FRAMED CORRESPONDENCES AND THE ZEROTH STABLE MOTIVIC HOMOTOPY GROUP IN ODD CHARACTERISTIC

ANDREI DRUZHININ AND JONAS IRGENS KYLLING

Abstract. We prove the finite descent for framed correspondences and Neshitov’s moving lemma over a perfect fields. This allows to extend the results of G. Garkusha and I. Panin on framed motives of algebraic varieties \[11\] to finite base fields, and extend the computation of the zeroth cohomology group \(H^0(ZF(\Delta_k^n, G_m^n)) = K_{MW}^n, n \geq 0,\) by A. Neshitov \[16\] to the case of a perfect field \(k\) of odd characteristic.

1. Introduction

1.1. Framed correspondences and Morel’s theorem. In the unpublished notes \[20\] V. Voevodsky introduced the theory of framed correspondences. This theory grew and blossomed into the theory of framed motives introduced and developed by G. Garkusha and I. Panin in \[11, 12, 1, 13\]. The theory of framed motives gives an explicit fibrant resolution of motivic spectra of smooth algebraic varieties, and in particular of the motivic sphere spectrum. A consequence is the identification of the zeroth motivic homotopy groups \(\pi_{n,n}(S)(pt_k)\) over an infinite perfect base field \(k\) with the zeroth cohomology of the Suslin complex of the presheaf of stable linear framed correspondences.

\[
\pi_{-n,-n}(S)(pt_k) \simeq H^0(ZF(\Delta_k^n, G_m^n))
\]

In \[16\] A. Neshitov computed the right hand side of (1.1) to be Milnor-Witt K-theory when the base field has characteristic zero

\[H^0(ZF(\Delta_k^n, G_m^n)) \simeq K^n_{MW}(k), n \geq 0.\]

This recovers a remarkable theorem of F. Morel \[18, Theorem 5.40\] for fields of characteristic 0.

Our work extends the results of \[11\] to finite fields, and extend Neshitov’s computation \[16\] to perfect fields \(k\) of odd characteristic. This recovers Morel’s theorem for perfect fields of odd characteristic.

The assumptions on the base field in this paper are as follows:

- In section 2 the base field can be arbitrary though the interesting case is only finite fields;
- In section 4 the base field is assumed to be perfect;
- In section 5 the base field is assumed to be perfect of odd characteristic.
- In section 6 the base field is assumed to be perfect.

1.2. Additional ingredients and modifications. The present text is written as a complement to the above mentioned papers of G. Garkusha, I. Panin, and A. Ananyevskiy and A. Neshitov. We only give new proofs of the statements in \[11\] and \[16\] which require the assumptions on the base field being infinite or of characteristic 0. Here is a list of the places that require the stronger restrictive assumptions with respect to our ones, and the list of modifications and additional arguments we use to improve the result.

1. (finite descent) The reason of the assumption in \[11\] on the base field to be infinite are some geometrical constructions of framed correspondences and homotopies used in \[12\], namely these constructions are needed for the injectivity and excision isomorphism theorems for stable linear framed presheaves. This leads to the restrictive assumption in the formations of strictly homotopy invariance theorem \[12\] and cancellation theorem \[1\] for stable linear framed presheaves, and consequently in the main results of the theory. In Section 2 we prove a variant of a descent for framed correspondences with respect to a set of coprime extensions.

The second author was partially supported by the RCN Frontier Research Group Project no. 250399 Motivic Hopf equations”.

1
With the descent theorem we prove the properties required by [12], [1] and [11] for presheaves over finite fields.

2. In Neshitov’s work the assumptions stronger then the perfect fields of characteristic different from two are required because of the following.

2.1. (Steinberg relation) Neshitov’s arguments provides the homomorphism

\[ \Psi_* : K_n^{MW}(k) \to H^0(\mathbb{Z}F(\Delta^*_k, G^{\cdot\cdot})) \]

for any field \( k \), \( \text{char } k \neq 2, 3 \). The assumption \( \text{char } k \neq 3 \) is because of the proof of the Steinberg relation in \( H^0(\mathbb{Z}F(\Delta^*_k, G^{\cdot\cdot})) \) [16] Lemma 8.9 that uses a certain curve of degree 3 and traces with respect to extensions of degree 3, which play an important part of the proof. It is the same curve as in the proof of the Steinberg relation in motivic cohomology [21], but in the case of motivic cohomology this did not lead to the restrictive assumption since derivative of the polynomial defining the curve has no effect for Cor-correspondences, and it has for framed ones.

In the present text we replace this argument by the reference to the original geometrical proof of the Steinberg relation in \( \pi^2 \) by Po Hu and Igor Kritz [15] or the alternative one [19]. Let us refer also to [4], where the homomorphism \( \Psi_* \) is constructed for an arbitrary base scheme.

2.2. (moving lemmas) The assumption on the base field to be of a characteristic zero and to be infinite is needed in the moving lemmas [16] Lemma 4.11, Lemma 5.4], which are essential ingredients providing the surjectivity

\[ \Psi_* : K_n^{MW}(k) \to H^0(\mathbb{Z}F(\Delta^*_k, G^{\cdot\cdot})). \]

[16] Lemma 4.11] allows to move an element in \( \mathbb{Z}F_*(pt_k, Y) \), with \( Y \subset k^n \) open, to a correspondence with the (non reduced) support being a set of points with the separable residue fields; moving lemma [16] Lemma 5.4], moves an element in \( \mathbb{Z}F_*(pt_k, pt_k) \) to a correspondence with the (non reduced) support a disjoint union of rational points.

[16] Lemma 4.11] is the main result of section 4 in [16]. The proof of lemma assumes that the base field is of characteristic zero because of the use of the generic smoothness theorem [14] III, Corollary 10.7] (in [16] Lemma 4.2, Lemma 4.6]). Also it is needed that the field is infinite because of the generic position lemma about hypersurfaces in projective space [16] Lemma 4.1].

In the article we prove [16] Lemma 4.11] over a perfect fields of an arbitrary characteristic. The strategy of the proof is completely different to the original one. For a given framed correspondence the moving process consists of two parts:

Firstly, we move the framing functions to generic position, see Lemma [6,3] but do not modify the support of the correspondence, nor the framing functions on the first order thickening of the support. Next, in Lemma [6,4] we change the framing functions \( \phi_i \) from the \( n \)th to 1st function to obtain a so called \( (i)\)-simple linear framed correspondence. Here \( (i)\)-simplicity is a “continuous version” of the notion of simplicity of framed correspondences, see Definition [6,1]. In particular a \( (1)\)-simple framed correspondence is simple.

[16] Lemma 5.4] requires the infiniteness of the base field, since the proof uses the existence of a separable monic polynomial in one variable with rational roots of arbitrary degree. As shown in lemma [6,9] the original proof of [16] Lemma 5.4] can easily be modified to cover the case of an arbitrary field. Alternatively, the assumption can be avoided by use of the finite descent theorem of Section 2.

1.3. Characteristic two. The main reason of the assumption the base field is of odd characteristic in the present proof is that the construction of the left inverse to the homomorphism \( \Psi_* \) uses the theory of Chow-Witt cohomology introduced by Barge-Morel [2] and developed by Fasel [9], [10]. Actually the main problem are pushforwards for the complexes \( C(X, G^n, L)_Z \), see [10].

If we replace the pushforwards of the complexes \( C(X, G^n, L)_Z \) by the pushforwards of the Rost-Schmidt complexes of [16] Chapter 5, Lemma 4.18] then the argument above would give a proof in arbitrary characteristic. However this would not be independent of Morel’s proof.

With out using of mentioned pushforwards but with using of the traces for Milnor-Witt K-theory along finite separable field extensions the present proof would give a surjective homomorphism \( K^{MW}_n(k) \to H^0(\mathbb{Z}F(\Delta^*_k, G^{\cdot\cdot}_n)). \)

1.4. Other work on framed motives over finite fields. Similar results on framed motives over finite fields (presented in Section [11] were simultaneously and independently obtained by other authors: In [3] Appendix B] similar results are obtained in terms of the conservativity property of the scalar extension functors. The
basic construction on the level of correspondences is close to ours. Also, there is an alternative construction of the descent map due to Alexey Tsybyshev based on the homomorphism $\text{GW}(k) \to \overline{\text{GW}}([pt_k, pt_k])$.

The results on framed motives over finite fields in this paper was submitted to the Arxiv e-Print archive in a preliminary form as the Appendix of [3]. This was to announce the results in the first part of this work while the final parts were still work in progress.

1.5. Acknowledgment. The authors are grateful to Ivan Panin for discussions about framed motives over finite fields and to Alexander Neshitov for discussions about extending his work [16] to fields of positive characteristic. The first author thanks the university of Oslo for the hospitality, where the essential part of this work was done.

1.6. Notation and conventions. Throughout the text we work with explicit framed correspondences considered as classes in the category of linear framed correspondences $ZF_*$ and framed correspondences of pairs. We refer the reader to [11, Definition 2.1, Definition 8.4], and [12, Definition 3.2, Definition 3.5] for the definitions of categories $ZF_*$, $\overline{ZF}_*$, $\overline{ZF}_*$, and $\overline{ZF}_*$.

We need to extent the categories to the essentially smooth schemes, i.e. schemes that are localisations of smooth schemes at a point. We use the following definition. Note that precisely in the text we never work with the correspondences with the target being except the correspondences defined by regular morphisms of essentially smooth schemes.

**Definition 1.1.** An essentially smooth scheme $Y$ is a scheme such that there is a sequence of open embeddings $Y_i \to Y_{i+1}$, $i \in \mathbb{Z}$, $Y = \lim_{\leftarrow i} Y_i$. Denote by $\text{EssSm}_k$ the category of essentially smooth schemes.

For an essentially smooth scheme $Y = \lim_{\leftarrow i} Y_i$ and a scheme $X$ define $ZF_*(X, Y) = \lim_{\leftarrow i} ZF_*(X, Y_i)$. For essentially smooth schemes $X = \lim_{\leftarrow j} X_j$, $Y = \lim_{\leftarrow i} Y_i$ define $ZF_*(X, Y) = \lim_{\leftarrow j} \lim_{\leftarrow i} ZF_*(X_j, Y_i)$.

Denote by $\text{Sm}_k^{\text{pair}}$ the full subcategory in the category of arrows in $\text{Sm}_k$ spanned by the pairs $(X, U)$ of a smooth scheme $X$ and open subscheme. An open pair of essentially smooth schemes $(Y, V)$ is a morphism of essentially smooth schemes $V \to Y$ that is limit of a sequence open embeddings $V_i \to Y_i$ with respect to open embeddings of pairs $(Y_i, V_i) \to (Y_{i+1}, V_{i+1})$.

Define $ZF_*(((X, U), (Y, V))) = \lim_{\leftarrow j} \lim_{\leftarrow i} ZF_*((X_j, U_j), (Y_i, V_i))$ for pairs $(X, U) = \lim_{\leftarrow j} (X_j, U_j)$, $(Y, V) = \lim_{\leftarrow i} (Y_i, V_i)$.

**Example 1.2.** Any morphism of essentially smooth schemes in $\text{EssSm}_k$ or a pair of essentially smooth schemes in the sense of above definition defines a morphism in the categories $ZF_*$ and $ZF_*$.

As noted above this is only one example of correspondences with the target being an essentially smooth scheme we use in the text.

In addition to this list we use the following.

**Definition 1.3.** Denote by $ZF_*$ the factor-category of $ZF_*$ obtained by annihilating of the ideal generated by identity morphisms $id_{(X, X)}$ of $(X, X)$, $X \in \text{Sm}_k$ ($X \in \text{EssSm}_k$).

Denote by $ZF_*$ the factor-category of $ZF_*$ obtained by annihilating of the ideal generated by endomorphisms $[i_0 \circ pr - [id_{(X, X)} \times \mathbb{A}^1]]$ of the objects $(X, U) \times \mathbb{A}^1$, $X \in \text{Sm}_k$, $U \subset X$ open, $i_0: (X, U) \to (X, U) \times \mathbb{A}^1$ is the zero section, $pr: (X, U) \times \mathbb{A}^1 \to (X, U)$ is the projection. For a morphisms of pairs $a \in ZF_*(((X, U), (Y, V)))$ we denote the class of $a$ in $ZF_*$ by $[a]$.

For a pair of morphisms $a, b \in ZF_*$ (or $a, b \in ZF_*$) we write $a \sim b$ iff $[a] = [b]$ in $ZF_*(X, Y)$ (or $ZF_*(X, Y)$).

Finally, denote $ZF(-, Y) = \lim_{\leftarrow i} ZF_n(\cdot, Y)$, $ZF(-, Y) = \lim_{\leftarrow i} ZF_n(-, Y)$, where the limits are with respect to morphisms $\sigma: ZF_n(-, \cdot) \to ZF_{n+1}(-, \cdot)$. Similarly $ZF(-, (Y, V)) = \lim_{\leftarrow i} ZF_n(-, (Y, V))$, $ZF(-, (Y, V)) = \lim_{\leftarrow i} ZF_n(-, (Y, V))$.

