Abstract

We develop a set of tools for doing computations in and of (partially) wrapped Fukaya categories. In particular, we prove (1) a descent (cosheaf) property for the wrapped Fukaya category with respect to so-called Weinstein sectorial coverings and (2) that the partially wrapped Fukaya category of a Weinstein manifold with respect to a mostly Legendrian stop is generated by the cocores of the critical handles and the linking disks to the stop. We also prove (3) a ‘stop removal equals localization’ result, and (4) that the Fukaya–Seidel category of a Lefschetz fibration with Weinstein fiber is generated by the Lefschetz thimbles. These results are derived from three main ingredients, also of independent use: (5) a Künneth formula (6) an exact triangle in the Fukaya category associated to wrapping a Lagrangian through a Legendrian stop at infinity and (7) a geometric criterion for when a pushforward functor between wrapped Fukaya categories of Liouville sectors is fully faithful.

0 Introduction

The goal of this paper is to develop a set of computational tools for wrapped Fukaya categories. The capstone result, called (Weinstein) sectorial descent, gives a Čech-type decomposition of the wrapped Fukaya category $\mathcal{W}(X)$ of a Weinstein manifold (or sector) $X$ from a Weinstein sectorial cover $X = X_1 \cup \cdots \cup X_n$. In such a cover, all multiple intersections $X_i \cap \cdots \cap X_k$ are Weinstein sectors. Sectorial descent (Theorem 1.27) is the assertion that the following natural map is a pre-triangulated equivalence (i.e. a quasi-equivalence on twisted complexes):

$$\text{hocolim}_{\varnothing \neq I \subseteq \{1, \ldots, n\}} \mathcal{W}\left( \bigcap_{i \in I} X_i \right) \rightarrow \mathcal{W}(X).$$

Note that on the left hand side, in the definition of $\mathcal{W}(\bigcap_{i \in I} X_i)$ both holomorphic disks and wrappings are localized to the sector $\bigcap_{i \in I} X_i$.

The descent formula (0.1) is a variation on Kontsevich’s conjecture [34] that the wrapped Fukaya category of a Weinstein manifold $X$ is the category of global sections of a natural cosheaf of categories on any core of $X$; note that such a core is in general highly singular and depends on a choice of symplectic primitive (Liouville form). Our formulation (0.1) of this cosheaf property, on the other hand, has the virtue of neither requiring a discussion of singular spaces nor depending on a choice of primitive. Roughly speaking, a choice of primitive should induce a Weinstein sectorial cover; for example, a ribbon graph as the core of a punctured surface determines a covering by ‘$A_{n-1}$ Liouville sectors’ ($D^2$ minus $n$ boundary punctures) corresponding to the vertices of the graph (with $n$ being the degree of a given vertex). Our formulation (0.1) also refines Kontsevich’s original conjecture by giving a Floer-theoretic interpretation of the local categories: they are partially wrapped Fukaya categories.

The main tool in the proof of (0.1), and also our central object of study in this paper, is the partially wrapped Fukaya category. Along the way to the proof of Theorem 1.27, we establish a package of new structural results of independent interest concerning partially wrapped Fukaya categories, including a Künneth formula, an exact triangle, generation results, and geometric criteria for functors between such Fukaya categories to be fully faithful embeddings or to be localizations.

The partially wrapped Fukaya category $\mathcal{W}(X, f)$ depends not only on a Liouville manifold $X$ but also a closed subset $f \subseteq \partial_{\infty} X$ known as the stop. Its objects are (possibly non-compact) Lagrangian submanifolds of $X$ disjoint from $f$, with morphisms given by Floer cohomology after wrapping Lagrangians in the complement of $f$. The idea that Fukaya categories of non-compact Lagrangians with some sort of wrapping should exist and be of interest goes back to early work on mirror symmetry. Fukaya categories of Landau–Ginzburg models $f : X \rightarrow \mathbb{C}$, which were introduced by Kontsevich [35] and developed by Seidel [41], are partially wrapped Fukaya categories with stop $f = f^{-1}(-\infty)$. The wrapped Fukaya category defined by Abouzaid–Seidel [6] is the case $f = \varnothing$. The general framework of partially wrapped Fukaya categories was introduced by Auroux [7, 8], and precise definitions in the case that the stop is a Liouville hypersurface $F \subseteq \partial_{\infty} X$ are given in [42, 26]. In addition, the study of Legendrian contact homology for Legendrian $\Lambda$, going back to ideas of Chekanov [13] and Eliashberg [21], can be understood as the study of a partially wrapped Fukaya category with
The enormous variety of possible stops \( f \) gives great expressive power to the partially wrapped Fukaya category compared with the (fully) wrapped Fukaya category. The stopped Liouville manifold \((\mathbb{C}, \{\pm \infty\})\) allows for a stabilization operation in the partially wrapped context, namely there is a fully faithful embedding \( \mathcal{W}(X) \hookrightarrow \mathcal{W}(X \times (\mathbb{C}, \{\pm \infty\})) \). By contrast, in the fully wrapped context there is no such embedding: \( \mathcal{W}(X \times \mathbb{C}) = 0 \); multiplying by base or fiber in \( T^*S^1 \) gives a map \( \mathcal{W}(X) \to \mathcal{W}(X \times T^*S^1) \) which is faithful, but still not fully faithful.

In this paper, we focus on stops \( f \subseteq \partial_\infty X \) which are *mostly Legendrian* in the sense of admitting a closed-open decomposition \( f = f_{\text{subcrit}} \cup f_{\text{crit}} \) where \( f_{\text{crit}} \) is Legendrian and the dimension of \( f_{\text{subcrit}} \) is strictly smaller (see Definition 1.6). This class of stops is related to Liouville hypersurface stops in that \( \mathcal{W}(X, F) = \mathcal{W}(X, \text{core}(F)) \), and when \( F \) is Weinstein, its core is mostly Legendrian. We emphasize, however, that mostly Legendrian stops arise naturally in other ways as well (for example as conormals to stratifications), and it is highly desirable to have a theory which does not require the stop to be the core of a Liouville hypersurface.

The key property of mostly Legendrian stops \( f \) which we exploit in our study of their partially wrapped Fukaya categories is that a generic isotopy of Legendrians inside \( \partial_\infty X \) will intersect \( f \) at a discrete set of times by passing transversally through \( f_{\text{crit}} \). The effect of such a crossing can be quantified using the *small Lagrangian linking disks* \( D_p \) at the smooth Legendrian points \( p \in f_{\text{crit}} \). Namely, if \( L^w \subseteq X \) is obtained from \( L \) by passing \( \partial_\infty L \) positively transversally through a smooth Legendrian point \( p \in f \), then there is an exact triangle \( L^w \to L \to D_p \) in \( \mathcal{W}(X, f) \) (see Theorem 1.9). This *wrapping exact triangle* is fundamental to our work in this paper.

As a first application of the wrapping exact triangle (and stabilization), we offer a suprisingly simple proof that the wrapped Fukaya category of a Weinstein manifold is generated by its cocores (Theorem 1.10; another proof of this result is due independently to Chantraine–Dimitroglou Rizell–Ghiggini–Golovko [12]).

The wrapping exact triangle also allows one to relate the partially wrapped Fukaya categories with respect to different stops, leading to a powerful computational method. This should be contrasted with the fact that direct computation of \( \mathcal{W}(X, f) \) involves understanding explicitly the long time Reeb flow on \( \partial_\infty X \setminus f \), which outside a small class of examples is essentially intractable. However, perhaps counterintuitively, carefully enlarging the stop often has the effect of simplifying the Reeb flow. That is, there is often a natural choice of \( g \supseteq f \) for which the category \( \mathcal{W}(X, g) \) is easy to calculate or has convenient categorical properties such as properness, etc. The two categories are then related by the *stop removal formula* Theorem 1.16: for stops \( f \subseteq g \) with \( g \setminus f \) mostly Legendrian, the pushforward functor \( \mathcal{W}(X, g) \to \mathcal{W}(X, f) \) is the quotient by the small Lagrangian disks linking \((g \setminus f)_{\text{crit}}\). This formula reduces the study of \( \mathcal{W}(X, f) \) to the study of \( \mathcal{W}(X, g) \) together with the linking disks of \((g \setminus f)_{\text{crit}}\). It is a direct consequence of the wrapping exact triangle; its precursors include [5, 42].

Of particular importance is the use of stop enlargement to create fully faithful functors. Given an inclusion of Liouville sectors \( X \hookrightarrow Y \), we may add a stop to \( Y \) along the ‘exit set’ of \( \partial_\infty X \) to obtain a Liouville sector \( Y|_X \) and a chain of inclusions \( X \hookrightarrow Y|_X \hookrightarrow Y \). Now the induced functor \( \mathcal{W}(X) \to \mathcal{W}(Y|_X) \) is fully faithful, simply because Lagrangians
in $X$, when wrapped in $Y|_X$, fall immediately into the stop without exploring the rest of $Y|_X \setminus X$. Corollary: if $F$ is a Liouville hypersurface inside $\partial_\infty Y$, then there is a fully faithful embedding $\mathcal{W}(F) \hookrightarrow \mathcal{W}(F \times T^*[0, 1]) \hookrightarrow \mathcal{W}(Y, F \sqcup F^+)$, where $F^+$ denotes a small positive pushoff of $F$. Even a complicated $F$ may sit in a simple $Y$ (e.g. a cotangent bundle).

In the factorization $X \hookrightarrow Y|_X \hookrightarrow Y$, the same reasoning shows moreover that $\mathcal{W}(Y|_X)$ contains both $\mathcal{W}(X)$ and $\mathcal{W}(Y \setminus X)$ as semi-orthogonal full subcategories. Adding appropriate Weinstein hypotheses so as to know generation by cocores, this is moreover a semi-orthogonal decomposition

$$\mathcal{W}(Y|_X) = \langle \mathcal{W}(Y \setminus X), \mathcal{W}(X) \rangle$$

from which it follows formally that

$$\text{hocolim}(\mathcal{W}(Y \cap Z) \Rightarrow \mathcal{W}(Z|_{Y \cap Z}) \oplus \mathcal{W}(Y|_{Y \cap Z})) \sim \mathcal{W}(X|_{Y \cup Z}).$$

Appealing to stop removal and the fact that homotopy colimits commute with localizations, we deduce the corresponding formula for the covering $X = Y \cup Z$. Arguing by induction proves (0.1).

## 1 Statement of results

### 1.1 Partially wrapped Fukaya categories

Let us begin by fixing our notation and terminology for partially wrapped Fukaya categories (see §2 for a full treatment); our setup is rather more general than that considered before [7, 8, 42, 32, 26].

For a Liouville manifold $X$ and any closed subset $\mathfrak{f} \subseteq \partial_\infty X$, henceforth referred to as a stop, we denote by $\mathcal{W}(X, \mathfrak{f})$ the partially wrapped Fukaya category of $X$ stopped at $\mathfrak{f}$: this is the Fukaya category whose objects are exact cylindrical Lagrangians inside $X$ disjoint at infinity from $\mathfrak{f}$ and whose morphisms are calculated by wrapping Lagrangians in the complement of $\mathfrak{f}$. For an inclusion of stops $\mathfrak{f} \supseteq \mathfrak{f}'$, there is a canonical pushforward “acceleration” functor

$$\mathcal{W}(X, \mathfrak{f}) \rightarrow \mathcal{W}(X, \mathfrak{f}').$$

We will refer to a pair $(X, \mathfrak{f})$ as a stopped Liouville manifold. More generally, we can take $X$ to be a Liouville sector in the following sense:

**Definition 1.1** (Liouville sector [26, Definition 2.4]). A Liouville sector is an exact symplectic manifold-with-boundary $(X, \lambda)$ which is cylindrical at infinity and for which there exists a function $I : \partial X \rightarrow \mathbb{R}$ which is linear at infinity and whose Hamiltonian vector field $X_I$ is outward pointing along $\partial X$.  

1 Statement of results
Remark 1.2 (Coordinates near the boundary of a Liouville sector). The existence of the “defining function” \( I \) above is equivalent to the existence of coordinates of the form \( X = F \times \mathbb{C}_{\Re \geq 0} \) (or, equivalently, \( X = F \times T^* \mathbb{R}_{ \geq 0} \)) over a cylindrical neighborhood of the boundary, where \( F \) is a Liouville manifold called the *symplectic boundary* of \( X \) (see [26, §2.6]). The associated projection \( \pi : \text{Nbd}_Z \partial X \to \mathbb{C}_{\Re \geq 0} \) prevents holomorphic curves in \( X \) from approaching \( \partial X \) (for almost complex structures which make \( \pi \) holomorphic, of which there is a plentiful supply).

Given a stopped Liouville sector \((X, \mathcal{f})\) (meaning \( \mathcal{f} \) is a closed subset of \((\partial_\infty X)^\circ\)), there is a partially wrapped Fukaya category \( \mathcal{W}(X, \mathcal{f}) \) as above, where we compute morphisms by wrapping inside \((\partial_\infty X)^\circ \setminus \mathcal{f}\). For an inclusion of stopped Liouville sectors \((X, \mathcal{f}) \hookrightarrow (X', \mathcal{f}')\) (meaning \( X \hookrightarrow X' \) and \( \mathcal{f} \cap (\partial_\infty X)^\circ \subseteq \mathcal{f}' \)), there is a pushforward functor \( \mathcal{W}(X, \mathcal{f}) \to \mathcal{W}(X', \mathcal{f}') \) (the case \( \mathcal{f} = \mathcal{f}' = \emptyset \) was described in [26, §3]).

There is a correspondence between Liouville sectors and certain stopped Liouville manifolds which preserves the wrapped Fukaya category. To spell this out, let \((\bar{X}, F)\) be a *Liouville pair* [9, 22], meaning \( \bar{X} \) is a Liouville manifold and \( F_0 \subseteq \partial_\infty \bar{X} \) is a *Liouville hypersurface*, namely a hypersurface-with-boundary along with a contact form \( \alpha \) on \( \partial_\infty \bar{X} \) for which \((F_0, \alpha|_{F_0})\) is a Liouville domain whose completion is \( F \). By removing from \( \bar{X} \) a standard neighborhood of \( F_0 \), we obtain a Liouville sector \( X = \bar{X} \setminus \text{Nbd} F_0 \) [26, Definition 2.14]. Going in the other direction, \( \bar{X} \) may be obtained from \( X \) by gluing \( F \times \mathbb{C}_{\Re \leq \varepsilon} \) onto \( X \) via the coordinates \( X = F \times \mathbb{C}_{\Re \geq 0} \) from Remark 1.2. Up to contractible choice, this gives a correspondence between Liouville sectors \( X \) and Liouville pairs \((\bar{X}, F)\) (see [26, Lemma 2.32]); \( \bar{X} \) is known as the *convex completion* (or *convexification*) of \( X \) and \( F \) as the *symplectic boundary* of \( X \).

Now for a Liouville pair \((\bar{X}, F)\) and \( X = \bar{X} \setminus \text{Nbd} F_0 \) the associated Liouville sector, the natural functor

\[
\mathcal{W}(X) \xrightarrow{\sim} \mathcal{W}(X, F_0)
\]  (1.2)

is a quasi-equivalence (see Corollary 2.11); in view of the invariance of the wrapped Fukaya category under deformations of Liouville sectors, we may at times omit the subscript \( F \) and write \( \mathcal{W}(\bar{X}, F) \). The core \( c_F =: \mathcal{f} \) of \( F \) refers to the set of points which do not escape to the boundary under the Liouville flow. The core is a closed subset, in general highly singular. In the other direction, we call \( F_0 \) a *ribbon* for \( \mathcal{f} \). The natural functor

\[
\mathcal{W}(\bar{X}, F_0) \xrightarrow{\sim} \mathcal{W}(\bar{X}, \mathcal{f})
\]  (1.3)

is also a quasi-equivalence (see Corollary 2.11). It is frequently convenient to have at hand both descriptions \( \mathcal{W}(X) \) and \( \mathcal{W}(\bar{X}, \mathcal{f}) \) of the same Fukaya category.

Remark 1.3 (Existence and choice of ribbons). It is likely a subtle question whether a given closed subset \( \mathcal{f} \subseteq \partial_\infty X \) admits a ribbon, and whether such a ribbon is unique. A choice of ribbon is needed to define the corresponding Liouville sector (whose Fukaya category admits a greater range of pushforward functors); though note that the pair \((X, \partial_\infty X \setminus \mathcal{f})\) is an *open Liouville sector* in the sense of [26, Remark 2.8] given only the existence of a ribbon for \( \mathcal{f} \). Of course, the partially wrapped Fukaya category \( \mathcal{W}(X, \mathcal{f}) \) is defined without any assumptions at all about ribbons for \( \mathcal{f} \).
A deformation of Liouville sectors $X$ or of Liouville pairs $(\bar{X}, F)$ induces an equivalence on partially wrapped Fukaya categories. Note, however, that during a deformation of Liouville pairs, the core $f$ of $F$ may change rather drastically, and hence it is natural to ask the general question of which sorts of deformations of a stop $f$ induce equivalences on partially wrapped Fukaya categories. Among other results in this direction, we show that constancy of the complement of $f$ as a contact manifold is sufficient:

**Theorem 1.4.** Let $X$ be a Liouville sector, and let $f_t \subseteq (\partial_\infty X)^\circ$ be family of closed subsets. If $\bigcup_{t \in [0,1]} [t] \times f_t \subseteq [0,1] \times (\partial_\infty X)^\circ$ is closed and the projection of its complement to $[0,1]$ is (equipped with its fiberwise contact structure) isomorphic to a trivial family over $[0,1]$, then there is a natural quasi-equivalence $W(X, f_0) = W(X, f_1)$.

### 1.2 Künneth embedding

Floer theory is generally well-behaved under taking products of symplectic manifolds and Lagrangian submanifolds, and this extends to the wrapped setting. Oancea [39] proved a Künneth formula for symplectic cohomology of Liouville manifolds (see also Groman [31]). The analogous problem for wrapped Fukaya categories was first studied by Gao [28, 29], who constructed a Künneth functor after enlarging the target category to include product Lagrangians.\(^1\)

In §6, we construct the Künneth functor for partially wrapped Fukaya categories (which moreover does not require enlarging the target category). For stopped Liouville manifolds $(X, f)$ and $(Y, g)$, we denote by $(X, f) \times (Y, g)$ the product $X \times Y$ equipped with the product stop

$$(f \times c_Y) \cup (f \times g \times \mathbb{R}) \cup (c_X \times g),$$

where $c_X$ and $c_Y$ denote the cores of $X$ and $Y$, respectively. To make sense of this definition, note that if we let $c_{X,f} := c_X \cup (f \times \mathbb{R}) \subseteq X$ denote the “relative core”, then we have $c_{(X,f) \times (Y,g)} = c_{X,f} \times c_{Y,g}$.

**Theorem 1.5** (Künneth embedding). For Liouville sectors $X$ and $Y$, there is a fully faithful functor\(^2\)

$$W(X) \otimes W(Y) \hookrightarrow W(X \times Y),$$

and for stopped Liouville manifolds $(X, f)$ and $(Y, g)$, there is a fully faithful functor

$$W(X, f) \otimes W(Y, g) \hookrightarrow W((X, f) \times (Y, g)).$$

Both these functors send $(L \subseteq X, K \subseteq Y)$ to a canonical cylindrical perturbation $L \times K \subseteq X \times Y$ of the product $L \times K \subseteq X \times Y$. If $\lambda_X|_L \equiv 0$ and $\lambda_Y|_K \equiv 0$, then $L \times K$ is already cylindrical and no perturbation is necessary.

---

\(^1\)Recall that products of cylindrical Lagrangians are in general not themselves cylindrical—this is one source of difficulties in establishing the Künneth formula in this setting; see §6.2 for further discussion.

\(^2\) We use the notation $A \otimes B \to \mathcal{C}$ to indicate an $A_\infty$-bilinear-functor from $(A, B)$ to $\mathcal{C}$ in the sense of [38], rather than an $A_\infty$-functor from “the tensor product of $A$ and $B$” to $\mathcal{C}$. These notions should be quasi-equivalent for a suitable notion of tensor product of $A_\infty$-categories.
The Künneth embedding immediately gives rise to “stabilization functors”

\[ W(X) \hookrightarrow W(X \times T^*[0,1]), \]

\[ W(X, f) \hookrightarrow W(X \times \mathbb{C}, (\xi_X \times \{ \pm \infty \}) \cup (f \times \mathbb{R})), \]

(1.7)

(the former for Liouville sectors sending \( L \mapsto L \times [\text{fiber}] \), the latter for stopped Liouville manifolds sending \( L \mapsto L \times \varepsilon \mathbb{R} \)), which are of particular interest and use.

### 1.3 Mostly Legendrian stops

In this paper, we are primarily interested in stops which are mostly Legendrian in the sense of the following working definition:

**Definition 1.6 (Mostly Legendrian).** A closed subset \( \mathcal{f} \) of a contact manifold \( Y^{2n-1} \) is called **mostly Legendrian** iff it admits a decomposition \( \mathcal{f} = \mathcal{f}_{\text{subcrit}} \cup \mathcal{f}_{\text{crit}} \) for which \( \mathcal{f}_{\text{subcrit}} \) is closed and is contained in the smooth image of a second countable manifold of dimension \( < n - 1 \) (i.e. strictly less than Legendrian), and \( \mathcal{f}_{\text{crit}} \subseteq Y \setminus \mathcal{f}_{\text{subcrit}} \) is a Legendrian submanifold. When working with mostly Legendrian stops \( \mathcal{f} \), we will usually specify a decomposition \( \mathcal{f} = \mathcal{f}_{\text{subcrit}} \cup \mathcal{f}_{\text{crit}} \) (though for the most part, one could also simply take \( \mathcal{f}_{\text{crit}} \) to be as large as possible, namely the entire smooth Legendrian locus of \( \mathcal{f} \)). The notion of a **mostly Lagrangian** closed subset of a symplectic manifold is defined similarly.

