0, \gamma \rightarrow 0^+, \hbar \kappa_\sigma \ll 1 \) where the polariton-BEC is realized, Eq. (11) reduces to [51]

\[
\tilde{\mathcal{A}}_\text{BEC} = \left( \begin{array}{cc} \hbar \omega_{{\text{cav}}} - i \kappa & g_R \\ g_R & \hbar \omega_{{\text{cav}}} + U_X |\lambda_0^\text{ch}|^2 + iR_X \end{array} \right),
\]

in the Hartree-Fock-Bogoliubov approximation (HFBA) [44], being justified in this limit. In Eq. (7), \( \hbar \omega_{{\text{cav}}} \) is the exciton energy \( (E_\text{exc}^\text{BEC} \text{ is the excitation energy (}E_\text{exc}). \) \( g_R = g \phi(r = 0) \) is the Rabi splitting, where \( \phi(r) \) is an exciton wave function obeying the Schrödinger equation \( \int dr' (-\delta(r-r')\hbar^2 \nabla^2 + V(r-r')|\phi(r')| = -E_\text{exc} \phi(r) [62]. \) The eigenvalues are given as \( E_{\pm \text{BEC}} = |\hbar \omega_{{\text{cav}}} + U_X |\lambda_0^\text{ch}|^2 + iR_X |^2 \), that are just the lower and upper polariton energies \( \) (where \( \delta = \hbar \omega_{{\text{cav}}} - \hbar \omega_{{\text{X}}} \) is the (conventional) detuning parameter). Comparison of the free energies of the two solutions tells us that the “-”-solution always emerges.

When the photon decay rate \( \kappa \) is turned on, a phase transition can occur. In the so-called polariton laser regime, where the gas is dilute enough to maintain the polariton picture, the equation of motion is governed by the driven-dissipative Gross-Pitaevskii (ddGP) equation [4, 51], given by,

\[
\tilde{\mathcal{A}}_\text{GP} = \left( \begin{array}{cc} \hbar \omega_{{\text{cav}}} - i \kappa & g_R \\ g_R^* & \hbar \omega_{{\text{X}}} + U_X |\lambda_0^\text{ch}|^2 + iR_X \end{array} \right),
\]

where \( U_X \) is an exciton-exciton interaction strength and \( R_X > 0 \) describes the net gain of exciton coherence that feeds the condensate [64], arising microscopically.
from processes such as stimulated scattering. This gives 
\[ E_{\text{GP}}^2 = \left[ \hbar \omega_{\text{cav}} + \hbar \omega_X \right] |\lambda_{\text{cav}}^0|^2 - i(k - R_X) + \Omega_{\text{GP}} \] 
where \( \Omega_{\text{GP}} = \sqrt{\delta^2 + 4|g_r|^2 - (k + R_X)^2 - 2i\delta(k + R_X)} \), \( \delta = \hbar \omega_{\text{cav}} - (\hbar \omega_X + U_X |\lambda_{\text{ch}}^0|^2) \) is an effective detuning that takes into account the Hartree shift of the exciton component. One can find an EP (\( \Omega_{\text{GP}} = 0 \)) at \( \delta = 0 \) and \( g_r = R_X = k \), giving rise to a phase transition in its vicinity.

We demonstrate this by explicitly solving Eq. (8) when \( \tilde{A} = A_{\text{GP}} \) (Eq. 8). Figure 4 shows the calculated emission energy \( E \) as a function of the decay rate \( k/g_r \) and the coherent photon number \( n_{\text{ph}}^0 = |\lambda_{\text{cav}}^0|^2 \). The solid line projected onto the \( n_{\text{ph}}^0/k/g_r \) plane is a phase boundary. The star represents the exceptional point \( \Omega_{\text{GP}} = 0 \). We set \( \delta/g_r = 0.1, \hbar \omega_X/g_r = -2, U_X/g_r = 0.1 \).

 physically, these transition and crossover at different detunings can be understood from the property that the effective red detuning drives the lower (upper)-branch more photonic (excitonic), and vice versa for the blue detuning. 

Our scenario may be experimentally realized by track-
ing the emission energy $E$ and observing that a jump associated with the phase transition occurs an odd number of times when encircling the EP.

To summarize, we have shown and demonstrated that the non-Hermitian nature of an electron-hole-photon condensate can give rise to a phase transition. We have shown that the phase boundary may have an endpoint, in analogy to a liquid-gas phase diagram. The endpoint corresponds to the exceptional point discussed in the context of non-Hermitian quantum mechanics. These conclusions, although derived mainly for microcavity polarization systems, should apply to general driven-dissipative condensates composed of two complex fields.

[47] References [2–4] has shown within the Hartree-Fock-Bogoliubov approximation that, taking the equilibrium limit of Eqs. (1)-(3) yields the gap equation of the Bardeen-Cooper-Schrieffer theory that describes an electron-hole-photon condensate in equilibrium, and at a high-density regime, these equations collapse to the semiconductor Maxwell Bloch equation that describes a VCSEL.
[51] See the Supplemental Material for details.
[56] Precisely speaking, our assumption is that the Dyson’s equation (where its explicit form is given in the Supplemental Material) is solved to obtain all the terms in Eqs. (1)–(3).
[58] We emphasize that such a coalescence of eigenvectors may only occur for non-Hermitian matrices, since Hermitian matrices has orthogonal eigenvectors.
[60] It is shown in the Supplemental Material [51] that the weak- (strong-) coupling regime δ^2 + 4Re[g^0 g^0] < 4κ^2(≥ 4κ^2) is realized at ReΛ < 0(≥ 0), at least in the vicinity of ImΛ = 0.
[61] We have implicitly assumed that ̂A is a smooth function of the input parameters and has maximum of one solution per solution type.
[62] In deriving Eq. (7), we have assumed gR ≪ E^\text{bind}_X, for simplicity.
Supplemental Material for “Non-Hermitian phase transition from a polariton Bose-Einstein condensate to a photon laser”

MODEL

We provide here the explicit form of the Hamiltonian \( H \) of our model, depicted schematically in Fig. 2 in the main text \[1–4\]. The Hamiltonian is given by the sum of three parts \( H = H_\text{s} + H_\text{env} + H_\Gamma \). Here,

\[
H_\text{s} = \sum_{k,\sigma} \varepsilon_{k,\sigma} c_{k,\sigma}^\dagger c_{k,\sigma} + \sum_q \varepsilon_{q,\text{cav}} a_q^\dagger a_q + \sum_{k,k',q} V_{k-k'} c_{k+q,\sigma}^\dagger c_{k',q,\sigma} + \varepsilon_{q,\text{cav}},
\]

where \( \varepsilon_{k,\sigma} \) is the on-site energy of the electron (hole), \( V_{k-k'} \) is the dipole coupling constant. The last term describes the varying the microcavity length \( \varepsilon_{q,\text{cav}} \) is the dielectric constant (panence) band and \( \varepsilon_{q,\text{cav}} \) is the energy gap of the material. \( a_q \) is an annihilation operator of a photon in the cavity, and \( \varepsilon_{q,\text{cav}} \) is the energy of an electron (hole), where \( m_{e(h)} \) is the effective mass of an electron (hole) in the conduction (valence) band and \( E_\text{g} \) is the energy gap of the material. \( \varepsilon_{q,\text{cav}} \) is the kinetic energy of photons, where \( h\omega_{\text{cav}} = (c/n_c)h(2\pi/\lambda) \) can be controlled by varying the microcavity length \( \lambda \) (\( n_c \) is the refractive index of the microcavity). The second term describes the pair-annihilation (creation) of electrons and holes accompanied by creation (annihilation) of photons, where \( g \) is the dipole coupling constant. The last term describes the repulsive and attractive Coulomb interactions between the electrons and holes, where \( V_{k-k'} = e^2/(2\epsilon|k-k'|) \) (\( \epsilon \) is the dielectric constant).