**Remark 1.4.** According to the above definition $ZF_*$ precisely is the category with objects being pairs $(X, U)$, $X \in \text{Sm}_k$, $U \subset X$ open, and $ZF_*$ is the homology group in the middle term of the complex $ZF_*(X, V) \to ZF_*(X, Y) \oplus ZF_*(U, V) \to ZF_*(U, Y)$.
Remark 1.5. For two pairs \((X, U), (Y, V)\) the group of morphisms \(\overline{\mathcal{F}_{\text{pair}}} ((X, U), (Y, V))\) is equal to

\[
\text{Coker}(\mathcal{F}_{\text{pair}} ((X, U) \times \mathbb{A}^1, (Y, V)) \xrightarrow{i_0 \circ \iota_1} \overline{\mathcal{F}_{\text{pair}}} ((X, U), (Y, V)),
\]

where \(i_0, i_1 : (X, U) \rightarrow (X, U) \times \mathbb{A}^1\) are zero and unit sections.

The category \(\overline{\mathcal{F}_{\text{pair}}}\) is not equal to the category \(\overline{\mathcal{F}}\) in [12], but it is equal to the category \(\overline{\mathcal{F}}\). The only difference is the notation for morphisms; so in [12] morphisms in \(\overline{\mathcal{F}}\) are denoted as \([a]\), but morphisms in \(\overline{\mathcal{F}_{\text{pair}}}\) we denote by \([a]\).

Remark 1.6. Finally let us note that in the definitions of framed correspondences we usually mean implicitly the inverse image of the regular functions on \(\mathbb{A}^n\) over \(Z\) where the first equality holds by the definition of the group of linear framed correspondences

\[
\text{Remark 2.5.} \ 	ext{For the readers convenience we repeat the proof: Firstly we}
\]

The first statement is [16, remark 7.8]. For the readers convenience we denote morphisms \(\overline{\mathcal{F}}\) with respect to a set of a finite field extensions of co-prime degrees, which we call the finite descent. The difference is the notation for morphisms; so in [11] morphisms in \(\overline{\mathcal{F}}\) are denoted as \([a]\), but morphisms in \(\overline{\mathcal{F}_{\text{pair}}}\) we denote by \([a]\).

In this section we prove that linear framed correspondences satisfy a descent property up to \(\mathbb{A}^1\)-homotopy with respect to a set of a finite field extensions of co-prime degrees, which we call the finite descent. The main results are corollaries 2.13 and 2.15.

Definition 2.1. Let \(K/k, K = k(\alpha)\) be a separable extension of finite fields. Denote by

\[
T_k/ \mathcal{F}_1 = (\text{Spec } K, V \rightarrow \mathbb{A}^1_k, f, r : V \rightarrow \text{Spec } K) \in \mathcal{F}_1(\mathbb{A}^1_k, \text{Spec } K)
\]

the framed correspondence, where Spec \(K\) is considered as a closed subscheme of \(\mathbb{A}^1_k\) via the function \(\alpha, f\) is the monic irreducible polynomial of the extension \(K/k\), \(V\) is an open subscheme in \(\mathbb{A}^1_k\) that is complement \(V = \mathbb{A}^1_k - W\) to the closed subscheme \(W \subseteq \mathbb{A}^1_k\), such that (Spec \(K\))^2 = \(W \cap \Delta_k\), where \(\Delta_k\) is the graph of \(\alpha : \text{Spec } K \rightarrow \mathbb{A}^1_k\), the étale morphism \(v : V \rightarrow \mathbb{A}^1_k\) is given by the composition \(V \rightarrow \mathbb{A}^1_k \rightarrow \mathbb{A}^1_k\) and \(f\) is considered as a regular function on \(V\) under the inverse image along \(v\), finally, \(r : V \rightarrow \text{Spec } K\) is given by the projection \(\mathbb{A}^1_k \rightarrow \text{Spec } K\).

Definition 2.2. Let \(\Lambda_\ell \in \mathcal{F}_1(\mathbb{A}^1_k, \mathbb{A}^1_k)\) be the framed correspondence defined by the function \(x^\ell\) on \(\mathbb{A}^1_k\) (i.e., \((0, \mathbb{A}^1_k, \mathbb{A}^1_k, \mathbb{A}^1_k) \rightarrow \text{Spec } k))\).

Let \(\Lambda_\ell' \in \mathcal{F}_1(\mathbb{A}^1_k, \mathbb{A}^1_k)\) be the framed correspondence given by \(\mathcal{F}_1\) if \(l = 2m\) and \(\mathcal{F}_1 + (\mathcal{F}_1)\) if \(l = 2m + 1\), where \(\mathcal{F}_1 = \mathcal{F}_1 + (\mathcal{F}_1)\) is the hyperbolic plane. Here \((\mathcal{F}_1) \in \mathcal{F}_1(\mathbb{A}^1_k, \mathbb{A}^1_k)\) is the framed correspondence defined by the function \(-x\) on \(\mathbb{A}^1_k\) (i.e., \(\Lambda_1\)), and \((-1) \in \mathcal{F}_1(\mathbb{A}^1_k, \mathbb{A}^1_k)\) is the framed correspondence defined by the function \(x\) on \(\mathbb{A}^1_k\).

Definition 2.3. Let \(c = (Z, V, \phi, g) \in \mathcal{F}_n(X, Y)\) be an explicit framed correspondence such that \(V \subseteq \mathbb{A}^n_X\) is a Zariski neighbourhood of \(Z\), and the regular functions \(\phi_i, i = 1, \ldots, n\) on \(V\) are restrictions of globally defined regular functions on \(\mathbb{A}^n_X\). Then to shorten the notations we often omit writing either the support \(Z\) or \(V\), and write \(c = (V, \phi, g)\) or \(c = (Z, \phi, g)\).

If moreover, \(\mathcal{F}_n = \mathbb{A}^n_X\), we will write just \(c = (\phi, g)\); or if \(Y = \mathbb{A}^n_k\) then we omit the canonical map \(g\) and write \(c = (V, \phi)\) or \(c = (Z, \phi)\).

We denote by \((\lambda) \in \mathcal{F}_1(\mathbb{A}^1_k, \mathbb{A}^1_k)\) the framed correspondence given by \((\mathbb{A}^1_k, \lambda x)\).

Lemma 2.4. The classes of \(\Lambda_\ell\) and \(\Lambda_\ell'\) in the group \(\overline{\mathcal{F}}(\mathbb{A}^1_k, \mathbb{A}^1_k)\) coincide. For any positive integers \(l_1, l_2\) and any \(n_1, n_2\) such that \(l_1n_1 - l_2n_2 = 1\) we have \(\mathcal{F}_1(\mathbb{A}^1_k, \mathbb{A}^1_k) = \{((-1)^{l_2n_2})\} \in \overline{\mathcal{F}}(\mathbb{A}^1_k, \mathbb{A}^1_k)\).

Proof. The first statement is [16] remark 7.8. For the readers convenience we repeat the proof: Firstly we note that in the group of linear framed correspondences \(\mathcal{F}_n(\mathbb{A}^1_k, \mathbb{A}^1_k)\) we have

\[
(\mathbb{A}^1_k, x^\ell(1 + x)) = (\mathbb{A}^1_k - \{0\}, x^\ell(1 + x)) + (\mathbb{A}^1_k - \{-1\}, x^\ell(1 + x)) \sim \Lambda_{\ell} + (\{-1\}^\ell),
\]

where the first equality holds by the definition of the group of linear framed correspondences \(\mathcal{F}_1(\mathbb{A}^1_k, \mathbb{A}^1_k)\).

Then by induction it follows that \(\Lambda_{\ell} = \sum_{i=0}^{l-1} (-1)^i \) and \(\Lambda_{\ell}' \in \overline{\mathcal{F}}(\mathbb{A}^1_k, \mathbb{A}^1_k)\).

The second statement is then straightforward.

Lemma 2.5. For any separable finite extension \(K/k\) we have \(\text{pr}_{K/k} \circ T_{K/k} \overset{\sim}{\rightarrow} \Lambda_{\deg K/k}\), where \(\text{pr}_{K/k} : \text{Spec } K \rightarrow \text{Spec } k\).
Proof. The claimed equivalence is provided by the homotopy defined by the framed correspondence $(\mathbb{A}_k^1 \times \mathbb{A}_k^1, \lambda f + (1 - \lambda)f_{\deg}, pr) \in Fr_1(\mathbb{A}_k^1, pt_k)$, where $f$ is the monic polynomial from the definition $\phi_k$. $\lambda$ denotes the second coordinate on $\mathbb{A}_k^1 \times \mathbb{A}_k^1$, which is the homotopy parameter, and $pr: \mathbb{A}_k^1 \times \mathbb{A}_k^1 \to pt_k$ is the canonical projection.

Definition 2.6. We call by a small precategory $\Gamma = (O_{\Gamma}, Mor_{\Gamma}, U_{\Gamma}, \circ)$ a set of vertices $O_{\Gamma}$, a set of arrows $Mor_{\Gamma}$, a subset $U_{\Gamma} \in Mor_{\Gamma} \times Mor_{\Gamma}$, and a map $\circ: U \to Mor_{\Gamma}$ such that $f \circ (g \circ h) = (f \circ g) \circ h$ for any $f, g, h \in Mor_{\Gamma}$.

Let $\Gamma$ be a small precategory.

Definition 2.7. A $\Gamma$-diagram in the category $\mathcal{F}$ is a pairs of maps $f_{O\beta}: O_{\Gamma} \to O_{\mathcal{F}}$ and $f_{Mor}: Mor_{\Gamma} \to Mor_{\mathcal{F}}$ such that for any arrows $\alpha_1, \alpha_2, \alpha_3 \in Mor_{\Gamma}$, $\alpha_3 = \alpha_1 \circ \alpha_2$, $(\alpha_1, \alpha_2) \in U_{\Gamma}$, we have $f_{Mor}(\alpha_1) \circ f_{Mor}(\alpha_2) = f_{Mor}(\alpha_3)$.

Definition 2.8. Let $\Gamma'$ be an embedding of precategories (in sense of def. 2.6). We say that the embedding is good with respect to descent if and only if for each pair of morphisms $\gamma_1, \gamma_2 \in \Gamma$ such that the composite $\gamma_1 \circ \gamma_2$ is defined, $\gamma_1$ or $\gamma_2$ is the image of a morphism in $\Gamma'$.

Example 2.9. 1) Any small category $\Gamma$ is a small precategory with $U_{\Gamma} = Mor_{\Gamma}$. 2) Any graph $\Gamma$ can be considered as a small precategory with $U_{\Gamma} = \emptyset$. 3) Main examples of the embeddings of small precategories we will work with are represented by the diagrams

\[
\begin{array}{ccc}
O_{\Gamma_1} & \xrightarrow{f_3} & O_{\Gamma_2} \\
\downarrow f_1 & & \downarrow g_1 \\
O_{\Gamma_3} & \xrightarrow{g_3} & O_{\Gamma_4}
\end{array}
\]

where the left diagram represents the embedding $\Gamma_1 \to \Gamma_2$ with $O_{\Gamma_1} = O_{\Gamma_2} = \{V_1, V_2, V_3\}$, $Mor_{\Gamma_1} = \{f_1, f_2\}$, $Mor_{\Gamma_2} = \{f_1, f_2, f_3\}$, $f_2 \circ f_1 = f_3$, and the embedding $\Gamma_3 \to \Gamma_4$ with $O_{\Gamma_3} = O_{\Gamma_4} = \{V_4, V_5, V_6, V_7\}$, $Mor_{\Gamma_3} = \{g_1, g_2, g_3, g_4, g_5\}$, $Mor_{\Gamma_4} = \{g_1, g_2, g_3, g_4, g_5, g_6\}$, $g_2 \circ g_3 = g_5$, $g_4 \circ g_1 = g_5$, $g_4 \circ g_6 = g_2$, $g_6 \circ g_3 = g_1$.

Definition 2.10. Let $\Gamma$ be a small precategory.

A weak $\Gamma$-diagram in the category $ZF_*(k)$ is a map $\gamma: \Gamma \to ZF_*(k)$ such that for any morphisms $\alpha_1 \circ \alpha_2 = \alpha_3 \in Mor_{\Gamma}(a, c)$, we have $[\gamma(\alpha_1) \circ \gamma(\alpha_2)] = [\gamma(\alpha_3)] \in ZF(\gamma(a), \gamma(c))$.

A weak homotopy $\Gamma$-diagram in $ZF_*(k)$ is a weak $\Gamma$-diagram in $ZF_*(k)$. Precisely it is a map $\gamma: \Gamma \to ZF_*(k)$ such that for any morphisms $\alpha_1 \circ \alpha_2 = \alpha_3 \in Mor_{\Gamma}(a, c)$, we have $[\gamma(\alpha_1) \circ \gamma(\alpha_2)] = [\gamma(\alpha_3)] \in ZF(\gamma(a), \gamma(c)) = ZF(\gamma(a), \gamma(c))/\sim_{\mathbb{A}_k^1}$.

Weak (homotopy) $\Gamma$-diagrams in the category of pairs $ZF_*(pair)(k)$ are defined similarly.

Definition 2.11. Let $j: \Gamma' \to \Gamma$ be an embedding of precategories (in sense of def. 2.6) that is good with respect to descent (in sense of def. 2.8), and let $\gamma' \Gamma$ be a $\Gamma'$-diagram in the category $ZF_*$ (or the category of pairs $ZF_(pair)^*(k)$).