The key property of this definition is that a generic positive Legendrian isotopy will intersect a given mostly Legendrian \( \mathcal{f} \) only by passing through \( \mathcal{f}_{\text{crit}} \) transversally (Lemma 2.3). In most applications, the relevant mostly Legendrian stops admit some sort of reasonable finite (or at least locally finite) stratification by disjoint locally closed isotropic submanifolds. However, the definition allows for rather more general phenomena (see Example 1.8).

Weinstein hypersurfaces (i.e. Liouville hypersurfaces which are Weinstein) are an important source of mostly Legendrian stops. Recall that a **Weinstein manifold** is a Liouville manifold \( W \) for which the Liouville vector field \( Z \) is gradient-like with respect to a proper Morse function \( \phi : W \to \mathbb{R}_{\geq 0} \) (see [15]). The zeroes of the Liouville vector field on a Weinstein manifold have index \( \leq \frac{1}{2} \dim W \); those for which this inequality is strict are called subcritical, and those of index \( = \frac{1}{2} \dim W \) are called critical. We extend this terminology to isotropic submanifolds of symplectic and contact manifolds: critical isotropics are those which are Lagrangian/Legendrian, and those of smaller dimension are called subcritical. The core \( c_W \) of a Weinstein manifold \( W \) is the union of the cores of the handles (i.e. the stable manifolds of the zeroes of \( Z \)). If the cocores of the critical handles are properly embedded (this is a generic condition), then writing \( c_W = c_{\text{subcrit}}^W \cup c_{\text{crit}}^W \) as the union of the cores of the subcritical and critical handles, respectively, we see that \( c_{\text{subcrit}}^W \) is closed, and hence this decompositions exhibits \( c_W \) as mostly Lagrangian. The cores of the handles of \( W \) are not only isotropic: the Liouville form vanishes identically on them (since \( Z \) is tangent to them). Thus the core \( \mathcal{f} \) of a Weinstein hypersurface \( F_0 \subseteq \partial_{\infty}X \) (with properly embedded critical cocores) is mostly Legendrian.

**Remark 1.7.** Even for the mostly Legendrian stops which arise naturally in practice, the question of whether they admit Weinstein ribbons (after small deformation) does not have an obvious answer. It is hence important, from a practical standpoint, to have a theory
which applies in the generality of mostly Legendrian stops, without any assumptions about the existence of ribbons.

**Example 1.8.** The union \( \mathfrak{f} \) of a Legendrian of dimension \( > 0 \) and a sequence of points limiting to a point on the Legendrian is mostly Legendrian—one takes \( \mathfrak{f}^{\text{crit}} \) to be the Legendrian minus the limit point. A cantor set contained in a submanifold of dimension \( < n - 1 \) is also mostly Legendrian. On the other hand, if \( \mathfrak{f} \subseteq Y \) is a Legendrian and \( \mathfrak{g} \subseteq Y \setminus \mathfrak{f} \) is a Legendrian accumulating at all points of \( \mathfrak{f} \), then \( \mathfrak{f} \subseteq Y \) and \( \mathfrak{g} \subseteq Y \setminus \mathfrak{f} \) are both mostly Legendrian, but \( \mathfrak{f} \cup \mathfrak{g} \subseteq Y \) is not. Note that the maps covering \( \mathfrak{f}^{\text{crit}} \) need not be disjoint: the union of two submanifolds of dimension \( < n - 1 \) interesecting along a cantor set is mostly Legendrian. Finally, note that there is no constraint on behavior approaching the boundary: the collection of conormals to inverses of integers \( \{\frac{1}{n}\}_{n \geq 2} \) is mostly Legendrian inside \( (\partial \infty T^*[0,1])^\circ \), although its closure inside \( (\partial \infty T^*[-1,1])^\circ \) is not.

### 1.4 Wrapping exact triangle

Underlying almost all of our results is an exact triangle (constructed in §§3–4) describing the effect in the Fukaya category of “wrapping through a stop”. To state it, recall that given a local Legendrian submanifold \( \Lambda \subseteq \partial \infty X \) near a point \( p \in \Lambda \), there is a small Lagrangian linking disk \( D_p \subseteq X \) whose boundary at infinity is a small Legendrian unknot linking \( \Lambda \) at \( p \) (these are defined in detail in §3.3). These linking disks may be thought of as ‘cocores at infinity’; precisely, if a stop \( \mathfrak{f} \) is the core of a Weinstein hypersurface \( F_0 \), then the canonical embedding \( F \times T^*[0,1] \hookrightarrow (X,\mathfrak{f}) \) sends a cocore in \( F \) times a fiber of \( T^*[0,1] \) to the linking disk at the corresponding smooth Legendrian point of \( \mathfrak{f} \).

**Theorem 1.9 (Wrapping exact triangle).** Let \( (X,\mathfrak{f}) \) be a stopped Liouville sector, and let \( p \in \mathfrak{f} \) be a point near which \( \mathfrak{f} \) is a Legendrian submanifold. If \( L \subseteq X \) is an exact Lagrangian submanifold and \( L^w \subseteq X \) is obtained from \( L \) by passing \( \partial \infty L \) through \( \mathfrak{f} \) transversally at \( p \) in the positive direction, then there is an exact triangle

\[
L^w \to L \to D_p \xrightarrow{[1]} \tag{1.9}
\]

in \( \mathcal{W}(X,\mathfrak{f}) \), where \( D_p \subseteq X \) denotes the small Lagrangian disk linking \( \mathfrak{f} \) at \( p \) and the map \( L^w \to L \) is the continuation map.

Many previous authors have also found exact triangles in the Fukaya category associated to other geometric operations, e.g. Seidel’s exact triangle of a Dehn twist [40], the exact triangle associated to Polterovich surgery (which was studied on Floer cohomology in [25]), and Biran–Cornea’s work on exact triangles in the Fukaya category of \( M \) associated to Lagrangian cobordims in \( M \times \mathbb{C} \) [10]. We will discuss the ingredients which go into the proof of the wrapping exact triangle in §1.10 below.

### 1.5 Generation by cocores and linking disks

An important problem in Floer theory is to find objects which generate the Fukaya category. In §7, we show how to prove a number of different generation results using the wrapping exact triangle.
**Theorem 1.10** (Generation by cocores and linking disks). Let \((X, f)\) be a stopped Weinstein manifold with \(f = f^{\text{subcrit}} \cup f^{\text{crit}}\) mostly Legendrian. Suppose that the cocores of the critical handles of \(X\) are properly embedded and disjoint from \(f\) at infinity. Then \(W(X, f)\) is generated by the cocores of the critical handles and the small Lagrangian disks linking \(f^{\text{crit}}\).

Note that since the linking disk \(D_p\) at \(p \in f^{\text{crit}}\) varies continuously in \(p\), its isomorphism class depends only on the connected component of \(p\) in \(f^{\text{crit}}\), so we need only take one such linking disk for each component of \(f^{\text{crit}}\) in Theorem 1.10.

The case of Theorem 1.10 in which \(f\) admits a Weinstein ribbon (compare Remark 1.7) was recently proven independently by Chantraine–Dimitroglou Rizell–Ghiggini–Golovko [12]. This generation result for Weinstein manifolds has long been expected (see Bourgeois–Ekholm–Eliashberg [11] and the discussion beneath [2, Theorem 1.1]), however it evaded proof for some time.

Let us sketch the proof of Theorem 1.10. Begin with the Künneth embedding

\[
W(X, f) \hookrightarrow W(X \times \mathbb{C}, (c_X \times \{\pm \infty\}) \cup (f \times \mathbb{R})), \quad (1.10)
\]

and the geometric observation that the images of the cocores and linking disks under this functor are precisely the linking disks of the product stop \((c_X \times \{\pm \infty\}) \cup (f \times \mathbb{R})\). It therefore suffices to show that \(L \times i\mathbb{R}\) is generated by the linking disks of this product stop. By the wrapping exact triangle Theorem 1.9, this will be the case as long as \(L \times i\mathbb{R}\) can be isotoped through the product stop to a zero object. For such an isotopy, we can simply take (a generic perturbation of) the (cylindrized) product of \(L\) with an isotopy of \(i\mathbb{R}\) inside \((\mathbb{C}, \{\pm \infty\})\) which passes one end through \(+\infty \in \partial_\infty \mathbb{C}\) to obtain a zero object of \(W(\mathbb{C}, \{\pm \infty\})\).

In fact, this argument can be made to work under weaker hypotheses, giving the following result:

**Theorem 1.11** (Generation by generalized cocores). Let \((X, f)\) be a stopped Liouville manifold whose relative core \(c_{X, f} := c_X \cup (f \times \mathbb{R})\) is mostly Lagrangian: \(c_{X, f} = c_{X, f}^{\text{subcrit}} \cup c_{X, f}^{\text{crit}}\). For every component of \(c_{X, f}^{\text{crit}}\), fix a ‘generalized cocore’: an exact Lagrangian \(c_X^{\text{crit}}\) exactly once, transversally, somewhere in the given component. Then \(W(X, f)\) is generated by these generalized cocores.

Observe that Theorem 1.11 is indeed a generalization of Theorem 1.10: the hypotheses of Theorem 1.10 imply that the relative core \(c_{X, f}\) is mostly Lagrangian, and we may take the cocores and the linking disks as the generalized cocores. Note that the existence of generalized cocores is a hypothesis of Theorem 1.11, not a conclusion. A stopped Liouville

---

3The results of [12] are phrased in the equivalent (by (1.2) and (1.3)) language of wrapped Fukaya categories of Weinstein sectors, which are Liouville sectors \(X\) whose convexification \(\tilde{X}\) and symplectic boundary \(F\) are both (up to deformation) Weinstein. They show that \(W(X)\) is generated by the cocores of \(\tilde{X}\) together with the stabilized cocores of \(F\), which by our discussion in §7.2 coincide with the linking disks to the critical part of the core \(f = c_F\) at infinity.

4Interestingly, while we do not know how to define (in general) the generalized cocore associated to a smooth Lagrangian point \(p \in c_{X, f}\), or even the corresponding object of \(W(X, f)\), the corresponding “once stabilized” object in \(W((X, f) \times (C_{Re \geq 0}, \infty))\) is easy to define: it is simply the small Lagrangian linking disk at \(p \times \infty\).
manifold \((X, \mathcal{f})\) satisfying the hypotheses of Theorem 1.11 will be called \textit{weakly Weinstein}. Note that if \(X\) is Weinstein and \(\mathcal{f}\) is mostly Legendrian, then \((X, \mathcal{f})\) is weakly Weinstein after small perturbation.

Theorem 1.11 is useful since many naturally arising (stopped) Liouville manifolds are weakly Weinstein but not Weinstein. For example, this is true for a cotangent bundle with a mostly Legendrian stop, or an affine algebraic variety equipped with a non-Morse plurisubharmonic function. While these usually can be perturbed to become Weinstein, it is often more convenient to deal directly with the given Liouville vector field, e.g. because it is more explicit or symmetric.

**Example 1.12** (\(\mathcal{W}(T^*Q)\) is generated by fibers). Let \(Q\) be a compact manifold-with-boundary. The cotangent bundle \(T^*Q\) is a Liouville sector, whose associated stopped Liouville manifold may be described as \((T^*Q^\circ, Z_{T^*Q^\circ} + \pi^*V)\) where \(V\) is a complete vector field on \(Q^\circ\) supported near the boundary and given in collar coordinates \((−\infty, 0] \times \partial Q\) by \(\varphi(t)\partial_t\) for \(\varphi\) supported near zero (\(\pi\) denotes the tautological lift from vector fields on \(Q^\circ\) to Hamiltonian vector fields on \(T^*Q^\circ\)). The relative core is simply \(Q^\circ\) itself, and any cotangent fiber is a generalized cocore. Thus Theorem 1.11 implies that [fiber] \(\in \mathcal{W}(T^*Q)\) (or rather one fiber over each connected component of \(Q\)) generates. In the case \(Q\) has no boundary, this result is due originally to Abouzaid [3].

Another generation result which follows from the wrapping exact triangle is the following:

**Theorem 1.13.** Let \(F\) be a Liouville manifold, and let \(\Lambda \subseteq \partial_{\infty}(F \times \mathbb{C}_{\text{Re} \geq 0})\) be compact and mostly Legendrian. Then the linking disks to \(\Lambda_{\text{crit}}\) generate \(\mathcal{W}(F \times \mathbb{C}_{\text{Re} \geq 0}, \Lambda)\).

Note that we do not assume that \(F\) is Weinstein in Theorem 1.13. By combining Theorems 1.10 and 1.13, we also derive:

**Corollary 1.14** (Generation by Lefschetz thimbles). Let \(\pi : \tilde{X} \to \mathbb{C}\) be a Lefschetz fibration with Weinstein fiber \(F\). The Fukaya–Seidel category \(\mathcal{W}(\tilde{X}, \mathcal{f} \times \{-\infty\})\) is generated by the Lefschetz thimbles.

The above generation results allow us to deduce in many cases that the K"unneth embedding is a \textit{pre-triangulated equivalence} (meaning fully faithful and image generates; compare with ‘quasi-equivalence’ = fully faithful and essentially surjective, and ‘Morita equivalence’ = fully faithful and image split-generates). In particular, since being weakly Weinstein is closed under taking products, and products of generalized cocores are generalized cocores, we have:

**Corollary 1.15** (Surjectivity of K"unneth). If \((X, \mathcal{f})\) and \((Y, \mathcal{g})\) are (up to deformation) weakly Weinstein, then the K"unneth embedding \(\mathcal{W}(X, \mathcal{f}) \otimes \mathcal{W}(Y, \mathcal{g}) \xrightarrow{\sim} \mathcal{W}((X, \mathcal{f}) \times (Y, \mathcal{g}))\) is a pre-triangulated equivalence.

Corollary 1.15 provides a potential path towards exhibiting Liouville manifolds which are not Weinstein: if \(\mathcal{W}(X \times Y)\) is not generated by cylindrizations of product Lagrangians, then at least one of \(X\) or \(Y\) cannot be deformed to be Weinstein (or even weakly Weinstein). In particular, if \(\mathcal{W}(X \times T^*[0,1])\) is not generated by \(L \times \text{[fiber]}\) for \(L \subseteq X\), then \(X\) is not Weinstein.
1.6 Stop removal

The real power of the partially wrapped Fukaya category comes from the ability to relate the partially wrapped Fukaya categories associated to different stops. The precise way in which these categories are related is the following result proved in §5:

**Theorem 1.16 (Stop removal)**. Let $X$ be a Liouville manifold (or sector) with two stops $f \subset g \subset (\partial_{\infty} X)^o$, such that $g \setminus f \subset (\partial_{\infty} X)^o \setminus f$ is mostly Legendrian. Then pushforward induces a quasi-equivalence
\[
\mathcal{W}(X, g)/\mathcal{D} \xrightarrow{\sim} \mathcal{W}(X, f),
\]
where $\mathcal{D}$ denotes the collection of small Lagrangian disks linking $(g \setminus f)^{\text{crit}}$.

This statement builds on two prior results: Abouzaid–Seidel [5] proved that for Lefschetz fibrations, the wrapped Fukaya category of the total space is a localization of the Fukaya–Seidel category, and Sylvan [42] showed (under certain hypotheses) that the partially wrapped Fukaya category of a Liouville pair localizes to give the (fully) wrapped Fukaya category. Note that both these results concern removing an entire connected component of a stop, whereas in Theorem 1.16 it is not required that $f$ be a connected component of $g$. This gives a significant added flexibility which is important in applications, being in particular essential in the proof of Theorem 1.27 and in [27]. Also note that Theorem 1.16 does not require the existence of a ribbon (compare Remark 1.7).

At the conceptual level at least, Theorem 1.16 is a straightforward consequence of the wrapping exact triangle Theorem 1.9. The functor $\mathcal{W}(X, g) \to \mathcal{W}(X, f)$ is essentially surjective by general position, so the content is in proving full faithfulness. To compare morphisms in $\mathcal{W}(X, g)$ and $\mathcal{W}(X, f)$, we must compare wrapping in the complement of $f$ with wrapping in the complement of $g$. A generic positive Legendrian isotopy in the complement of $f$ will intersect $g \setminus f$ at a discrete set of times, at each such time passing transversally through a single point of $(g \setminus f)^{\text{crit}}$. Theorem 1.9 states that the operation of passing $\partial_{\infty} L$ through $(g \setminus f)^{\text{crit}}$ once transversally at a point $p$ corresponds in $\mathcal{W}(X, g)$ to taking the cone of $L$ with the small Lagrangian disk linking $g \setminus f$ at $p$. Thus the pro-object of $\mathcal{W}(X, g)$ given by cofinally wrapping $L$ in the complement of $f$ is equivalent to $L$ in the category $\mathcal{W}(X, g)/\mathcal{D}$. Since this pro-object represents morphisms from $L$ in $\mathcal{W}(X, f)$ (by definition) and objects of $\mathcal{D}$ become zero objects in this category, this pro-object is left orthogonal to $\mathcal{D}$. It follows that this pro-object also represents morphisms in $\mathcal{W}(X, g)/\mathcal{D}$ from $L$, which thus proves the quasi-equivalence of Theorem 1.16.

**Example 1.17**. For a Weinstein manifold $X$, consider again the pair $(X \times \mathbb{C}_{\text{Re} \geq 0}, \epsilon_X \times \infty)$ (compare with the proof of Theorem 1.10). Applying Theorem 1.16 gives $\mathcal{W}(X \times \mathbb{C}_{\text{Re} \geq 0}, \epsilon_X \times \infty)/\mathcal{D} = \mathcal{W}(X \times \mathbb{C}_{\text{Re} \geq 0}) = 0$. Combined with the Künneth stabilization functor, we learn that the cocores split-generate $\mathcal{W}(X)$. Getting generation as in Theorem 1.10 requires the more controlled argument via the wrapping exact triangle given above.

**Example 1.18** (Calculation of $\mathcal{W}(T^*S^1)$). Let $X = T^*S^1$ and let $\Lambda$ be the co-0-sphere over some fixed point $x \in S^1$. Let $L$ be the cotangent fiber over a different point, and let $L(1)$ be $L$ ‘wrapped once around’. The objects $L, L(1) \in \mathcal{W}(T^*S^1, \Lambda)$ give a generating exceptional collection with $HW^\bullet(L, L(1))_{T^*S^1, \Lambda} = \mathbb{Z}^{\oplus 2}$, generated by one trajectory at infinity.
in each component of $T^\infty S^1$. This exceptional collection provides the mirror symmetry $\mathcal{W}(T^*S^1, \Lambda) \cong \text{Perf}(\bullet \hookrightarrow \bullet) \cong \text{Coh}(\mathbb{P}^1)$, intertwining

\begin{align*}
L &\rightarrow L(1) \rightarrow D_1 \xrightarrow{[1]} \Leftrightarrow \quad \mathcal{O} \rightarrow \mathcal{O}(1) \rightarrow \mathcal{O}_0 \xrightarrow{[1]} & (1.13) \\
L &\rightarrow L(1) \rightarrow D_2 \xrightarrow{[1]} \Leftrightarrow \quad \mathcal{O} \rightarrow \mathcal{O}(1) \rightarrow \mathcal{O}_\infty \xrightarrow{[1]} & (1.14)
\end{align*}

where $D_1, D_2 \in \mathcal{W}(T^*S^1, \Lambda)$ are the linking arcs around $\Lambda$.

As is well known, $HW(\mathcal{L}, L) \cong \mathbb{Z}[t, t^{-1}]$; however, a direct computation requires some infinite process or picture. One can instead argue by stop and removal. We already saw that the linking disks (arcs in this case) are sent under the above isomorphism to the skyscraper sheaves at $0, \infty \in \mathbb{P}^1$. Thus by stop removal we have

$\mathcal{W}(T^*S^1) = \mathcal{W}(T^*S^1, \Lambda)/\mathcal{D} \cong \text{Coh}(\mathbb{P}^1)/\langle \mathcal{O}_0, \mathcal{O}_\infty \rangle = \text{Coh}(\mathbb{P}^1 \setminus \{0, \infty\}) \cong \text{Perf}(\mathbb{Z}[t, t^{-1}]).$ (1.15)

Following $L$ (or $L(1)$) along this sequence of equivalences shows that it goes to the object $\mathbb{Z}[t, t^{-1}] \in \text{Perf}(\mathbb{Z}[t, t^{-1}])$, and hence we can conclude $HW(\mathcal{L}, L) \cong \mathbb{Z}[t, t^{-1}]$. (The reader may be more familiar with this example in its incarnation as the Lefschetz fibration / Landau–Ginzburg model $z + \frac{1}{z} : \mathbb{C} \times \to \mathbb{C}$.)

For a generalization of this example to other surfaces, see Lekili–Polishchuk [36].