Incoherent pumping of electrons and holes is modeled as a coupling to a (free) bath via the tunneling coefficient \( \Gamma_{b,e(h)} \). Similarly, we model the photon decay as a coupling to a (free) vacuum via \( \Gamma_\text{v} \). These are described by the Hamiltonian,

\[
H_\Gamma = \sum_{k,K,\sigma} \Gamma_{b,e,h} \epsilon_{k,K,\sigma} c_{k,\sigma}^\dagger e^{-iK\mathbf{R}_e} + \text{h.c.}
\]

Here, \( b_{P,e(h)} \) and \( \psi_Q \) are annihilation operators of the bath electrons (holes) and the vacuum photons, respectively, and \( \varepsilon_{P,e(h)}^{b} \) and \( \varepsilon_{Q}^{v} \) are the kinetic energy of the bath electrons (holes) and the vacuum photons, respectively. We have assumed that the carriers tunnel from position \( \mathbf{r}_i \) in the system to \( \mathbf{R}_i \) in the bath or vacuum \( (i = 1, 2, \ldots, N_i) \). The positions \( \mathbf{r}_i \) and \( \mathbf{R}_i \) are assumed to be randomly distributed, in order to model homogeneous pumping and decay of carriers \[1\]. As shown soon later, this results in a decay rate of photons given by

\[
\kappa = \pi N_i |\Gamma_\text{v}|^2 \rho_e,
\]

and an incoherent pumping rate of the electrons (holes)

\[
\gamma_e(h) = \pi N_i |\Gamma_{b,e(h)}|^2 \rho_{b,e(h)}.
\]

Here, the bath electron (hole) density of states \( \rho_{b,e(h)} \) and the vacuum photon density of states \( \rho_v \) are both assumed to be white (i.e., \( \rho_e = \text{const}, \rho_{b,e}=\text{const} \)).

For the system to converge into a steady state, we assume that the bath and the vacuum are large compared to the system such that they stay in equilibrium. The bath electron and hole distribution is given by the Fermi distribution function,

\[
f_{b,e,h}(\omega) = \frac{1}{e^{(\omega-\mu_{b,e,h})/T_b} + 1},
\]

characterized by the bath temperature \( T_b \) and the electron and hole chemical potential \( \mu_{b,e,h} \). The vacuum photon distribution is given by \( f_\text{v}(\omega) = 0 \).

DERIVATIvE OF THE EQUATION OF MOTION

We now derive the (exact) equation of motion of the above model, given by the generalized Boltzmann equations [Eqs. (1) and (2) in the main text] and the Heisenberg equation of the photon amplitude [Eq. (3) in the main text]. Let us first derive the former. To study the dynamics of an interacting many-body system, it is convenient to consider the Nambu-Keldysh single-particle Green’s function of electrons and holes, defined by \[3\],

\[
\hat{G}(\mathbf{r}_1, \mathbf{r}_2; t_1, t_2) = \begin{pmatrix} \hat{G}_b^R(\mathbf{r}_1, \mathbf{r}_2; t_1, t_2) & \hat{G}_b^K(\mathbf{r}_1, \mathbf{r}_2; t_1, t_2) \\ 0 & \hat{G}_A^R(\mathbf{r}_1, \mathbf{r}_2; t_1, t_2) \end{pmatrix}
\]
An especially important quantity of interest is the lesser Green's function, with the relative coordinate \( r \). Below, we show that the equation of motion of these valuables are given by the generalized Boltzmann equations (1) which directly relates to the electron (hole) density \( \hat{c}_1^\dagger(r,t) \) and \( \hat{c}_1^\dagger(r,t) \) are obtained as,

\[
\begin{align*}
\Psi(r,t) &= \begin{pmatrix} c_e(r,t) \\ c_h(r,t) \end{pmatrix} = \begin{pmatrix} \Psi_1(r,t) \\ \Psi_2(r,t) \end{pmatrix},
S(n) \equiv \Psi_s(r_1,t_1)\Psi_s^\dagger(r_2,t_2) = \begin{pmatrix} c_e(r_1,t_1)c_e^\dagger(r_2,t_2) & c_e(r_1,t_1)c_h(r_2,t_2) \\ c_h^\dagger(r_1,t_1)c_e(r_2,t_2) & c_h(r_1,t_1)c_h(r_2,t_2) \end{pmatrix},
S(0) = \frac{1}{2}(\hat{c}_e^\dagger(r_2,t_2)\hat{c}_h(r_1,t_1) - \hat{c}_h^\dagger(r_2,t_2)\hat{c}_e(r_1,t_1)),
S(k,v) = \int d^3r e^{-ik\cdot r} S(r,v;0,0).
\end{align*}
\]

An especially important quantity of interest is the lesser Green's function, which directly relates to the electron (hole) density \( n_{k_e}(r,t) \) and the polarization \( p_k(r,t) \). By transforming this quantity to the so-called Wigner representation, we have \( S(n) \equiv \Psi_s(r_1,t_1)\Psi_s^\dagger(r_2,t_2) \) and \( S(0) = \frac{1}{2}(\hat{c}_e^\dagger(r_2,t_2)\hat{c}_h(r_1,t_1) - \hat{c}_h^\dagger(r_2,t_2)\hat{c}_e(r_1,t_1)) \). By transforming this quantity to the so-called Wigner representation, where the coordinates \( (r_1,t_1) \) and \( (r_2,t_2) \) are rewritten in terms of the relative coordinate \( r = r_1 - r_2, t = t_1 - t_2 \) and the center of motion coordinate \( r = (r_1 + r_2)/2, t = (t_1 + t_2)/2, n_{k_e}(r,t) \) and \( p_k(r,t) \) are obtained as,

\[
\begin{align*}
\begin{pmatrix} n_{k_e}(r,t) \\ p_k(r,t) \\ 1 - n_{k_h}(r,t) \end{pmatrix} = -i\hbar \int d^3r e^{-ik\cdot r} G^\le(r_0, t = 0; r, t) = -i\hbar \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} G^\le(k,\omega; r, t).
\end{align*}
\]

Below, we show that the equation of motion of these valuables are given by the generalized Boltzmann equations (1) and (2).

The dynamics of the single-particle Green’s function \( \hat{G} \) is determined by the Dyson’s equation \[\hat{G} = \hat{G}_0 + \hat{G}_0 \otimes \hat{S} \otimes \hat{G},\]

where we have introduced a short-hand notation,

\[
[A \otimes B](r_1,t_1; r_2,t_2) = \int_{-\infty}^{\infty} dt'_1 \int d^3r_1' \hat{A}(r_1,t_1;r_1',t_1') \hat{B}(r_1',t_1';r_2,t_2),
\]

and have omitted the space-time index in Eq. (S13). The (Fourier transformed) free electron-hole Green’s function is given by,

\[
\begin{pmatrix} G_0^R(k,\omega) \\ G_0^A(k,\omega) \\ G_0^K(k,\omega) \end{pmatrix} = \begin{pmatrix} \hat{G}_0^R(k,\omega) \\ \hat{G}_0^A(k,\omega) \\ \hat{G}_0^K(k,\omega) \end{pmatrix}
\]