We say that we have the weak lifting property in the category $ZF_*$ with respect to $j$ and $\gamma'$ if there is a weak $\Gamma$-diagram in $ZF_*(k)$ (def. 2.10) that restriction on $\Gamma'$ is $\gamma'$.

Similarly we define weak lifting properties in $ZF_*$, and weak lifting properties in $ZF_*(pair)$, and $ZF_(pair)^*$ with respect to a $\Gamma'$-diagram in the category of pairs.

Lemma 2.12. 1) For any small (finite) precategory $\Gamma$ (in sense of def. 2.6) there is a small (finite) precategory $\Gamma_s$ such that the category of week $\Gamma$-diagrams in the category $ZF_*$ (or $ZF_(pair)^*$) is equivalent to the category of week $\Gamma_s$-diagrams in the category $ZF_*(k)$ (or $ZF_(pair)^*(k)$).

2) For any small (finite) precategory $\Gamma$ (in sense of def. 2.6) there is a small (finite) precategory $\Gamma_s$ such that the category of week $\Gamma$-diagrams in the category $ZF_(pair)^*$ is equivalent to a full subcategory in the category of week $\Gamma_s$-diagrams in the category $ZF_*(k)$, defined by the condition that some arrows in the (week) $\Gamma_s$-diagram are open embeddings of schemes.
Proof. We note the following: (1) An equality $[\Phi_1] = [\Phi_2] \in \mathbb{ZF}_e(X_1, X_2)$ is represented by a morphism $ZF_e(X_1 \times \mathbb{A}^1, X_2)$. (2) Any morphism in the category of pairs $(X, U) \rightarrow (Y, V)$ in the category $ZF_e(k)$ is represented by a commutative square in the category of correspondences

\begin{equation}
\begin{array}{c}
X \\
\downarrow \\
U \\
\downarrow \\
V
\end{array} \quad \begin{array}{c}
Y \\
\downarrow \\
\uparrow \\
\uparrow \\
\uparrow
\end{array}
\end{equation}

An equality in the category of pairs is equivalent to the existence of the diagonal in the square above.

The lemma is proven in two steps: 1) Firstly, using observation (1) we can replace all equalities in the diagram $\mathbb{ZF}^\text{pair}_e(k)$ of the form $\gamma(\alpha_1) \circ \gamma(\alpha_2) = \gamma(\alpha_1 \circ \alpha_2)$ by equalities in $\mathbb{ZF}^\text{pair}_e(k)$. Each source vertex $(X, U)$ of the arrow $\alpha_2$ is replaced by the triple $(X, U) \times 0 \rightarrow (X, U) \times \mathbb{A}^1 \leftarrow (X, U) \times 1$. We denote the resulting diagram by $\gamma'$.

2) Next we replace each vertex $(X, U)$ of $\gamma'$ by the pair of vertices $X \leftarrow U$, we replace each arrow by a square of the form (2.1), and add a diagonal arrow to the square for each relation of the form $\gamma'(\alpha_1) \circ \gamma'(\alpha_2) = \gamma'(\alpha_1 \circ \alpha_2)$. □

Lemma 2.13. Let $\Gamma' \rightarrow \Gamma$ be an embedding of precategories (in sense of def. 2.4) that is good with respect to descent (def. 2.8), and let $\gamma'$ be a $\Gamma'$-diagram in the category $\mathbb{ZF}_e$ (or the category of pairs $\mathbb{ZF}^\text{pair}_e$).

Let $K_1, K_2$ be two finite field extensions of a finite field $k$, such that $\deg K_1/k$ and $\deg K_2/k$ are relatively prime, i.e., $(\deg K_1/k, \deg K_2/k) = 1$. Suppose that there exist lift of the weak $\Gamma$-diagram $\gamma'$ (def. 2.10) to a weak $\Gamma$-diagram in $\mathbb{ZF}_e(K)$ (or $\mathbb{ZF}^\text{pair}_e(K)$) for $K = K_1, K_2$.

Then there exists a lift of $\gamma'$ to a weak $\Gamma$-diagram in $\mathbb{ZF}_e(k)$ (or $\mathbb{ZF}^\text{pair}_e(k)$) (see def. 2.10).

Proof. The question on the diagrams in the categories $\mathbb{ZF}_e$, the case of $\mathbb{ZF}^\text{pair}_e$ follows form the case of $ZF_e$, and the case of $ZF^\text{pair}_e$ is similar.

Let $l_1 = \deg K_1, l_2 = \deg K_2$. Since $(l_1, l_2) = 1$ there are integers $n_1, n_2$ such that $l_1n_1 - l_2n_2 = 1$. Up to remuneration of $K_1$ and $K_2$ we can assume that $n_1, n_2 > 0$. Let $S = \text{Spec } K_1 \amalg \text{Spec } K_2$, with inclusions $j_i : \text{Spec } K_i \rightarrow S$, $i = 1, 2$. Define a framed correspondence

\begin{equation}
L = \langle (-1)^{l_1n_1+1} \circ (j_1 \circ T_{K_1/k} \circ A_{n_1} - j_2 \circ T_{K_2/k} \circ A_{n_2}) \rangle \in \mathbb{ZF}_e(\text{pt}_k, S),
\end{equation}

and let $pr : S \rightarrow \text{Spec } k$ be the projection. Then Lemma 2.4 and Lemma 2.5 imply that

\begin{equation}
|pr \circ L| = \langle (-1)^{l_1n_1+1} \circ pr \circ (j_1 \circ T_{K_1/k} \circ A_{n_1} - j_2 \circ T_{K_2/k} \circ A_{n_2}) \rangle_{\text{pair}} \bigg|\bigg|\langle (-1)^{l_1n_1+1} \circ (\Lambda_{l_1} \circ A_{n_1} - \Lambda_{l_2} \circ A_{n_2}) \rangle_{\text{pair}} \bigg|\bigg| = \mathbb{ZF}_e(\text{pt}_k, \text{pt}_k).
\end{equation}

Consider the base change $\gamma'_S : ZF_e(S)$ of the $\Gamma'$-diagram $\gamma'$, where $ZF_e(S)$ denotes the category of framed correspondences over $S$. By assumption there is a lift of $\gamma'_S$ to a $\Gamma$-diagram $\gamma_S : \Gamma \rightarrow ZF_e(S)$. Denote by $L_S$ the base change of $L$.

To define the required lift $\gamma$ for any morphism $\alpha \in \Gamma$ that is not a morphism in $\Gamma'$ we put

\begin{equation}
\gamma(\alpha) = ((id_Y \times pr) \circ \gamma_S(\alpha) \circ (X \times L)) \cdot \langle (-1)^{l_1n_1} \rangle,
\end{equation}

where $X$ and $Y$ are varieties (or pairs) that are the source and the target of $\gamma_S(\alpha)$, $X \times L_S$ is the base change of $L_S$ with respect to $X \rightarrow \text{pt}_k$, and $\cdot$ is the external product of correspondences (if $\alpha \in \Gamma'$ we put $\gamma(\alpha) = \gamma'(\alpha)$). Denote $L_X = L \boxtimes id_X$, for $X \in \mathbb{Sm}_k$.

Now let $\alpha, \beta \in \Gamma$ be a pair of morphisms such that the target of $\alpha$ is equal to the source of $\beta$. Let $X$ and $Y$ be images of the source and target of $\alpha$ in $ZF_e(K)$, and let $Y$ and $Z$ be images of the sources and target of $\beta$ in $ZF_e(K)$. Since the embedding $\Gamma' \rightarrow \Gamma$ is good with respect to descent, for any such a pair either $\alpha \in \Gamma'$, or $\beta \in \Gamma'$.
Suppose $\beta \in \Gamma'$, then
\[
[\gamma(\beta) \circ \gamma(\alpha)] = [\gamma'(\beta) \circ \gamma(\alpha)] = [\gamma'(\beta) \circ pr_Y \circ \gamma_S(\alpha) \circ L_X] = [pr_Z \circ \gamma'_S(\beta) \circ \gamma_S(\alpha) \circ L_X] = [pr_Z \circ \gamma_S(\beta \circ \alpha) \circ L_X] = [\gamma(\beta \circ \alpha)]
\]
since we have the diagram
\[
\begin{array}{ccc}
S \times X & \xrightarrow{\gamma_S(\alpha)} & S \times Y \xrightarrow{\gamma'_S(\beta)} S \times Z \\
L_X \uparrow & & \downarrow pr_Y & & \downarrow pr_Z \\
X & \xrightarrow{\gamma(\alpha)} & Y \xrightarrow{\gamma'(\beta)} Z.
\end{array}
\]

Now suppose $\alpha \in \Gamma'$, then
\[
[\gamma(\beta) \circ \gamma(\alpha)] = [\gamma(\beta) \circ \gamma'(\alpha)] = [pr_Z \circ \gamma_S(\beta) \circ L_Y \circ \gamma'(\alpha)] = [pr_Z \circ \gamma_S(\beta) \circ \gamma'_S(\alpha) \circ L_X] = [pr_Z \circ \gamma_S(\beta) \circ \gamma_S(\alpha) \circ L_X] = [pr_Z \circ \gamma_S(\beta \circ \alpha) \circ L_X] = [\gamma(\beta \circ \alpha)]
\]
since we have the diagram
\[
\begin{array}{ccc}
S \times X & \xrightarrow{\gamma_S(\alpha)} & S \times Y \xrightarrow{\gamma'_S(\beta)} S \times Z \\
L_X \uparrow & & \downarrow pr_Y & & \downarrow pr_Z \\
X & \xrightarrow{\gamma(\alpha)} & Y \xrightarrow{\gamma'(\alpha)} Z.
\end{array}
\]

Corollary 2.14. Let $\Gamma' \to \Gamma$ be an embedding of precategories (in sense of def. 2.6) that is good with respect to descent (def. 2.8), and let $\gamma'$ be a $\Gamma'$-diagram in the category $\mathbb{Z}_p\Gamma_*(k)$ (or the category of pairs $\mathbb{Z}_p\Gamma_*(\text{pair})(k)$).

Suppose that there is an integer $N$ such that for all field extensions $K/k$ of degree $\deg K/k \geq N$ there is a lift of $\gamma'$ to a weak $\Gamma$-diagram (def. 2.10) in the category $\mathbb{Z}_p\Gamma_*(K)$ (or $\mathbb{Z}_p\Gamma_*(\text{pair})(K)$).

Then there is such a lift of $\gamma'$ over $k$.

Proof. Consider any two separable extensions $K_1/k$, $K_2/k$ such that $\deg K_1, \deg K_2 > N$, $\deg K_1, \deg K_2 = 1$. Then by assumption the required lift of the diagram $\gamma'$ over $K_1$ and $K_2$, so the claim follows from lemma 2.13.

\[ \square \]

Corollary 2.15 (Tsbyshhev, Panin). Let $\Gamma' \to \Gamma$ be an embedding of finite precategories (in sense of def. 2.6) that is good with respect to descent (def. 2.8), and let $\gamma'$ be a $\Gamma'$-diagram in the category $\mathbb{Z}_p\Gamma_*(k)$ (or the category of pairs $\mathbb{Z}_p\Gamma_*(\text{pair})(k)$).

Suppose that for all infinite field extensions $K/k$ there is a lift of $\gamma'$ to a weak $\Gamma$-diagram (def. 2.10) in the category $\mathbb{Z}_p\Gamma_*(K)$ (or $\mathbb{Z}_p\Gamma_*(\text{pair})(K)$).

Then there is such a lift of $\gamma'$ over $k$.

In other words, if the weak lifting property (in sense of def. 2.11) with respect to the diagram $\gamma'$ and the embedding $\Gamma' \to \Gamma$ holds in the category $\mathbb{Z}_p\Gamma_*(K)$ (or $\mathbb{Z}_p\Gamma_*(\text{pair})(K)$) for any infinite field extension $K/k$ then it holds in $\mathbb{Z}_p\Gamma_*(k)$ (or $\mathbb{Z}_p\Gamma_*(\text{pair})(k)$).

Proof. The claim follows from lemma 2.13 if we consider the towers of extensions of degrees $p$ and $q$ for two different prime numbers, prime to the characteristic.

In detail, let $K_1 = \lim_{\longrightarrow} k(\xi^{1/p^i})$ and $K_2 = \lim_{\longrightarrow} k(\xi^{1/q^j})$ be the infinite extensions of $k$ for a pair of different prime numbers $p, q$, $(p, \text{char } k) = 1$, $(q, \text{char } k) = 1$. Then by assumption there is a lift of the $\Gamma'$-diagram $\gamma'$ to a weak $\Gamma$-diagram. Since the precategory $\Gamma$ is finite it follows that there is a lift of $\gamma'$ to a weak $\Gamma$-diagram over a finite field extensions $K_1 = k(\xi^{1/p^i})$ and $K_2 = k(\xi^{1/q^j})$. Now the claim follows from lemma 2.13. \[ \square \]
Lemma 2.16. Let $B \subset \mathbb{A}^n_k$ be a closed subscheme in affine $n$-space over some field $k$. Then there is $N \in \mathbb{Z}$ such that for all field extensions $K/k$ of degree $\text{deg } K/k > N$ there is a $K$-rational point $p \in \mathbb{A}^n_K - B_K$, where $B_K = B \times \text{Spec } K$.

