key-words: congruent number elliptic curves, integral Pythagorean triples

2010 Mathematics Subject Classification: 11G05 11D09

Abstract
We give an infinite family of congruent number elliptic curves, each with rank at least two, which are related to integral solutions of \( m^2 = n^2 + nl + l^2 \).

1 Introduction
Elliptic curves and their geometric and algebraic structure have been a flourishing field of research in the past. They find prominent applications in cryptography and played a key role in the proof of Fermat’s Last Theorem. A salient feature of the algebraic structure of an elliptic curve is its rank. Among general elliptic curves, congruent number curves of high rank are of particular interest (see, e.g., [3]). More difficult than finding an individual congruent number curve of high rank is to find infinite families of such curves. Johnstone and Spearman [8] constructed such a family with rank at least three which is related to rational points on the biquadratic curve \( w^2 = t^4 + 14t^2 + 4 \). In the present paper, we show an elementary construction for an infinite family of congruent number curves of rank at least two which are related to the quadratic diophantine equation \( m^2 = n^2 + nl + l^2 \), and which have three integral points with positive \( y \)-coordinate on a straight line. Incidentally, some members of the family exhibit surprisingly high individual rank. We start by fixing the notions and notations used throughout the text.

A positive integer \( A \) is called a **congruent number** if \( A \) is the area of a right-angled triangle with three rational sides. So, \( A \) is congruent if and only if there exists a rational Pythagorean triple \( (a, b, c) \) (i.e., \( a, b, c \in \mathbb{Q}, a^2 + b^2 = c^2 \), and \( ab \neq 0 \)), such that \( \frac{ab}{2} = A \). The sequence of integer congruent numbers starts with

\[
5, 6, 7, 13, 14, 15, 20, 21, 22, 23, 24, 28, 29, 30, 31, 34, 37, \ldots
\]

(see, e.g., the On-Line Encyclopedia of Integer Sequences [11]). For example, \( A = 7 \) is a congruent number, witnessed by the rational Pythagorean triple

\[
\left( \frac{24}{5}, \frac{35}{12}, \frac{337}{60} \right).
\]
It is well-known that \( A \) is a congruent number if and only if the cubic curve
\[ C_A : y^2 = x^3 - A^2x \]
has a rational point \((x_0, y_0)\) with \( y_0 \neq 0 \). The cubic curve \( C_A \) is called a **congruent number elliptic curve** or just **congruent number curve**. This correspondence between rational points on congruent number curves and rational Pythagorean triples can be made explicit as follows: Let
\[ C(Q) := \{(x, y, A) \in Q \times Q^* \times Z^* : y^2 = x^3 - A^2x\}, \]
where \( Q^* := Q \setminus \{0\} \), \( Z^* := Z \setminus \{0\} \), and
\[ P(Q) := \{(a, b, c, A) \in Q^3 \times Z^* : a^2 + b^2 = c^2 \text{ and } ab = 2A\}. \]
Then, it is easy to check that
\[
\psi : P(Q) \to C(Q) \quad \quad \quad (1)
\]
is bijective and
\[
\psi^{-1} : C(Q) \to P(Q) \quad \quad \quad (2)
\]
For positive integers \( A \), a triple \((a, b, c)\) of non-zero rational numbers is called a **rational Pythagorean \( A \)-triple** if \( a^2 + b^2 = c^2 \) and \( A = \frac{ab}{2} \). Notice that if \((a, b, c)\) is a rational Pythagorean \( A \)-triple, then \( A \) is a congruent number and \(|a|, |b|, |c|\) are the lengths of the sides of a right-angled triangle with area \( A \). Notice also that we allow \( a, b, c \) to be negative.