with

\[
\begin{align*}
G_0^R(k,\omega) &= \frac{\hbar \omega + i\delta - \epsilon_{k,e}}{\hbar \omega + i\delta + \epsilon_{k,h}}^{\frac{1}{2}}, \\
G_0^A(k,\omega) &= \frac{\hbar \omega - i\delta + \epsilon_{k,e}}{\hbar \omega - i\delta + \epsilon_{k,h}}^{\frac{1}{2}}, \\
G_0^K(k,\omega) &= \begin{pmatrix} -2\pi i[1 - 2f(\omega)][\delta(\hbar \omega - \epsilon_{k,e})] \\ 2\pi i[1 - 2f(-\omega)][\delta(\hbar \omega + \epsilon_{k,h})] \end{pmatrix}^{\frac{1}{2}},
\end{align*}
\]
where \( \tau_{i=1,2,3} \) are Pauli matrices acting on the Nambu space. Here, \( f(\omega) \) in the Keldysh component is the initial distribution of the relevant system, which, as shown below, does not affect the final form of the equation of motion. The effects of the many-body interaction and the coupling to the bath are described by the self-energy,

\[
\hat{\Sigma}(r_1, t_1; r_2, t_2) = \left( \begin{array}{c}
\hat{\Sigma}^R(r_1, t_1; r_2, t_2) \\
\hat{\Sigma}^K(r_1, t_1; r_2, t_2)
\end{array} \right),
\]

(S19)

We can proceed by formally solving the Dyson’s equation (S13) as,

\[
\hat{G}^R = \left[ [G_0^R]^{-1} - \hat{\Sigma}^R \right]^{-1},
\]

(S20)

\[
\hat{G}^A = \left[ [G_0^A]^{-1} - \hat{\Sigma}^A \right]^{-1} = [\hat{G}^R]^\dagger,
\]

(S21)

\[
\hat{G}^K = \hat{G}^R \otimes \hat{\Sigma}^K \otimes \hat{G}^A + (1 + \hat{G}^R \otimes \hat{\Sigma}^R) \hat{G}_0^K (1 + \hat{\Sigma}^A \otimes \hat{G}^A) \\
= \hat{G}^R \otimes \hat{\Sigma}^K \otimes \hat{G}^A + \hat{G}^R \otimes \hat{G}_0^R \otimes \hat{G}_0^K \otimes \hat{G}^A \\
= \hat{G}^R \otimes \hat{\Sigma}^K \otimes \hat{G}^A.
\]

(S22)

In deriving Eq. (S22), we have used Eqs. (S20) and (S21) in the second equality and have used the relation,

\[
\left[ [\hat{G}_0^R]^{-1} \otimes \hat{G}_0^K \otimes [\hat{G}_0^A]^{-1} \right] (k, \omega) = [\hat{G}_0^R]^{-1} (k, \omega) \hat{G}_0^K (k, \omega) [\hat{G}_0^A]^{-1} (k, \omega) = 0,
\]

(S23)

in the third. From Eq. (S22), the lesser Green’s function \( \hat{G}^< \) satisfies,

\[
0 = \left[ \hat{G}^R - \hat{G}^A + \hat{\Sigma}^< \right] - \hat{G}^R \otimes \left[ \hat{\Sigma}^A + \hat{\Sigma}^K \right] \otimes \hat{G}^A \\
\]

\[
= \hat{G}^R \otimes \left[ 1 + \hat{\Sigma}^A \otimes \hat{G}^A \right] - \hat{G}^R \otimes \hat{\Sigma}^R \otimes \hat{G}^A + \hat{\Sigma}^< - \hat{G}^R \otimes \hat{\Sigma}^K \otimes \hat{G}^A \\
= \left[ \hat{G}^R \otimes [\hat{G}_0^R]^{-1} \otimes \hat{G}^A - \hat{G}^R \otimes [\hat{G}_0^R]^{-1} \otimes \hat{G}^A \right] + \left[ \hat{\Sigma}^< - \hat{G}^R \otimes \hat{\Sigma}^K \otimes \hat{G}^A \right] = \hat{G}^< - \hat{G}^R \otimes \hat{\Sigma}^K \otimes \hat{G}^A,
\]

(S24)

or

\[
\hat{G}^< = \hat{G}^R \otimes \hat{\Sigma}^< \otimes \hat{G}^A,
\]

(S25)

where

\[
\hat{\Sigma}^< = \frac{1}{2} [-\hat{\Sigma}^R + \hat{\Sigma}^A + \hat{\Sigma}^K],
\]

(S26)

is the lesser component of the self-energy. We have used Eqs. (S20) and (S21) in obtaining the third equality of Eq. (S24) and \([\hat{G}_0^R]^{-1} = [\hat{G}_0^A]^{-1}\) in the last. This yields,

\[
[\hat{G}^R_0]^{-1} \otimes \hat{G}^< = \hat{\Sigma}^R \otimes \hat{G}^< + \hat{\Sigma}^< \otimes \hat{G}^A,
\]

(S27)

\[
\hat{G}^< \otimes [\hat{G}_0^A]^{-1} = \hat{G}^< \otimes \hat{\Sigma}^A + \hat{G}^R \otimes \hat{\Sigma}^<,
\]

(S28)

giving,

\[
-\hat{G}^R \otimes \hat{G}^< + \hat{G}^< \otimes [\hat{G}_0^A]^{-1} = -\hat{G}^R \otimes \hat{G}^< + \hat{G}^< \otimes \hat{\Sigma}^A + \hat{\Sigma}^< \otimes \hat{G}^A + \hat{G}^R \otimes \hat{\Sigma}^<.
\]

(S29)

Let us obtain the explicit form of Eq. (S29). The two terms on the left-hand side are written as,

\[
[\hat{G}_0^R]^{-1} \otimes \hat{G}^<(r_1, t_1; r_2, t_2) = \left( \begin{array}{c}
\frac{i}{\hbar} \frac{\partial}{\partial t_1} - \left( -\frac{\hbar^2 \nabla^2}{2m_e} + E_e \right) \\
0
\end{array} \right) \hat{G}^<(r_1, t_1; r_2, t_2),
\]

(S30)

\[
[\hat{G}^< \otimes [\hat{G}_0^A]^{-1}] (r_1, t_1; r_2, t_2) = \hat{G}^<(r_1, t_1; r_2, t_2) \left( \begin{array}{c}
\frac{i}{\hbar} \frac{\partial}{\partial t_1} - \left( -\frac{\hbar^2 \nabla^2}{2m_e} + E_e \right) \\
0
\end{array} \right) \hat{G}_0^A(r_1, t_1; r_2, t_2)
\]

(S31)

where the partial derivatives with arrows pointing to the right (left) operates to the quantity on the right (left). In the Wigner representation, Eqs. (S30) and (S31) are expressed as,

\[
[\hat{G}_0^R]^{-1} \otimes \hat{G}^<(k, \omega; r, t)
\]
\[
\hat{\Sigma}_{\text{env}}^{\alpha,\beta} = \begin{pmatrix}
\hat{\Gamma}_b & \hat{\Gamma}_b^\dagger
\end{pmatrix}
\]

FIG. S1: (Color online) Diagrammatic expression \(\hat{\Sigma}_{\text{env}}\). The dashed line represents the bath Green’s function \(\hat{G}_b\) and the cross represents \(\hat{\Gamma}_b\).