Proof. Let $f \in k[t_1, \ldots, t_n]$ be a function, $f|_B = 0$, $f \neq 0$. Assume $f|_{\mathbb{A}^n_k - \{p\}} = 0$ for any $P \in \mathbb{A}^1_k(K)$. This is impossible if $f$ is nonzero and $\text{deg } K/k \gg 0$, since the number of rational roots of a nonzero one-variable polynomial is not greater than its degree. □

3. Injectivity and excision theorems for framed presheaves over a field.

In the section we apply the result of the previous section to extend the injectivity and excision theorems for homotopy invariant linear stable framed presheaves $[\_ , \_ ]$ to the finite base field case.

Theorem 3.1 (injectivity on local schemes). For a field $k$ let $X \in \text{Sm}_k$, $x \in X$ be a point, $U = \text{Spec } (O_{X,x})$, $i: D \to X$ be a proper closed subset. Then there exists an integer $N$ and a morphism $r \in \mathbb{Z}F_N(U, X - D)$ such that $[r|_D = [\text{can}] \circ [\sigma^U]$ in $\mathbb{Z}F_N(U, X)$ with $j: X - D \to X$ the open inclusion and $i: U \to X$ the canonical morphism.

Theorem 3.2 (injectivity on affine line). For a field $k$ let $U \subset \mathbb{A}^1_k$ be an open subset and let $i: V \to U$ be a non-empty open subset. Then there is a morphism $r \in \mathbb{Z}F_1(U, V)$ such that $[i|_r = \sigma^U \in \mathbb{Z}F_1(U, U)$.

Theorem 3.3 (Zariski excision on affine line). For a field $k$ let $U \subset \mathbb{A}^1_k$ be an embedding. Let $i: V \to U$ be an open inclusion with $V$ non-empty. Let $S \subset V$ be a closed subset. Then there are morphisms $r \in \mathbb{Z}F_1((U, U - S), (V, V - S))$ and $\pi_1 \in \mathbb{Z}F_1((U, U - S), (V, V - S))$ such that

$[i \circ [r] = \sigma^U \text{ and } [i \circ [\pi] = \sigma^V$](in $\mathbb{Z}F_1$).

Theorem 3.4 (étale excision). Let $S \subset X$ and $S' \subset X'$ be closed subsets. Let $V$ be an elementary distinguished square with $X$ and $X'$ affine $k$-smooth. Let $S = X - V$ and $S' = X' - V'$ be closed subschemes equipped with reduced structures. Let $x \in S$ and $x' \in S'$ be two points such that $\Pi(x') = x$. Let $U = \text{Spec } (O_{X,x})$ and $U' = \text{Spec } (O_{X',x'})$. Let $\pi: U' \to U$ be the morphism induced by $\Pi$.

Under the notation above there is an integer $N$ and a morphism $r \in \mathbb{Z}F_N((U, U - S), (X', X' - S'))$ such that $[\Pi \circ [r] = \text{can} \circ [\sigma^U]$ in $\mathbb{Z}F_N$.

There are an integer $N$ and a morphism $r \in \mathbb{Z}F_N((U, U - S), (X, X - S'))$ such that $[\pi \circ [r] = \text{can} \circ [\sigma^U]$ in $\mathbb{Z}F_N$.

Lemma 3.5. Any theorem of the list 3.1-3.4 states a weak lifting property (in sense of def. 2.11) in the categories $\mathbb{Z}F_*$ (or $\mathbb{Z}F_*^{pair}$) with respect to some diagram $\gamma'$: $\Gamma' \to \mathbb{Z}F_*$ (or $\gamma': \Gamma' \to \mathbb{Z}F_*^{pair}$) and an embedding $\Gamma' \to \Gamma$ good with respect to a descent (see def 2.3) for a finite precategories $\Gamma$ and $\Gamma'$ (in sense of def. 2.4).
Proof. The list of diagrams follows.

\[ \begin{array}{cc}
\text{Th. 3.1} & \text{Th. 3.2} \\
\begin{array}{c}
\begin{array}{c}
X \\
U
\end{array}
\end{array} & \begin{array}{c}
\begin{array}{c}
X - D \\
V
\end{array}
\end{array}
\end{array} \]

\[ \begin{array}{cc}
\text{Th. 3.3} & \text{Th. 3.4} \\
\begin{array}{c}
\begin{array}{c}
(U, U - S) \\
| [\sigma]
\end{array}
\end{array} & \begin{array}{c}
\begin{array}{c}
(V, V - S) \\
| [\sigma]
\end{array}
\end{array}
\end{array} \]

\[ \begin{array}{cc}
\text{Th. 3.3} & \text{Th. 3.4} \\
\begin{array}{c}
\begin{array}{c}
(U, U - S) \\
| [\sigma]
\end{array}
\end{array} & \begin{array}{c}
\begin{array}{c}
(V, V - S) \\
| [\sigma]
\end{array}
\end{array}
\end{array} \]

Since there is no one pair of composable dashed arrows in the following diagrams all of them are good with respect to a descent in sense of 2.8.

\[ \begin{array}{ccc}
\text{Corollary 3.6} & \text{(see theorem 2.15 in [12] for the infinite field case). Let } \mathcal{F} \text{ be a homotopy invariant stable linear framed presheaf. Then the following properties hold:} \\
1) \text{Under the assumptions of theorem 3.7 the homomorphisms } \eta^* \mathcal{F}(U) \to \mathcal{F}(k(X)) \text{ and } (\eta^h)^* \mathcal{F}(U^h_x) \to \mathcal{F}(\text{Spec } k(U^h_x))) \text{ are injective.} \\
2) \text{Under the assumptions of theorem 3.7 the restriction homomorphism } \mathcal{F}(U) \to \mathcal{F}(V) \text{ is injective.} \\
3) \text{Under the assumptions of theorem 3.7 the homomorphism } i^*: \mathcal{F}(U - S) \to \mathcal{F}(U) \to \mathcal{F}(V - S)/\mathcal{F}(V) \text{ is an isomorphism;} \\
4) \text{Under the notation of theorem 3.7 the homomorphism } \pi^*: \mathcal{F}(U - S_x)/\mathcal{F}(U) \to \mathcal{F}(U' - S_x') \to \mathcal{F}(U') \text{ is an isomorphism, where } S_x = \text{Spec } \mathcal{O}_{S, x}, S'_x = \text{Spec } \mathcal{O}_{S', x'}.
\end{array} \]

Proof. The claim follows from theorem 3.7 by the same argument as in [12] theorem 2.15.

\[ \begin{array}{c}
\text{Theorem 3.7. Let } X \in \text{Sm}_k, \ x \in X \text{ be a point, } W = \text{Spec}(\mathcal{O}_{X, x}). \text{ Let } i: V \subset A^1_W \text{ be an open subset, } 0_W \subset V. \text{ Then there are morphisms } r \in ZF^{\text{pair}}_1((A^1_W, A^1_W - 0 \times W), (V, V - 0 \times W)) \text{ and } l \in ZF^{\text{pair}}_1((A^1_W, A^1_W - 0 \times W), (V, V - 0 \times W)) \text{ such that} \\
[l] \circ [r] = [\sigma_{A^1_W}] \text{ and } [l] \circ [i] = [\sigma_V] \\
in ZF^{\text{pair}}_1((A^1_W, A^1_W - 0 \times W), (A^1_W, A^1_W - 0 \times W)) \text{ and } ZF^{\text{pair}}_1((V, V - 0 \times W), (V, V - 0 \times W)) \text{ respectively.}
\end{array} \]

Proof. We follow the scheme of the arguments of 3 or 6 translated to the case of framed correspondences.

To prove the first claim we need to construct

\[ r \in ZF^{\text{pair}}_1((A^1_W, A^1_W - 0_W), (V, V - 0_W)), \ h_r \in ZF^{\text{pair}}_1((A^1_W, A^1_W - 0_W) \times \lambda^1, (A^1_W, A^1_W - 0_W)) \]
such that
\[ h_r \circ i_0 = i \circ r, \quad h_r \circ i_1 = \text{id}_{(\mathbb{A}_W^1, \mathbb{A}_W^1 \setminus 0_W)}. \]

Consider the following sections:
\[
\begin{align*}
  s \in \Gamma(\mathbb{P}^1_{W \times \mathbb{A}^1_t}, \mathcal{O}(n)) & \quad \bar{s} \in \Gamma(\mathbb{P}^1_{W \times \mathbb{A}^1_t \times \mathbb{A}^1_t}, \mathcal{O}(n)) & \quad s' \in \Gamma(\mathbb{P}^1_{W \times \mathbb{A}^1_t}, \mathcal{O}(n-1)) \\
  \bar{s} \mid_{\mathbb{P}^1_{W \times \mathbb{A}^1_t \times 0}} = s & \quad \bar{s} \mid_{(\mathbb{P}^1_{W \times \mathbb{A}^1_t})^n} = t^n & \quad \bar{s} \mid_{\mathbb{P}^1_{W \times \mathbb{A}^1_t \times 1}} = (t_0 - x t_\infty) s' \\
  \bar{s} \mid_{0 \times \mathbb{W} \times \mathbb{A}^1_t} = t^n \bar{s} \mid_{0 \times \mathbb{W} \times \mathbb{A}^1_t} = t^n (t_0 - x t_\infty) & \quad \bar{s} \mid_{0 \times \mathbb{W} \times \mathbb{A}^1_t} = t^n \bar{s} \mid_{0 \times \mathbb{W} \times \mathbb{A}^1_t} = t^n (t_0 - x t_\infty) & \quad \bar{s} \mid_{0 \times \mathbb{W} \times \mathbb{A}^1_t} = t^n \bar{s} \mid_{0 \times \mathbb{W} \times \mathbb{A}^1_t} = t^n (t_0 - x t_\infty)
\end{align*}
\]

where \([t_0 : t_\infty]\) denotes coordinates on \(\mathbb{P}^1\). Such sections \(s\) and \(s'\) exist for \(n\) large enough by the Serre theorem \[\text{[14, Theorem 5.2]}\] on sections of a powers of ample bundles, since \(U\) is affine or local, and consequently \(\mathcal{O}(1)\) is ample on \(\mathbb{P}^1 \times U \times \mathbb{A}^1_t\) and \(\mathbb{P}^1 \times U \times \mathbb{A}^1_t \times \mathbb{A}^1_t\). Having \(s\) and \(s'\), we then put \(\bar{s} = (1 - \lambda)s + \lambda(t_0 - x t_\infty)s'\).

Denote by \(t = t_\infty/t_0\) the coordinate on \(\mathbb{A}^1 = \mathbb{P}^1 - \infty\). Define the correspondence \(r\) as a correspondence of pairs given by the pair of explicit framed correspondences
\[
\begin{align*}
  (V \times \mathbb{A}^1_t, 1) & \quad Z(s), s/t^n, \quad (pr_1) \in F_{1}(W \times \mathbb{A}^1_t, V) \\
  ((V - 0_W) \times (\mathbb{A}^1 - 0), Z(s) \times \mathbb{A}^1_t, s/t^n, \quad (pr_1) \in F_{1}(W \times (\mathbb{A}^1 - 0), (V) - 0_W),
\end{align*}
\]

where
\[
pr_1 : V \times \mathbb{A}^1_t \rightarrow V, \quad pr_1 : (V - 0) \times (\mathbb{A}^1 - 0) \rightarrow V - 0_W.
\]
denote the projections. Let us write in short that
\[
r = [(\mathbb{A}^1 \times W \times \mathbb{A}^1_t, Z(s), s/t^n, (pr_1)) \in ZF_{1}(W \times (\mathbb{A}^1 \times \mathbb{A}^1 - 0), (V) - 0_W)].
\]

In a similar way define the correspondence \(h\)
\[
h_{r,1} = [(\mathbb{A}^1 \times W \times \mathbb{A}^1_t \times \mathbb{A}^1_t, Z(\bar{s}), \bar{s}/t^n, (pr_1^2)) \in ZF_{1}(W \times (\mathbb{A}^1 \times \mathbb{A}^1 - 0) \times \mathbb{A}^1, W \times (\mathbb{A}^1 \times \mathbb{A}^1 - 0)),
\]

where \(pr_1^2\) is the projection \(\mathbb{A}^1 \times W \times \mathbb{A}^1_t \times \mathbb{A}^1_t \rightarrow W \times \mathbb{A}^1_t\).

Then the properties of \(s\) and \(\bar{s}\) above implies that
\[
h_{r,1} \circ i_0 = i \circ r;
\]
\[
h_{r,1} \circ i_1 = [(\mathbb{A}^1 \times W \times \mathbb{A}^1_t, Z(t - x), (t - x)g, (pr_1^2))]
\]
where \(g = s'/t^n - 1 \in k[\mathbb{A}^1 \times \mathbb{A}^1 \times U]\). By the definition of the correspondences of pairs we see that the second summand is trivial in \(ZF_{1}(W \times (\mathbb{A}^1 \times \mathbb{A}^1 - 0) \times \mathbb{A}^1, W \times (\mathbb{A}^1, \mathbb{A}^1 - 0))\). Now define the correspondence in \(ZF_{1}(W \times (\mathbb{A}^1 \times \mathbb{A}^1 - 0) \times \mathbb{A}^1, W \times (\mathbb{A}^1, \mathbb{A}^1 - 0))\)
\[
h_{r,2} = [(\mathbb{A}^1 \times W \times \mathbb{A}^1_t \times \mathbb{A}^1_t, Z(t - x) \times \mathbb{A}^1, (t - x)g(1 - \lambda) + (t - x), (pr_1^2))]
\]

using the fact that \(g|_{Z(t-x)} = 1\). Then
\[
h_{r,2} \circ i_0 = [(\mathbb{A}^1 \times W \times \mathbb{A}^1_t, Z(t - x), (t - x)g, (pr_1^2))],
\]
\[
h_{r,2} \circ i_1 = [(\mathbb{A}^1 \times W \times \mathbb{A}^1_t, Z(t - x), (t - x), (pr_1^2)) = \text{id}_{(\mathbb{A}^1, \mathbb{A}^1 \setminus 0_W)}
\]

Thus we put \(h = h_{r,1} + h_{r,2} - [(\mathbb{A}^1 \times W \times \mathbb{A}^1_t, Z(t - x), (t - x)g, (pr_1^2))\), and the claim follows.