**Example 1.19 (Fukaya–Seidel categories).** Let $\pi : \bar{X} \to \mathbb{C}$ be a Liouville Landau–Ginzburg model with Weinstein fiber $F$ with core $f$. Theorem 1.16 implies that the functor $\mathcal{W}(\bar{X}, f \times \{\infty\}) \to \mathcal{W}(\bar{X})$ (1.16)

(from the Fukaya–Seidel category of $\pi$ to the wrapped Fukaya category of the total space) is precisely localization at the linking disks of $f \times \{\infty\}$. By Theorem 1.10, the full subcategory they span is also the essential image of the functor $\mathcal{W}(F) \to \mathcal{W}(\bar{X}, f \times \{\infty\})$ obtained by composing the Künneth stabilization functor (1.7) with pushforward under the canonical embedding $F \times T^*[0,1] \to (\bar{X}, f \times \{\infty\})$ near the stop. This is comparable to, but not quite the same as, the localization presentation of the wrapped Fukaya category obtained in Abouzaid–Seidel’s work in the case of Lefschetz fibrations [5]. For a concrete example of such a situation in mirror symmetry, see Keating [33].

If the critical locus of $\pi$ is compact, then $F$ is the page of an open book decomposition of $\partial_\infty \bar{X}$, and hence the boundary at infinity of the associated Liouville sector is, up to deformation, $F_0 \times [0,1]$ by [26, Lemma 2.18], which implies that $\mathcal{W}(\bar{X}, f \times \{\infty\})$ is *proper* in the sense of non-commutative geometry (i.e. has finite-dimensional morphism spaces) [26, Lemma 3.44]. Such a fibration $\pi$ thus provides a geometrically motivated categorical compactification of $\mathcal{W}(\bar{X})$, in the sense that the Fukaya–Seidel category $\mathcal{W}(\bar{X}, f \times \{\infty\})$ is proper and localizes to give $\mathcal{W}(X)$. The flexibility of adding stops at will allows for more general, and partial, compactifications.

### 1.7 Stopped inclusions

While stop removal Theorem 1.16 provides a situation where a functor between partially wrapped Fukaya categories is a localization, we also formulate in §8 geometric conditions which ensure a functor between partially wrapped Fukaya categories is fully faithful.
Since wrapped Floer cohomology is computed by wrapping only one factor, to ensure that a pushforward functor \( W(X, f) \to W(X', f') \) is fully faithful, it is enough to ensure that when any Lagrangian \( L \subset X \) disjoint from \( f \) is wrapped inside \( X' \) stopped at \( f' \), then once it leaves \( X \) it never returns (at least for a cofinal collection of wrappings). We formulate two geometric conditions on inclusions of Liouville sectors, called being (tautologically) forward stopped (see Definitions 8.3 and 8.8), which guarantee this property of wrapping and hence that the associated pushforward functor is fully faithful (Corollary 8.13). This notion naturally depends only on the contact geometry of the boundary at infinity.

The notion of forward/backward stopped inclusions is a crucial ingredient in the proof of the homotopy pushout/colimit formulas below. It is also an important ingredient (see §8.3) in Sylvan’s proposal [43] to define (and generalize) Abouzaid–Seidel’s Viterbo restriction functor [6] in terms of stop removal functors.

1.8 Homotopy pushout formula

The question of ‘locality’ in Floer theory is quite subtle and far from completely understood. In §9, we use stop removal and forward stopped inclusions to prove descent formulae for wrapped Fukaya categories. The first such result (also observed by Sylvan [43]) is the following homotopy pushout formula:

**Theorem 1.20** (Homotopy pushout formula). Let \( X = X_1 \cup X_2 \) be a Liouville sector written as the union of two Liouville sectors \( X_1 \) and \( X_2 \) meeting along a hypersurface \( X_1 \cap X_2 \) inside \( X \) disjoint from \( \partial X \). Writing a neighborhood of this hypersurface as \( F \times T^*[0, 1] \), suppose in addition that \( F \) is Weinstein (up to deformation). Let \( r \subset (\partial X)^\circ \) be a stop disjoint from \( \partial_{\infty}(X_1 \cap X_2) \), and let \( r_i := r \cap (\partial_{\infty}X_i)^\circ \). Then the induced diagram of \( A_\infty \)-categories

\[
\begin{array}{ccc}
W(F) & \longrightarrow & W(X_1, r_1) \\
\downarrow & & \downarrow \\
W(X_2, r_2) & \longrightarrow & W(X, r)
\end{array}
\]  

(1.17)

induces a fully faithful functor

\[
\text{hocolim}(W(X_2, r_2) \leftarrow W(F) \to W(X_1, r_1)) \hookrightarrow W(X, r)
\]  

(1.18)

(so we say (1.17) is an almost homotopy pushout). If, in addition, \( X \) is a Liouville manifold, (the convexifications of) \( X_i \) are Weinstein (up to deformation), and the \( r_i \) are mostly Legendrian, then (1.18) is a pre-triangulated equivalence (so we say (1.17) is a homotopy pushout).

The real content here is the full faithfulness, as the final statement about generation is simply an application of Theorem 1.10. The origin of the hypothesis that \( F \) is Weinstein is the use of Theorems 1.10 and 1.16 in the proof.

A special case of particular interest of the gluing operation in Theorem 1.20 is Weinstein handle attachment (compare [22, §3.1]). Theorem 1.20 thus provides some understanding of the effect of Weinstein handle attachment on the wrapped Fukaya category. In particular, it
recovers the folklore result that subcritical handle attachment does not change the wrapped Fukaya category (the closest results in the literature concern the closed string analogue symplectic cohomology [14]; see also [19]). In the case of critical handle attachment, we recover a formula for the wrapped Floer cochains of the cocore in terms of the partially wrapped Floer cochains of the linking disk of the attaching locus (which is conjectured [43, 18] to agree with the Legendrian contact homology of the attaching sphere, compare Bourgeois–Ekholm–Eliashberg [11, Remark 5.9]).

**Corollary 1.21** (Effect of Weinstein handle attachment). Let \((X, f)\) be a stopped Liouville sector of dimension \(2n\) obtained from a stopped Liouville sector \((X^\text{in}, f^\text{in})\) by attaching a Weinstein \(k\)-handle along an isotropic sphere \(\Lambda^k \subseteq (\partial^\infty X^\text{in})^o \setminus f^\text{in}\). In the subcritical case \(k < n\), there is a fully faithful embedding

\[
W(X^\text{in}, f^\text{in}) \hookrightarrow W(X, f) \tag{1.19}
\]

acting on Lagrangians inside \(X^\text{in}\) by perturbing to make them disjoint from \(\Lambda\) and then completing inside \(X\). In the critical case \(k = n\), there is an almost homotopy pushout

\[
\begin{array}{ccc}
C_\ast(\Omega S^{n-1}) & \longrightarrow & W(X^\text{in}, f^\text{in} \cup \Lambda) \\
\downarrow & & \downarrow \\
\mathbb{Z} & \longrightarrow & W(X, f),
\end{array} \tag{1.20}
\]

implying, in particular, a quasi-isomorphism of \(A_\infty\)-algebras

\[
CW^\ast([\text{cocore}], [\text{cocore}])_{X,f} = CW^\ast(D, D)_{X^\text{in}, f^\text{in} \cup \Lambda} \otimes_{C_\ast(\Omega S^{n-1})} \mathbb{Z}, \tag{1.21}
\]

where \(D\) denotes the linking disk of \(\Lambda\) and \([\text{cocore}] \subseteq X\) denotes the cocore of the added handle.

**Example 1.22** (Partially wrapped Fukaya categories of surfaces). Let \(\Sigma\) be any 2-dimensional Liouville sector. That is, \(\Sigma\) is a surface-with-boundary with no compact components and no circle boundary components. Choose any collection of arcs going from non-compact ends to non-compact ends dividing \(\Sigma\) into \(A_2\) Liouville sectors (a disk minus three boundary punctures). The wrapped Fukaya category of the \(A_2\) sector is given by

\[
\text{Tw } W(\mathbb{C}, \{e^{2\pi ik/3}\}_{k=0,1,2}) = \text{Perf}(\bullet \to \bullet) \tag{1.22}
\]

(for example, this follows from Theorem 1.9). The \(A_2\) sectors overlap over \(A_1\) sectors \(T^*[0,1]\) with wrapped Fukaya category

\[
\text{Tw } W(T^*[0,1]) = \text{Tw } W(\mathbb{C}, \{\pm \infty\}) = \text{Perf}(\bullet). \tag{1.23}
\]

Iterated applications of Theorem 1.20 thus yield a description of \(W(\Sigma)\) as a homotopy colimit of copies of these categories \(\text{Perf}(\bullet \to \bullet)\) and \(\text{Perf}(\bullet)\).
Example 1.23 (Partially wrapped Fukaya categories of fibrations over surfaces). Continuing the preceding example, suppose \( \pi : X \to \Sigma \) is an exact symplectic (non-singular) fibration with Weinstein fiber \( F \). The same decomposition of \( \Sigma \) pulled back to \( X \) yields a description of \( W(X) \) as a homotopy colimit of copies of \( W(F) \) and \( W(F) \otimes \text{Perf}(\bullet \to \bullet) \).

Finally, consider the case where \( \pi \) is allowed to have singularities (e.g. a Lefschetz fibration). We now choose arcs dividing \( \Sigma \) into \( A_2 \) sectors containing no critical values and half-planes \( C_{\text{Re} \geq 0} \) each containing a single critical value. This again yields a homotopy colimit presentation of \( W(X) \). Note that in the case of a Lefschetz fibration, the pieces \( X_\alpha \) resulting as inverse images of half-planes containing a single critical value satisfy \( W(X_\alpha) = \text{Perf}(\bullet) \) by Corollary 1.14 and observing that wrapping the thimble creates no new self intersections.

The proof of Theorem 1.20 consists of adding and removing a stop via Theorem 1.16, similar in spirit to Example 1.18. In the coordinates \( X \times T^* [0,1] \) near the splitting hypersurface \( X_1 \cap X_2 \), we consider the stop \( f \times \partial_{\infty} N^* \{0\} \), namely the core of \( F \) times the boundary at infinity of a cotangent fiber. Now the functors

\[
W(X_i, r_i) \hookrightarrow W(X, r \cup (f \times \partial_{\infty} N^* \{0\})), \quad i = 1, 2,
\]

(1.24)

are fully faithful, since the stop \( f \times \partial_{\infty} N^* \{0\} \) stops Lagrangians inside \( X_i \) from being wrapped beyond \( X_i \) (more precisely, the associated inclusion of Liouville sectors is forward stopped). Similarly, there is a fully faithful inclusion

\[
W(F) \hookrightarrow W(X, r \cup (f \times \partial_{\infty} N^* \{0\})),
\]

(1.25)

defined by embedding \( F \times T^* [0,1] \) as the neighborhood of \( F \) times a small positive Reeb pushoff of the cotangent fiber over \( \frac{1}{2} \in [0,1] \). The wrapping analysis involved in showing full faithfulness of (1.24)–(1.25) shows moreover that the full subcategory spanned by the images of all three of these embeddings is given (up to quasi-equivalence) by the Grothendieck construction of the diagram

\[
W(X_1, r_1) \hookrightarrow W(F) \to W(X_2, r_2),
\]

(1.26)

namely the semi-orthogonal gluing of \( W(F) \) with \( W(X_1, r_1) \cup W(X_2, r_2) \) along the disjoint union of the pullback of the diagonal bimodules. That is, the space of morphisms from an object of \( W(F) \) to an object of \( W(X_i, r_i) \) is given by the morphism space in \( W(X_i, r_i) \) from the image of the first object to the second.

The homotopy colimit of (1.26) is the localization of the Grothendieck construction at the morphisms \( L \to Q_i(L) \) for \( L \in W(F) \) corresponding to the identity map of \( Q_i(L) \), where \( Q_i \) (\( i = 1, 2 \)) denotes the two functors in (1.26). As \( L \) runs over the cocores of \( F \), which generate \( W(F) \) by Theorem 1.10, the cones of the morphisms \( L \to Q_i(L) \) are quasi-isomorphic to the linking disks of the stop \( f \times \partial_{\infty} N^* \{0\} \). Hence by Theorem 1.16, the functor

\[
W(X, r \cup (f \times \partial_{\infty} N^* \{0\})) \to W(X, r)
\]

(1.27)

is precisely localization at the cones of \( L \to Q_i(L) \) in the Grothendieck construction of (1.26), thought of as a full subcategory of the domain via (1.24)–(1.25). It follows that the localization of the Grothendieck construction (i.e. the homotopy colimit of (1.26)) maps fully faithfully into \( W(X, r) \), as desired.
In fact, the proof of Theorem 1.20 given in §9.1 is formulated in terms of more abstract properties of homotopy colimits, rather than depending directly on their explicit construction via the Grothendieck construction, and hence, in particular, we do not need to identify the bimodule of morphisms between the full subcategories (1.24)–(1.25), rather we need only verify that they are semi-orthogonal.

1.9 Homotopy colimit formula

We continue in §9 to generalize the homotopy pushout formula Theorem 1.20 to a descent (homotopy colimit) formula for \( n \)-element covers of Liouville sectors by Liouville sectors. To even be able to formulate this descent property, we must require our covers to be ‘sectorial’ in the following sense:

**Definition 1.24** (Sectorial covering). Let \( X \) be a Liouville manifold-with-boundary (meaning it is exact and cylindrical at infinity). A collection of hypersurfaces \( H_1, \ldots, H_n \subseteq X \) is called **sectorial** iff their characteristic foliations are \( \omega \)-orthogonal over their intersections and there exist functions \( I_i : \text{Nbd}^Z H_i \to \mathbb{R} \) (linear near infinity) satisfying \( d I_i|_{\text{char.fol.}(H_i)} \neq 0 \) (equivalently, \( X_{I_i} \notin TH_i \)), \( d I_i|_{\text{char.fol.}(H_j)} = 0 \) (equivalently, \( X_{I_i} \in TH_j \)) for \( i \neq j \), and \( \{I_i, J_j\} = 0 \). A covering of a Liouville manifold (or sector) \( X \) by finitely many Liouville sectors \( X_1, \ldots, X_n \subseteq X \) is called sectorial iff the collection of their boundaries \( \partial X, \partial X_1, \ldots, \partial X_n \) is sectorial (here we understand \( \partial X_i \) as the part of the boundary of \( X_i \) not coming from \( \partial X \), i.e. the boundary in the point set topological sense).

It follows easily that for any sectorial collection of hypersurfaces \( H_1, \ldots, H_n \subseteq X \), they are mutually transverse and all multiple intersections \( H_{i_1} \cap \cdots \cap H_{i_k} \) are coisotropic (see §9.3). Also note that a Liouville manifold-with-boundary \( X \) is a Liouville sector iff \( \partial X \) is sectorial.

**Example 1.25.** If \( Q \) is a compact manifold-with-boundary and \( Q_1, \ldots, Q_n \subseteq Q \) are codimension zero submanifolds-with-boundary whose boundaries are, together with \( \partial Q \), mutually transverse, then \( T^*Q_1, \ldots, T^*Q_n \subseteq T^*Q \) is sectorial.

Given a sectorial collection of hypersurfaces \( H_1, \ldots, H_n \subseteq X \), there is an induced stratification of \( X \) by strata \( \bigcap_{i \in I} H_i \setminus \bigcup_{i \notin I} H_i \) for \( I \subseteq \{1, \ldots, n\} \). Each stratum is coisotropic and the symplectic reduction of its closure (not necessarily embedded in \( X \)) is a Liouville sector (with corners). A sectorial covering is called Weinstein iff (the convexifications of) each of these Liouville sectors are Weinstein (up to deformation, i.e. the Liouville form can be deformed by \( df \) so that the associated Liouville flow is gradient-like).

**Example 1.26.** Continuing Example 1.25, we note that the symplectic reductions of the strata of the covering \( T^*Q_1, \ldots, T^*Q_n \subseteq T^*Q \) are simply the cotangent bundles of the strata of the covering \( Q_1, \ldots, Q_n \subseteq Q \). In particular, they are all Weinstein (after deformation).

**Theorem 1.27** (Descent for Weinstein sectorial coverings). For any Weinstein sectorial covering \( X_1, \ldots, X_n \) of a Liouville sector \( X \), the induced functor

\[
\hocolim_{\varnothing \neq I \subseteq \{1, \ldots, n\}} \mathcal{W} \left( \bigcap_{i \in I} X_i \right) \xymatrix{\ar[r]^{\sim} & \mathcal{W}(X) }
\]
is a pre-triangulated equivalence. More generally, the same holds for any mostly Legendrian stop \( r \subseteq (\partial_\infty X)^0 \) which is disjoint from every \( \partial X_i \) and does not approach \( \partial X \).

Theorem 1.27 is easily reduced to proving (under suitable Weinstein assumptions) the generalization of the homotopy pushout formula Theorem 1.20 in which we allow \( F \) to be a Liouville sector (as opposed to a Liouville manifold). Establishing this generalization involves further study of the geometry of the relevant stops at infinity in order to show that the relevant inclusions of Liouville sectors are forward stopped.

Example 1.28 (Calculation of \( \mathcal{W}(T^*Q) \)). Continuing Examples 1.25–1.26, we may apply Theorem 1.27 to deduce that \( \mathcal{W}(T^*Q) = \operatorname{hocolim}_{\varnothing \neq I \subseteq \{1, \ldots, n\}} \mathcal{W}(T^* \bigcap_{i \in I} Q_i) \). Taking a cover for which the multiple intersections \( Q_1 \cap \cdots \cap Q_n \) are (after smoothing corners) all balls, we may deduce that \( CW^*(T^*_q Q, T^*_q Q) \) is quasi-isomorphic to \( C_{-*}(\Omega_q Q) \) as \( A_\infty \)-algebras, as proven by Abbondandolo–Schwarz [1] and Abouzaid [4] in the case \( Q \) has no boundary.

1.10 Cobordism attachment and twisted complexes

To conclude the introduction, we discuss the ingredients which give rise to the wrapping exact triangle Theorem 1.9, as they may be of independent interest.

The first ingredient is Floer theoretic, and it concerns the effect in the Fukaya category of attaching an exact Lagrangian cobordism at infinity. Before making the precise general statement, let us explain a special case. Let \( X \) be a Liouville manifold, let \( L \subseteq X \) be an exact cylindrical Lagrangian whose primitive \( f_L : L \to \mathbb{R} \) vanishes at infinity, and let \( C \subseteq S\partial_\infty X \) be an exact symplectic cobordism in the symplectization of \( \partial_\infty X \) whose primitive vanishes at minus infinity. Denoting by \( \# C L \) the result of attaching \( C \) to \( L \) at infinity, there is then a quasi-isomorphism in the wrapped Fukaya category

\[
\# C L = L.
\] (1.29)

To see this, consider the Viterbo restriction functor constructed by Abouzaid–Seidel [6]. Given a Liouville subdomain \( X_0 \subseteq X \) whose completion is \( X \), this is a functor to \( \mathcal{W}(X) \) from the full subcategory of \( \mathcal{W}(X) \) spanned by Lagrangians \( K \subseteq X \) whose primitives \( f_K \) vanish identically near \( \partial X_0 \) (this implies that \( K \) is cylindrical near \( \partial X_0 \)). On objects, this functor is simply “intersect with \( X_0 \) and complete”, and hence for suitable choice of \( X_0 \), the objects \( \# C L \) and \( L \) are both sent to \( L \) under this functor. On the other hand, since the inclusion \( X_0 \subseteq X \) is “trivial” (the completion of \( X_0 \) is \( X \)) this restriction functor is (canonically quasi-isomorphic to) the identity functor. Note that the vanishing of the primitive of \( L \) near infinity and of the primitive of \( C \) near minus infinity was crucial for this argument. In §4, we prove the following result which extends the above picture to the “relatively non-exact” setting:

Proposition 1.29 (Cobordism attachment and twisted complexes). Let \( (X, \mathfrak{f}) \) be a stopped Liouville sector, and let \( L_1, \ldots, L_n \subseteq X \) be disjoint exact Lagrangians (disjoint from \( \mathfrak{f} \) at infinity) whose primitives vanish at infinity. Let \( C \subseteq S\partial_\infty X \) be an exact Lagrangian cobordism (disjoint from \( \mathbb{R} \times \mathfrak{f} \)) with negative end \( \partial_\infty L_1 \sqcup \cdots \sqcup \partial_\infty L_n \), such that the primitive \( f_C : C \to \mathbb{R} \) of \( \lambda|_C \) satisfies

\[
f_C|_{\partial_\infty L_1} < \cdots < f_C|_{\partial_\infty L_n},
\] (1.30)
regarding $\partial_{\infty}L_i$ as the negative ends of $C$ (note that these restrictions $f_C|_{\partial_{\infty}L_i}$ are simply real numbers).

Suppose in addition that the image of $C$ under the projection $S\partial_\infty X \to \partial_{\infty}X$ is “thin” in the sense that for every Lagrangian $K \subseteq X$ disjoint at infinity from $f$, there exists a positive wrapping $K \leadsto K^w$ (away from $f$) such that $\partial_{\infty}K^w$ is disjoint from $C$.

Then there is a quasi-isomorphism

$$\#^C_i L_i = [L_1 \to \cdots \to L_n]$$

(1.31) in $\text{Tw} \mathcal{W}(X,f)$, where $\#^C_i L_i$ denotes the result of attaching the cobordism $C$ to $L_1 \sqcup \cdots \sqcup L_n$ at infinity, and $[L_1 \to \cdots \to L_n]$ denotes a twisted complex $(\bigoplus_{i=1}^n L_i, \sum_{i<j} D_{ij})$.