\[
\hat{G}(k, \omega; r, t) = \left(\begin{array}{cc}
\frac{\hbar}{2} \vec{\partial} + \hbar \omega - \frac{\hbar^2}{2m} \left(\vec{\nabla} - ik\right)^2 + \frac{E_k}{2} & 0 \\
0 & \frac{\hbar}{2} \vec{\partial} + \hbar \omega + \frac{\hbar^2}{2m} \left(\vec{\nabla} + ik\right)^2 + \frac{E_k}{2}
\end{array}\right) \hat{G}^<(k, \omega; r, t),
\] (S32)

\[
\left[\hat{G}^< \otimes \hat{G}_0^A\right]^{-1}(k, \omega; r, t)
= \hat{G}^<(k, \omega; r, t) \left(\begin{array}{cc}
\frac{\hbar}{2} \vec{\partial} + \hbar \omega - \frac{\hbar^2}{2m} \left(\vec{\nabla} - ik\right)^2 + \frac{E_k}{2} & 0 \\
0 & \frac{\hbar}{2} \vec{\partial} + \hbar \omega + \frac{\hbar^2}{2m} \left(\vec{\nabla} + ik\right)^2 + \frac{E_k}{2}
\end{array}\right)
\] (S33)

Integrating both sides of Eq. (S29) over \(\omega\), we obtain the generalized Boltzmann equation,

\[
\frac{\hbar}{2m} \vec{\partial} n_{k,e}(r, t) + v_{k,e} \cdot \nabla n_{k,e}(r, t) = \frac{\hbar}{2m} \vec{\partial} p_k(r, t) + \frac{i}{\hbar} (\epsilon_{k,e} + \epsilon_{k,h} - \frac{\hbar^2v^2}{2m_{eh}}) p_k(r, t) - \frac{\hbar}{m_{eh}} \nabla n_{k,h}(r, t) - v_{k,h} \cdot \nabla n_{k,h}(r, t)
\] (S34)

where \(2m_{eh}^{-1} = m_e^{-1} + m_h^{-1}\) is twice the reduced mass. The right-hand side can be interpreted as the collision term.

To show that the coupling to the bath induces dephasing and decay, we separate the self-energy into two terms,

\[
\hat{\Sigma} = \hat{\Sigma}_{\text{env}} + \hat{\Sigma}_{\text{int}},
\] (S35)

where the first term \(\hat{\Sigma}_{\text{env}}\) describes the effects from the system-bath coupling and the second term \(\hat{\Sigma}_{\text{int}}\) describes the many-body interaction effects. We note that, unlike in the conventional Boltzmann equation, the collision term depends explicitly on time and space.

The diagrammatic expression of \(\hat{\Sigma}_{\text{env}}\) is shown in Fig. S1 where its explicit form is given by,

\[
\hat{\Sigma}_{\text{env}}^R(k, \omega; r, t) = \hat{\Sigma}_{\text{env}}^R = N_i \sum_P \hat{\Gamma}_b^\dagger \hat{B}_b^R(P, \omega) \hat{\Gamma}_b = \begin{pmatrix}
-i\gamma_e & 0 \\
0 & -i\gamma_h
\end{pmatrix},
\] (S36)

\[
\hat{\Sigma}_{\text{env}}^A(k, \omega; r, t) = \hat{\Sigma}_{\text{env}}^A = N_i \sum_P \hat{\Gamma}_b^\dagger \hat{B}_b^A(P, \omega) \hat{\Gamma}_b = \begin{pmatrix}
-i\gamma_e & 0 \\
0 & i\gamma_h
\end{pmatrix},
\] (S37)

\[
\hat{\Sigma}_{\text{env}}^K(k, \omega; r, t) = \hat{\Sigma}_{\text{env}}^K(\omega) = N_i \sum_P \hat{\Gamma}_b^\dagger \hat{B}_b^K(P, \omega) \hat{\Gamma}_b = \begin{pmatrix}
2i\epsilon_e[1 - 2f_{b,e}(\omega)] & 0 \\
0 & -2i\gamma_h[1 - 2f_{b,h}(-\omega)]
\end{pmatrix},
\] (S38)

and the lesser component is given by,

\[
\hat{\Sigma}_{\text{env}}^<(\omega) = 2i \begin{pmatrix}
\epsilon_{f,b,e}(\omega) & 0 \\
0 & \gamma_{f,b,h}(-\omega)
\end{pmatrix}.
\] (S39)

Here, \(\hat{\Gamma}_b = \text{diag}(\Gamma_{b,e}, \Gamma_{b,h})\) and

\[
\hat{B}_b^R(k, \omega) = \begin{pmatrix}
\hbar \omega + i\delta - \epsilon_{k,e}^b & 0 \\
0 & \hbar \omega + i\delta + \epsilon_{k,h}^b
\end{pmatrix}^{-1},
\] (S40)

\[
\hat{B}_b^A(k, \omega) = \begin{pmatrix}
\hbar \omega - i\delta - \epsilon_{k,e}^b & 0 \\
0 & \hbar \omega - i\delta + \epsilon_{k,h}^b
\end{pmatrix}^{-1},
\] (S41)

\[
\hat{B}_b^K(k, \omega) = \begin{pmatrix}
-2\pi i[1 - 2f_{b,e}(\omega)]\delta(\hbar \omega - \epsilon_{k,e}^b) & 0 \\
0 & 2\pi i[1 - 2f_{b,h}(-\omega)]\delta(\hbar \omega + \epsilon_{k,h}^b)
\end{pmatrix},
\] (S42)
is the electron-hole single-particle Green’s function in the bath. In the derivation, we have assumed that the bath is white \(\rho_{e,c}(h) = i \sum_{P} \rho_{c}^{R}(h) |P\rangle \langle P| = \text{const.}\) and used the definition of \(\gamma_c\) given by Eq. (S5). Since we have assumed that the bath is large compared to the system, the bath Green’s function is unaffected by the system dynamics. From Eqs. (S36)-(S39),

\[
\int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \sum_{\alpha} \langle k, \omega | \hat{G}_{\alpha}^{<} + \hat{G}_{\alpha}^{c} \otimes \hat{\Sigma}_{\text{env}}^{<} - \hat{\Sigma}_{\text{env}}^{<} \otimes \hat{G}_{\alpha}^{c} + \hat{G}_{\alpha}^{R} \otimes \hat{\Sigma}_{\text{env}}^{<} \rangle (k, \omega; r, t) \]

\[
= -\frac{1}{\hbar} \left( 2 \gamma_c n_{k,c}(r, t) - n_{k,c}^{\text{env}}(r, t) \right) \left[ 2 \gamma \left[ p_{k}(r, t) - p_{k}^{\text{env}}(r, t) \right] - 2 \gamma \left[ n_{k,h}(r, t) - n_{k,h}^{\text{env}}(r, t) \right] \right)
\]

(S43)

where \(\gamma = (\gamma_c + \gamma_h)/2\) and

\[n_{k,c}^{\text{env}}(r, t) = \frac{\hbar}{2 \gamma_c} \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \left[ -\hat{\Sigma}_{\text{env}}^{<} \otimes \hat{G}_{c}^{c} + \hat{G}_{c}^{R} \otimes \hat{\Sigma}_{\text{env}}^{<} \right]_{11} (k, \omega; r, t),\]

(S44)

\[1 - n_{k,h}^{\text{env}}(r, t) = \frac{\hbar}{2 \gamma_h} \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \left[ -\hat{\Sigma}_{\text{env}}^{<} \otimes \hat{G}_{h}^{c} + \hat{G}_{h}^{R} \otimes \hat{\Sigma}_{\text{env}}^{<} \right]_{22} (k, \omega; r, t),\]

(S45)

\[p_{k}^{\text{env}}(r, t) = \frac{\hbar}{2 \gamma_h} \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \left[ -\hat{\Sigma}_{\text{env}}^{<} \otimes \hat{G}_{c}^{c} + \hat{G}_{c}^{R} \otimes \hat{\Sigma}_{\text{env}}^{<} \right]_{12} (k, \omega; r, t).\]