If \( a, b, c \) are positive integers such that \( a^2 + b^2 = c^2 \) and \( A = \frac{ab}{2} \) is integral, then the triple \((a, b, c)\) is a called a **Pythagorean \( A \)-triple**. For any positive integers \( m \) and \( n \) with \( m > n \), the triple
\[
\left( \frac{2mn}{a}, \frac{m^2 - n^2}{b}, \frac{m^2 + n^2}{c} \right)
\]
is a Pythagorean \( A \)-triple. In this case, we obtain \( A = mn(m^2 - n^2) \) and
\[
\psi(a, b, c, A) = \left( \frac{m^2(m^2 - n^2)}{x}, \frac{m^2(m^2 - n^2)}{y}, A \right). \quad (3)
\]
In particular, the point \((x, y)\) on \( C_A \) which corresponds to the Pythagorean \( A \)-triple \((a, b, c)\) is an integral point.

Concerning the equation
\[ m^2 = n^2 + nl + l^2, \]
we would like to mention the following fact (see Dickson [2, Exercises XXII.2, p. 80] or Cox [1, Chapter 1]):
Fact 1. Let \( p_1 < p_2 < \ldots < p_j \) be primes, such that \( p_i \equiv 1 \mod 6 \) for \( 1 \leq i \leq j \), and let

\[
m = \prod_{i=1}^{j} p_i.
\]

Then the number of positive, integral solutions \( l < n \) of

\[
m = n^2 + nl + l^2
\]

is \( 2^{j-1} \). By definition of \( m \), for each integral solution of \( m = n^2 + nl + l^2 \), \( n \) and \( l \) are relatively prime, denoted \((n, l) = 1\).

Moreover, the number of positive, integral solutions \( l < n \) of

\[
m^2 = n^2 + nl + l^2
\]

is \( \frac{3^j - 1}{2} \). Among the \( \frac{3^j - 1}{2} \) integral solutions \( l < n \) of \( m^2 = n^2 + nl + l^2 \) we find \( 2^{j+1} \) solutions with \((n, l) = 1\). In particular, if \( j = 1 \) and \( p \equiv 1 \mod 6 \), then the solution in positive integers \( n < l \) of

\[
p^2 = n^2 + nl + l^2
\]

is unique and \((n, l) = 1\).

For a geometric representation of integral solutions of \( x^2 + xy + y^2 = m^2 \), see Halbeisen and Hungerbühler [5].

If \( m, n, l \) are positive integers such that \( m^2 = n^2 + nl + l^2 \), then, for \( k := n + l \), each of the following three triples

\[
\left( \frac{2mn}{a_1}, \frac{m^2 - n^2}{b_1}, \frac{m^2 + n^2}{c_1} \right),
\]

\[
\left( \frac{2ml}{a_2}, \frac{m^2 - l^2}{b_2}, \frac{m^2 + l^2}{c_2} \right),
\]

\[
\left( \frac{2mk}{a_3}, \frac{k^2 - m^2}{b_3}, \frac{k^2 + m^2}{c_3} \right),
\]

is a Pythagorean \( A \)-triple for \( A = mn(m^2 - n^2) = ml(m^2 - l^2) = km(k^2 - m^2) \) (see Hungerbühler [7]). In particular, with \( m, n, l \) and (3) we obtain three distinct integral points on \( C_A \).

Let us now turn back to the curve \( C_A \). It is convenient to consider the curve \( C_A \) in the projective plane \( \mathbb{RP}^2 \), where the curve is given by

\[
C_A : y^2z = x^3 - A^2xz^2.
\]

On the points of \( C_A \), one can define a commutative, binary, associative operation “\( + \)”, where \( \mathcal{O} \), the neutral element of the operation, is the projective point \((0, 1, 0)\) at infinity. More formally, if \( P \) and \( Q \) are two points on \( C_A \), then let \( P \# Q \) be the third intersection
point of the line through \( P \) and \( Q \) with the curve \( C_A \). If \( P = Q \), the line through \( P \) and \( Q \) is replaced with the tangent in \( P \). Then \( P + Q \) is defined by stipulating
\[
P + Q := \mathcal{O}^\#(P \# Q),
\]
where for a point \( R \) on \( C_A \), \( \mathcal{O}^\# R \) is the point reflected across the \( x \)-axis. The following figure shows the congruent number curve \( C_A \) for \( A = 5 \), together with two points \( P \) and \( Q \) and their sum \( P + Q \).