2) To prove the second claim we need to construct
\[
l \in ZF_{1}(W \times (\mathbb{A}^1 - 0_W), (V) - 0_W), h_l \in ZF_{1}(W \times (V) - 0_W, (V) - 0_W)
\]
such that \(h_l \circ i_0 = l \circ i\) and \(h_l \circ i_1 = \text{id}_{(V, V \setminus 0_W)}\).
For $n$ large enough similarly as above using the Serre theorem [14 Theorem 5.2] we find the following sections:

\[
\begin{align*}
& s \in \Gamma( \mathbb{P}^1_{W} \times \mathbb{A}^1, \mathcal{O}(n)) \quad \tilde{s} \in \Gamma( \mathbb{P}^1_{\mathbb{V}} \times \mathbb{A}^1, \mathcal{O}(n)) \quad s' \in \Gamma( \mathbb{P}^1_{\mathbb{V}} \times \mathbb{A}^1, \mathcal{O}(n-1)) \\
& s \big|_{(\mathbb{P}^1 \times W) \setminus \mathbb{V} \times \mathbb{A}^1} = t_0^2 \\
& s \big|_{0 \times W \times \mathbb{A}^1} = t_0 - xt_\infty \\
& s' \big|_{\mathbb{P}^1 \times \mathbb{V} \times \mathbb{A}^1} = t_0^2 \\
& g\big|_{(\mathbb{A}^1 \setminus \mathbb{V}) \times \mathbb{A}^1} = t_0^2(t_0 - xt_\infty)^{-1} \\
& g\big|_{0 \times \mathbb{V} \times \mathbb{A}^1} = t_\infty^2 \\
& g\big|_{Z(t_0 - xt_\infty) \times W} = t_\infty^{-1},
\end{align*}
\]

where $g = s'/t_\infty^{-1} \in k[\mathbb{A}^1 \times \mathbb{V}]$.

Next, under the same notation as above in the point (1) of the proof define

\[
l = \left( \mathbb{A}^1 \times W \times \mathbb{A}^1, Z(s, s/t_\infty, pr_1) \right) \in \mathbb{Z}F_{pair}(W \times (\mathbb{A}^1, \mathbb{A}^1 - 0), (\mathbb{V}, \mathbb{V} - 0W)),
\]

\[
h_{t,1} = \left( W \times \mathbb{V} \times \mathbb{A}^1, Z(\tilde{s}, \tilde{s}, \tilde{s}/t_\infty, pr_1) \right) \in \mathbb{Z}F_{pair}((\mathbb{V}, \mathbb{V} - 0W) \times \mathbb{A}^1, (\mathbb{V}, \mathbb{V} - 0W)),
\]

where $t = t_0/t_\infty$ denotes the coordinate on $\mathbb{A}^1 = \mathbb{P}^1 - 0$, and $pr_1^2 : W \times \mathbb{V} \times \mathbb{A}^1 \to \mathbb{V}$ is the projection.

Then the properties of $s$ and $s'$ above imply that

\[
h_t \circ i_0 = i \circ l; \quad h_t \circ i_1 = \left[ ((\mathbb{A}^1 \times W \times \mathbb{A}^1 \times \mathbb{A}^1, Z(t-x), (t-x)g, pr_1)] + \left[ ((\mathbb{A}^1 \times W \times \mathbb{A}^1 \times \mathbb{A}^1, Z(g, (y-x)g, pr_1^2)].
\]

The second summand is trivial by the definition of the group $\mathbb{Z}F(W \times (\mathbb{A}^1, \mathbb{A}^1 - 0) \times \mathbb{A}^1, W \times (\mathbb{A}^1, \mathbb{A}^1 - 0))$.

Then since $g|_{Z(t-x)} = 1$ we can define

\[
h_{t,2} = \left[ (\mathbb{V} \times \mathbb{V} \times \mathbb{A}^1, Z(t-x), (t-x)g(1-\lambda) + (t-x), pr_1^2) \right] \in \mathbb{Z}F_{pair}((\mathbb{V}, \mathbb{V} - 0W) \times \mathbb{A}^1, (\mathbb{V}, \mathbb{V} - 0W)).
\]

Finally we put $h = h_{t,1} + h_{t,2} - [(\mathbb{V} \times W, Z(t-x), (t-x)g, pr_1^2)]$, and then

\[
h_t \circ i_0 = l; \quad h_t \circ i_1 = \left[ (\mathbb{V} \times W, Z(t-x), (t-x)g, pr_1^2) + \left[ (\mathbb{V} \times W, Z(g, (t-x)g, pr_1^2)] - [(\mathbb{V} \times W, Z(t-x), (t-x)g, pr_1^2)] + \left[ (\mathbb{V} \times W, Z(t-x), (t-x), pr_1^2) \right] = id_{V, V - 0W}.
\]

So the claim is done. \hfill \square

**Corollary 3.8** (see corollary 2.16 in [12] for the infinite base field case for the second claim). Suppose that $W \in Sm_k$ is an affine scheme or a local scheme, and let $V_1 \subseteq V_2 \subseteq \mathbb{A}^1_W$ be a pair of open subschemes such that $0_W \subseteq V_1$. Let $i : V_1 \subseteq V_2$ denote the inclusion. Then, for any homotopy invariant stable framed presheaf $\mathcal{F}$, the restriction homomorphism $i^*$ induces an isomorphism

\[
i^* : \mathcal{F}(V_2 \setminus 0_W)/\mathcal{F}(V_2) \cong \mathcal{F}(V_1 \setminus 0_W)/\mathcal{F}(V_1).
\]

And consequently

\[
\mathcal{F}(\mathbb{A}^1_W \setminus 0_W)/\mathcal{F}(\mathbb{A}^1_W) \cong \mathcal{F}(\mathbb{V} \setminus 0_W)/\mathcal{F}(\mathbb{V}).
\]

where $V = (\mathbb{A}^1_W)_{0_W}$ is the local scheme corresponding to the closed point of the subscheme $0_W \subset \mathbb{A}^1_W$.

**Proof.** It follows from the theorem 3.7 that

\[
\mathcal{F}((\mathbb{A}^1_W - 0_W)/\mathcal{F}(\mathbb{A}^1_W) \cong \mathcal{F}(\mathbb{V}' \setminus 0_W)/\mathcal{F}(\mathbb{V'}),
\]

for any open $V' \subset \mathbb{A}^1_W, 0_W \subset V$. Now the first claim follows since we have

\[
\mathcal{F}(V_1 \setminus 0_W)/\mathcal{F}(V_2) \cong \mathcal{F}(\mathbb{A}^1_W - 0_W)/\mathcal{F}(\mathbb{A}^1_W) \cong \mathcal{F}(V'_1 \setminus 0_W)/\mathcal{F}(V'_1).
\]
The second claim follows, since
\[
\mathcal{F}(V \setminus 0_W)/\mathcal{F}(V) = \lim_{V' \subset A^1_W, 0_W \subset V'} \mathcal{F}(V' \setminus 0_W)/\mathcal{F}(V').
\]

\[\square\]

4. Framed motives over finite fields

In this section we apply the finite descent from the previous section to extend the theory of framed motives \([11]\) to the finite base field case. The results of the theory of framed motives are based on sequence on theorems about framed correspondences (and corresponding \(S^1\)-spectra of representable sheaves), and on (pre)sheaves with framed transfers including the strictly homotopy invariance theorem proven in \([12]\), cancellation theorem \([2]\), and the so called 'cone' theorem \([3]\). The assumption on the base field to be infinite is needed in the strictly homotopy invariance theorem and cancellation theorem. So to extend the results of the theory to the case if finite fields it is enough to prove the mentioned theorems for the case such fields. Let us recall this theorems.

4.1. In \([11]\) the theory of framed motives is constructed over an infinite perfect field of characteristic different from 2. In this section we explain how the result of the previous section extend the theory to the finite base field case.

The reason of the restrictive assumption on the base field in \([11]\) are the strictly homotopy invariance \([12]\) and cancellation theorems \([2]\), and up to the references to these results the assumptions on the base field are not needed. Moreover the proof of the cancellation theorem \([2]\) does not use the infiniteness assumption except the references to \([12]\).

In its turn for an arbitrary perfect field the strictly homotopy invariance by the arguments of \([12]\) follows from the injectivity and excision theorems \([12]\) theorems 2.9, 2.10, 2.11, 2.13, 2.14, 2.15]. This means that the text of the proofs in \([12]\) uses the infiniteness assumption nowhere except the references to the injectivity and excision theorems \([12]\) theorems 2.9, 2.10, 2.11, 2.13, 2.14, 2.15].

So whenever we have proven the injectivity and excision properties over finite fields, see theses \([5,1,3,4]\) and corollary \([6,6]\) we have got the strictly homotopy invariance and cancellation theorems consequently the results on framed motives \([11]\).

In what follows we recall the list of steps in the mentioned above reductions and give precise references to the arguments in the mentioned sources. All the proofs form \([12]\) and \([1]\) we refer to hold word by word in the general prefect base field case.

4.2. Strictly homotopy invariance.

**Theorem 4.1** (strictly homotopy invariance, see theorem 1.1 in \([12]\) for infinite base fields). *Any homotopy invariant linear framed \(\sigma\)-stable presheaf \(F\) over a perfect field \(k\) is strictly homotopy invariant and \(\sigma\)-stable.*

**Proof.** As shown in \([12]\) section 16] the claim follows from corollary \([5,6]\) and corollary \([8,8]\). \[\square\]

**Remark 4.2.** Let us list the sequence of lemmas and propositions by which \([, , ]\) is proven: Namely, it is reduction is given by the sequences of \([12]\) 16.9 16.8 16.7 16.6 16.4 16.3 16.2] and \([12]\) 16.12 16.14 16.3].

4.3. Cancellation theorem.

**Theorem 4.3** (linear cancellation theorem, see theorem C in \([1]\) for infinite base fields). *For a prefect base field \(k\) the natural homomorphism of complexes of abelian groups

\[
ZF(X \times \Delta^\bullet, Y) \rightarrow ZF(X \times \Delta^\bullet \wedge (\mathbb{G}_m, 1), Y \wedge (\mathbb{G}_m, 1))
\]

is an quasi-ismorphism.*

**Proof.** The claim follows from theorems \([11]\) and \([5,1,3,4]\) by the arguments as in \([1]\) theorem C]. \[\square\]
4.4. Remarks on more precise and shorter arguments.

Remark 4.4. The infiniteness assumption on the base field in [12] actually is needed only in theorems 2.11, 2.13, 2.14, and corollary 2.16. So we could not to reprove theorems 3.2, 3.3 that are [12] th 2.9, th 2.10.

Remark 4.5. In the above argument we have extended [12] th 2.9, th. 2.10, th 2.11 to the finite field case applying corollary 2.15 and we have gave the independent argument for [12] corollary 5 for the case of such fields. In the same time let us note that if we reformulate [12] corollary 5 in terms of the category of correspondences of pairs, in a similar form to the theorem 3.7 or [12] theorem 2.12, then [12] corollary 5 could deduced in the case of finite fields form the infinite field case applying corollary 2.15 as well.

Remark 4.6. Using corollary 2.15 instead of corollary 2.16 theorems 3.1 and 3.4 could be deduced from the inner results of [12]. Namely we mean some inner statements in the proof of theorems 3.1 and 3.4 in [12].

Let us explain this argument. The assumption in the proofs is needed to satisfy some conditions of generic position. Namely,

1. constructing a relative curve with a “good” compactification in both theorems it is needed to choose some projection in affine space such that the restriction to some smooth subscheme of codimension one is étale;
2. constructing of the morphism from the étale neighbourhood V of the support of the framed correspondence to the target Y of the framed correspondence, it is assumed to choose a generic projection again;
3. in the injective étale excision, when choosing a section of a line bundle on a projective curve that does not satisfy some closed property.

All these constructions require to find a k-rational point in a non-empty open subscheme U ⊂ P^N_k for some N. By lemma 2.16 such point exists for all enough big field extensions K/k, and so theorem 3.4 holds for all fields K, k ⊂ K, such that such that deg K/k > L for some L ≫ 0. Now the case of a finite base field k follows by lemma 2.14.

Remark 4.7. The finite descent argument allow us to deduce theorem 4.3 over finite base fields from the infinite base field case directly without references to the inner scheme of the proof in [1]. We show the surjectivity of the homomorphism 4.11 the injectivity is similar and simpler.