(S46)

This gives

\[\partial_t p_{k}(r, t) = -\frac{i}{\hbar} \left( \varepsilon_{k,c} + \varepsilon_{k,h} - \frac{\hbar^2 \nabla^2}{4m_{\text{eh}}} - 2i \gamma \right) p_{k}(r, t) + I_{k}^{\text{pol}}(r, t),\]

(S47)

\[\partial_t n_{k,c} = n_{k,c}^{\text{env}}(r, t) \cdot \nabla n_{k,c} = n_{k,c}(r, t) = -\frac{2 \gamma_c}{\hbar} n_{k,c}^{\text{env}}(r, t) + I_{k}^{\text{pol}}(r, t),\]

(S48)

where \(v_{k,\sigma} = \hbar k / m_{\sigma}\), and

\[I_{k,c}(r, t) = \frac{2 \gamma_c}{\hbar} n_{k,c}^{\text{env}}(r, t) + \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \left[ -\hat{\Sigma}_{\text{int}}^{<} \otimes \hat{G}_{c}^{c} + \hat{G}_{c}^{R} \otimes \hat{\Sigma}_{\text{int}}^{<} - \hat{\Sigma}_{\text{int}}^{<} \otimes \hat{G}_{c}^{c} + \hat{G}_{c}^{R} \otimes \hat{\Sigma}_{\text{int}}^{<} \right]_{11} (k, \omega; r, t),\]

(S49)

\[I_{k,h}(r, t) = \frac{2 \gamma_h}{\hbar} n_{k,h}^{\text{env}}(r, t) - \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \left[ -\hat{\Sigma}_{\text{int}}^{<} \otimes \hat{G}_{h}^{c} + \hat{G}_{h}^{R} \otimes \hat{\Sigma}_{\text{int}}^{<} - \hat{\Sigma}_{\text{int}}^{<} \otimes \hat{G}_{h}^{c} + \hat{G}_{h}^{R} \otimes \hat{\Sigma}_{\text{int}}^{<} \right]_{22} (k, \omega; r, t),\]

(S50)

\[I_{k}^{\text{pol}}(r, t) = \frac{2 \gamma_h}{\hbar} p_{k}^{\text{env}}(r, t) + \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \left[ -\hat{\Sigma}_{\text{int}}^{<} \otimes \hat{G}_{c}^{c} + \hat{G}_{c}^{R} \otimes \hat{\Sigma}_{\text{int}}^{<} - \hat{\Sigma}_{\text{int}}^{<} \otimes \hat{G}_{c}^{c} + \hat{G}_{c}^{R} \otimes \hat{\Sigma}_{\text{int}}^{<} \right]_{12} (k, \omega; r, t).\]

(S51)

Equation (S18) is the desired Boltzmann equation (2) for \(n_{k,\sigma}(r, t)\).

We finally note that, the term \(I_{k}^{\text{pol}}(r, t)\) in Eq. (S17) should vanish in the normal phase, since \(p_{k}(r, t) = \lambda_{\text{cav}}(r, t) = 0\) in this phase. The condensed phase is characterized by the order parameter (See Refs. [1,4] and the later discussion for the analysis within the Hartree-Fock-Bogoliubov approximation as an example.),

\[\Delta_{k}(r, t) = \sum_{k'} V_{k-k'} p_{k'}(r, t) - g \lambda_{\text{cav}}(r, t).\]

(S52)

Since \(\Delta_{k}(r, t) = 0\) in the normal phase, \(I_{k}^{\text{pol}}(r, t)\) can be written in the form,

\[I_{k}^{\text{pol}}(r, t) = \frac{i}{\hbar} \sum_{k'} L_{k,k'}(r, t) \Delta_{k'}(r, t),\]

(S53)

which gives our final form of the Boltzmann equation for \(p_{k}(r, t)\) [Eq. (2) in the main text].

The other piece of interest is the dynamics of the photon amplitude \(\lambda_{\text{cav}}(r, t) = \langle a(r, t) \rangle\), given by Eq. (3) in the main text. The Heisenberg equation of the photon annihilation operator \(a(r, t)\) is given by;

\[i \hbar \partial_t a(r, t) = \{a(r, t), H\} = \left( \hbar \omega_{\text{cav}} - \frac{\hbar^2 \nabla^2}{2m_{\text{cav}}} \right) a(r, t) + g \sum_{k,q} c_{k+q/2,\text{cav}}(r, t) c_{k+q/2,\text{cav}}(r+q, t) + \sum_{q,Q} \Gamma_{\nu} \psi_{Q}(t) e^{iQ \cdot R_{t}}.\]

(S54)
Taking the statistical average of Eq. \( \text{S54} \), we get,

\[
 i\hbar \partial_t \lambda_{\text{cav}}(r, t) = \left( \hbar \omega_{\text{cav}} - \frac{\hbar^2 \nabla^2}{2m_{\text{cav}}} \right) \lambda_{\text{cav}}(r, t) + g \sum_k p_k(r, t) + \langle \sum_{q, Q, i} \Gamma_v \psi_Q(t) e^{iq \cdot (r - r_i)} e^{-iQ \cdot R_i} \rangle. \tag{S55}
\]

By applying the Wick’s theorem, as diagrammatically described in Fig. S2 we obtain

\[
 \langle \sum_{q, Q, i} \Gamma_v \psi_Q(t) e^{iq \cdot (r - r_i)} e^{-iQ \cdot R_i} \rangle = N_t |\Gamma_v|^2 \int_{-\infty}^{\infty} dt' \sum_Q \hat{B}^R_v(Q, t - t') \sum_q e^{iq \cdot r} \langle a_q(t') \rangle
 = N_t |\Gamma_v|^2 \int_{-\infty}^{\infty} dt' \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} e^{-i(\omega(t' - t))} \sum_Q \hat{B}^R_v(Q, \omega) \sum_q e^{iq \cdot r} \langle a_q(t') \rangle = -i\kappa \int_{-\infty}^{\infty} dt' \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} e^{-i(\omega(t' - t))} \sum_q e^{iq \cdot r} \langle a_q(t') \rangle
 = -i\kappa \lambda_{\text{cav}}(r, t), \tag{S56}
\]

where \( \hat{B}^R_v(Q, \omega) = [i\hbar \omega - \epsilon_Q + i\delta]^{-1} \) is the vacuum photon Green’s function, and a white noise vacuum is assumed, i.e., \( \rho = \sum_Q \hat{B}^R_v(Q, \omega)/\pi = \text{const.} \) and the photon decay rate \( \kappa \) is defined in Eq. \( \text{S4} \). This yields the desired Heisenberg equation [Eq. (3) in the main text],

\[
 i\hbar \partial_t \lambda_{\text{cav}}(r, t) = \left[ \hbar \omega_{\text{cav}} - \frac{\hbar^2 \nabla^2}{2m_{\text{cav}}} - i\kappa \right] \lambda_{\text{cav}}(r, t) + g \sum_k p_k(r, t). \tag{S57}
\]