More explicitly, for two points \( P = (x_0, y_0) \) and \( Q = (x_1, y_1) \) on a congruent number curve \( C_A \), the point \( P + Q = (x_2, y_2) \) is given by the following formulas:

- If \( x_0 \neq x_1 \), then
  \[
x_2 = \lambda^2 - x_0 - x_1, \quad y_2 = \lambda(x_0 - x_2) - y_0,
\]
  where
  \[
  \lambda := \frac{y_1 - y_0}{x_1 - x_0}.
\]

- If \( P = Q \), i.e., \( x_0 = x_1 \) and \( y_0 = y_1 \), then
  \[
x_2 = \lambda^2 - 2x_0, \quad y_2 = 3x_0\lambda - \lambda^3 - y_0,
\]
  where
  \[
  \lambda := \frac{3x_0^2 - A^2}{2y_0}.
\]

Below we shall write \( 2 \ast P \) instead of \( P + P \).

- If \( x_0 = x_1 \) and \( y_0 = -y_1 \), then \( P + Q := \mathcal{O} \). In particular, \((0,0) + (0,0) = (A,0) + (A,0) = (-A,0) + (-A,0) = \mathcal{O} \).

- Finally, we define \( \mathcal{O} + P := P \) and \( P + \mathcal{O} := P \) for any point \( P \), in particular, \( \mathcal{O} + \mathcal{O} = \mathcal{O} \).
With the operation “+”, \((C_A, \cdot)\) is an abelian group with neutral element \(\cdot\). Let \(C_A(\mathbb{Q})\) be the set of rational points on \(C_A\) together with \(\cdot\). It is easy to see that \((C_A(\mathbb{Q}), \cdot)\) is a subgroup of \((C_A, \cdot)\). Moreover, it is well known that the group \((C_A(\mathbb{Q}), \cdot)\) is finitely generated. One can readily check that the three points \((0,0)\) and \((\pm A,0)\) are the only points on \(C_A\) of order 2, and one easily finds other points of finite order on \(C_A\). However, it is well known that if \(A\) is a congruent number and \((x_0,y_0)\) is a rational point on \(C_A\) with \(y_0 \neq 0\), then the order of \((x_0,y_0)\) is infinite. In particular, if there exists one rational Pythagorean \(A\)-triple, then there exist infinitely many such triples (for an elementary proof of this result, which is based on a theorem of Fermat’s, see Halbeisen and Hungerbühler [6]). Furthermore, Mordell’s Theorem states that the group of rational points on \(C_A\) is finitely generated, and by the Fundamental Theorem of Finitely Generated Abelian Groups, the group of rational points on an elliptic curve is isomorphic to some group of the form

\[
\mathbb{Z}/n_1\mathbb{Z} \times \ldots \times \mathbb{Z}/n_k\mathbb{Z} \times \mathbb{Z}^r,
\]

where \(n_1, \ldots, n_k\) and \(r\) are positive integers. The group \(\mathbb{Z}/\mathbb{Z}_{n_1} \times \ldots \times \mathbb{Z}/\mathbb{Z}_{n_k}\), which is generated by rational points of finite order, is the so-called torsion group, and \(r\) is called the rank of the curve. Now, since \(C_A\) does not have rational points of finite order besides the points \((0,0)\) and \((\pm A,0)\), the torsion group of \(C_A\) is isomorphic to \(\mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}\).

Based on integral solutions of \(m^2 = n^2 + nl + l^2\), we will show that there are infinitely many congruent number curves \(C_A\) with rank at least two (for congruent number curves with rank at least three see Johnstone and Spearman [8]).