The thinness hypothesis on $C$ is convenient in the proof, but we expect that the result remains true without it (for example, no such hypothesis is required in Abouzaid–Seidel [6]). A sufficient condition that $C$ be thin is that its projection to $\partial_{\infty}X$ be contained in a small neighborhood of a Weinstein hypersurface (see Proposition 2.2 for a more general statement).

The proof of Proposition 1.29 proceeds by testing $\#^C_i L_i$ against arbitrary Lagrangians $A$ and considering the limit as the cobordism $C$ is pushed to infinity. For any Lagrangian $A \subseteq X$ disjoint at infinity from $C$, there is a natural isomorphism of abelian groups

$$CF^\bullet(A, \#^C_i L_i) = CF^\bullet(A, L_1) \oplus \cdots \oplus CF^\bullet(A, L_n).$$

(1.32)

In the limit as the cobordism is pushed to infinity, the actions of the intersections with $L_i$ become much larger than the actions of the intersections with $L_j$ for $i < j$. The differential on $CF^\bullet(A, \#^C_i L_i)$ is thus lower triangular with respect to the above direct sum decomposition. Moreover, the diagonal components of this differential coincide with the differentials on $CF^\bullet(A, L_i)$, since by action and monotonicity arguments, such disks cannot travel far enough to see the difference between $L_i$ and $\#^C_i L_i$. This produces an isomorphism of complexes

$$CF^\bullet(A, \#^C_i L_i) = [CF^\bullet(A, L_1) \to \cdots \to CF^\bullet(A, L_n)],$$

(1.33)

where the right hand side denotes a twisted complex of $CF^\bullet(A, L_i)$ with unspecified maps $CF^\bullet(A, L_i) \to CF^\bullet(A, L_j)$ for $i < j$. Similar reasoning shows that (1.33) is in fact an isomorphism of modules (i.e. is compatible with $A_\infty$-multiplication on the left). Hence the Yoneda lemma provides the desired quasi-isomorphism (1.31) in the Fukaya category. (Some algebraic complications arise from the fact that, by pushing the cobordism towards infinity, we can only guarantee (1.33) for finitely many Lagrangians $A$ at a time, however these can be dealt with.)

In fact, for our work in this paper, we only need a very special case of Proposition 1.29, namely when $C$ is a relatively non-exact embedded Lagrangian 1-handle as defined in §3.4. Given two Lagrangians $L, K \subseteq X$ together with a short Reeb chord $\gamma$ from $\partial L$ to $\partial K$, we denote by $L\#_{\gamma} K$ the result of attaching this cobordism at infinity (more precisely, to define this surgery requires a certain Darboux chart, which contains an obvious Reeb chord $\gamma$). Topologically, $L\#_{\gamma} K$ is simply the boundary connect sum of $L$ and $K$ along $\gamma$ (see Figure 1). For this particular cobordism, we can enhance the statement of Proposition 1.29 slightly in that we identify the differential in the twisted complex:
Figure 1: Left: Two Lagrangians $L$ and $K$ together with a short Reeb chord $\gamma$ from $\partial_\infty L$ to $\partial_\infty K$. Right: The result $L\#_\gamma K$ of attaching a relatively non-exact embedded Lagrangian 1-handle to $L \sqcup K$ along $\gamma$.

**Proposition 1.30** (Reeb chord surgery exact triangle). Let $(X, \mathfrak{f})$ be a stopped Liouville sector. Let $L, K \subseteq X$ be disjoint exact Lagrangians (disjoint from $\mathfrak{f}$ at infinity), and let $L\#_\gamma K$ be the result of attaching a relatively non-exact embedded Lagrangian 1-handle to $L$ and $K$ along the short Reeb chord $\gamma$ (taking place in the complement of $\mathfrak{f}$). There is an exact triangle in $W(X, \mathfrak{f})$: 

$$L \xrightarrow{\gamma} K \rightarrow L\#_\gamma K \xrightarrow{[1]}.$$  

(1.34)

To identify the morphism $L \rightarrow K$ in the Reeb chord surgery exact triangle as $\gamma$, we consider testing the exact triangle (produced by Proposition 1.29) against $A = L^w$, a positive wrapping of $L$ which wraps through the surgery locus (thus creating an intersection point with $K$) but not farther. The cycle in $HW^\bullet(L, K)$ we are looking for is thus represented by the image of the continuation element under the map

$$HF^\bullet(L^w, L) \rightarrow HF^\bullet(L^w, K)$$

(1.35)

forming the differential on the right side of (1.33) with $A = L^w$. Since $HF^\bullet(L^w, K) = \mathbb{Z}$ is generated freely by (the intersection point corresponding to) the short Reeb chord $\gamma$, this proves the desired statement up to an unknown integer factor. If this integer factor were divisible by a prime $p$, then there would be a quasi-isomorphism $L\#_\gamma K = L \oplus K$ over $\mathbb{Z}/p$. We can preclude the existence of such a quasi-isomorphism (in a further stopped Fukaya category) by testing both sides against a suitably chosen small Lagrangian disk linking both $L$ and $K$ but unlinked with $L\#_\gamma K$.

Now the following geometric fact (proved in §3.5 and motivated in Figure 2) together with Proposition 1.30 yields the wrapping exact triangle Theorem 1.9 (modulo identifying the morphism $L^w \rightarrow L$ in the exact triangle as the continuation map, which requires an extra argument):

**Proposition 1.31.** Let $X$ be a Liouville sector, $L \subseteq X$ a cylindrical Lagrangian, and $\Lambda \subseteq \partial_\infty X$ a Legendrian. Let $L \rightsquigarrow L^w$ be a positive wrapping which passes through $\Lambda$ exactly once, transversely, at $p \in \Lambda$. Then $L^w$ is isotopic to the result $L\#_\gamma D_p$ of attaching a relatively non-exact embedded Lagrangian 1-handle to $L$ and the linking disk $D_p$. 

21
Figure 2: Picture proof of Proposition 1.31 in dimension two. This picture provides at least a moral proof in all dimensions by taking product with \((\mathbb{C}^{n-1}, \mathbb{R}^{n-1})\).

1.11 Acknowledgements

We thank Tobias Ekholm, Oleg Lazarev, Patrick Massot, and Zack Sylvan for helpful discussions.

S.G. was partially supported by NSF grant DMS–1907635, and would also like to thank the Mathematical Sciences Research Institute for its hospitality during a visit in Spring 2018 (supported by NSF grant DMS–1440140) during which some of this work was completed. This research was conducted during the period J.P. served as a Clay Research Fellow and was partially supported by a Packard Fellowship and by the National Science Foundation under the Alan T. Waterman Award, Grant No. 1747553. V.S. was supported by the NSF CAREER grant DMS–1654545.

2 Partially wrapped Fukaya categories

In this section, we review the definition of the partially wrapped Fukaya category which we will use in this paper, and we prove some basic results about it which we will need later.

2.1 Wrapping categories

We begin with a general discussion of wrapping.

For a compact Legendrian submanifold \(\Lambda\) of a contact manifold \(Y\), the \((\text{positive})\) wrapping category \((\Lambda \rightsquigarrow -)_Y^+\) of \(\Lambda\) inside \(Y\) has objects (arbitrary) Legendrian isotopies \(\Lambda \rightsquigarrow \Lambda_0\) and morphisms from \(\Lambda \rightsquigarrow \Lambda_0\) to \(\Lambda \rightsquigarrow \Lambda_1\) given by homotopy classes of positive Legendrian isotopies \(\Lambda_0 \rightsquigarrow \Lambda_1\) such that the composite isotopy \(\Lambda \rightsquigarrow \Lambda_0 \rightsquigarrow \Lambda_1\) is homotopic (through Legendrian isotopies) to \(\Lambda \rightsquigarrow \Lambda_1\). (Recall that a Legendrian isotopy \(\Lambda_t\) is said to be \text{positive}\) if, for some (equivalently any) contact form \(\alpha\), we have \(\alpha(\partial_t \Lambda_t) > 0\) for all \(t\); compare \([26, \text{Definition 3.22}]\).)

Similarly, there is a wrapping category of a cylindrical Lagrangian \(L\) inside a stopped Liouville manifold-with-boundary \((X, \mathfrak{f})\), denoted \((L \rightsquigarrow -)^+_X,\mathfrak{f}\), where we consider Lagrangians (and isotopies thereof) whose boundary at infinity lies inside \((\partial_\infty X)^\circ \setminus \mathfrak{f}\), and positivity of an isotopy simply means positivity at infinity. When doing Floer theory, one usually cares
not only about Lagrangian submanifolds, but also Lagrangian submanifolds equipped with auxiliary topological data (used to define gradings/orientations); the relevant wrapping category is then defined in terms of Lagrangians equipped with such auxiliary data, and isotopies thereof.

Positive wrapping categories in all of the above senses are filtered by [26, Lemma 3.27] (the proof there is given for wrapping categories of Lagrangians inside Liouville sectors, but it applies in general). We will often use the following criterion for cofinality in wrapping categories.

**Lemma 2.1.** Let \( \{ \Lambda_t \}_{t \geq 0} \subseteq Y \) be an isotopy of compact Legendrians inside a (not necessarily compact) contact manifold \( Y \). If there exists a contact form \( \alpha \) on \( Y \) such that
\[
\int_0^\infty \min_{\Lambda_t} \alpha \left( \frac{\partial \Lambda_t}{\partial t} \right) \, dt = \infty,
\]
(2.1)
then \( \{ \Lambda_t \}_{t \geq 0} \) is a cofinal wrapping of \( \Lambda_0 \). In particular, if \( \Lambda_t \) escapes to infinity as \( t \to \infty \) (i.e. is eventually disjoint from any given compact subset of \( Y \)), then it is a cofinal wrapping of \( \Lambda_0 \).

The same statement holds for Lagrangian wrapping categories, replacing \( Y \) with the relevant boundary at infinity where wrapping takes place.

**Proof.** This is [26, Lemma 3.29 and Remark 3.31]. We will phrase the proof for Legendrian wrapping categories, though it works in general.

Without loss of generality, we may replace \( \alpha \) with a larger contact form whose Reeb vector field is complete (to see that such a contact form exists, it is easier to think in terms of the associated positive contact Hamiltonian \( Y \to (TY/\xi)_+ \) and argue that there are arbitrarily rapidly decreasing such contact Hamiltonians whose associated positive contact vector fields are complete).

The \( f = \infty \) hypothesis ensures that we may reparameterize \( \Lambda_t \) such that \( \alpha \left( \frac{\partial \Lambda_t}{\partial t} \right) \geq 2 \) everywhere. It follows from this inequality that \( \{ e^{(a-t)R_\alpha} \Lambda_t \}_{t \geq 0} \) is a positive isotopy, and hence that the positive isotopy \( \Lambda_0 \rightsquigarrow \Lambda_a \) can be deformed through positive isotopies to \( \Lambda_0 \rightsquigarrow e^{aR_\alpha} \Lambda_0 \rightsquigarrow \Lambda_a \). On the other hand, \( \Lambda_0 \rightsquigarrow e^{aR_\alpha} \Lambda_0 \) is cofinal as \( a \to \infty \) (see [26, Lemma 3.29]).

There are functors
\[
(L \rightsquigarrow -)^+_X, f \xleftarrow{\partial_\infty \circ \text{(drag at } \infty)} \Rightarrow (\partial_\infty L \rightsquigarrow -)^+_f \cdot (\partial_\infty X)^c \vert_f^+,
\]
(2.2)
and the composition \( \partial_\infty \circ \text{(drag at } \infty) \) is naturally isomorphic to the identity functor. Using the cofinality criterion Lemma 2.1, it follows immediately that both of these functors are cofinal. This formalizes the idea (which is also clear from Lemma 2.1) that wrapping is an operation which happens entirely at contact infinity. Note that one does not in general expect the functors above to be an equivalence of categories; this is due to the words “homotopy class of” in the definition of the wrapping categories (the corresponding functors on the ‘wrapping \( \infty \)-categories’ as alluded to in [26, Remark 3.32] do indeed form an equivalence of \( \infty \)-categories, however we will not need this fact).
For later purposes, it will be important to know that a given Lagrangian \( L \subseteq X \) admits cofinal wrappings which are disjoint from certain sufficiently small subsets of \( \partial_{\infty}X \). We will just state this result for wrapping Legendrians—this implies the corresponding statement for Lagrangians in view of the cofinal functors (2.2).

**Lemma 2.2.** Let \( Y^{2n-1} \) be a contact manifold, and let \( f \subseteq Y \) be a closed subset. Let \( \Lambda \subseteq Y \) be a compact Legendrian.

(i) If \( f \) is contained in the smooth image of second countable manifold of dimension \( \leq n-1 \), then \( \Lambda \) admits cofinal wrappings \( \Lambda \rightsquigarrow \Lambda^w \) with \( \Lambda^w \) disjoint from \( f \).

(ii) If, in addition, \( f \) is the core of a Liouville hypersurface inside \( Y \), then \( \Lambda \) admits cofinal wrappings \( \Lambda \rightsquigarrow \Lambda^w \) with \( \Lambda^w \) disjoint from a neighborhood of \( f \).

**Proof.** Statement (i) follows immediately from a general position argument. Indeed, we first claim that for any compact manifold-with-boundary \( f : N^k \to Y^{2n-1} \) of dimension \( k \leq n-1 \), the locus of Legendrians \( \Lambda \subseteq Y \) which are disjoint from the image of \( N \) is open and dense (in all Legendrians). To see this, consider the maps

\[
\{ \Lambda \subseteq Y \} \leftarrow \{ p \in \Lambda \subseteq Y \} \times N \xrightarrow{(p,f)} Y \times Y. \tag{2.3}
\]

The second map is transverse to the diagonal, and hence the inverse image of the diagonal is a smooth codimension \( 2n-1 \) submanifold of the middle space. The first map has \((k+n-1)\)-dimensional fibers, so the projection of something of codimension \( 2n-1 > k + n - 1 \) is nowhere dense by Sard–Smale. This shows that the locus of Legendrians disjoint from the image of \( N \) is dense, and openness is obvious. By the Baire category theorem, the locus of Legendrians disjoint from any countable collection of such \( N \) is also dense. Now simply note that for any positive Legendrian isotopy \( \Lambda \rightsquigarrow \Lambda^w \), every sufficiently small perturbation \( \Lambda^w \) of \( \Lambda \) also has a positive Legendrian isotopy \( \Lambda \rightsquigarrow \Lambda^w \). (For similar arguments, see [16, Proposition 5.2].)

For statement (ii), consider local coordinates on \( Y \) given by \(([-1,1] \times F, dz + \lambda) \), where \( F \) is the Liouville hypersurface with core \( f \). What we should show is that for any Legendrian \( \Lambda \) possibly intersecting the neighborhood \([-1,1] \times F \), it can be pushed out by a positive isotopy. In coordinates \(([-1,1] \times F, dz + \lambda) \), we have a positive contact vector field \( V_\varphi := \varphi(z)\partial_z + \varphi'(z)Z_\lambda \) for any smooth function \( \varphi : [-1,1] \to \mathbb{R}_{\geq 0} \). Consider specifically the case that \( \varphi(z) = \varphi(-z), z\varphi'(z) \leq 0, \text{supp} \varphi = [-\frac{2}{3},\frac{2}{3}], \text{and} \varphi|_{[-\frac{3}{4},\frac{3}{4}]} \equiv 1. \) Now the inverse image of \( [-\frac{1}{3},\frac{1}{3}] \times F \) under the time \( t \) flow of \( V_\varphi \) is eventually contained in any neighborhood of \( \{ -\frac{2}{3} \} \times f \) as \( t \to \infty \) (to see this, note that \( V_\varphi \) is proportional to \( \partial_z + (\log \varphi)'(z)Z_\lambda \), so as the \( z \) coordinate decreases towards \( -\frac{2}{3} \) from above, we flow for infinite time by \( -Z_\lambda \)). It follows that if \( \Lambda \) is disjoint from \( \{ -\frac{2}{3} \} \times f \), then flowing under (an arbitrary positive extension of) \( V_\varphi \) for sufficiently large time \( t \) produces the desired positive isotopy \( \Lambda \rightsquigarrow \Lambda^w \). To conclude, simply note that an arbitrary \( \Lambda \) can be first perturbed in the positive direction to become disjoint from \( \{ -\frac{2}{3} \} \times f \) by the first part of the Lemma.

**Lemma 2.3.** Let \( Y \) be a contact manifold, and let \( f = f_{\text{subcrit}} \cup f_{\text{crit}} \subseteq Y \) be mostly Legendrian.

For compact Legendrians \( \Lambda_1, \Lambda_2 \subseteq Y \) disjoint from \( f \), consider the space of positive Legendrian isotopies \( \Lambda_1 \rightsquigarrow \Lambda_2 \). The subspace of isotopies which

(i) remain disjoint from \( f_{\text{subcrit}} \) and
(ii) intersect $f_{\text{crit}}$ only finitely many times, each time passing through transversally at a single point, is open and dense.

Proof. (For similar arguments, see [16, Proposition 5.2].)

Consider first the locus of positive isotopies which remain disjoint from $f_{\text{subcrit}}$ but have no constraint with respect to $f_{\text{crit}}$. We claim that this locus is open and dense inside the space of all positive isotopies. This follows from an argument identical to that used to prove the first part of Lemma 2.2.

It now suffices to show that the locus of positive isotopies disjoint from $f_{\text{subcrit}}$ and only intersecting $f_{\text{crit}}$ by passing through transversally finitely many times is open and dense in the space of positive isotopies disjoint from $f_{\text{subcrit}}$. To see this, we consider the maps

$$\{\Lambda_1 \leadsto \Lambda_2 \subseteq Y \setminus f_{\text{subcrit}}\} \leftarrow \left\{ \Lambda_1 \leadsto \Lambda_2 \text{ inside } Y \setminus f_{\text{subcrit}}, (p,v) \text{ a point and a tangent direction in the total space of the isotopy} \right\} \xrightarrow{(p,v)} (TY \setminus Y)/\mathbb{R}_{>0}. \tag{2.4}$$

The second map is again a submersion, and hence the inverse image of $Tf_{\text{crit}}$ is a smooth codimension $(2(2n - 1) - 1) - (2(n - 1) - 1) = 2n$ submanifold of the middle space. The first map has fibers of dimension $2n - 1$, so the projection of something of codimension $2n$ is nowhere dense by Sard–Smale. This shows that the locus of positive Legendrian isotopies which pass through $f_{\text{crit}}$ transversally is dense, and openness is obvious.

2.2 $A_\infty$-categories

We work throughout with cohomologically unital $A_\infty$-categories, modules, and bimodules, over a commutative ring $R$, with cofibrancy assumptions as in [26, §3.1] (these are vacuous over a field), graded by an abelian group $G$ with specified maps $\mathbb{Z} \to G \to \mathbb{Z}/2$ (‘degree shift’ and ‘parity’) composing to the usual map $\mathbb{Z} \to \mathbb{Z}/2$. The reasoning in this paper is essentially agnostic about the choice of grading and coefficient ring (which we will often just write as $\mathbb{Z}$ for clarity). As much of the $A_\infty$-category literature assumes field coefficients, we record in §A proofs in the context of commutative ring coefficients of some facts we will require. All of the $A_\infty$-categories in this paper are small (i.e. they have a set of objects).

We will make frequent use of the quotient and localization operations on $A_\infty$-categories, for which we use [26, §3.1.3] as a basic reference. Given an $A_\infty$-category $\mathcal{C}$, we may consider its quotient $\mathcal{C}/\mathcal{A}$ by any set $\mathcal{A}$ of objects of $\text{Tw} \mathcal{C}$ (meaning, $\mathcal{A}$ is a set, and for each element of $\mathcal{A}$ there is specified an object of $\text{Tw} \mathcal{C}$; sometimes, but not always, $\mathcal{A}$ is simply a subset of the set of objects of $\mathcal{C}$). Note that making this definition does not require us to fix a particular small model of $\text{Tw} \mathcal{C}$, rather only to specify the set $\mathcal{A}$. There is also no need to assume that distinct elements of $\mathcal{A}$ are mapped to distinct objects (or to distinct isomorphism classes) of $\mathcal{C}$ or of $\text{Tw} \mathcal{C}$. The localization $\mathcal{C}[W^{-1}]$ at a class of morphisms $W$ in $H^0\mathcal{C}$ is the quotient by all cones $[X \xrightarrow{a} Y]$ where $a \in \mathcal{C}(X,Y)$ is a cycle representing an element of $W$ (since $\mathcal{C}$ is small, this is indeed a set of objects of $\text{Tw} \mathcal{C}$). The quotient by $\mathcal{A}$ depends (up to quasi-equivalence) only on the set of isomorphism classes split-generated by $\mathcal{A}$ [26, Corollary 3.14]. We also have the following (which is implicit in [26, §3.1.3]):

25
Lemma 2.4. Let $F : \mathcal{C} \to \mathcal{D}$ be a functor, and let $A$ be a set of objects of $\mathcal{C}$ (or $\text{Tw} \mathcal{C}$). If $F$ is fully faithful, then so is the resulting quotient functor $\mathcal{C}/A \to \mathcal{D}/F(A)$.