**TWO TYPES OF STEADY STATE SOLUTION**

As discussed in the main text, the equation of motion of the coherent photon amplitude \( \lambda_{\text{cav}}(r, t) = \lambda_0^0 e^{-iEt/\hbar} \) [Eq. (1) in the main text] and the electron-hole dipole polarization \( p_k = \lambda_{\text{eh}}^k \phi_k e^{-iEt/\hbar} \) [Eq. (2) in the main text] in the steady state fulfills [Eq. (4) in the main text],

\[
 \hat{A} \begin{pmatrix} \lambda_0^0 \\ \lambda_{\text{eh}}^0 \\
 \end{pmatrix} = \begin{pmatrix} \hbar \lambda_0^0 g_0 \\ \hbar \lambda_{\text{eh}}^0 \\
 \end{pmatrix} \begin{pmatrix} \lambda_0^0 \\ \lambda_{\text{eh}}^0 \\
 \end{pmatrix} = E \begin{pmatrix} \lambda_0^0 \\ \lambda_{\text{eh}}^0 \\
 \end{pmatrix}, \tag{S58}
\]

where \( \hbar \omega_{\text{cav}} = -i\kappa, g_0 = g \sum_k \phi_k = g \phi(\rho = 0), \)

\[
 \bar{g}_0 = g \sum_{k,k'} \phi_k^* L_{k,k'}, \quad \text{and} \quad \hbar \lambda_{\text{eh}} = \sum_k (\epsilon_{k,e} + \epsilon_{k,h} - 2i\gamma) |\phi_k|^2 - \sum_{p,k'} V_{k-p} \phi_p^* \phi_p L_{k,k'}. \]

Due to the driven-dissipative nature of the condensate, the matrix \( \hat{A} \) is non-Hermitian, which plays a central role on the occurrence of the phase transition, as mentioned in the main text and discussed in detail later in this Supplemental Material. The matrix \( \hat{A} \) can be diagonalized with the eigenvectors

\[
 u_- = \begin{pmatrix} \frac{-z + \Omega}{2} \\ \frac{-z - \Omega}{2} \\
 \end{pmatrix}, \quad u_+ = \begin{pmatrix} g_0 \\ \frac{z + \Omega}{2} \\
 \end{pmatrix}, \tag{S59}
\]

that satisfies

\[
 \hat{A} u_{\pm} = E_{\pm} u_{\pm}, \tag{S60}
\]

with eigenvalues

\[
 E_{\pm} = [\hbar \omega_{\text{cav}} + h_{\text{eh}} \pm \Omega]/2. \tag{S61}
\]

Here,

\[
 \Omega = \sqrt{\varphi^2 + 4\bar{g}_0 g_0}, \tag{S62}
\]

with \( \varphi = h_{\text{cav}} - h_{\text{eh}} \) where we have assumed \( \text{Re}\Omega \geq 0, \) or \( \text{Re}E_+ \geq \text{Re}E_-, \) without losing generality. In the diagonal basis, Eq. \( \text{S58} \) is transformed to [Eq. (5) in the main text],

\[
 \begin{pmatrix} E_- & 0 \\ 0 & E_+ \end{pmatrix} \begin{pmatrix} \lambda_0^0 \\ \lambda_{\text{eh}}^0 \end{pmatrix} = E \begin{pmatrix} \lambda_0^0 \\ \lambda_{\text{eh}}^0 \end{pmatrix}, \tag{S63}
\]

with

\[
 \begin{pmatrix} \lambda_0^0 \\ \lambda_{\text{eh}}^0 \end{pmatrix} = \hat{U} \begin{pmatrix} \lambda_0^0 \\ \lambda_{\text{eh}}^0 \end{pmatrix}, \tag{S64}
\]

where \( \hat{U}^{-1} = (u_-, u_+)^T \) or

\[
 \hat{U} = \frac{2}{\Omega(\Omega - \varphi)} \begin{pmatrix} \frac{-z + \Omega}{2} & -g_0 \\ \frac{-z - \Omega}{2} & -\bar{g}_0 \end{pmatrix}. \tag{S65}
\]
Here, we show that the steady state solution satisfying Eq. (S53) can be classified into two types. One type satisfies $\lambda_0^0 \neq 0$ and $E = E_-$ ("-" solution). In this case, $\lambda_0^0 = 0$ is automatically satisfied since
\[
\lambda_+^0 \propto g_0^* \lambda_{\text{cav}} + h_{\text{eh}} \lambda_{\text{eh}}^0 + E \lambda_{\text{eh}}^0 = 0,
\] (S66)
where we have used the relation $h_{\text{cav}} + h_{\text{eh}} - 2E = \Omega$ and the second line of Eq. (S55). The other type, "+"-solution, is a solution with $\lambda_0^0 \neq 0$ and $E = E_+$. Similarly to the former case, from $h_{\text{cav}} + h_{\text{eh}} - 2E = -\Omega$ and the first line of Eq. (S53), we find
\[
\lambda_0^0 \propto -h_{\text{cav}} \lambda_{\text{cav}}^0 - g_0 \lambda_{\text{eh}}^0 + E \lambda_{\text{cav}}^0 = 0.
\] (S67)
Thus, $\lambda_0^0 \neq 0$ and $\lambda_0^0 \neq 0$ cannot be satisfied simultaneously, letting us classify the solutions into two types.

**HARTREE-FOCK-BOGOLIUBOV APPROXIMATION**

We show here that Eqs. (1)-(3) reduces to the conventional polariton (condensate) picture, by showing within the Hartree-Fock-Bogoliubov approximation (HFBA) [1–4] that the matrix $\hat{\Lambda}$ is given by [Eq. (7) ($\kappa = 0, \gamma \rightarrow 0^+, n_{k, \sigma} \ll 1$) in the main text],
\[
\hat{\Lambda}_{\text{BEC}} = \begin{pmatrix} \hbar \omega_{\text{cav}} g_R & g_0 \\ g_0^* & \hbar \omega_{X} \end{pmatrix},
\] (S68)
in the dilute equilibrium limit. We briefly note that the matrix $\hat{\Lambda}$ Eq. (S68) is Hermitian in this limit. The interaction part of the self-energy $\Sigma_{\text{int}}$ within this approximation is given by,
\[
\Sigma_{\text{HFB}}(k, \omega; r, t) = -\begin{pmatrix} 0 & \Delta_k(r, t) \\ -\Delta_k^*(r, t) & 0 \end{pmatrix},
\] (S69)
\[
\Sigma_{\text{HFB}}^0(k, \omega; r, t) = -\begin{pmatrix} 0 & \Delta_k^0(r, t) \\ -\Delta_k^0(r, t) & 0 \end{pmatrix},
\] (S70)
\[
\Sigma_{\text{HFB}}^0(k, \omega; r, t) = \Delta_{\text{HFB}}(k, \omega; r, t) = 0.
\] (S71)

We refer to Refs. [1–4] for the derivation. This yields,
\[
I_{k, c}(r, t) = \frac{2\gamma_0}{\hbar} n_{k, c}^{\text{env}}(r, t) - 2\text{Im}[\Delta_k p_k^0],
\] (S72)
\[
I_{k, h}(r, t) = \frac{2\gamma_0}{\hbar} n_{k, h}^{\text{env}}(r, t) - 2\text{Im}[\Delta_k p_k^0],
\] (S73)
\[
I_{k}^{\text{pol}}(r, t) = \frac{1}{\hbar}[2\gamma_0 p_k^{\text{env}}(r, t) + i\Delta_k(r, t) N_k(r, t)],
\] (S74)
where $N_k(r, t) = 1 - n_{k, c}(r, t) - n_{k, h}(r, t)$ is the population inversion.