2 Rank at Least Two

In order to “compute” the rank of a curve of the form

\[\Gamma : y^2 = x^3 + Bx,\]

according to Silverman and Tate [10, Chapter III.6.], we first have to write down several equations of the form

\[
b_1M^4 + b_2e^2 = N^4 \tag{4}
\]

\[
\bar{b}_1\bar{M}^4 + \bar{b}_2\bar{e}^2 = \bar{N}^4 \tag{5}
\]

namely one for each factorisation \(B = b_1b_2\) and \(-4B = \bar{b}_1\bar{b}_2\), respectively, where \(b_1\) and \(\bar{b}_1\) are square-free. Then we have to decide, how many of these equations have integral solutions: Let \(#\alpha(\Gamma)\) be the number of equations of the form (4) for which we find integral solutions \(M, e, N\) with \(e \neq 0\), and let \(#\alpha(\bar{\Gamma})\) be the corresponding number with respect to equations of the form (5). Then, if \(r > 0\),

\[
2^r = \frac{#\alpha(\Gamma) \cdot #\alpha(\bar{\Gamma})}{4}.
\]
Moreover, one can show that if \((x, y)\) is a rational point on \(\Gamma\), where \(y \neq 0\), then one can write that point in the form

\[
x = \frac{b_1 M^2}{e^2}, \quad y = \frac{b_1 M N}{e^3},
\]

where \(M, e, N\) is an integral solution of an equation of the form (4), and vice versa. The analogous statement holds for rational points on the curve \(\Gamma : y^2 = x^3 - 4Bx\) with respect to equations of the form (5).

Now we are ready to prove

**Theorem 2.** Let \(m, n, l\) be pairwise relatively prime positive integers, where \(m = \prod_{i=1}^{l} p_i\) is a product of pairwise distinct primes \(p_i \equiv 1 \mod 6\) and \(m^2 = n^2 + nl + l^2\). Furthermore, let \(k := n + l\) and let \(A := klmn\). Then the rank of the curve

\[
C_A : y^2 = x^3 - A^2 x
\]

is at least two.

**Proof.** Since we have at least one rational point \((x, y)\) on \(C_A\) with \(y \neq 0\), we know that the rank \(r\) of \(C_A\) is positive. So, to show that the rank of the curve \(C_A\) is at least two, it is enough to show that \(#\alpha(C_A) \geq 9\). For this, we have to show that there are integral solutions for (4) for at least 9 distinct square-free integers \(b_1\) dividing \(-A^2\), or equivalently, we have to find at least 9 rational points on \(C_A\), such that the 9 corresponding integers \(b_1\) are pairwise distinct, which we will do now.

Notice that because of (6), to compute \(b_1\) from a rational point \(P = (x, y)\) on \(C_A\) with \(x \neq 0\), it is enough to know the \(x\)-coordinate of \(P\) and then compute \(x \mod Q^{x^2}\) (i.e., we compute \(x\) modulo squares of rationals). The \(x\)-coordinates of the three integral points we get by (1) from the three Pythagorean \(A\)-triples \((a_1, b_1, c_1), (a_2, b_2, c_2), (a_3, b_3, c_3)\) generated by \(m, n, l, k\), are

\[
x_1 = m^2(m^2 - n^2) = m^2 kl, \quad x_2 = m^2(m^2 - l^2) = m^2 kn, \quad k^2(k^2 - m^2) = k^2 nl,
\]

and modulo squares, this gives us three values for \(b_1\), namely

\[
b_{1,1} = kl, \quad b_{1,2} = kn, \quad b_{1,3} = nl.
\]

Now, exchanging in each of the three Pythagorean \(A\)-triples the two catheti \(a_i\) and \(b_i\) (for \(i = 1, 2, 3\)), we obtain again three distinct integral points on \(C_A\), whose \(x\)-coordinates modulo squares give us

\[
b_{1,4} = mn, \quad b_{1,5} = ml, \quad b_{1,6} = mk.
\]