Proof. The action of the quotient functor on morphisms is given by

$$
\bigoplus_{p \geq 0} \mathcal{C}(X, Y_1) \otimes \cdots \otimes \mathcal{C}(Y_p, Z) \to \bigoplus_{p \geq 0} \mathcal{D}(F(X), F(Y_1)) \otimes \cdots \otimes \mathcal{D}(F(Y_p), F(Z)).
$$

(2.5)

The induced map on associated gradeds is a quasi-isomorphism since $F$ is fully faithful, and hence the map itself is also quasi-isomorphism. 

2.3 Construction via localization

Given a stopped Liouville sector $(X, f)$ together with a choice of projection $\pi_X : \text{Nbd}^2 \partial X \to \mathbb{C}_{\text{Re} \geq 0}$, we define a category

$$
W(X, f).
$$

(2.6)

The case $f = \emptyset$ was explained in detail in [26, §3]. The only difference in the case of general $f$ is that we restrict our Lagrangians (and isotopies thereof) to be disjoint from $f$ at infinity. For this reason, we will be brief, leaving the interested reader to consult [26, §3] for a more detailed treatment.

All statements about partially wrapped Fukaya categories should be interpreted as “up to inverting quasi-equivalences”. (We choose not to address the question of whether such quasi-equivalences are invertible up to natural quasi-isomorphism under our cofibrancy assumptions; it is well-known that quasi-equivalences are invertible up to natural quasi-isomorphism over a field, see [41, Theorem 2.9 and Remark 2.11].)

The most concrete definition of $W(X, f)$ begins with a countable collection $I$ of exact cylindrical Lagrangians in $X$, disjoint from $f$ at infinity and from $\partial X$, equipped with grading/orientation data, such that $I$ contains every isotopy class of such Lagrangians. For each $L \in I$ we choose a cofinal sequence of wrappings in $(L \sim -)_{X, f}$

$$
L = L^{(0)} \sim L^{(1)} \sim L^{(2)} \sim \cdots.
$$

(2.7)

We define a strictly unital $A_{\infty}$-category $\mathcal{O}$ as follows. The objects of $\mathcal{O}$ are the $L^{(i)}$ for $(i, L) \in \mathbb{Z}_{\geq 0} \times I$. To define the morphisms, we first equip the objects with the partial order inherited from the first factor, namely $L^{(i)} > K^{(j)}$ iff $i > j$. By choosing wrappings generically, we ensure that every totally ordered tuple of Lagrangians $L_0 > \cdots > L_k$ are mutually transverse.  

We define morphisms by:

$$
\mathcal{O}(L, K) := \begin{cases} 
CF^*(L, K) & L > K \\
\mathbb{Z} & L = K \\
0 & \text{else}
\end{cases}
$$

(2.8)

5We could, of course, ensure that every tuple of Lagrangians in $\mathcal{O}$ is mutually transverse. There is no need to assume this though, and it is convenient for many later purposes (e.g. defining pushforward functors) to have the flexibility of choosing $I$ arbitrarily.
The $A_\infty$ operations

$$\mu^k : \mathcal{O}(L_0, L_1) \otimes \cdots \otimes \mathcal{O}(L_{k-1}, L_k) \to \mathcal{O}(L_0, L_k)$$

for $L_0 > \cdots > L_k \in \mathcal{O}$ are constructed using compatible families of universal strip-like coordinates

$$\xi^+_{L_0,\ldots,L_k} : [0, \infty) \times [0, 1] \times \mathbb{R}_{k,1} \to \mathbb{R}_{k,1} \quad j = 1, \ldots, k$$

$$\xi^-_{L_0,\ldots,L_k} : (-\infty, 0] \times [0, 1] \times \mathbb{R}_{k,1} \to \mathbb{R}_{k,1}$$

and families of cylindrical almost complex structures

$$J_{L_0,\ldots,L_k} : \mathbb{R}_{k,1} \to \mathcal{J}(X)$$

which make a fixed choice of projection $\pi_X : \text{Nbd}^Z \partial X \to \mathbb{C}_{\Re \geq 0}$ holomorphic. (Note that the $A_\infty$ operations (2.9) in the case some $L_i = L_{i+1}$ are fixed by the requirement that $\mathcal{O}$ be strictly unital.)

We denote by $C$ the class of continuation morphisms in $HF^0(L^{i+1}, L^{i})$, and we define $W = W(X, f)$ to be the localization $\mathcal{O}[C^{-1}]$. This definition and its basic properties (such as $H^\bullet W$ being partially wrapped Floer cohomology) are due to Abouzaid–Seidel and are proved in detail in [26, §3].

The above construction works just as well for a much more general class of posets of Lagrangians $\mathcal{O}$, and using this additional flexibility one may show that $W$ is, up to zig-zag of quasi-equivalence, independent of the choices involved in its definition [26, Proposition 3.39].

### 2.4 Covariant functoriality

The partially wrapped Fukaya category is functorial under inclusions of stopped Liouville sectors $(X, f) \hookrightarrow (X', f')$, meaning $X \hookrightarrow X'$ is an inclusion of Liouville sectors (satisfying either $X \cap \partial X' = \emptyset$ or $X = X'$ and $\pi_X = \pi_{X'}$) and $f' \cap (\partial X) = \emptyset$. For a single inclusion $(X, f) \hookrightarrow (X', f')$, we may inductively define posets of Lagrangians in each of the relevant stopped Liouville sectors (which include into each other in a natural way), leading hence to a functor $W(X, f) \to W(X', f')$. Likewise from a diagram of stopped Liouville sectors $(X_\sigma, f_\sigma)$ indexed by a finite poset, we can produce a diagram of $A_\infty$-categories $W(X_\sigma, f_\sigma)$.

There is also a canonical model of $W(X, f)$ which is strictly functorial under arbitrary inclusions of stopped Liouville sectors, defined in terms of a ‘universal’ poset of Lagrangians $\mathcal{O}$ [26, §3.8]; it comes at the cost that these universal posets are (almost) always uncountable.

### 2.5 Equivalent presentations of the same Fukaya category

**Definition 2.5.** An inclusion of Liouville sectors is said to be **trivial** if it is isotopic, through inclusions of Liouville sectors, to a symplectomorphism.

**Lemma 2.6 ([26, Lemmas 3.41]).** For a trivial inclusion of Liouville sectors $X \hookrightarrow X'$, the pushforward on wrapped Fukaya categories is a quasi-equivalence. Thus a deformation of Liouville sectors $\{X_t\}_{t \in [0,1]}$ induces a natural quasi-equivalence $W(X_0) = W(X_1)$.  

27
Proof Sketch. By a sandwiching argument, it is enough to show that \( X_a \to X \) induces a quasi-equivalence on wrapped Fukaya categories for \( X_a := e^{-aX(X)} \) where \( I \) is a fixed defining function for \( X \). Essential surjectivity is trivial since we may use \( X_I \) to isotope Lagrangians in \( X \) into \( X_a \), and a Hamiltonian isotopy of Lagrangians induces a quasi-isomorphism in the wrapped Fukaya category. The point is to show that

\[
HW^\bullet(L, K)_{X_a} \to HW^\bullet(L, K)_X
\]  

(2.13)

is an isomorphism. This is shown in [26, Lemma 3.33] by explicitly comparing the cutoff Reeb vector fields on \( \partial(\partial\infty X) \) and \( \partial(\partial\infty X_a) \) to show that no new Reeb chords are created when enlarging \( X_a \) to \( X \).

**Lemma 2.7.** If \( f_0 \supseteq f_1 \supseteq \cdots \) is a decreasing family of closed subsets of \( (\partial\infty X)^\circ \), then the natural map

\[
\lim_{i \to i} HW^\bullet(L, K)_{X,f_i} \to HW^\bullet(L, K)_{X, \bigcap_{i=0}^\infty f_i}
\]  

(2.14)

is an isomorphism.

**Proof.** The wrapping categories (see \( \S 2.1 \)) are the same: \( \bigcup_{i=1}^\infty (L \to -)_{f_i} = (L \to -)_{f_i=0} \).

**Lemma 2.8.** Let \( X \) be a Liouville sector. A deformation of codimension zero submanifolds-with-corners \( f_t \subseteq (\partial\infty X)^\circ \) with every \( \partial f_t \) convex induces a natural quasi-equivalence \( W(X, f_0) = W(X, f_1) \).

**Proof.** By the same sandwiching argument, it is enough to show that the map \( W(X, f) \to W(X, e^V f) \) is a quasi-equivalence, where \( V \) is any contact vector field inward pointing along \( \partial f \). When \( \partial f \) is smooth (i.e. no corners), this follows from the analysis of the cutoff Reeb vector field from [26, Lemma 3.33] cited in the proof of Lemma 2.6. For general \( f \) with corners, we may write \( f \) as a decreasing intersection of smoothings \( f^1 \supseteq f^2 \supseteq \cdots \) each with convex boundary and appeal to the smooth boundary case and Lemma 2.7.

**Lemma 2.9.** Let \( X \hookrightarrow X' \) be an inclusion of Liouville sectors and let \( f \subseteq (\partial\infty X)^\circ \) and \( f' \subseteq (\partial\infty X')^\circ \) be closed subsets with \( f' \cap \partial\infty X = f \cup \partial(\partial\infty X) \). Then \( W(X, f) \hookrightarrow W(X', f') \) is fully faithful.

**Proof.** The hypothesis on \( f \) and \( f' \) implies that wrapping inside \( \partial\infty X \setminus f \) is the same as wrapping inside \( \partial\infty X' \setminus f' \). Holomorphic disks in \( X' \) are forced to lie in \( X \) by the usual maximum principle argument [26, Lemma 3.20].

**Lemma 2.10.** Let \( X \hookrightarrow \bar{X} \) be the inclusion of a Liouville sector \( X \) into its convex completion \( \bar{X} \). The map \( W(X) \xrightarrow{\sim} W(\bar{X}, \partial\infty \bar{X} \setminus (\partial\infty X)^\circ) \) is a quasi-equivalence.

**Proof.** The map is fully faithful by Lemma 2.9. To show essential surjectivity, we just need to show that every Lagrangian in \( \bar{X} \) with boundary contained in \( (\partial\infty X)^\circ \) is isotopic to a Lagrangian in \( X \). This statement is invariant under deformation of the pair \( (X, \bar{X}) \), as can be seen from the “pushing by \( X_I \)” argument from the proof of Lemma 2.6.
By [26, Lemma 2.32], we may deform to the situation to \( X = \bar{X} \setminus (\mathbb{R}_{s>0} \times \mathbb{R}_{|t|\leq 1} \times F_0)^{\circ} \subseteq \bar{X} \). In local coordinates \( \mathbb{R}_{s>0} \times \mathbb{R}_{|t|\leq 1} \times F_0 \), the Liouville form is given by \( e^s(dt - \lambda) \), which is preserved by the vector field \( -\frac{\partial}{\partial s} + t \frac{\partial}{\partial t} + Z_{\lambda} \). Extending this vector field arbitrarily to a Hamiltonian vector field linear at infinity on \( \bar{X} \), we see that it pushes any Lagrangian \( \bar{X} \) with boundary disjoint from \( \mathbb{R}_{|t|\leq 1} \times F_0 \) into \( X \).

**Corollary 2.11.** Let \( X \hookrightarrow \bar{X} \hookrightarrow F \times \mathbb{C}_{\text{Re} \geq 0} \) be the inclusion of a Liouville sector into its convex completion and the complement. The natural functors

\[
\mathcal{W}(X) \cong \mathcal{W}(X, \partial_{\infty}(F \times \mathbb{C}_{\text{Re} \geq 0})) \cong \mathcal{W}(X, F_0) \cong \mathcal{W}(X, \mathfrak{f})
\]

are quasi-equivalences, where \( \mathfrak{f} = \mathfrak{c}_F \subseteq F = F \times \{\infty\} \subseteq F \times \partial_{\infty}\mathbb{C}_{\text{Re} \geq 0} \subseteq \partial_{\infty}(F \times \mathbb{C}_{\text{Re} \geq 0}) \subseteq \partial_{\infty}\bar{X} \).

**Proof.** The first equivalence is just Lemma 2.10. The second two equivalences follow from Lemmas 2.7 and 2.8 since \( \partial_{\infty}(F \times \mathbb{C}_{\text{Re} \geq 0}) \) can be deformed down to either \( F_0 \) or \( \mathfrak{f} \) through codimension zero submanifolds with convex boundary by [26, Lemma 2.18].

**Proof of Theorem 1.4.** By passing to the convex completion and appealing to Lemma 2.10, it suffices to treat the case when \( X \) is a Liouville manifold.

The hypothesis on \( \{f_i\}_{t \in [0,1]} \) is equivalent to the existence of contact vector fields \( V_t \) on \( \partial_{\infty}X \setminus f_i \), varying smoothly in \( t \), such that the flow of \( V_t \) defines a contactomorphism \( \partial_{\infty}X \setminus f_0 \to \partial_{\infty}X \setminus f_1 \). Using this contact isotopy at infinity to define isotopies of exact cylindrical Lagrangians, we obtain at least an identification of the objects of \( \mathcal{W}(X, f_0) \) with the objects of \( \mathcal{W}(X, f_1) \).

We lift this contact isotopy at infinity to a Hamiltonian symplectomorphism \( \Phi : X \to X \) as follows. Fix a sequence of smooth contact vector fields \( V^1_t, V^2_t, \ldots \) on \( \partial_{\infty}X \) which agree with \( V_t \) away from smaller and smaller neighborhoods of \( \bigcup_{t \in [0,1]} \{t\} \times f_i \). Let \( \Phi^i_t : X \to X \) \((t \in [0,1])\) be any Hamiltonian isotopy which agrees with \( V^i_t \) at infinity. Iteratively define \( \Phi^i_t : X \to X \) by modifying \( \Phi^{-1}_t \) to agree with \( V^i_t \) near infinity. By performing these successive modifications in smaller and smaller neighborhoods of \( \bigcup_{t \in [0,1]} \{t\} \times f_i \) (further and further out at infinity), we ensure that \( \Phi^i_t \) converges to a Hamiltonian isotopy \( \Phi_t : X \to X \) as \( i \to \infty \), in the sense that \( \Phi^i_t \) eventually agrees with \( \Phi_t \) over the complement of any fixed neighborhood of \( \bigcup_{t \in [0,1]} \{t\} \times f_i \). We define \( \Phi := \Phi_1 : X \to X \) to be the resulting time one flow map.

We will construct an \( A_{\infty} \)-functor

\[
\mathcal{W}(X, f_0) \to \mathcal{W}(X, f_1)
\]

which is, morally speaking, given by pushing forward under \( \Phi \). Taken literally, this does not make sense since \( \Phi \) is not cylindrical at infinity, though note that \( \Phi \) does at least send exact cylindrical Lagrangians disjoint from \( f_0 \) to exact cylindrical Lagrangians disjoint from \( f_1 \).

To begin the construction of (2.16), let us define canonical isomorphisms

\[
HF^\bullet(L, K) = HF^\bullet(\Phi L, \Phi K)
\]

for exact cylindrical Lagrangians \( L, K \subseteq X \) disjoint from \( f_0 \) at infinity. The group \( HF^\bullet(L, K) \) may be viewed equivalently as the Floer cohomology of \( \Phi L \) and \( \Phi K \) with respect to \( \Phi_* \) of a
cylindrical at infinity almost complex structure. Thus the point of the isomorphism (2.17) is to compare the Floer cohomology of $\Phi L$ and $\Phi K$ defined via almost complex structures cylindrical at infinity with that defined via almost complex structures which are $\Phi_*$ of cylindrical at infinity. To make this comparison, fix a choice of cylindrical almost complex structure $J$, and let $J'$ denote a modification of $\Phi_* J$ taking place far out near infinity to make it cylindrical. It suffices to show that the holomorphic curves contributing to the differentials of the complexes $CF^\bullet(\Phi L, \Phi K; \Phi_*, J)$ and $CF^\bullet(\Phi L, \Phi K; J')$ lie entirely within the large compact subset of $X$ over which $J' = \Phi_* J$ (as long as this compact set is sufficiently large in terms of $J$). To bound the holomorphic curves contributing to $CF^\bullet(\Phi L, \Phi K; \Phi_*, J)$ and $CF^\bullet(\Phi L, \Phi K; J')$ away from infinity, we examine the proof [26, Proposition 3.19] guaranteeing the moduli spaces of such disks are compact. We observe that there is a lower bound on the distance between $\Phi_0$ and $\Phi_1$ in terms of $X$, and let $s = \Phi_0 - \Phi_1$ denote a modification of $\Phi_0$ taking place far out near infinity to make it $s$-invariant in the thin parts of the domain, as always) defined as follows. We require that for every interval $I$ of length $> N$ and every holomorphic map contributing to the differential in either $CF^\bullet(\Phi L, \Phi K; \Phi_*, J)$ or $CF^\bullet(\Phi L, \Phi K; J')$, there is a point in $I \times [0, 1]$ which is mapped to $C$. On the other hand, the subsequent monotonicity argument from the proof of [26, Proposition 3.19] shows that in fact this point cannot be mapped to the complement of the large compact subset where $\Phi_* J = J'$, since there is not enough energy for $u$ to cross the complement of $C$ in order to return to the compact subset of $X$ containing the intersections of $\Phi L$ and $\Phi K$. This proves (2.17).

The proof of the isomorphisms (2.17) extends immediately to show that these isomorphisms respect Floer composition (after possibly increasing the compact subset over which $J' = \Phi_* J$). It follows that they also respect continuation elements, and hence induce isomorphisms on wrapped Floer cohomology $HF^\bullet(L, K)_{X, f_0} = HF^\bullet(\Phi L, \Phi K)_{X, f_1}$ as well. This defines an equivalence of cohomology categories $H^\bullet W(X, f_0) = H^\bullet W(X, f_1)$.

We now lift this equivalence of cohomology categories to an $A_\infty$-functor (2.16). Choose posets of Lagrangians $\mathcal{O}_0$ and $\mathcal{O}_1$ as in §2.3 away from $f_0$ and $f_1$, respectively. By choosing these Lagrangians generically, we ensure that for every pair of tuples $K_k > \cdots > K_0 \in \mathcal{O}_1$ and $L_0 > \cdots > L_\ell \in \mathcal{O}_0$, the collection of Lagrangians $(K_k, \ldots, K_0, \Phi L_0, \ldots, \Phi L_\ell)$ is mutually transverse. Denote by $C_{k_0} \times C_{k_1}$ the respective collections of continuation morphisms. Thus $\mathcal{W}_i := W(X, f_i) := \mathcal{O}_i[C_{k_0}^{-1}]$ for $i = 0, 1$, and our goal is to construct a functor $\mathcal{W}_0 \to \mathcal{W}_1$.

We define an $(\mathcal{O}_1, \mathcal{O}_0)$-bimodule $\mathcal{B}$ by counting holomorphic strips up to translation as in Figure 3, for $K_k > \cdots > K_0 \in \mathcal{O}_1$ and $L_0 > \cdots > L_\ell \in \mathcal{O}_0$, with respect to compatible families of almost complex structures

\[ J_{K_k, \ldots, K_0, L_0, \ldots, L_\ell} : \mathcal{B}_{k+\ell+1, 1} \to \mathcal{J}(X) \tag{2.18} \]

(s-invariant in the thin parts of the domain, as always) defined as follows. We require that the negative strip-like coordinates (2.11) for $\mathcal{O}_0$ and $\mathcal{O}_1$ extend as in [26, Equation (5.7)] and that on the bimodule domain strips, we use the tautological strip-like coordinates at $s = \pm \infty$ (these assumptions ensure that the gluing maps on the bimodule domain strips respect the global $(s, t)$-coordinates). To state the conditions we impose on the almost complex structures (2.18), let $C$ denote the bimodule domain strip (identified with $\mathbb{R} \times [0, 1]$ up to $\mathbb{R}$-translation) and let $N_r \subseteq C$ denote the closed $r$-neighborhood of the marked points.
on the left of the strip (i.e. those mapping to intersection points $Φ(L_i \cap L_{i+1})$) with respect to the Riemannian metric $ds^2 + dt^2$. The almost complex structures (2.18) are required to satisfy the following conditions:

(i) Over $C \setminus N_{\frac{r}{4}}$, we require the almost complex structures to be cylindrical at infinity.
(ii) Over $N_{\frac{r}{4}}^0$, we require the almost complex structures to be $Φ^*$ of cylindrical at infinity.
(iii) Fix once and for all an exhaustion $K_1 \subseteq U_1 \subseteq K_2 \subseteq U_2 \subseteq \cdots \subseteq X$ (2.19) with $U_i$ open and $K_i$ compact, such that
\[
\inf_i d(X \setminus U_{2i}, K_{2i}) > 0, \tag{2.20}
\]
\[
\inf_i d(X \setminus Φ^{-1}(U_{2i+1}), Φ^{-1}(K_{2i+1})) > 0, \tag{2.21}
\]
where distance is with respect to a cylindrical metric $g$, meaning $L_Zg = g$ near infinity (such an exhaustion is trivial to construct by completeness of $g$). Over $(C \setminus N_{\frac{r}{2}}) \times \bigcup_i(U_{2i} \setminus K_{2i})$, we require the almost complex structures to agree (away from a compact subset of $X$) with a family of cylindrical at infinity almost complex structures. Over $N_{\frac{r}{2}}^0 \times \bigcup_i(U_{2i+1} \setminus K_{2i+1})$, we require them to agree (away from a compact subset of $X$) with $Φ^*$ of a family of cylindrical at infinity almost complex structures.