In the dilute equilibrium limit ($\kappa = 0, \gamma \rightarrow 0^+, N_k \approx 1$) in the steady state, the term $I_{k}^{\text{pol}}(r, t)$ simplifies to,
\[
I_{k}^{\text{pol}}(r, t) = \frac{i}{\hbar} \Delta_k(r, t)
\]
\[
= \frac{i}{\hbar} \left[ \sum_{k'} V_{k-k'} \phi_{k'}^0 - g \lambda_{\text{cav}}^0 \right] e^{-iEt/\hbar},
\] (S75)
which gives $I_{k, k'}^{\text{eq.dil}} = \delta_{k, k'}$. In this case, from Eq. (S71),
\[
\left( \frac{\hbar^2 k^2}{m_{\text{eh}}} + (E_g - E) \right) \lambda_{\text{eh}}^0 \phi_k = \sum_{k'} V_{k-k'} \phi_{k'} \lambda_{\text{eh}}^0 - g \lambda_{\text{cav}}^0.
\] (S76)

For simplicity, let us assume that
\[
\sum_{k'} V_{k-k'} \lambda_{\text{eh}}^0 \phi_{k'} \gg g \lambda_{\text{cav}}^0.
\] (S77)

This assumption implies $g_R \ll E_{X}^{\text{bind}}$ (where $g_R$ and $E_{X}^{\text{bind}}$ are the Rabi splitting and the exciton binding energy, respectively), as shown soon later. In this situation, Eq. (S76) reduces to the Schrödinger equation of an exciton,
\[
\frac{\hbar^2 k^2}{m_{\text{eh}}} \phi_k^X = \sum_{p} V_{k-k'} \phi_k^X = -E_{X}^{\text{bind}} \phi_k^X,
\] (S78)
or
\[
\int dr' \left[ \delta(r - r') \frac{\hbar^2 \nabla^2}{m_{\text{eh}}} - V(r - r') \right] \phi_X(r') = -E_{X}^{\text{bind}} \phi_X(r),
\] (S79)
where $\phi_k = \phi_X$ is the dilute exciton wave function. Here, note that
\[
|E_g - E| - E_{X}^{\text{bind}} \ll E_{X}^{\text{bind}},
\] (S80)
needs to be satisfied for Eqs. (S76) and (S78) to be compatible under the assumption (S77). As a result, the off-diagonal components in the matrix
\[
\hat{\Lambda} = \begin{pmatrix} \hbar \omega_{\text{cav}} g_0 & g_0 \\ g_0^* & \hbar \omega_{X} \end{pmatrix},
\] (S81)
reduces to the Rabi splitting $g_R$,
\[
g_0 \approx g_0 \approx g \phi_X(r = 0) = g_R,
\] (S82)
and
\[
\hbar_{\text{eh}}^{\text{eq.dil}} \approx \sum_{k} \left[ \left( \frac{\hbar^2 k^2}{m_{\text{eh}}} + E_g \right) |\phi_k^X|^2 - \sum_{k'} V_{k-k'} |\phi_k^X|^2 \phi_{k'}^X \right],
\]
\[
= \sum_{k} \left[ \left( \frac{\hbar^2 k^2}{m_{\text{eh}}} \phi_k^X - \sum_{k'} V_{k-k'} \phi_k^X \phi_{k'}^X \right) \phi_{k'}^X + E_g \right]
\]
\[
= -E_{X}^{\text{bind}} \sum_{k} |\phi_k^X|^2 + E_g = E_g - E_{X}^{\text{bind}} = \hbar \omega_{X},
\] (S83)
which yields the desired Eq. (7). Since $|E_g - E| - E_{X}^{\text{bind}} = |E_g - E_\pm| - E_{X}^{\text{bind}} \sim g_R$ unless the system is not in an extreme red or blue detuning, from Eq. (S80), our assumption (S77) is satisfied at $g_R \ll E_{X}^{\text{bind}}$. 
DRIVEN-DISSIPATIVE GROSS-PITAEVSKII EQUATION (8)

Let us turn to the polariton laser regime, where the nonequilibrium condensate is dilute enough such that the polariton picture still holds, and show that the matrix $\hat{A}$ in this regime is given by \[8\] (Eq. (8) in the main text),

$$\hat{A}_{\text{GP}} = \left( \begin{array}{cc} \hbar \omega_{\text{cav}} - i \kappa & g_R \sqrt{g_{\text{R}}} \\ g_R^* & \hbar \omega_X + U_X |\phi_{\text{ch}}|^2 + i R_X \end{array} \right). \tag{S84}$$

In this regime, $\Delta L_{k,k'} = L_{k,k'} - L_{k,k'}^{\text{eq,dil}}$ that characterizes the derivation from the dilute equilibrium is small ($|\Delta L_{k,k'}| \ll 1$). In this case, under the assumption \[S77\], we may approximate $\phi_k$ as $\phi_k \simeq \phi_k^X$ giving $g_0 \simeq g_R$ and

$$E_{\text{ch}}^0 = g_0^* \lambda_{\text{cav}}^0 + h_{\text{cav}} \lambda_{\text{ch}}^0 \\
\simeq g_R \lambda_{\text{cav}}^0 + (\hbar \omega_X - \sum_{k,k',p} V_{k-k',p} \phi_k^0 \phi_p^0 \Delta L_{k,k'}) \lambda_{\text{ch}}^0 \\
\equiv g_R \lambda_{\text{cav}}^0 + (\hbar \omega_X + \Delta U + i R_X) \lambda_{\text{ch}}^0. \tag{S85}$$

Here, $\Delta U$ and $R_X$ physically describe the blue shift of the exciton spectrum and the exciton gain, respectively. Expanding $\Delta U$ in terms of $|\lambda_{\text{ch}}^0|^2$ and neglecting the blue shift from the non-coherent part,

$$\Delta U \simeq U_X |\lambda_{\text{ch}}^0|^2, \tag{S86}$$

we obtain the desired matrix $\hat{A}_{\text{GP}}$ of the driven-dissipative Gross-Pitaevskii equation (8).

PROOF OF THE EXISTENCE OF A PHASE BOUNDARY WITH AN END POINT

Here, we prove the result in the main text: Whenever an exceptional point (EP) $\Omega = 0$ of the matrix $\hat{A}$, where the two eigenvectors $u_{\pm}$ and eigenvalues $E_{\pm}$ coalesce, is found, there exists a phase boundary in its vicinity that ends at that point. We emphasize that the existence of EP is crucially due to the non-Hermitian nature of matrix $\hat{A}$, since a Hermitian matrix always has orthogonal eigenvectors, two of which may never coalesce. We briefly note that, in the proof below, we assume implicitly that the matrix $\hat{A}$ is a smooth function of the input parameters and has maximum of one solution per solution type.

The central quantity for the proof is a complex splitting parameter,

$$\Lambda = \Omega^2 = \varphi^2 + 4\delta_0^* g_0 \tag{S87}$$

which is directly related to the difference between the two eigenvalues $E_{\pm}$ given by Eq. \[S64\]. As depicted in Fig. \[S3\]a), we divide $\Lambda$ into regions I-IV in terms of the sign of the imaginary part of $\Lambda$ and whether the system is in the weak- (strong-) coupling regime, i.e., $\delta^2 + 4 \text{Re}[\delta_0^* g_0] < 4 \kappa^2 (\geq 4 \kappa^2)$, where $\delta = \text{Re} \varphi$. As shown soon below, EP satisfies $\delta^2 + 4 \text{Re}[\delta_0^* g_0] = 4 \kappa^2$ and at least in the vicinity of $\text{Im} \Lambda = 0$, the weak- (strong-) coupling regime lies at $\text{Re} \Lambda < 0 (\geq 0)$.

We prove the above theorem by showing that the matrix $\Lambda$ satisfies the following three properties:

1. Only the “+(-)”-solution can arise in region II (III).

2. Sweeping $\Lambda$ from region III to II across the dotted line in Fig. \[S3\]a) ($\text{Re} \Lambda < 0$ and $\text{Im} \Lambda = 0$) changes the solution type from “−” to “+” without discontinuity in the emission energy $E$, resulting in a smooth crossover.