Finally, if we replace each hypothenuse \(c_j\) of these six Pythagorean \(A\)-triples with \(-c_j\), we obtain again six distinct integral points on \(C_A\), whose \(x\)-coordinates modulo squares give us

\[
b_{1,7} = -kl, \quad b_{1,8} = -kn, \quad b_{1,9} = -nl
\]

\[
b_{1,10} = -mn, \quad b_{1,11} = -ml, \quad b_{1,12} = -mk.
\]
In addition to these 12 integral points on $C_A$ (and the corresponding $b_1$’s), we have the two integral points $(\pm A, 0)$ on $C_A$, which give us

$$b_{1,13} = klmn\quad\text{and}\quad b_{1,14} = -klmn.$$ 

Recall that, by assumption, $m$ is square-free and $k, l, n$ are pairwise relatively prime. Therefore, if for some $i, j$ with $1 \leq i < j \leq 14$, $b_{1,i} \equiv b_{1,j}$ modulo squares, at least two of the integers $k, l, n$ are squares, say $n = u^2$, and $l = v^2$ or $k = v^2$. Then

$$m^2 = u^4 + u^2v^2 + v^4 \quad (\text{in the case when } l = v^2),$$

or

$$m^2 = u^4 - u^2v^2 + v^4 \quad (\text{in the case when } k = v^2).$$

If $l = v^2$, this implies that $u^2 = 1$ and $v = 0$, or $u = 0$ and $v^2 = 1$, and if $k = v^2$, this implies that $u^2 = 1$ and $v = 0$, $u = 0$ and $v^2 = 1$, or $u^2 = v^2 = 1$ (see, for example, Mordell [9, p.19f] or Euler [4, p.16]).

So, at most one of the integers $k, l, n$ is a square, which implies that $\#\alpha(C_A) \geq 14$ and this completes the proof. \textit{q.e.d.}

As an immediate consequence we get the following

**Corollary 3.** Let $m, n, l$ be as in Theorem 2 and let $q$ be a non-zero integer. Then the rank of the curve $C_{Aq^4}$ is at least two.

**Proof.** Notice that if $m, n, l$ are such that $m^2 = n^2 + nl + l^2$, then, for $mq, nq, lq$, we have $(mq)^2 = (nq)^2 + nq \cdot lq + (lq)^2$, which implies that for $\tilde{A} = kq \cdot lq \cdot mq \cdot nq = Ag^4$, the rank of the curve $C_{\tilde{A}}$ is at least two. \textit{q.e.d.}

### 3 Odds and Ends

As a matter of fact we would like to mention that the three integral points on $C_A$ which correspond to an integral solution of $m^2 = n^2 + nl + l^2$ lie on a straight line.

**Fact 4.** Let $m, n, l$ be positive integers such that $m^2 = n^2 + nl + l^2$, let $k = n + l$, and let $A = klmn$. Then the three integral points

$$\left(\frac{m^2(m^2 - n^2)}{x_1}, \frac{m^2(m^2 - n^2)^2}{y_1}\right),$$

$$\left(\frac{m^2(m^2 - l^2)}{x_2}, \frac{m^2(m^2 - l^2)^2}{y_2}\right),$$

$$\left(\frac{k^2(k^2 - m^2)}{x_3}, \frac{k^2(k^2 - m^2)^2}{y_3}\right),$$

on the curve $C_A$ lie on a straight line.
Proof. For $i = 2, 3$ let

$$
\lambda_{1,i} := \frac{y_i - y_1}{x_i - x_1}.
$$

It is enough to show that $\lambda_{1,2} = \lambda_{1,3}$, or equivalently, that $\lambda_{1,3} - \lambda_{1,2} = 0$. Now, an easy calculation shows that $\lambda_{1,2} = k^2$ and that $\lambda_{1,3} - k^2 = \frac{0}{k(k-n)^2} = 0$. \[\text{q.e.d.}\]

As a last remark we would like to mention that with the help of \texttt{sage} we found that some of the curves which correspond to an integral solution of $m^2 = n^2 + m + l^2$ have rank 3 or higher. In fact, we found several curves of rank 3 or 4, as well as the following curves of rank 5:

<table>

</table>

It is possible that these curves might be candidates for high rank congruent number elliptic curves (for another approach see Dujella, Janfada, Salami \cite{3}).