By choosing these almost complex structures generically, we can ensure that the moduli spaces of strips are cut out transversally.

To prove that the moduli spaces of such (stable) strips are compact, we follow the strategy used in [26, Propositions 3.19 and 4.23] based on ideas of Groman [31]. By standard Gromov compactness, it suffices to show that there exists a compact subset of $X$ containing the images of all stable holomorphic maps with specified boundary conditions (but allowing arbitrary pre-stable domain). We decompose the domain of a given stable holomorphic map into
the thin parts consisting of finite, semi-infinite, or infinite strips identified with $I \times [0, 1]$ ($I \subseteq \mathbb{R}$ an interval) and the thick parts consisting of the complement of the thin parts. The thin parts are by definition a neighborhood of the fiberwise nodes/punctures/marked points of the universal curve over $\overline{\mathcal{M}}_{g+\ell+1, 1}$ (more precisely, they are the inverse image of such a neighborhood inside the pre-stable domain curve under its canonical stabilization map to the universal stable curve). We equip a given domain curve with a Riemannian metric which in the thin parts equals $ds^2 + dt^2$ (with respect to the coordinates $I \times [0, 1]$) and in the thick parts has bounded geometry. In each component of the thin part $I \times [0, 1]$, the Lagrangian boundary conditions on $I \times \partial[0, 1]$ are constant, and the almost complex structures (2.18) are $s$-invariant. Furthermore, in each such component of the thin part, these Lagrangian boundary conditions and almost complex structures are either both cylindrical at infinity or $\Phi_*$ of cylindrical at infinity. Thus [26, Proof of Proposition 3.19] provides an $N < \infty$ and a compact subset $K \subseteq X$ (both depending on the Lagrangian boundary conditions of the stable strip) such that in each subinterval of $I$ of length $\geq N$, there exists a point which is mapped into $K$ by $u$. We have thus shown above that every point of $C$ is within bounded distance of a point which is mapped by $u$ into a fixed compact subset of $X$. Hence it suffices to show that for every small ball $B_{2\varepsilon}(p) \subseteq C$, the image $u(B_{\varepsilon}(p)) \subseteq X$ is bounded away from infinity in terms of $u(p)$. To show this, we apply monotonicity estimates to the graph of $u$ inside $B_{2\varepsilon}(p) \times X$. Over $N_\varepsilon \cup (C \setminus N_\varepsilon)$, the almost complex structures (2.18) give rise to bounded Kähler geometry on this product [26, Lemma 2.44], and the result follows. For general points of $C$, simply note that boundedness of geometry of $B_{2\varepsilon}(p) \times X$ over infinitely many “shells” $U_{2i} \setminus K_{2i}$ or $U_{2i+1} \setminus K_{2i+1}$ is sufficient for this argument to work, and this is precisely what we have assumed about our almost complex structures. This completes the proof of compactness, and hence also the definition of the $(\mathcal{O}_1, \mathcal{O}_0)$-bimodule $\mathcal{B}$.

We now study the $(\mathcal{O}_1, \mathcal{O}_0)$-bimodule $\mathcal{B}$. First observe that for every $L \in \mathcal{O}_0$, there is an isomorphism of $\mathcal{O}_1$-modules

$$\mathcal{B}(-, L) = CF^*(-, \Phi L).$$

Indeed, the domains defining the structure maps for $\mathcal{B}(-, L)$ have no boundary marked points on the left, and hence the almost complex structures (2.18) are everywhere cylindrical at infinity. Next, let us construct a homotopy between the two compositions in the diagram of $\mathcal{O}_1$-modules

$$\begin{align*}
&\downarrow (2.22) \otimes (2.17) \\
CF^*(-, \Phi L) \otimes CF^*(\Phi L, \Phi K) \xrightarrow{\mu^2} CF^*(-, \Phi K) \\
\downarrow (2.22) &
\mathcal{B}(-, L) \otimes CF^*(L, K) \xrightarrow{\mu^{11}} \mathcal{B}(-, K).
\end{align*}$$

Of course, the isomorphism (2.17) was only an isomorphism of homology groups, so we should first say what we mean by the map $CF^*(\Phi L, \Phi K) \rightarrow CF^*(L, K)$ above. We define this map as a continuation map counting strips $\mathbb{R} \times [0, 1]$ which are holomorphic with respect to almost complex structures which (1) are cylindrical at infinity for $s \geq 2$, (2) are $\Phi_*$ of cylindrical at infinity for $s \leq -2$, (3) agree over $\{s \geq -1\} \times \bigcup_i (U_{2i} \setminus K_{2i})$ (minus some compact subset of $X$) with cylindrical at infinity almost complex structures, and (4) agree over $\{s \leq 1\} \times \bigcup_i (U_{2i+1} \setminus K_{2i+1})$ (minus some compact subset of $X$) with $\Phi_*$ of cylindrical at infinity almost complex structures. This continuation map agrees on homology with the
isomorphisms (2.17), since we can just take our family of almost complex structures to be independent of \( s \) over a large enough compact subset of \( X \) to contain all holomorphic curves.

We may now define the homotopy between the two compositions in (2.23) by the family of domain curves illustrated in Figure 4. The domain on the left of Figure 4 defines the composition \( \mu^1 \mid \mu^1 \oplus (2.22) \oplus (2.17) \), and the domain on the right defines the composition \( (2.22) \oplus \mu^2 \). The striped regions indicate the interface between the regions where the almost complex structures are cylindrical at infinity and \( \Phi_* \) of cylindrical at infinity.

![Figure 4: The family of domains defining the homotopy between the two compositions in (2.23).](image)

Based on the properties of the \((O_1, O_0)\)-bimodule \( \mathcal{B} \) established above, we now argue that the functor

\[
\mathcal{W}_0 \to \text{Mod}_{\mathcal{W}_1} \\
L \mapsto \mathcal{C}^{-1}_{C_0^{-1}}(\mathcal{B})^{-1}(-, L)
\]

lands in the essential image of the Yoneda embedding \( \mathcal{W}_1 \hookrightarrow \text{Mod}_{\mathcal{W}_1} \) (see Lemma A.1) and hence, up to inverting quasi-equivalences, defines a functor \( \mathcal{W}_0 \to \mathcal{W}_1 \), which we will argue lifts the equivalence of cohomology categories constructed at the very beginning of the proof.

Fix \( L \in \mathcal{O}_0 \), and let us show that the \( \mathcal{W}_1 \)-module \( \mathcal{C}^{-1}_{C_0^{-1}}(\mathcal{B})^{-1}(-, L) \) is representable. According to [26, Corollary 3.38], the cohomology of the localization of the \( \mathcal{O}_1 \)-module \( \mathcal{B}(-, L) \) on the left by \( \mathcal{C}_1 \) is calculated by taking the direct limit over wrapping in \( \mathcal{O}_1 \). In view of the isomorphism (2.22), we deduce an isomorphism of \( H^\bullet \mathcal{W}_1 \)-modules

\[
H^\bullet \mathcal{C}^{-1}_{C_0^{-1}}(\mathcal{B})(-L) = H\mathcal{W}^\bullet(-L, \Phi L).
\]

Furthermore, by commutativity of (2.23), these identifications over all \( L \) respect the natural multiplication on the right by \( H F^\bullet(L, K) = H F^\bullet(\Phi L, \Phi K) \). In particular, it follows that \( \mathcal{C}^{-1}_{C_0^{-1}}(\mathcal{B}) \) is \( C_0 \)-local on the right, so the map \( \mathcal{C}^{-1}_{C_0^{-1}}(\mathcal{B})(-L) \to \mathcal{C}^{-1}_{C_0^{-1}}(\mathcal{B})(-L) \) is a quasi-isomorphism by [26, Lemma 3.13]. Hence for every \( L \in \mathcal{W}_0 \), the \( \mathcal{W}_1 \)-module \( \mathcal{C}^{-1}_{C_0^{-1}}(\mathcal{B})(-L) \) is
quasi-isomorphic to $c^{-1}_2 \mathcal{B}(-, L)$ which in turn is quasi-isomorphic to $c^{-1}_1 CF^*(-, \Phi L)$ (in fact strictly isomorphic under the definition above). On the other hand, $c^{-1}_1 CF^*(-, \Phi L)$ by definition is the representable (i.e., Yoneda) module $\mathcal{W}_1(-, \Phi L)$, so we conclude $c^{-1}_1 \mathcal{B} c^{-1}_0(-, L)$ is represented by $\Phi L$. Hence the functor $c^{-1}_1 \mathcal{B} c^{-1}_0 : \mathcal{W}_0 \to \text{Mod}_{\mathcal{W}_1}$ from (2.24) above lands in the image of the Yoneda embedding and thus by the Yoneda Lemma A.1 defines (up to inverting quasi-equivalences) our functor $\mathcal{W}_0 \to \mathcal{W}_1$.

It remains to show that this functor $\mathcal{W}_0 \to \mathcal{W}_1$ induces the natural isomorphisms on cohomology constructed at the beginning of the proof. To calculate the image of a given class in $HF^*(L, K)$ under the functor defined by the localized bimodule $c^{-1}_1 \mathcal{B} c^{-1}_0$, we should consider the map of $\mathcal{W}_1$-modules $c^{-1}_1 \mathcal{B} c^{-1}_0(-, L) \otimes CF^*(L, K) \to c^{-1}_1 \mathcal{B} c^{-1}_0(-, K)$. Under the quasi-isomorphism between $c^{-1}_1 \mathcal{B} c^{-1}_0(-, L)$ and $c^{-1}_1 CF^*(-, \Phi L)$ explained above, this corresponds (in view of (2.23)) to the usual multiplication $c^{-1}_1 CF^*(-, \Phi L) \otimes CF^*(L, K) \to c^{-1}_1 CF^*(-, \Phi K)$. This usual multiplication map is also by definition the action of the Yoneda functor on morphism spaces $CF^*(\Phi L, \Phi K) \to \text{Hom}_{\text{Mod}_{\mathcal{W}_1}}(c^{-1}_1 CF^*(-, \Phi L), c^{-1}_1 CF^*(-, \Phi K))$, so we are done.

**Example 2.12.** Let us show that if $F_t \subseteq (\partial_\infty X)^\circ$ is a deformation of Liouville hypersurfaces then the family of their cores $f_t$ satisfies the hypothesis of Theorem 1.4 (though note that in this case the conclusion of Theorem 1.4 follows much more easily from Corollary 2.11 and Lemma 2.6; the whole point of Theorem 1.4 is that verifying its hypothesis for a given family of stops $f_t$ is supposed to be easier than producing a corresponding family of ribbons $F_t$). To see that the complement is a locally trivial bundle of contact manifolds, write a neighborhood of $F_t$ in local coordinates $(\mathbb{R}_z \times F_t, dz + \lambda_t)$, and observe that there is a contact vector field $W_t := -z \partial_z - Z_{\lambda_t}$ which is complete in the positive direction. There thus exists a smooth trivialization of the complement of $\bigcup_{t \in [0, L]} \{t\} \times f_t \subseteq [0, L] \times (\partial_\infty X)^\circ$ which is standard near $\partial(\partial_\infty X)$ and which preserves $W_t$ near $f_t$. With respect to this trivialization, we thus have a family of contact structures $\xi_t$ on a manifold-with-boundary $M$, such that $\xi_t$ is constant near $\partial M$, and $\xi_t$ is $W$-invariant near infinity for a fixed vector field $W$ giving $M$ a complete cylindrical structure near infinity. Recall that for any deformation of contact structures $\xi_t$ on a manifold $M$, there exists a unique family of vector fields $V_t$ satisfying $\mathcal{L}_{V_t} \xi_t = \partial_t \xi_t$ and $V_t \in \xi_t$. If the flow of $V_t$ is complete, then this provides an isotopy $\Phi_t : M \to M$ with $\Phi_t^* \xi_t = \xi_0$. In our particular example, $V_t$ vanishes near $\partial M$ since $\xi_t$ is constant there, and $V_t$ is $W$-invariant near infinity since $\xi_t$ is $W$-invariant there. These two conditions clearly imply the flow of $V_t$ is complete, thus concluding the proof.

## 3 Lagrangian linking disks and surgery at infinity

The purpose of this section is to introduce and perform some basic manipulations with the Lagrangian cobordisms we are interested in, namely the small Lagrangian linking disks and the relatively non-exact embedded Lagrangian 1-handle. Our definitions of and reasoning about Lagrangian submanifolds of symplectizations will be given primarily in terms of the front projections of their Legendrian lifts, however we will also give descriptions in terms of Weinstein handles in some cases.
In particular, we give a careful account of the higher-dimensional version of the following series of pictures:

The picture on the left illustrates the small Lagrangian disk $D$ linking a Legendrian submanifold $\Lambda$ at infinity. The picture in the middle illustrates the result $L\# D$ of attaching a relatively non-exact Lagrangian 1-handle along a short Reeb chord from a given Lagrangian $L$ to $D$. The picture on the right illustrates the result $L^w$ of positively isotoping $L$ through $\Lambda$, which evidently is isotopic to $L\# D$.

### 3.1 Front projections

![Front projections](image)

Figure 5: Left: the front projection of the standard Legendrian unknot in contact $\mathbb{R}^3 = \mathbb{R} \times T^*\mathbb{R}$. Right: the front projection of the standard Legendrian unknot in contact $\mathbb{R}^5 = \mathbb{R} \times T^*\mathbb{R}^2$, obtained by spinning the picture on the left.

A function $f : M \to \mathbb{R}$ gives rise to its graph $\Gamma_f$ inside $\mathbb{R} \times T^*M$ as well as to the graph $\Gamma_{(f,df)}$ of $(f,df)$ inside $(\mathbb{R} \times T^*M, dz - \lambda_{T^*M})$, which is Legendrian. The projection $\mathbb{R} \times T^*M \to \mathbb{R} \times M$ is called the front projection, and we can represent Legendrian submanifolds of $\mathbb{R} \times T^*M$ by drawing their front projection in $\mathbb{R} \times M$. For example, $\Gamma_f$ is the front projection of the Legendrian $\Gamma_{(f,df)}$.

Unlike the case of the graph as just mentioned, usually this front has singularities, as in Figure 5. The part of the front which is locally the graph of a smooth function lifts uniquely to a smooth Legendrian. The fronts we draw in this paper all have the property that taking the closure of the lift of the smooth locally graphical part recovers the original Legendrian.

An exact Lagrangian submanifold $L \subseteq (T^*M, \lambda_{T^*M})$ lifts to a Legendrian submanifold of $(\mathbb{R} \times T^*M, dz - \lambda_{T^*M})$, and a choice of lift is equivalent (via taking the $z$-coordinate) to a choice of function $g : L \to \mathbb{R}$ satisfying $dg = \lambda_{T^*M}|_L$. We may thus represent a pair $(L, g) \subseteq (T^*M, \lambda_{T^*M})$ by drawing its front projection in $\mathbb{R} \times M$.

To represent exact Lagrangian submanifolds of symplectizations via a front projection, we consider the following setup. We consider the cotangent bundle $T^*(\mathbb{R} \times M)$ equipped
with the Liouville vector field $Z_{\text{cyl}}$ defined by adding to $Z_{T^*M}$ the canonical Hamiltonian lift of the vector field $\frac{\partial}{\partial s}$ on the base $\mathbb{R}_s \times M$ (denote by $\lambda_{\text{cyl}}$ the associated Liouville form). In coordinates $T^*(\mathbb{R}_s \times M) = \mathbb{R}_t \times \mathbb{R}_s \times T^*M$, we have

$$\lambda_{T^*(\mathbb{R}_s \times M)} = \lambda_{T^*M} + t \, ds, \quad \lambda_{\text{cyl}} = \lambda_{T^*M} + t \, ds - dt. \quad (3.1)$$

Now $(T^*(\mathbb{R}_s \times M), Z_{\text{cyl}})$ is the symplectization of the contact type hypersurface $\{s = 0\} = \mathbb{R}_t \times T^*M$, over which the Liouville form $\lambda_{\text{cyl}}$ restricts to the contact form

$$-dt + \lambda_{T^*M}. \quad (3.3)$$

We represent exact Lagrangians $L \subseteq T^*(\mathbb{R}_s \times M)$ via their front projection inside $\mathbb{R}_z \times \mathbb{R}_s \times M$ (note that a Lagrangian submanifold $L \subseteq T^*(\mathbb{R}_s \times M)$ is exact with respect to $\lambda_{\text{cyl}}$ iff it is exact with respect to $\lambda_{T^*(\mathbb{R}_s \times M)}$). If such a front projection is given locally by the graph of a function $g : \mathbb{R}_s \times M \to \mathbb{R}_z$, then $g$ is the primitive of $\lambda_{T^*(\mathbb{R}_s \times M)}$, and $f = g - \partial_s g$ is the primitive of $\lambda_{\text{cyl}}$. In particular, the Lagrangian $L \subseteq T^*(\mathbb{R}_s \times M)$ is cylindrical precisely where $g = e^s h + \text{const}$ for some function $h : M \to \mathbb{R}$. A Legendrian submanifold $\Lambda \subseteq (\mathbb{R}_t \times T^*M, -dt + \lambda_{T^*M})$ gives rise to a cylindrical Lagrangian in its symplectization $(T^*(\mathbb{R}_s \times M), Z_{\text{cyl}})$. In terms of front projections, this corresponds to taking a front inside $\mathbb{R}_t \times M$ and setting $z = e^s t + \text{const}$ to obtain a front inside $\mathbb{R}_z \times \mathbb{R}_s \times M$ (representing the cylinder over the original Legendrian equipped with the primitive $f \equiv \text{const}$), see Figure 6 (for ease of illustration, we will use the coordinate $r = e^s$ in place of $s$ in figures).

![Figure 6](image)

Figure 6: Below: the front projection inside $\mathbb{R}_z \times \mathbb{R}_r \times M$ of the cylinder over the standard Legendrian unknot. Above: cross-sections $r = \text{const}$ of the same.

It is important to know when a front projection in $\mathbb{R}_z \times \mathbb{R}_s \times M$ corresponds to an embedded Lagrangian (rather than just an immersed Lagrangian). This holds, of course, whenever the Legendrian lift has no Reeb chords, in other words whenever the front projection has no common tangencies with any of its vertical translates (other than itself). Note that this is always the case for a front in $\mathbb{R}_z \times \mathbb{R}_s \times M$ obtained as $e^s$ times a front in $\mathbb{R}_t \times M$ representing an embedded Legendrian.
3.2 Weinstein handles

We recall the basics of Weinstein handles. Weinstein handles were introduced by Weinstein [45], motivated by the construction of Stein structures due to Eliashberg [20] and work of Gromov–Eliashberg [24]. The connection between Weinstein and Stein structures was developed fully by Cieliebak–Eliashberg [15]. Our present perspective, however, is purely symplectic.

A Weinstein \(k\)-handle of dimension \(2n\) (\(0 \leq k \leq n\)) is a germ of a Liouville cobordism near a point \(p\) at which \(Z\) vanishes and in a neighborhood of which \(Z\) is gradient-like for a function \(\phi\) having a Morse critical point of index \(k\) at \(p\). The standard Weinstein \(k\)-handle is (the germ near zero of)

\[
(X_k, \omega_k, Z_k) := \left( \mathbb{R}^{2k} \times \mathbb{R}^{2(n-k)}, \omega_{\text{std}}, \sum_{i=1}^{k} \frac{1}{2}(-x_i \partial x_i + 3y_i \partial y_i) + \sum_{j=1}^{n-k} \frac{1}{2}(x'_j \partial x'_j + y'_j \partial y'_j) \right).
\] (3.4)

A general Weinstein \(k\)-handle need not be locally modelled on this standard Weinstein \(k\)-handle, however it can always be canonically deformed to it [30, Proof of Lemma 6.6]. The fundamentals of Morse theory (reordering of critical values, handle cancellation, handle slides, etc.) for Weinstein handles were developed by Cieliebak–Eliashberg [15].

Coupled Weinstein handles were introduced more recently by Eliashberg–Ganatra–Lazarev [23]. A coupled Weinstein \((k, \ell)\)-handle \((0 \leq \ell \leq k \leq n)\) is a Weinstein \(k\)-handle together with a (germ of) Lagrangian submanifold \(L\) passing through \(p\) such that \(Z\) is tangent to \(L\) and the restriction of \(\phi\) to \(L\) has a Morse critical point of index \(\ell\). The standard coupled Weinstein \((k, \ell)\)-handle is given by

\[
(X_k, \omega_k, Z_k, L_{k, \ell} := \{y_1 = \cdots = y_\ell = x_{\ell+1} = \cdots = x_k = 0 = y'_1 = \cdots = y'_{n-k}\}).
\] (3.5)

Again, a general coupled Weinstein handle need not be locally modelled on the standard coupled handle, but it can be canonically deformed to the standard one. Of course, there is no reason to stop with just one Lagrangian—we could just as well consider (as we will later) multiple \(Z\)-invariant Lagrangians passing through \(p\) on which the restriction of \(\phi\) is Morse.

Dimitroglou Rizell [17, §4] introduced what we shall call an exact embedded Lagrangian \(k\)-handle for \(0 \leq k < n\). This consists of attaching a coupled Weinstein \((k, k)\)-handle followed by a Weinstein \((k+1)\)-handle, such that the pair cancel (as Weinstein handles), so the result is an exact Lagrangian cobordism inside a trivial Liouville cobordism (i.e. a symplectization). We will not appeal to this notion logically, but it provides relevant context for the constructions of this section.