4.5. Corollary on zeroth motivic homotopy groups. By the above all results of [11] hold over an arbitrary perfect field. A particular consequence of [11] theorem 11.7 is the following result on the zeroth motivic homotopy groups

Theorem 4.8. Let k be a perfect field, then

\[ [pt, G_m^{(n)}]_{SH^\bullet(k)} \simeq H^0(ZF(\Delta^\bullet_k, G_m^{(n)})). \]

5. Proof of the isomorphism $K_{MW}^n \simeq H^0(ZF(\Delta^\bullet_k, G_m^{(n)})).$

In this section we recall Neshitov’s proof of the isomorphism (5.11) in the case characteristic zero [10], and extend the arguments to obtain a proof for perfect fields of characteristic different from two. Actually, here we repeat the same arguments as in [10] replacing some references to the results that require alternative proof. Namely the reference to the proof of Steinberg relation given in [10] subsection 8.3 is replaced by the reference to [15], [19] or [3]; and the reference to the moving lemma [10] lemma 4.10] is replaced by the lemma 6.4 proven in the next section of the present article.
It is written at the beginning of [10] that throughout the text the base field is of characteristic 0. In the same time the assumption is used only in few places and many of the arguments works in any characteristic or in any odd characteristic. Let us cite some of original lemmas from [10] indicating what are essential assumptions on the base field in the proofs for each statement.

**Theorem 5.1.** For a perfect field $k$ of characteristic different form 2 there is a graded ring isomorphism

\[(5.1) K^{MW}_{\geq 0}(k) \simeq H^0(\mathbb{Z}F(\Delta^*_k, G^\wedge_m)) \]

that takes the symbol $[a_1, \ldots, a_n] \in K^{MW}_n(k)$, $a_i \in k^\times$, to the class of the correspondences defined by the regular map $(a_1, \ldots, a_n): pt_k \to G^\wedge_m$. 

**Proof.** The lemmas [5,2.5,3] give us the injective ring homomorphism $K^{MW}_n(k) \to H^0(\mathbb{Z}F(\Delta^*_k, G^\wedge_m))$. The homomorphism is surjective by lemma [5,4].

**Lemma 5.2** (section 6.2, lemma 9.1, section 7 in [10]). For a perfect field $k$, char $k \neq 2$, there are homomorphisms

\[
\Phi_{n,k}: H^0(\mathbb{Z}F(\Delta^*_k, G^\wedge_m)) \to K^{MW}_n(k), n \geq 0,
\]

that takes the class of the correspondences defined by the map $(a_1, \ldots, a_n): pt_k \to G^\wedge_m$ to the symbol $[a_1, \ldots, a_n]$.

**Lemma 5.3.** For a field $k$, char $k \neq 2$, there is a graded ring homomorphism

\[
\Psi_{*,k}: K^{MW}_{\geq 0}(k) \to H^0(\mathbb{Z}F(\Delta^*_k, G^\wedge_m))
\]

that takes the symbol $[a_1, \ldots, a_n] \in K^{MW}_n(k)$, $a_i \in k^\times$, to the class of the correspondences defined by the regular map $(a_1, \ldots, a_n): pt_k \to G^\wedge_m$.

The arguments of [10] section 7, section 8] proves the claim for a field $k$, char $k \neq 2$, char $k \neq 3$. The assumption char $k \neq 2$ is needed for the proof of the relations in $GW(k)$ [10 section 7], and the assumption char $k \neq 3$ for the Steinberg relation [10 subsection 8.2]. Neverthelss theorem [1,8] provides that the original work [15], where the Steinberg relation is proven in $\pi^{2,2}(S)$ over an arbitrary base scheme $S$, implies the relation in $H^0(\mathbb{Z}F(\Delta^*_k, G^\wedge_m^2))$ for a prefect $k$. Thus repeating the arguments replacing the proof of Steinberg relation by the reference to [15] we get the construction of $\Psi_*$ over a perfect fields of odd characteristic. Let us note that as shown in the preprint [1] the required homomorphism of rings $\Psi_*$ actually exists over an arbitrary base scheme.

**Proof of lemma [5,3]** To construct the homomorphism it is needed to prove the relations of the Milnor-Witt $K$-theory ring $K^{MW}_n(k)$ in $H^0(\mathbb{Z}F(\Delta^*_k, G^\wedge_m))$. Due to theorem [13] this is equivalent to prove the relations in the ring $\pi^*_n(pt_k)$. Firstly, the arguments of [10] lemma 7.6 provides the homomorphism $\Psi_0: GW(k) \to H^0(\mathbb{Z}F(\Delta^*_k, pt_k))$. The moving lemma [6,9] proven in the next section yields immediately that $\Psi_0$ is surjective. Then by lemma [5,2] it follows that $\Psi_0$ is an isomorphism.

As shown in [16] subsection 8.3] the isomorphism $\Psi_0$ and the Steinberg relation implies the rest relations of $K^{MW}$. In detail, [16] lemmas 8.5, corollary 8.14, lemma 8.15] provides the homomorphism $\Psi_1: K^{MW}_1(k) \to H^0(\mathbb{Z}F(\Delta^*_1, G^\wedge_m^1))$. Hence since by [18] remark 3.2] the Steinberg relation defines a factor algebra of the tensor algebra $T(\delta_{W,k}(k^{MW}(k))$ we get the homomorphism $\Psi_*$. 

**Lemma 5.4** (proposition 9.6 [10] for char $k = 0$). The homomorphism $\Psi_{*,k}$ is surjective for any perfect field $k$, char $k \neq 2$.

**Proof.** As noted above the case of $\Psi_0$ follows from the moving lemma proven in the next section [6,9]. The general case follows form lemmas [5,5] and lemma [5,8] in a similar way to [10] proposition 9.6].

**Lemma 5.5** (see lemma 9.5 and subsection 3.1 in [10]. Let $k$ be a field, char $k \neq 2$. Let $L/k$ be a finite field extension of a field $k$, char $k \neq 2$. There are a transfer map $T\rho_{L}: K^{MW}_n(L) \to K^{MW}_n(k)$ given by [18] definition 4.26] and [18] theorem 4.27] and a transfer map $tr_{L}: H^0(\mathbb{Z}F(\Delta^*_k, G^\wedge_m)) \to H^0(\mathbb{Z}F(\Delta^*_k, G^\wedge_m))$ such that $tr_{L} \circ \Psi_{n,L} = \Psi_{n,k} \circ T\rho_{L}$ for all integer $n \geq 0$.

**Proof.** The claim follows similar as in [10] lemma 9.5] using lemmas [5,6] and [5,7] and the Steinberg relation.
Lemma 5.6 (Lemma 7.9 [16]). Let $k$ be a field, char $k \neq 2$. Suppose $L/k$ is separable field extension, $[L: k] = l$ is a prime number, and $k$ has no prime-to-$l$ extensions. Then the transfer diagram is commutative

$$
\begin{align*}
K^\text{MW}_0(L) \xrightarrow{\Psi_0} H^0(\mathbb{Z}F(\Delta^*_L, \text{pt}_L)) & \xrightarrow{\text{Tr}_{k/l}^L} H^0(\mathbb{Z}F(\Delta^*_L, \text{pt}_L)) \\
K^\text{MW}_0(k) \xrightarrow{\Psi_0} H^0(\mathbb{Z}F(\Delta^*_L, \text{pt}_L)) & \xrightarrow{\text{Tr}_{k/k}^L} H^0(\mathbb{Z}F(\Delta^*_L, \text{pt}_L))
\end{align*}
$$

where $\text{Tr}_{k/k}^L$ is the transfer map homomorphism from Milnor-Witt K-theory defined in [18] Definition 4.28].

Proof. We repeat the proof from [16].

Take $L = k(\alpha)$. Since $l$ is prime, we may assume that $L = k(\alpha)$. Then $\text{tr}_{L/k}(\Psi(\langle \alpha \rangle)) = \text{tr}_{L/k}(\langle \alpha \rangle) = (\mathbb{A}^1_k, \alpha(x - \alpha), pr_k)$. Let $p(x)$ be the minimal monic polynomial of $\alpha$. Then $(\mathbb{A}^1_k, \alpha(x - \alpha), pr_k) \sim (U', xp'(x)p(x), pr_k)$, where $U' \subset \mathbb{A}^1_k$ is an open subset does not contain any root of $xp'(x)p(x)$ except $\alpha$. Take $U \subset \mathbb{A}^1_k$ to be the image of $U'$. Then $\text{tr}_{L/k}(\Psi(\langle \alpha \rangle)) = (U', xp'(x)p(x), pr_k) = (U, xp'(x)p(x), pr_k) = \langle c_d x^{l+d+1} - (\mathbb{A}^1_k - Z(p), xp'(x)p(x), pr_k) \rangle$, where $d = \deg p'(x) < l$, and $c_d$ is the leading coefficient of $p'(x)$. Since $k$ has no prime-to-$l$ extensions, all roots of $p'(x)$ are rational, so $xp'(x) = c_d(x - \lambda_1)^{l+1}(x - \lambda_2)^{l+2}$. Then by [16] Lemma 7.9

$$
\Phi_0(\text{tr}_{L/k}(\Psi_0(\langle \alpha \rangle))) = \langle c_d \rangle s_e - \left( \sum_{i=1}^g (r_i) \langle c_d p(\lambda_i) \rangle \prod_{j \neq i} (\lambda_i - \lambda_j)^{l+1} \right), s = 1 + d + l.
$$

Let $\tau_k^L$ be the geometrical transfer map defined in [18] 4.2. Then $\text{Tr}_{k/k}^L(\langle \alpha \rangle) = \tau_k^L(\langle \alpha \rangle)(\langle p'(x) \rangle) = -d^{-1/2} \sum_{i=1}^g [x - \lambda_i]^{l+1} c_d p(\lambda_i) \prod_{j \neq i} (\lambda_i - \lambda_j)^{l+1} = \langle c_d \rangle s_e - \left( \sum_{i=1}^g (r_i) \langle c_d p(\lambda_i) \rangle \prod_{j \neq i} (\lambda_i - \lambda_j)^{l+1} \right)$ by [16] Lemma 7.9. Thus $\Phi_0(\text{tr}_{L/k}(\Psi_0(\langle \alpha \rangle))) = \text{Tr}_{k/k}^L(\langle \alpha \rangle)$. Hence the diagram commutes since $\Psi_0 \circ \Phi_0$ is identity.

Lemma 5.7 (Lemma 9.3 [16]). Let $k$ be a field, char $k \neq 2$. Suppose $L/k$ is separable field extension, $[L: k] = l$ is a prime number, and $k$ has no prime-to-$l$ extensions. Then is generated as abelian group by $GW(L)K^\text{MW}_0(k) + S$, where $S = \{ \langle \pm \omega_0(a) \rangle | a \in L^\times \}$, where for any $a \in L^\times \omega_0(a) = p'(a)$ and $p'$ is a derivative of the minimal polynomial of $a$.

Proof. The proof is the same as for [16] lemma 9.3] just without the equality $d + m = l - 1$ in the fourth row of the proof.

Lemma 5.8. For any element in $ZF(\text{pt}_k, G_{m}^\wedge_n)$ the class $[c] \in H^0(\mathbb{Z}(\Delta^*_L, G_{m}^\wedge_n))$ is equivalent to the class of some $\hat{c} \in ZF(\text{pt}_k, G_{m}^\wedge_n)$ such that the support of $c$ is smooth.

Proof. Any framed correspondences is equivalent to a correspondences in $ZF(\text{pt}_k, G_{m}^\wedge_n)$ that support is smooth, by lemma 6.4 (with $i = 0$), which is proven in the next section. In other words this means that the support is a set of points (with the separable residue fields). Now since any simple correspondences in $ZF(\text{pt}_k, G_{m}^\wedge_n)$ is equivalent to a simple one in $ZF(\text{pt}_k, G_{m}^\wedge_n)$ by [16] Lemma 4.10 the claim follows.

6. Moving lemma

In this section we prove Lemma 5.8. Throughout we assume that $k$ is perfect.

Definition 6.1. Let $c = (Z \subset \mathbb{A}^n, \varphi: \mathcal{V} \to \mathbb{A}^n, \varphi = (\varphi_i) \in k[\mathcal{V}][n], g: \mathcal{V} \to Y) \in F_{\text{sn}}(\text{pt}_k, Y)$ be a framed correspondence such that $\mathcal{V}$ is an open immersion, and $Y \subset \mathbb{A}^e$ is an open subscheme. Then $c$ is said to be an $(i)$-simple correspondence for $i = 1, \ldots, n$ if there is a vector of sections $(s_j)_{j}, s_j \in \Gamma(\mathbb{P}^n, \mathcal{O}(d_j))$, such that

1) $v^*(s_j/t^d_j)|_{Z(\mathbb{P}(\mathcal{Z})^2)} = \varphi_j|_{Z(\mathbb{P}(\mathcal{Z})^2)}$, $s_j|_{\mathbb{P}^{n-1}} = t^d_j$, $j = 1, \ldots, n$,
2) $Z \subset \mathbb{P}^n - B_i$, where $B_i = \bigcup_{s_{j} < s_{j}} \text{Sing} Z_{\text{red}}(s_1, \ldots, s_j)$, and
3) $Z_{\text{red}}(s_1, \ldots, s_{i-1}) \cap Z(s_1, \ldots, s_n)$ is smooth.