3. In contrast, when sweeping parameters in a route where $\Lambda$ encircles the EP as III → IV → I → II, there must exist a point where the solution type switches discontinuously, resulting in a phase transition.

From the assumption that $\hat{A}$ is a smooth function of the input parameters, these properties result in a phase boundary that ends at the EP, proving the theorem.

Let us first prove the property 1. The “−” and “+”-solutions satisfy

$$0 = E_- - E = \frac{1}{2} [2 \xi - i (\kappa - R_{\text{ch}}) - \Omega], \tag{S88}$$

$$0 = E_+ - E = \frac{1}{2} [2 \xi - i (\kappa - R_{\text{ch}}) + \Omega], \tag{S89}$$

respectively, where

$$\xi = \frac{1}{2} [\text{Re}[h_{\text{cav}}] + \text{Re}[h_{\text{ch}}]] - E, \tag{S90}$$

$$R_{\text{ch}} = \text{Im} h_{\text{ch}}, \tag{S91}$$

and

$$\Omega = \sqrt{\Lambda} = \sqrt{\delta^2 - (\kappa + R_{\text{ch}})^2 + 4 \text{Re}[\delta_0^* g_0] - 2 i [\delta (\kappa + R_{\text{ch}}) - 2 \text{Im}[\delta_0 g_0]]}. \tag{S92}$$
FIG. S3: (Color online) (a) Definition of regions I-IV. In region II (III), only “+(-)”-solution can be realized (property 1). (b) Plot of the real part of $\sqrt{\Lambda}$. The blue solid and the red dashed line represent different Riemann sheets, where the branch cut lies at $\text{Re}\Lambda < 0$ and $\text{Im}\Lambda = 0$ (the dotted line in panel (a)). The Riemann surface depicted in thin green lines is the sheet we do not use, due to the restriction from the property 1.

Since we have taken $\text{Re}\Omega \geq 0$ among the two quantities that $\sqrt{\Lambda}$ takes, from the real part of Eqs. $\text{S88}$ and $\text{S89}$, the “−(+)”-solution has $\xi > 0(\leq 0)$ since we have defined $\text{Re}\Omega \geq 0$.

Equations $\text{S88}$ and $\text{S89}$ both satisfy,

$$[4\xi^2 - (\kappa - R_{eh})^2] - 4i(\kappa - R_{eh})\xi = \Lambda,$$

(S93)

or

$$\xi^2 = \frac{1}{4}[(\kappa - R_{eh})^2 + \text{Re}\Lambda] = \frac{1}{4}[-4\kappa R_{eh} + \delta^2 + 4\text{Re}[\tilde{g}_0^* g_0]],$$

(S94)

$$4(\kappa - R_{eh})\xi = -\text{Im}\Lambda,$$

(S95)

where we have used,

$$\text{Re}\Lambda = \delta^2 + 4\text{Re}[\tilde{g}_0^* g_0] - (\kappa + R_{eh})^2,$$

(S96)

in the second equality of Eq. $\text{S94}$.

Equation $\text{S95}$ gives,

$$\text{sgn}[\kappa - R_{eh}]\text{sgn}[\xi] = -\text{sgn}[\text{Im}\Lambda],$$

(S97)

telling us that the sign of $\text{Im}\Lambda$ affects either the magnitude relation of $\kappa$ and $R_{eh}$, or the solution type determined by the sign of $\xi$.

In the weak-coupling regime (regions II and III) $\delta^2 + 4\text{Re}[\tilde{g}_0^* g_0] < 4\kappa^2$, from Eq. $\text{S94}$,

$$R_{eh} = \frac{1}{4\kappa}[\delta^2 + 4\text{Re}[\tilde{g}_0^* g_0] - 4\xi^2]$$

$$\leq \frac{1}{4\kappa}[\delta^2 + 4\text{Re}[\tilde{g}_0^* g_0]] < \kappa,$$

(S98)

where we have used $\kappa > 0$. As a result, we get

$$\text{sgn}[\xi] = -\text{sgn}[\text{Im}\Lambda],$$

(S99)

proving that only the “−(+)”-solution given by $\xi > 0(\leq 0)$ can be realized in region III (II).

We can now show that the EP satisfies,

$$\delta^2 + 4\text{Re}[\tilde{g}_0^* g_0] = 4\kappa^2,$$

(S100)

as schematically drawn in Fig. $\text{S3(a)}$). This follows from the properties that we get $\xi = 0$ at $\text{Re}\Omega = 0$ and $\kappa = R_{eh}$ at $\text{Im}\Omega = 0$ (which may readily be seen from Eqs. $\text{S88}$ and $\text{S89}$), as well as the property that $\text{Re}\Lambda$ given by Eq. $\text{S96}$ vanishes at the EP ($\Omega = 0$).

We can also show that the weak- (strong)-coupling regime II and III (I and IV), i.e., $\delta^2 + 4\text{Re}[\tilde{g}_0^* g_0] < 4\kappa^2(\geq 4\kappa^2)$, lies at $\text{Re}\Lambda < 0(\geq 0)$, at least in the vicinity of $\text{Im}\Lambda = 0$, as also depicted in Fig. $\text{S3(a)}$: At $\text{Im}\Lambda = 0$ with $\text{Re}\Lambda < 0$, $\text{Re}\Omega = 0$, thus we obtain $\xi = 0$. (See the discussion below Eq. $\text{S100}$.) In this situation, from Eq. $\text{S94}$,

$$0 = -4\kappa R_{eh} + \delta^2 + 4\text{Re}[\tilde{g}_0^* g_0]$$

$$> \delta^2 + 4\text{Re}[\tilde{g}_0^* g_0] - 4\kappa^2.$$

(S101)

Thus, $\text{Im}\Lambda = 0$ with $\text{Re}\Lambda < 0$ is in the weak-coupling regime. On the other hand, when $\text{Im}\Lambda = 0$ with $\text{Re}\Lambda \geq 0$ giving $\text{Im}\Omega = 0$, the state is in the strong-coupling regime, because it satisfies $\kappa = R_{eh}$ and thus from Eq. $\text{S96}$,

$$0 \leq \text{Re}\Lambda = \delta^2 + 4\text{Re}[\tilde{g}_0^* g_0] - 4\kappa^2.$$

(S102)

We next show the properties 2 and 3. These properties can be understood from the plot of $\sqrt{\Lambda}$, depicted in Fig. $\text{S3(b)}$. As seen in the figure, $\sqrt{\Lambda}$ is in general a two-valued quantity, consisting of two Riemann sheets (i.e.,
the sheets drawn with blue solid lines and red dashed lines). Noting our definition that \(\text{Re}E_+ \geq \text{Re}E_-\), or \(\text{Re}\Omega \geq 0\), it can be seen from Eq. (S61) that the Riemann sheet with \(\text{Re}[\sqrt{\Lambda}] < 0(\geq 0)\), depicted with blue solid lines (red dashed lines) in Fig. S3(b), is used in computing the emission energy \(E\) of the “−(+)”-solution.

From the restriction of the solution types in regions II and III (property 1), we can ignore the Riemann sheet depicted with thin green lines in Fig. S3(b). Since the two Riemann sheets that are used for “−” and “+”-solutions are connected at the boundary between regions II and III (i.e., the dotted line in Fig. S3(a)), the solution types can switch continuously by passing through that boundary, proving the property 2. Conversely, since that boundary is the only place that connects the two Riemann sheets, it is otherwise associated with exhibiting a discontinuity in physical quantities. This proves the property 3, and therefore the theorem.