3.3 Small Legendrian linking spheres and Lagrangian linking disks

At any point \(p\) of a Legendrian submanifold \(\Lambda\) there is a small linking disk \(S_p\) defined by the picture in Figure 7 (this is the picture inside contact 3-space, and the general case is obtained by spinning). The picture takes place in a small Darboux chart around \(p\) in which \(\Lambda\) is the horizontal line. The small Legendrian linking spheres \(S_p\) bound small Lagrangian linking disks \(D_p\) in the symplectization obtained by modifying the cylinder \(\mathbb{R} \times S_p\) as in
Figure 7: The small linking sphere around a given point of a Legendrian submanifold (seven views, related by Legendrian isotopy).

Figure 8: Below: the front projection inside \( \mathbb{R}_z \times \mathbb{R}_r \times M \) of the small Lagrangian linking disk. Above: cross-sections \( r = \text{const} \) of the same.

Figure 8. Note there are two possible interpretations of Figure 8, namely either as a filling of the leftmost picture or the rightmost picture of Figure 7. The disks defined by these two interpretations are canonically Lagrangian isotopic (this can be seen by extending the Legendrian isotopy in Figure 7 in the natural way, or by comparing with the description in terms of Weinstein handles given below).

The small Lagrangian linking disk \( D_p \) can be alternatively described as follows in terms of coupled Weinstein handles (it is basically an exact embedded Lagrangian 0-handle in the sense of §3.2). Let \( p \in \Lambda \subseteq Y \) be a (germ near the point \( p \) of a) Legendrian submanifold of a contact manifold \( Y^{2n-1} \). Let \( 0 \leq \ell < n \), and attach to the pair \((Y, \Lambda)\) a coupled \((\ell, \ell)\)-handle and a coupled \((\ell + 1, \ell + 1)\)-handle which form a cancelling pair near \( p \). At either such handle, we can consider another Lagrangian passing through the critical point which is transverse to \( \Lambda \) and on which the restriction of the Morse function has a critical point of index zero. This gives a properly embedded Lagrangian \( \mathbb{R}^n \) inside the symplectization of \( Y \), and this Lagrangian is our alternative definition of \( D_p \).

To see that \( D_p \) does not depend on \( \ell \) or on whether we take it over the \((\ell, \ell)\)-handle or over the \((\ell + 1, \ell + 1)\)-handle, argue as follows. We consider the cylindrical Lagrangian \( L = SA \subseteq SY = X \). We introduce a cancelling pair of coupled Weinstein handles of indices \((\ell, \ell)\) and \((\ell + 1, \ell + 1)\) on \( L \). Locally, the model for this is as follows. The pair \((X, L)\) is locally modelled on

\[
(T^*(\mathbb{R}_s \times \Lambda), \mathbb{R}_s \times \Lambda, Z_{\text{cyl}} = Z_{T^*(\mathbb{R}_s \times \Lambda)} + \pi^* \partial_s)
\]

as described in §3.1, where we now use \( \pi^* \) to denote the canonical lift of vector fields on \( \mathbb{R}_s \times \Lambda \) to Hamiltonian vector fields on \( T^*(\mathbb{R}_s \times \Lambda) \). If we deform \( \partial_s \) by introducing a pair
of cancelling Morse handles of indices $\ell$ and $\ell + 1$, the resulting deformation of Hamiltonian lifts realizes the operation of introducing a cancelling pair of coupled Weinstein handles of indices $(\ell, \ell)$ and $(\ell + 1, \ell + 1)$. (More precisely, for this to work we may need to work with $\varepsilon > 0$ times this deformed vector field to ensure that $Z_{cyl}$ is indeed a Weinstein structure.)

In this description, the small Lagrangian linking disk $D_p$ is simply the cotangent fiber over one of the zeroes of the deformed vector field on $\mathbb{R}_s \times \Lambda$. When the critical points come together and cancel, these two fibers also come together, thus showing that we can define $D_p$ as the fiber over either of them. To see that the disk $D_p$ is independent of $\ell$, consider adding cancelling Morse handles of indices $\ell, \ell + 1, \ell + 1, \ell + 2$ to $L$ (for example, using the vector field $(x^2 + t_1)\partial_t + (y^2 + t_2)\partial_y$ with $t_1, t_2 < 0$). These handles can be cancelled in two ways, depending on which of the $(\ell + 1)$-handles cancels with the $\ell$-handle and which with the $(\ell + 2)$-handle (in the example, this corresponds to raising $t_1$ to be positive or raising $t_2$ to be positive). It follows that the cotangent fibers over each of these handles are all isotopic. This shows that $D_p$ is independent of $\ell$.

To see that the description of the small Lagrangian linking disk in terms of Weinstein handles is indeed equivalent to the picture in Figure 8, argue as follows. We consider the local model given above with $\ell = 0$. Namely, we consider the Liouville vector field $Z_V$ on $T^*(\mathbb{R}_s \times M)$ given by $Z_{T^*(\mathbb{R}_s \times \Lambda)}$ plus the Hamiltonian lift of a vector field $V$ on $\mathbb{R}_s \times M$ which is obtained from $\partial_s$ by a compactly supported perturbation (within the class of gradient-like vector fields) which introduces a pair of cancelling zeroes of indices 0 and 1, as illustrated in Figure 9. We suppose in addition that near the zero of index zero, $V$ is locally smoothly conjugate to $\frac{2}{3} \sum_i x_i \frac{\partial}{\partial x_i}$, and hence $Z_V$ is given locally by $\frac{2}{3} \sum_i x_i \frac{\partial}{\partial x_i} + \frac{1}{3} \sum_j y_j \frac{\partial}{\partial y_j}$. (This local requirement on $V$ is not compatible with the need, mentioned earlier, to replace $V$ with $\varepsilon \cdot V$ for small $\varepsilon > 0$ to ensure that $Z_V$ is Weinstein. So, to be precise, we must first choose $V$, then scale it down to $\varepsilon \cdot V$, and finally perform a local modification near the index zero critical point to ensure the correct local form.)

Figure 9: The vector field $V$ on $\mathbb{R}_s \times M$ with cancelling critical points of indices 0 and 1, and the hypersurface $H \subseteq \mathbb{R}_s \times M$.

Consider a hypersurface $H \subseteq \mathbb{R}_s \times M$ passing through the index 0 zero of $V$, with $V$ tangent to $H$, and $H$ non-compact only in the $s = +\infty$ direction (see Figure 9). The conormal $N^*H$ is a $Z_V$-invariant Lagrangian submanifold which intersects $L = \mathbb{R} \times \Lambda$ cleanly along $H$. A small transverse pushoff of $N^*H$ to intersect $\mathbb{R} \times \Lambda$ exactly once is precisely the
small Lagrangian linking disk as described via Weinstein handles. To draw this transverse pushoff, we first deform $N^*H$ to $\tilde{N}^*H$ (which still intersects $L$ cleanly along $H$) as follows. The conormal $N^*H$ is given in local coordinates by $\{x_1 = 0 = y_2 = \cdots = y_n\}$, and we define $\tilde{N}^*H$ to be given in local coordinates by $\{x_1 - y_1^2 = 0 = y_2 = \cdots = y_n\}$ extended globally by $Z_V$-invariance (note that this locus is indeed locally invariant under $Z_V$). Now the front projection of $\tilde{N}^*H$ is precisely the picture in Figure 8. Now the small Lagrangian linking disk as described by Weinstein handles (which intersects $L$ once transversally) is a small perturbation of $\tilde{N}^*H$ (which intersects $L$ cleanly along $H$). This perturbation may be described as simply a small positive or negative pushoff via the Reeb vector field on the local contact sphere near the zero of $Z_V$. At infinity, the effect on $\tilde{N}^*H$ is the same, simply a small positive or negative Reeb pushoff, which yields the same picture from Figure 8 except now perturbed either up or down to coincide at infinity with either the far left or far left picture from Figure 7, respectively.

3.4 Relatively non-exact embedded Lagrangian 1-handle

![Figure 10: Left: Two Legendrians $\Lambda_1$ and $\Lambda_2$ and a positive arc $\gamma$ from $\Lambda_1$ to $\Lambda_2$. Right: The connect sum $\Lambda_1 \#_r \Lambda_2$. The relatively non-exact embedded Lagrangian 1-handle has negative end $\Lambda_1 \sqcup \Lambda_2$ and positive end $\Lambda_1 \#_r \Lambda_2$. (In higher dimensions, the picture is obtained by spinning.)](image)

Fix two disjoint Legendrians $\Lambda_1$ and $\Lambda_2$ inside a contact manifold $Y$ and a Darboux chart for $Y$ with front projection as on the left of Figure 10, containing an obvious “short” Reeb chord $\gamma$ from $\Lambda_1$ to $\Lambda_2$. Given such data (compare also Remark 3.6), we define an exact Lagrangian cobordism $L \subseteq SY$ asymptotic at $s = -\infty$ to $\Lambda_1 \sqcup \Lambda_2$ and asymptotic at $s = +\infty$ to the connect sum $\Lambda_1 \#_r \Lambda_2$ (see Figure 10). Topologically, $L$ is simply a 1-handle.

**Remark 3.1.** One cannot produce a Darboux chart as in Figure 10 from a general positive arc $\gamma : [0, 1] \to Y$ from $\gamma(0) \in \Lambda_1$ to $\gamma(1) \in \Lambda_2$ together with a “framing” consisting of a Lagrangian subbundle of $\gamma^*\xi$ which coincides with $T\Lambda_1$ at 0 and with $T\Lambda_2$ at 1. Indeed, the Maslov index of the framing must be sufficiently of a certain sign.

**Remark 3.2.** It is important to point out that the cobordism $L$ is not “local” to a neighborhood of $\gamma$, that is to say that outside the local picture in Figure 10, the cobordism $L$ does not coincide with the cylinder over $\Lambda_1 \sqcup \Lambda_2$. Rather, away from $\gamma$, the cobordism $L$ is an arbitrarily small (but necessarily nontrivial) perturbation of the cylinder over $\Lambda_1 \sqcup \Lambda_2$. 40
Figure 11: Construction of the relatively non-exact embedded Lagrangian 1-handle $L$. Each row is the cross-sections $\{r = \text{const}\}$ of a front inside $\mathbb{R}_z \times \mathbb{R}_r \times M$.

Figure 12: Construction of the relatively non-exact embedded Lagrangian 1-handle $L$.

We define the relatively non-exact embedded Lagrangian 1-handle $L$ by the illustrations in Figures 11 and 12, which we explain in more detail below. As usual, we are considering here the front projection inside $\mathbb{R}_z \times \mathbb{R}_r \times M$ to describe an exact Lagrangian inside $T^* (\mathbb{R}_r \times M)$ with a choice of primitive. Recall (from the discussion in §3.1) that the front of a Lagrangian cobordism inside $\mathbb{R}_z \times \mathbb{R}_r \times M$ is of the form $e^s h + \text{const}$ near $s = \pm \infty$ (equivalently, of the form $rh + \text{const}$ near $r = 0, \infty$) for $h$ a front inside $\mathbb{R}_z \times M$ representing the positive/negative ends of the cobordism. Note that the apparent asymmetry between $\Lambda_1$ and $\Lambda_2$ in the illustrations is only for ease of drawing.

The first line of Figure 11 and the left side of Figure 12 is simply (the cylinder over) a standard neighborhood of the (framed) positive path $\gamma$ from $\Lambda_1$ (the concave front) to $\Lambda_2$ (the horizontal front). Note the vertical coordinate is reversed in comparison with Figure 10 due to (3.3) being negative of the standard contact form on $\mathbb{R}_t \times T^* M$. Recall that the
primitive $f$ is given by $g - \partial_s g$ where $g$ is the $z$-coordinate, so the primitive vanishes on both components.

The second line of Figure 11 is obtained from the first line by performing a small isotopy of the cylinder over $\Lambda_2$. As a Lagrangian isotopy, this isotopy is fixed at $s = \pm \infty$, but as an isotopy of the front projection, it is fixed only at $s = +\infty$, because at $s = -\infty$ the primitive is shifted up by $\varepsilon > 0$. Note that this isotopy is not supported in the small neighborhood of $\gamma$ being illustrated, rather it is a small global perturbation of the cylinder over $\Lambda_2$ (fixed at $s = \pm \infty$). This extension may be defined by drawing the same picture in $\mathbb{R}_z \times \mathbb{R}_r \times \Lambda_2$, which describes a Weinstein neighborhood of $\Lambda_2$. The remaining steps will take place entirely inside the illustrated region.

The third line of Figure 11 is obtained from the second line by removing the part of the picture where the concave curve lies above the flat curve. Note that the slopes of these two curves differ where they intersect, so their Legendrian lifts (and their Lagrangian projections) are in fact disjoint.

The fourth line of Figure 11 is obtained from the third line by a local modification near the corners turning them into cusps which lift to smooth Legendrians/Lagrangians. The resulting front is also illustrated on the right side of Figure 12.

It is straightforward to check that the Lagrangians represented by the above pictures are indeed embedded (i.e. the Legendrians represented by each line have no Reeb chords).

**Remark 3.3.** Note that the primitive $f : L \to \mathbb{R}$ of $\lambda|_L$ satisfies

$$f|_{\{-\infty\} \times \Lambda_2} > f|_{\{-\infty\} \times \Lambda_1}$$

(this is the origin of the term “relatively non-exact” used to describe $L$). The pair $(L, f)$ cannot be deformed to satisfy $f|_{\{-\infty\} \times \Lambda_2} = f|_{\{-\infty\} \times \Lambda_1}$. Indeed, if such a deformation were to exist, then the proof of Proposition 1.30 would yield a direct sum decomposition $L#K = L \oplus K$ in the Fukaya category, and there are simple counterexamples to this statement.

**Remark 3.4.** The relatively non-exact embedded Lagrangian 1-handle should be contrasted with the exact embedded Lagrangian $k$-handles recalled in §3.2. The latter are exact, local, and their attachment does not alter the corresponding object of the Fukaya category (the proof of Proposition 1.30 applies easily to show this).

**Remark 3.5.** Using the pictures above, one can check (though we will not use this fact) that attaching a relatively non-exact embedded Lagrangian 1-handle followed by attaching an exact embedded Lagrangian $(n - 1)$-handle can be alternatively described as wrapping $\Lambda_1$ through $\Lambda_2$ to create a single transverse double point and then resolving that double point via Polterovich surgery.

**Remark 3.6.** The data necessary to define a relatively non-exact embedded Lagrangian 1-handle can be equivalently formulated as follows. We begin with two Legendrians $\Lambda_1^0, \Lambda_2^0 \subseteq Y$ intersecting exactly once, cleanly. We perturb $\Lambda_1^0$ in the negative direction to obtain $\Lambda_1$, and we perturb $\Lambda_2^0$ in the positive direction to obtain $\Lambda_2$. Near the intersection point $\Lambda_1^0 \cap \Lambda_2^0$ there is now a Darboux chart of the requisite form as on the left of Figure 10.

In this formulation, the projection of the relatively non-exact embedded Lagrangian 1-handle $Y$ is now clearly contained in a small neighborhood of $\Lambda_1^0 \cup \Lambda_2^0$, which (if $\Lambda_1^0$ and $\Lambda_2^0$ are compact) is the core of a Liouville hypersurface, namely the plumbing of their respective cotangent bundles.
3.5 Wrapping through a Legendrian

![Diagram](https://example.com/diagram13.png)

**Figure 13:** The proof that $\partial_{\infty}(L \#_{\gamma} D) = \partial_{\infty}L^w$.

![Diagram](https://example.com/diagram14.png)

**Figure 14:** The result of attaching a relatively non-exact Lagrangian 1-handle with a small Lagrangian linking disk (with inverted vertical coordinate; compare with the sign of (3.3)).

**Proof of Proposition 1.31.** It is enough to consider a single local model.

Figure 13 proves the desired statement at the level of the contact boundary, namely $\partial_{\infty}L^w = \partial_{\infty}(L \#_{\gamma} D_p)$. The left two diagrams in Figure 13 (related by Legendrian isotopy) show the stop $\Lambda$, the boundary $\partial_{\infty}L$ of our Lagrangian, the boundary $\partial_{\infty}D_p$ of the linking disk, and the positive arc $\gamma$ along which we attach a relatively non-exact Lagrangian 1-handle. The right two diagrams in Figure 13 (related by Legendrian isotopy) show the result after attaching the 1-handle, which is evidently the same as is obtained by simply passing $\partial_{\infty}L$ through $\Lambda$ in the positive direction to obtain $\partial_{\infty}L^w$.

To show the full statement $L^w = L \#_{\gamma} D_p$, we also argue via picture. Combining $D_p$ as illustrated on the bottom of Figure 8 with the 1-handle as illustrated on the right of Figure 12, we obtain Figure 14 as an illustration of $L \#_{\gamma} D_p$. To explain further: the very “first” (minimal $r$) cusp point in Figure 14 is the beginning of the linking disk, and slicing at a slightly larger value of $r$ produces the second front in Figure 13; the part above this slice (larger $r$) is the 1-handle. Now we apply a parameterized Legendrian Reidemeister I move to Figure 14 to obtain $L^w$. 

\[\square\]

4 Cobordism attachment and twisted complexes

The proof of Proposition 1.29 consists of two steps. First, we show in Lemma 4.1 the desired quasi-isomorphism at the level of Yoneda modules over any finite poset of Lagrangians
disjoint at infinity from the cobordism $C$. Then, we show, using the thinness hypothesis on $C$ and a direct limit argument, that testing against such finite posets is enough to ensure quasi-isomorphism in the wrapped Fukaya category.

**Lemma 4.1.** Let $(X, \mathfrak{f})$ be a stopped Liouville sector, and let $L_1, \ldots, L_n \subseteq X$ be disjoint exact Lagrangians (disjoint from $\mathfrak{f}$ at infinity) whose primitives vanish at infinity. Let $C \subseteq S\partial_{\infty} X$ be an exact Lagrangian cobordism (disjoint from $\mathbb{R} \times \mathfrak{f}$) with negative end $\partial_{\infty} L_1 \sqcup \cdots \sqcup \partial_{\infty} L_n$, such that the primitive $f_C : C \to \mathbb{R}$ of $\lambda|_C$ satisfies

$$f_C|_{\partial_{\infty} L_1} < \cdots < f_C|_{\partial_{\infty} L_n}, \quad (4.1)$$

regarding $\partial_{\infty} L_i$ as the negative ends of $C$.

Let $A$ be a finite poset of Lagrangians as in §2.3 which are disjoint from $C$ at infinity, and fix Floer data for $\{A > \} \ (i.e. \ the \ poset \ A \ union \ one \ additional \ object \ \ast \ \smaller \ \ things \ \ in \ A)$, thus defining an $A_{\infty}$-category $\mathcal{A}$ together with $A$-modules $CF^*(-, L_i)$, $\ldots$, $CF^*(-, \#_i^C L_i)$, and $CF^*(-, \#_i^C L_i)$ (regarding $\ast$ as any of $L_1$, $\ldots$, $L_n$, or $\#_i^C L_i$). For sufficiently large translates of $C$, there is an isomorphism of $A$-modules

$$CF^*(-, \#_i^C L_i) = [CF^*(-, L_1) \to \cdots \to CF^*(-, L_n)], \quad (4.2)$$

where the right hand side denotes a twisted complex $(\bigoplus_{i=1}^n CF^*(-, L_i), \sum_{i<j} D_{ij})$. Moreover, the continuation maps between $CF^*(-, \#_i^C L_i)$ induced by sufficiently small vertical translations of $C$ respect the filtration induced by (4.2) and act as the identity on the associated graded.

Before beginning the proof of Lemma 4.1, we clarify the meaning of $\#_i^C L_i$ and of translating $C$. Identify a neighborhood of infinity (i.e. the positive end) in the symplectization $S\partial_{\infty} X$ with its image inside $X$ under the canonical embedding. We translate the cobordism $C$ upwards towards infinity via the Liouville flow. For sufficiently large $t \in \mathbb{R}$, the locus where the translated-by-$t$ cobordism $C_t$ is cylindrical on its negative end will overlap with the region where the Lagrangians $L_i$ are cylindrical on their positive ends, and we may glue them using this common locus since by assumption $\partial_{-\infty} C = \partial_{\infty} L_1 \sqcup \cdots \sqcup \partial_{\infty} L_n$. We denote the result of this gluing by $L^t = \#_i^C L_i$ to emphasize the dependence on $t$, which will play a central role in what follows.

**Proof.** As $t \to \infty$, the Lagrangian $L^t$ coincides with $\bigsqcup_{i=1}^n L_i$ on larger and larger compact subsets of $X$. To compare primitives, fix primitives $f_i : L_i \to \mathbb{R}$ which vanish at infinity, and fix a primitive $f_C : C \to \mathbb{R}$. Let $c_i := f_C|_{\partial_{\infty} L_i} \in \mathbb{R}$, so we have $c_1 < \cdots < c_n$. As we translate $C$ by the Liouville flow, these constants $c_i$ scale exponentially, that is $f_{C_t}|_{\partial_{\infty} L_i} = e^t \cdot c_i$. Hence we may choose primitives $f_{L^t} : L^t \to \mathbb{R}$ such that

$$f_{L^t}|_{L_i} = f_i + e^t \cdot c_i, \quad (4.3)$$

where by assumption $c_1 < \cdots < c_n$.