Remark 6.2. Because of the condition (3), any $(1)$-simple correspondences $c$ is simple, i.e., the (non-reduced) support of $c$ is smooth.
Lemma 6.3. Suppose $k$ is perfect. Let $s = (s_i)_i$ be a vector of sections $s_i \in \Gamma(\mathbb{P}^n, \mathcal{O}(d_i))$ such that $s_i|_{\mathbb{P}^n-1} = \iota_i^d$, and denote $Z = Z(s)$. Then there is a vector of sections $\bar{s} = (\bar{s}_i)_i, \bar{s}_i \in \Gamma(\mathbb{P}^n, \mathcal{O}(d'_i))$ such that $\bar{s}_i|_{\mathbb{P}^n-1} = \iota_i^{d'_i},$ \( Z_{\text{red}}(\bar{s}_1, \ldots, \bar{s}_n) \not\subset B_n \), where

$$B_n = \bigcup_{1 \leq i < n} \text{Sing} Z_{\text{red}}(\bar{s}_1, \ldots, \bar{s}_i).$$

Here $\mathbb{P}^{n-1} \subset \mathbb{P}^n$ is the subspace at infinity and $t_\infty \in \mathcal{O}(1), Z(t_\infty) = \mathbb{P}^{n-1}$.

Proof. Firstly we will prove that for all $l \in \mathbb{Z}, 1 \leq l \leq n$, there is a vector of sections $\bar{s} = (\bar{s}_i)_{i=1}^n, \bar{s}_i \in \Gamma(\mathbb{P}^n, \mathcal{O}(d'_i))$ such that $\bar{s}_i|_{\mathbb{P}^n-1} = \iota_i^{d'_i},$ and denote $Z = Z_{\text{red}}(\bar{s}_1, \ldots, \bar{s}_n) \not\subset B_n$. Thus $\bar{s}_i$ is invertible on $P$. Denote $B_1' = B_1 \cup B_l$. Then $Z_{\text{red}}(\bar{s}_1, \ldots, \bar{s}_n) \not\subset B_1'$.

Consider the scheme $Z_{\text{red}} = Z_{\text{red}}(\bar{s}_1, \ldots, \bar{s}_n)$ and the reduced closed subschemes $B_{1-l} = Z_{1-l} \cap B_{1-l}$, $B_{1} = Z_{1} \cap B_{1}$. Note that since $s_i|_{\mathbb{P}^n-1} = \iota_i^{d_i}$, it follows that $Z_{n-1}$ is of pure dimension $n - l + 1$. Since $k$ is perfect and $Z_1$ is reduced, $Z_{1-l}$ is open dense in $Z_{1-l}$. Recall that by the induction assumption $Z_{1-l} \not\subset B_{1-l}$. Then $Z_{1-l} \not\subset B_{1-l}$. Thus $Z_{1-l} \not\subset B_{1-l}$ and such that $Z_{1-l} \not\subset B_{1-l}$. Hence $Z_{1-l} \not\subset B_{1-l} \cup Z_{1-l} = B_{1-l}$. Thus $B_1'$ is a proper subset of $Z_{1-l}$, and such that $Z_{1-l} \not\subset B_{1-l}$.

Denote $B_1'' = (B_1')_{\text{red}}$. Let $P \subset Z_{1-l}$ be a finite set of points in $Z_{1-l} - (Z \cup \mathbb{P}^{n-1})$ such that $P$ contains at least one point in each irreducible component of $B_1'' - (Z(s) \cup \mathbb{P}^{n-1})$. Using Serre’s theorem [14, Theorem 5.2] we can choose a section $\bar{s}_i \in \Gamma(\mathbb{P}^n, \mathcal{O}(d'_i))$ for some $d'_i \in \mathbb{Z}$ such that $\bar{s}_i|_{Z(I(Z(s)))} = \iota_i^{d'_i}|_{Z(I(Z(s)))},$ and such that $Z_{\text{red}}(\bar{s}_1, \ldots, \bar{s}_n) \not\subset B_n = \bigcup_{1 \leq i < n} \text{Sing} Z_{\text{red}}(\bar{s}_1, \ldots, \bar{s}_i).$

Lemma 6.4. Let $c = (Z \subset A^n, v; V \to A^n, \phi, g; V \to Y) \in Fr_n(pt_k, Y)$ for some open $Y \subset \mathbb{A}^n$. Then for any $i, 0 \leq i \leq n,$ there exist $c^+, c^- \in Fr_n(pt_k, Y),$ such that $c^+$ and $c^-$ are $(i)$-simple correspondences, and $[c] = [c^+] - [c^-] \in \mathbb{Z} Fr_n(pt_k, Y).$

Proof. The proof follows immediately from Lemma 6.5 and Lemma 6.6.

Lemma 6.5. Let $Y \subset \mathbb{A}^n_k$ be an open subscheme, and $c = (Z \subset A^n, v; V \to A^n, \phi, g; V \to Y) \in Fr_n(pt_k, Y).$ Then there exist $c^+, c^- \in Fr_n(pt_k, Y)$, such that $c^+$ and $c^-$ are $(n)$-simple correspondences, and $[c] = [c^+] - [c^-] \in \mathbb{Z} Fr_n(pt_k, Y)$.

Proof. By Serre’s theorem [14, Theorem 5.2] we can choose integers $d_i$ and sections $s_i \in \Gamma(\mathbb{P}^n, \mathcal{O}(d_i)), i = 1 \ldots n, s_i|_{\mathbb{P}^n-1} = \iota_i^{d_i}$, where $\mathbb{P}^{n-1} \subset \mathbb{P}^n$ is the subspace at infinity and $t_\infty \in \mathcal{O}(1), Z(t_\infty) = \mathbb{P}^{n-1}$. Similarly we can choose sections $s_i \in \Gamma(\mathbb{P}^n, \mathcal{O}(d_i)), 1 \leq i \leq k, e_i/t_i^{d_i}|_{Z(I(Z(s)))} = g_i|_{Z(I(Z(s)))}$.
where the \(g_i\)'s are the coordinates of the composition \(V \xrightarrow{g} Y \hookrightarrow \mathbb{A}^n\). The functions \(\lambda v^*(s_i/t_i^{d_i}) + (1 - \lambda)(\varphi_i)\) and \(\lambda v^*(\epsilon_i/t_i^{d_i}) + (1 - \lambda)g_i\) give a homotopy from \(c\) to the framed correspondence

\[
(\mathbb{A}^n - (Z(s_1, \ldots, s_n) - Z), Z, (s_i/t_i^{d_i}), (\epsilon_i/t_i^{d_i})).
\]

Then applying Lemma 5.3 we can change \(c\) in such way that for a new vector of sections \((s_i)\) we have

\[
(6.2) \quad Z_{red}(s_1, \ldots, s_{n-1}) \not\subseteq \bigcup_{1 \leq j < n} \text{Sing} Z_{red}(s_1, \ldots, s_j).
\]

Since the original framed correspondence \(c\) is equivalent, up to homotopy, to the resulting framed correspondence, we denote the resulting framed correspondence by the same symbol \(c \in Fr_n(pt_k, Y)\).

Consider the closed subscheme of dimension one \(\tilde{Z} = Z_{red}(s_1, \ldots, s_n) \subset \mathbb{P}^n\). Since \(k\) is perfect, the generic points of \(\tilde{Z}\) are smooth. Let \(C\) be the union of the irreducible components of \(\tilde{Z}\) that intersect \(Z\), where \(Z\) is the support of \(c\). Denote \(\mathfrak{C}_n = s_n|_C\). Since \(Z_{red}(\mathfrak{C}_n) = Z_{red}(s_1, \ldots, s_n) = Z \sqcup Z'\) there are line bundles \(\mathcal{L}\) and \(\mathcal{L}'\) on \(C\) such that \(\mathcal{L} \otimes \mathcal{L}' = \mathcal{O}(d_i)\), with sections \(\mathfrak{C} \in \Gamma(C, \mathcal{L}), \mathfrak{C}' \in \Gamma(C, \mathcal{L}')\), such that \(Z(\mathfrak{C}) = Z, Z(\mathfrak{C}') \cap Z = \emptyset\), and \(\mathfrak{C}_n = \mathfrak{C} \cdot \mathfrak{C}'\).

Denote

\[
D = C \cap \left( \mathbb{A}^n - C \cup \bigcup_{1 \leq j < n} \text{Sing}(Z_{red}(s_1, \ldots, s_j)) \cup Z' \cup U^c \right),
\]

where \(U^c\) is the complement in \(\mathbb{P}^n\) of the open subscheme \(U = g^{-1}(Y)\), and \(g = (e_j/t_j^{d_j})_j: \mathbb{A}^n \to \mathbb{A}^n\). It follows from Lemma 6.2 that \(D\) is proper in \(C\). Note that by definition \(C - D\) is smooth. Denote\(D_1 = D \cap \mathbb{P}^n - 1, D_2 = D - D_1\). Now applying Lemma 6.3 to the curve \(C\), the closed subsets \(D_1,\ D_2\), and \(B = D\), the section \(t_\infty\) of the ample sheaf \(\mathcal{O}(1)\), and the invertible sheaf \(\mathcal{L}\), for all \(d_j > N\), for some \(N \in \mathbb{Z}\), for all field extensions \(K/k\), \(\deg K > R(d)\), for some \(R(d) \in \mathbb{Z}\), we find a sections \(s_n \in \Gamma(C, \mathcal{L}(d_j))\), \(s_n \in \Gamma(C, \mathcal{O}(d_j))\) such that \(Z(s^+)\) and \(Z(s^-)\) are smooth, \(s^+|_{D_K} = (s - s^-)|_{D_K} = s^{|_{Z(s_1, \ldots, s_n) \cup D_2}} = t_\infty,\) and \(s^+, s^-\) are invertible on \(D_K = D \times \text{Spec} K\).

Define the correspondences \(c^+_K\) and \(c^-_K\) in \(Fr_n(pt_K, Y \times \text{Spec} K)\) as

\[
c^+_K = (Z(s_1, \ldots, s_{n-1}, s^+), \mathbb{A}^n - Z', (s_1/t_1^{d_1}, \ldots, s_{n-1}/t_{n-1}^{d_{n-1}}, f^+), g),
\]

\[
c^-_K = (Z(s_1, \ldots, s_{n-1}, s^-), \mathbb{A}^n - Z', (s_1/t_1^{d_1}, \ldots, s_{n-1}/t_{n-1}^{d_{n-1}}, f^-), g).
\]

where \(f^+ \in \mathcal{O}(\mathbb{A}^n)\) is a lift of a regular function \(\mathfrak{C} \cdot s^+/t_\infty^{d_1 + d_n} \in \mathcal{O}(C - (C \cap \mathbb{P}^n - 1))\), and \(f^- \in \mathcal{O}(\mathbb{A}^n)\) is a lift of \(\mathfrak{C} \cdot s^-/t_\infty^{d_1 + d_n} \in \mathcal{O}(C - (C \cap \mathbb{P}^n - 1))\).

Thus we see that \(c^+_K\) and \(c^-_K\) are \((n)\)-simple framed correspondences and \([c^+_K] = [c^-_K] = \sum Fr_n(pt_K, Y \times \text{Spec} K)\), where \(c^+_K\) is the image of \(c\) by base change from \(k\) to \(K/k\). Now using the finite descent from Section 2 we get that \([c] = [c^+] = [c^-] \in \mathbb{Z} Fr_n(pt_k, Y)\) for some \((n)\)-simple framed correspondences \(c^+\) and \(c^-\). More precisely, we consider a pair of extensions such that \((\deg K_1/k, \deg K_2/k) = (\deg K_1, \deg K_2, \deg \text{char} k) = (\deg K_2, \text{char} k)\). Then in the notation of Lemma 2.14 we can define \(c^+ = pr \circ (c^+_k \oplus c^-_k) \circ L\), and similarly for \(c^-\).

**Lemma 6.6.** Let \(i = 1 \ldots n - 1\). Then for any \((i + 1)\)-simple framed correspondence \(c = (Z \subset \mathbb{A}^n, v: V \to \mathbb{A}^n, \phi, g: V \to Y) \in Fr_n(pt_k, Y)\) for some open \(Y \subset \mathbb{A}^n\), there exist \(c^+, c^- \in Fr_n(pt_k, Y)\), such that \(c^+\) and \(c^-\) are \((i)\)-simple correspondences, and \([c] = [c^+] + [c^-] \in \mathbb{Z} Fr_n(pt_k, Y)\).

**Proof.** Consider the closed subscheme of dimension one \(\tilde{Z} = Z_{red}(s_1, \ldots, s_{n-1}) \cap Z(s_{i+1}, \ldots, s_n) \subset \mathbb{P}^n\). We will prove that \(\tilde{Z} \neq \text{Sing} \tilde{Z}i\).

Since \(c\) is \((i)\)-simple \(Z \subset Z_{red}(s_1, \ldots, s_i) - \text{Sing}(Z_{red}(s_1, \ldots, s_i)), \) and so any closed point \(z \in Z\) is a smooth point of \(Z_{red}(s_1, \ldots, s_i)\). Hence \(\dim T = n - i, \) where \(T = T_z(Z_{red}(s_1, \ldots, s_i))\) is the tangent vector space. On the other hand, by assumption \(Z'\) is smooth, where \(Z' = Z_{red}(s_1, \ldots, s_i) \cap Z(s_{i+1}, \ldots, s_n)\). Hence the gradients \(d\phi_j\) of the functions \(\phi_j = s_j/t_j^{d_j}, j > i,\) are linearly independent on \(T;\) and consequently the gradients \(d\phi_j, j > i,\) are linearly independent on the tangent space \(T_z(Z_{red}(s_1, \ldots, s_i)) \supset T.\) Thus \(z\) is a smooth point on \(\tilde{Z}_i\), and hence there is a smooth Zariski neighbourhood of \(z\) in \(\tilde{Z}_i\).

The rest of the proof is similar to the proof of Lemma 6.5. Namely, let \(C\) be the union of the irreducible components of \(\tilde{Z}_i\) that intersect \(Z_i\). Then there are line bundles \(\mathcal{L}\) and \(\mathcal{L}'\) on \(C\) such that \(\mathcal{L} \otimes \mathcal{L}' = \mathcal{O}(d_i)\),
and sections \( \overline{s} \in \Gamma(C, \mathcal{L}), \overline{s}' \in \Gamma(C, \mathcal{L}'), \) such that \( Z(\overline{s}) = Z_i, Z(\overline{s}') \subset Z' \), where \( Z \cup Z' = Z(s_1 \ldots s_n) \). Denote
\[
D = C \cap (\overline{Z_i} - C) \cup \bigcup_{j < i} \text{Sing}(Z_{\text{red}}(s_1, \ldots, s_j)) \cup Z' \cup U^c), D_1 = D \cap \mathbb{P}^{n-1}, D_2 = D - D_1.
\]
Since \( c \) is \((i)\)-simple, \( Z \subset \mathbb{P}^n - \bigcup_{j < i} \text{Sing}(Z_{\text{red}}(s_1, \ldots, s_j)) \). Hence \( D \subset \overline{Z_i} \) is proper. By the above \( B = D \cup \text{Sing} C \) is proper too. Applying Lemma \[\text{6.3}\] to the curve \( C \), and the proper closed subsets \( D_1, D_2 \), and \( B = D \cup \text{Sing} C \) we obtain the claim over all field extensions \( K/k \), \( \deg K > R \) for some integer \( R \). The finite descent of Section \[\text{2}\] finishes the proof as in the previous lemma. \( \square \)

**Lemma 6.7.** Let \( C \) be a reduced projective curve over a perfect field \( k \), and \( D \subset C \) a proper closed subscheme such that \( C - D \) is smooth. Let \( \mathcal{L} \) be an invertible sheaf on \( C \), \( \mathcal{O}(1) \) an ample invertible sheaf on \( C \), and \( r \) and \( r' \) invertible sections of \( \mathcal{L} \) and \( \mathcal{O} \) on \( D \). Then there exists an integer \( N \) such that for all \( d > N \) there exists an integer \( R(d) \) such that for all field extensions \( K/k \) of degree \( \deg K > R(d) \), there exists a section \( s \in \Gamma(C, \mathcal{L}(d)) \) such that \( Z(s) \) is smooth and \( s|_D = r \cdot r'^d \).

**Proof.** Consider the affine space \( \Gamma \part_\mathcal{L}(d), s \in \Gamma \part_\mathcal{L}(d) \) iff \( s|_D = r \cdot r'^d \). Consider the universal section \( \bar{s} \in \Gamma(C \times \Gamma \mathcal{L}(d), \Gamma \part \mathcal{L}(d)), \) and its vanishing locus \( Z(\bar{s}) \), which is a closed subscheme \( Z(\bar{s}) \subset C \times \Gamma \part \mathcal{L} \). The image of \( \text{Supp} \Omega_{Z(\bar{s})/\Gamma \mathcal{L}(d)} \subset Z(\bar{s}) \) under the projection to \( \Gamma \part \mathcal{L} \) is the closed subscheme which parametrizes the set of sections \( s \) such that \( Z(s) \subset C \) is non-reduced. Denote this image by \( B_d \) and let \( U_d \subset \Gamma \part \mathcal{L} \) be the complement of \( B_d \).

To find a section \( s \) satisfying the requirements of the lemma is equivalent to finding a rational point in \( U_d \) for all \( d \) greater than some integer \( N \). We want to prove that there exists \( R \) such that for all \( K \) of degree \( \deg K/k > R \) there exists \( s \in \Gamma \part \mathcal{L}(K) \). Since \( U_d \) is an open subscheme in an affine space over \( k \), it suffices to show that there exists some integer \( N \) such that for all \( d > N \) we have \( U_d \neq \emptyset \). At the same time, to prove that \( U_d \neq \emptyset \) it suffices to prove this over an algebraic closure \( \overline{k} \), that is, \( (U_d)_{\overline{k}} \neq \emptyset \).

Thus we need to prove that \( U_d \neq \emptyset \) for all \( d \) greater than some \( N \) under the assumption that \( k \) is algebraically closed. For an algebraically closed field \( K \), \( \deg K > R(d) \), there exists a section \( s \in \Gamma(C, \mathcal{L}(d)) \) such that \( Z(s) \) is smooth and \( s|_D = r \cdot r'^d \).

We claim that there exists some \( d \in Z \) such that for each point \( p \in C' \) we have
\[
(\text{codim}_{\mathcal{L}_d}(\{s \in \Gamma \part \mathcal{L}(d)|s|_{Z(I(p)^2)} = 0\}) = 2.
\]
Then (\text{6.3}) implies the lemma. Indeed, if for all \( p \in C' \), \( \text{codim}_{\mathcal{L}_d}(\{s \in \Gamma \part \mathcal{L}(d)|s|_{Z(I(p)^2)} = 0\}) = 2 \), then \( \text{dim}(E_d) \leq \text{dim}(C') + \text{dim}(\Gamma \part \mathcal{L}) - 2 \), and hence \( \text{codim}_{\mathcal{L}_d}(B_d) = \text{dim}(\Gamma \part \mathcal{L}) - \text{dim}(B_d) \geq \text{dim}(\mathcal{L}) - \text{dim}(E_d) \geq 1 \).

To prove (\text{6.3}) it suffices to prove that for some \( d \in Z \) and for all \( p \in C' \), the restriction homomorphism \( r^d_p : \Gamma(C, \mathcal{L}(d)) \to \Gamma(Z(I(p)^2) \cap D, \mathcal{L}(d)) \) is surjective. Consider the scheme \( C' \times C \) as a relative curve over \( C' \), and let \( \Delta \subset C' \times C \) be the graph of the embedding \( C' \to C \). Then the set of points \( p \in C' \) such that \( r^d_p \) is not surjective is equal to
\[
W_d = \text{Supp} \text{pr}_2(C \text{oker}(\mathcal{L}(d) \to j^*j_\ast \mathcal{L}(d))).
\]
where \( pr : C' \times C \to C' \), \( i : C' \times D \to C' \times C \), \( j : Z \to C' \times C \), \( Z = Z(I(\Delta)^2) \cap C' \times D \), and \( j_* \) and \( j^* \) are the direct and inverse images of coherent sheaves. Since \( \mathcal{O}(1) \) is ample, it follows that for each \( p \in C' \) there is \( N \) such that for all \( d > N \) the restriction homomorphism \( r^d_p \) is surjective. So (\text{6.3}) follows since \( C' \) is a noetherian scheme of finite Krull dimension. \( \square \)

**Lemma 6.8.** Let \( C \) be a reduced projective curve over a perfect field \( k \), \( D_1 \cup D_2 = D \subset B \subset C \) be closed subsets such that \( C - B \) is smooth and non-empty; let \( s \in \Gamma(C, \mathcal{L}) \) be a section in some invertible sheaf \( \mathcal{L} \) on \( C \) such that \( s|_D \) is invertible; let \( \mathcal{O}(1) \) be any ample bundle on \( C \) with a section \( t \in \Gamma(C, \mathcal{O}(1)) \) such that \( Z_{\text{red}}(t) \subset D_1 \).

Then for all \( d > N \), for some \( N \in Z \), for all field extensions \( K/k \), \( \deg_k K > R(d) \), for some \( R(d) \), there exist \( s^+ \in \Gamma(C_K, \mathcal{L}(d)), s^- \in \Gamma(C_K, \mathcal{O}(d)) \) such that \( Z(s^+) \) and \( Z(s^-) \) are smooth, \( s^+|_{D_K} = (s \cdot s^-)|_{D_K}, s^-|_{Z(s) \cup D_2} = t \), and \( s^+, s^- \) are invertible on \( B_K = B \times \text{Spec} K \) (and consequently on \( D_K = D \times \text{Spec} K \)).
Proof. Since $D_1 \cap D_2 = D_1 \cap Z(s) = D_2 \cap Z(s) = \emptyset$, and since $B$ is a zero-dimensional scheme, it follows that $B$ splits into a disjoint union of

$$B_1 = B - (D \cup Z(s)), \quad B_2 = B - (D_2 \cup Z(s) \cup B_4),$$

$$B_3 = B - (D_1 \cup Z(s) \cup B_4), \quad B_4 = B - (D \cup B_4).$$

Let $r_1$ be any invertible sections of $\mathcal{O}(1)$ on $B_1$, and let $w$ denote any invertible section on $\mathcal{L}$ on $B_3 \cup B_4$.

Applying Lemma 6.7 to the closed subset $B_1$, the line bundle $\mathcal{O}(1)$, and the invertible section $r_1 \oplus t^d|_{B_2 \cup B_3 \cup B_4}$, we see that there exists $N_1$, such that for all $d > N_1$ there exists $R_1(d)$ such that for all $K/k, \deg K/k > R_1(d)$, there exists a section $s^- \in \Gamma(C_K, \mathcal{O}(d))$ such that $s^−|_{Z(s) \cup D_2} = t^d$, $s^−|_{D_1} = r_1^d$, and such that $Z(s^-)$ is smooth.

Applying Lemma 6.7 to the closed subset $B$, the line bundles $\mathcal{L}(N_1)$, $\mathcal{O}(1)$ and the invertible section

$$(s \cdot s^-)_D \Pi((w \cdot t^N_1) \in \Gamma((B_1 \cup B_2) \Pi (B_3 \cup B_4), \mathcal{L}(N_1)),$$

we see that there exists $N$ such that for all $d > N$ there exists $R(d)$ such that for all $K, \deg K/k > R(d)$, there exists a section $s^+ \in \Gamma(C_K, \mathcal{L}(d))$ such that $s^+|_{D_2} = st^d|_{D_2}$, $s^+|_{D_1} = sr_1^d|_{D_1}$, $s^+|_{B_3 \cup B_4} = wt^d$, and $Z(s^+)$ is smooth.

So we get the sections $s^+$, $s^-$ with the required properties $s^+ = ss^-|_D$ and $Z(s) \subset C - B$, $Z(s)$ is smooth. \hfill \Box

**Lemma 6.9.** For any framed correspondence $c \in Fr_1(pt_k, pt_k)$ there is a pair of standard framed correspondences $c^+, c^- \in Fr_1(pt_k, pt_k)$ such that $[c] = [c^+] - [c^-] \in \overline{ZF}(pt_k, pt_k) = H_0(\overline{ZF}(\Delta^*, pt_k))$.

Proof. Following the original strategy of the proof of [16] Lemma 5.4] we see that it suffices to consider the case

$$c = \left( Z(f), A^1_k, f, pr \right) \in Fr_1(pt_k, pt_k),$$

where $f \in k[A^1_k]$, $pr: Z(f) \to pt_k$ is the projection. For completeness we recall the arguments from [16] Lemma 5.4].

Firstly, by Lemma 6.4 and [16] Lemma 4.10] we can reduce to consider a simple correspondence $c \in Fr_1(pt_k, pt_k)$. Now, let $c = \left( Z(f), A^1_k, f, pr \right) \in Fr_1(pt_k, pt_k)$, where $f \in k[A^1_k] = k[t] \deg f = n$, $g \in k[A^1_k] = k[t], Z(g) \cap Z(f) = \emptyset$, $pr: Z(f) \to pt_k$ is the projection. We prove that the class of $c$ is a sum of classes of correspondences of the form (6.4). Actually, let $g' \in k[t]$ be a polynomial of degree $n - 1$ such that $g|_{Z(f)} = g'|_{Z(f)}$. Then because of the homotopy given by $\lambda g' + (1 - \lambda) g$ we see that we can assume that $g' = g$. Then the class of the correspondence $c' = \left( Z(g), A^1_k, f, pr \right) \in Fr_1(pt_k, pt_k)$ satisfies the induction assumption. Hence the claim follows, since $[c] = \left( Z(f), A^1_k, f, pr \right) - \left( Z(g), A^1_k, f, pr \right) \in ZFr_1(pt_k, pt_k)$.

Now all that is needed is to show that the class of (6.4) is standard. But this is true, since the homotopy $\lambda x^n + (1 - \lambda) f$ and Lemma 6.4 implies that $[c] = mh$, for $n = 2m$, or $[c] = mh + 1$, for $n = 2m + 1$. \hfill \Box

**Remark 6.10.** Alternatively we could say that the proof of the above lemma presented in [16] Lemma 5.4] holds for an arbitrary infinite field and the deduce the finite field case using the finite descent form the section 2.