We now consider the Floer theory of $L_1$, $\ldots$, $L_n$, and $L^t$ with our fixed collection of Lagrangians $A$. Because all $A \in A$ are disjoint at infinity from $C$, we have (for sufficiently large $t < \infty$) natural identifications

$$A \cap L^t = \bigsqcup_{i=1}^n A \cap L_i \quad (4.4)$$
and thus isomorphisms of abelian groups
\[
CF^\bullet(A, L^t) = CF^\bullet(A, L_1) \oplus \cdots \oplus CF^\bullet(A, L_n).
\] (4.5)

We now study how the $A_\infty$ operations interact with this direct sum decomposition. Consider a Fukaya $A_\infty$ disk giving the $A$-module structure of $CF^\bullet(-, L^t)$. Such a disk has one boundary component mapping to $L^t$ and the remaining boundary components mapping to Lagrangians from our fixed collection $A$. In view of (4.4), the endpoints of the segment labelled with $L^t$ are mapped to intersections with some $L_i$ for $i = 1, \ldots, n$. Let us label the possible cases $(i, j)$ for $1 \leq i, j \leq n$ as on the left side of Figure 16.

\[\begin{array}{c}
A & L_i & L^t & L_j & B \\
\end{array}\]

Figure 15: Possibilities for a Fukaya $A_\infty$ disk with boundary on $L^t$.

The energy of such disks can be calculated as a function of $t$ using (4.3). In the case $i < j$, we conclude that such disks cannot exist for $t$ sufficiently large, since their energy would be negative. In the case $i = j$, we conclude that the boundary component labelled with $L^t$ must be mapped entirely to $L_i = L_j$ for $t$ sufficiently large. Indeed, the energy of such disks is independent of $t$, and the proof of compactness of the moduli spaces of such disks [26, Proposition 3.19] based on monotonicity produces an a priori $C^0$-estimate depending only on the energy (and on the geometry of the almost complex structures). Note that how large $t$ must be for this argument to work depends in particular on the actions of the intersections of $L_i$ with the Lagrangians in $A$ and between the Lagrangians in $A$ in each other, and hence we are using finiteness of $A$ in a crucial way here. We draw no conclusions about the case $i > j$ (there can be many such disks). We summarize this discussion in Figure 15.

This identification of disks immediately gives the isomorphism of $A$-modules (4.2). The same argument applies to justify the statement about continuation maps. 

\[\begin{array}{c}
?\
i > j \\
\emptyset \\
i = j \\
i < j \\
\end{array}\]

\[\begin{array}{c}
A & L_i & L^t & L_j & B \\
\end{array}\]

Proof of Proposition 1.29. Let $\mathcal{O}$ be a poset of Lagrangians as in §2.3 for defining the wrapped Fukaya category, and fix Floer data for defining the $\mathcal{O}$-modules of $L$ and $L_i$. Since $C$ is thin, we may assume that all Lagrangians in $\mathcal{O}$ are disjoint from $C$ at infinity.

Fix a sequence $t_1 < t_2 < \cdots \rightarrow \infty$ and isotopies $L^{t_r} \leadsto L^{t_{r+1}}$, thus defining a diagram of $\mathcal{O}$-modules
\[
CF^\bullet(-, L^{t_1}) \xrightarrow{\psi_1} CF^\bullet(-, L^{t_2}) \xrightarrow{\psi_2} \cdots.
\] (4.6)

Let $\mathcal{O}_1 \subseteq \mathcal{O}_2 \subseteq \cdots \subseteq \mathcal{O}$ be finite downward closed subposets with $\bigcup_{r=1}^\infty \mathcal{O}_r = \mathcal{O}$ such that there are isomorphisms of $\mathcal{O}_r$-modules
\[
CF^\bullet(-, L^{t_r}) = [CF^\bullet(-, L_1) \rightarrow \cdots \rightarrow CF^\bullet(-, L_n)]
\] (4.7)
and moreover that the continuation maps $\psi_r$ restricted to $\mathcal{O}_r$ respect the induced filtrations and act as the identity on the associated graded. The existence of such a sequence $t_r$ and subposets $\mathcal{O}_r$ follows from Lemma 4.1.

The mapping telescope

$$\bigoplus_{r=1}^{\infty} CF^\bullet(-, L^t_r) \otimes_{\text{id}_r - \psi_r} \bigoplus_{r=1}^{\infty} CF^\bullet(-, L^t_r)$$

models the homotopy colimit of the sequence of $\mathcal{O}$-modules (4.6). Since the maps in (4.6) are all quasi-isomorphisms, the inclusion of the first term $CF^\bullet(-, L^t_1)$ into the mapping telescope is a quasi-isomorphism.

We modify the mapping telescope as follows. Write $j_r: \mathcal{O}_r \hookrightarrow$ and note that since $\mathcal{O}_r \subseteq \mathcal{O}$ is downward closed, the restriction functor $j_r^!$ on modules has a left adjoint $(j_r)_!$ namely “extension by zero”. We consider now another mapping telescope

$$\bigoplus_{r=1}^{\infty} (j_r)_!(j_r)^* CF^\bullet(-, L^t_r) \otimes_{\text{id}_r - \psi_r} \bigoplus_{r=1}^{\infty} (j_r)_!(j_r)^* CF^\bullet(-, L^t_r)$$

which includes tautologically into the original mapping telescope. Moreover, this inclusion is a quasi-isomorphism. Indeed, this can be checked for each object of $\mathcal{O}$ individually. Each such object is in $\mathcal{O}_r$ for all sufficiently large $r$, which is enough.

The above discussion thus implies that the Yoneda module $CF^\bullet(-, L^t_1)$ is quasi-isomorphic to the second mapping telescope (4.9) above. Now this second mapping telescope has, by construction, a filtration whose subquotients are

$$\bigoplus_{r=1}^{\infty} (j_r)_!(j_r)^* CF^\bullet(-, L^t_i) \otimes_{\text{id}_r - \text{id}_{r+1}} \bigoplus_{r=1}^{\infty} (j_r)_!(j_r)^* CF^\bullet(-, L^t_i)$$

for $i = 1, \ldots, n$. These subquotients are, by the same argument as above, quasi-isomorphic to the Yoneda modules $CF^\bullet(-, L_i)$.

We have thus produced a (zig-zag of) quasi-isomorphism of $\mathcal{O}$-modules

$$CF^\bullet(-, L) = [CF^\bullet(-, L_1) \to \cdots \to CF^\bullet(-, L_n)].$$

To conclude, we just need to localize. Localizing on the left by the continuation morphisms produces, in view of [26, Corollary 3.38], a quasi-isomorphism of $\mathcal{W}$-modules

$$CW^\bullet(-, L) = [CW^\bullet(-, L_1) \to \cdots \to CW^\bullet(-, L_n)].$$

In view of the Yoneda Lemma A.1 and Lemma A.2, this produces the desired quasi-isomorphism (1.31).

Proof of Proposition 1.30. The relatively non-exact embedded Lagrangian 1-handle is thin in the sense of Proposition 1.29 by Remark 3.6 and Lemma 2.2. Thus Proposition 1.29 produces an exact triangle

$$L \rightarrow K \rightarrow L\#_{\gamma}K \rightarrow [1],$$

46
and our task is to show that the map $L \to K$ can be taken to be (the morphism in the wrapped Fukaya category corresponding to) the short Reeb chord $\gamma$.

Morally speaking, the reason one expects this to be true is that in the limit as the 1-handle is pushed to infinity, the analysis of disks in Figure 15 should admit a strengthening illustrated in Figure 16 in that the count of disks in the remaining case $(K, L)$ should coincide with the count of disks with the segment labelled with $L \# \gamma K$ replaced by two segments labelled $K$ and $L$ separated by a puncture asymptotic at infinity to $\gamma$. This is, however, purely motivation.

Figure 16: Possibilities for a Fukaya $A_\infty$ disk with boundary on $L \# \gamma K$.

Introduce a stop at a small negative pushoff of the plumbing of $\partial_\infty L$ and $\partial_\infty K$ (compare Remark 3.6). Now consider testing the exact triangle (4.13) against $L^w$, a small positive pushoff of $L$ intersecting $K$ exactly once, corresponding to $\gamma$. We obtain a long exact sequence

$$HF^\bullet(L^w, L) \to HF^\bullet(L^w, K) \to HF^\bullet(L^w, L \# \gamma K) \xrightarrow{[1]}$$

(4.14)

(note that when any of $L$, $K$, or $L \# \gamma K$ is wrapped backwards, it immediately falls into the new stop, and hence $HW^\bullet$ is $HF^\bullet$). The connecting homomorphism $L \to K$ we are looking for is thus simply the image in $HF^\bullet(L^w, K)$ of the continuation element in $HF^\bullet(L^w, L)$. Now $HF^\bullet(L^w, K)$ is freely generated by a single intersection point corresponding to $\gamma$. This proves the desired result up to an unknown integer multiple.

To fix the unknown integer multiple, we test $L$, $K$, and $L \# \gamma K$ against a small Lagrangian disk $D$ linking both $L$ and $K$ near $\gamma$ (see Figure 17). Clearly $HF^\bullet(D, L) = HF^\bullet(D, K) = \mathbb{Z}$ as both Floer complexes are generated by a single intersection point. On the other hand, $HF^\bullet(D, L \# \gamma K) = 0$ since $\partial_\infty D$ is unlinked with $\partial_\infty (L \# \gamma K)$ and hence $D$ can be disjoined from $L \# \gamma K$ (keeping boundaries at infinity disjoint). By introducing an auxiliary stop at a small positive Reeb pushoff of $\partial_\infty D$, these three $HF^\bullet$ groups are in fact $HW^\bullet$ (because $\partial_\infty D$ falls immediately into the stop, and this wrapping is cofinal by Lemma 2.1). It follows that the connecting homomorphism in $HW^\bullet(L, K)$ indeed equals $\pm \gamma$ in the category with the auxiliary stop, and this implies the same in the category without the auxiliary stop simply by pushing forward.

□
Proof of Theorem 1.9. Propositions 1.30 and 1.31 combine to show that $D$ is quasi-isomorphic to the cone on some morphism $a: L^w \to L$, and our goal is to show that this morphism can be taken to be the continuation morphism $L^w \to L$. Introduce a stop at a small positive pushoff of $\partial_\infty L^w$, and consider testing the exact triangle (in the wrapped Fukaya category with this additional stop) against a smaller positive pushoff $L^{ww}$ of $L^w$. Since wrapping of $L^{ww}$ is completely stopped by the additional stop, this yields an exact triangle

$$HF^\bullet(L^{ww}, L^w) \xrightarrow{\partial} HF^\bullet(L^{ww}, L) \to HF^\bullet(L^{ww}, D_p) \xrightarrow{[1]}.$$  

(4.15)

Since $HF^\bullet(L^{ww}, D_p) = 0$ (they are disjoint), we conclude that multiplication by $a$ is an isomorphism. Now the groups $HF^\bullet(L^{ww}, L^w)$ and $HF^\bullet(L^{ww}, L)$ are canonically isomorphic, and we may simply write them as $HF^\bullet(L^+, L)$, the Floer cohomology of $L$ with an unspecified small positive pushoff thereof (see [26, §3.3]). This group $HF^\bullet(L^+, L)$ is an algebra with respect to Floer composition. Since multiplication by $a \in HF^\bullet(L^+, L)$ is an isomorphism on $HF^\bullet(L^+, L)$, we conclude that $a \in HF^\bullet(L^+, L)$ is a unit. Now the quasi-isomorphism type of the cone $[L^w \xrightarrow{a} L]$ is unchanged by multiplying $a$ by a unit in either $HW^\bullet(L^w, L^w)$ or $HW^\bullet(L, L)$. Thus if $a \in HF^\bullet(L^+, L)$ is a unit, we may replace $a$ with the identity $1_L \in HF^\bullet(L^+, L)$ which is by definition the continuation element of $HF^\bullet(L^w, L)$.

\qed

5 Stop removal

Proof of Theorem 1.16. The functor $W(X, \mathfrak{g}) \to W(X, \mathfrak{f})$ is essentially surjective by general position. Indeed, it is enough to prove that every Legendrian inside $\partial_\infty X$ disjoint from $\mathfrak{f}$ is isotopic to one disjoint from $\mathfrak{g}$, and this is a special case of the first part of Lemma 2.2 (note the differing notation).

At any point of $\mathfrak{g} \setminus \mathfrak{f}$, there is a small linking disk $D \in W(X, \mathfrak{g})$. We claim that such linking disks become zero objects in $W(X, \mathfrak{f})$. To see this, note that each such disk $D$ is contained in a small neighborhood of a point of $\partial_\infty X \setminus \mathfrak{f}$, and hence every Lagrangian $L$ has a cofinal sequence of wrappings which are disjoint from $D$. (Alternatively, one could argue that $D$ has a cofinal sequence of wrappings disjoint from any fixed $L$, or one could argue that $D$ is contained in a halfspace $\mathbb{C}_{Re \geq 0} \times \mathbb{C}^{n-1}$ and appeal to Corollary 7.2.)
Denoting by $D \subseteq \mathcal{W}(X, g)$ the full subcategory of such linking disks, the functor $\mathcal{W}(X, g) \to \mathcal{W}(X, f)$ thus induces a functor

$$\mathcal{W}(X, g)/D \to \mathcal{W}(X, f). \quad (5.1)$$

To show full faithfulness of (5.1), we begin with the observation that

$$\mathcal{W}(X, g)/\mathcal{C} \to \mathcal{W}(X, f) \quad (5.2)$$

is fully faithful, where $\mathcal{C}$ denotes the collection of cones of continuation morphisms $L \to L$ for all positive wrappings $L \to L$ disjoint from $f$, with $L$ and $L$ disjoint from $g$. The proof that (5.2) is fully faithful is essentially same as the proof that the localization construction in §2.3 yields wrapped Floer cohomology [26, Lemma 3.37]. Given any $L$ disjoint from $g$, choose a sequence of wrappings $L = L \to L \to \cdots$ in the complement of $f$. By general position we may assume that each $L$ is disjoint from $g$ (though of course the isotopies $L \to L$ will in general pass through $g \setminus f$). We have

$$\lim_{\to} HW^*(L^{(i)}, K)_{(X, g)} = HW^*(L, K)_{(X, f)}. \quad (5.3)$$

Since multiplication by a continuation element induces an isomorphism on wrapped Floer cohomology, we conclude that the pro-object $\cdots \to L \to L$ in $\mathcal{W}(X, g)$ is left $\mathcal{C}$-local in the sense of [26, Lemma 3.16]. We now consider

$$H^*(\mathcal{W}(X, g)/\mathcal{C})(L, K) \iso \lim_{\to} H^*(\mathcal{W}(X, g)/\mathcal{C})(L^{(i)}, K) \iso \lim_{\to} H^*\mathcal{W}(X, g)(L^{(i)}, K) \quad (5.4)$$

The first map is an isomorphism since each cone $L^{(i+1)} \to L^{(i)}$ is in $\mathcal{C}$ [26, Lemma 3.12], and the second map is an isomorphism since the pro-object $\cdots \to L^{(i)} \to L^{(0)}$ is left $\mathcal{C}$-local [26, Lemma 3.16]. Now the sequence (5.4) maps to the corresponding sequence with $\mathcal{W}(X, f)$. In this latter sequence the maps are also isomorphisms, and the rightmost vertical map is obviously an isomorphism. We conclude that (5.2) is fully faithful.

The above argument can be refined somewhat to reduce the number of cones $\mathcal{C}$ needing to be considered. When wrapping a given Lagrangian $L$ away from $f$, we can ensure by general position (Lemma 2.3) that $L$ remains disjoint from $g$ except for a discrete set of times when $\partial L$ passes through $(g \setminus f)^{\text{crit}}$ transversally at a single point. It is thus enough to take $\mathcal{C}$ to consist of cones of continuation morphisms $L \to L$ where $L$ is obtained from $L$ by a positive wrapping $L \to L$ which intersects $g \setminus f$ only by passing through transversely at a single point of $(g \setminus f)^{\text{crit}}$. Hence to show full faithfulness of (5.1), it is enough to apply the wrapping exact triangle Theorem 1.9 to conclude that each such cone $L \to L$ is quasi-isomorphic in $\mathcal{W}(X, g)$ to the linking disk $D$ at the point where the wrapping $L \to L$ passes through $(g \setminus f)^{\text{crit}}$.  

\section{K"unneth embedding}

\subsection{Products of Liouville sectors and stopped Liouville manifolds}

We begin with a general discussion of products of Liouville sectors and products of stopped Liouville manifolds. We then compare these two product operations, arguing that the prod-
uct of Liouville sectors is a special case of the product of stopped Liouville manifolds. Note that we do not discuss products of stopped Liouville sectors.

A product of Liouville sectors is again a Liouville sector [26, Lemma 2.21], modulo the following two technicalities. First, in order to guarantee that the Liouville vector field on the product is tangent to the boundary near infinity, we must assume that the Liouville vector fields on each of the factors are everywhere tangent to the boundary. This can always be achieved by a canonical deformation [26, Lemma 2.11 and Proposition 2.28]. Second, a product of Liouville sectors is an exact symplectic manifold-with-corners, cylindrical at infinity, and it is a Liouville sector in the generalized sense that there exists \( I : \text{Nbd} \partial X \to \mathbb{R} \) linear at infinity for which \( X_I \) is outward pointing with respect to every boundary face incident at any given point of the boundary. It follows that any sufficiently small smoothing of the corners produces a Liouville sector in the usual sense [26, Remark 2.12]. Note that the operation of product interacts well with deformations of Liouville sectors.

Given two stopped Liouville manifolds \((X,f)\) and \((Y,g)\), their product is defined to be

\[
(X,f) \times (Y,g) := (X \times Y, (f \times c_Y) \cup (f \times g \times \mathbb{R}) \cup (c_X \times g)).
\]

To interpret the stop on \(X \times Y\), recall that \(\partial_\infty (X \times Y)\) is covered by \(\partial_\infty X \times Y\) and \(X \times \partial_\infty Y\), which overlap over \(\partial_\infty X \times \partial_\infty Y \times \mathbb{R}\). Note that the product stop can change drastically as the Liouville forms on \(X\) and \(Y\) are deformed or as the stops \(f\) and \(g\) undergo ambient contact isotopy (or the sort of deformation appearing in Theorem 1.4 and Lemmas 2.7 and 2.8).

We now compare the product of Liouville sectors with the product of stopped Liouville manifolds. Let \(X\) and \(Y\) be Liouville sectors, and let \(\bar{X}\) and \(\bar{Y}\) denote their convex completions. We may, after possibly deforming \(X\) and \(Y\), assume that we have very precise coordinates on the ends of these convex completions, namely of the form

\[
F \times (T^*\mathbb{R}_{\geq 0}, Z_{T^*\mathbb{R}_{\geq 0}} + \pi^* \varphi(s_1) \partial_{s_1}) \to \bar{X} \quad X = \bar{X} \setminus (F \times T^*\mathbb{R}_{> 1}),
\]

\[
G \times (T^*\mathbb{R}_{\geq 0}, Z_{T^*\mathbb{R}_{\geq 0}} + \pi^* \varphi(s_2) \partial_{s_2}) \to \bar{Y} \quad Y = \bar{Y} \setminus (G \times T^*\mathbb{R}_{> 1}),
\]

where \(F\) and \(G\) are Liouville manifolds, \(\pi^*\) denotes the lift from vector fields on \(\mathbb{R}\) to Hamiltonian vector fields on \(T^*\mathbb{R}\), and \(\varphi : \mathbb{R} \to [0,1]\) is smooth and satisfies \(\varphi(s) = 0\) for \(s \leq 2\) and \(\varphi(s) = 1\) for \(s \geq 3\). The product \(\bar{X} \times \bar{Y}\) is thus equipped with a chart of the form

\[
F \times G \times (T^*\mathbb{R}_{\geq 0}^2, Z_{T^*\mathbb{R}_{\geq 0}^2} + \pi^* [\varphi(s_1) \partial_{s_1} + \varphi(s_2) \partial_{s_2}]) \to \bar{X} \times \bar{Y}.
\]

Now as illustrated in Figure 18, the vector field \(\varphi(s_1) \partial_{s_1} + \varphi(s_2) \partial_{s_2}\) may be deformed over a compact subset of the interior of \(\mathbb{R}_{\geq 0}^2\) to a vector field of the form \(\varphi(s) \partial_s\) for some coordinates \((s,\theta)\) on \(\mathbb{R}_{\geq 0}^2 \setminus \{(0,0)\}\). The locus \(s \leq 1\) in this deformation is thus a smoothing \((X \times Y)^{\text{sm}}\) of the corners of \(X \times Y\), and its complement can be described as

\[
\left[ F \times Y \cup_{F \times G \times [0,1]} X \times G \right] \times (T^*\mathbb{R}_{\geq 0}^2, Z_{T^*\mathbb{R}_{\geq 0}^2} + \pi^* \varphi(s) \partial_s).
\]

We will denote this deformation of \(\bar{X} \times \bar{Y}\) by \((X \times Y)^{\text{sm}}\), since the above discussion shows it is the convex completion of \((X \times Y)^{\text{sm}}\) (we have thus shown that convex completion commutes with product of Liouville sectors, up to canonical deformation).

50
We now interpret the above picture in terms of stopped Liouville manifolds. The core of $F$ is a stop $f \subseteq F = F \times \{\infty\} \subseteq \partial_{\infty}(F \times (T^\ast\mathbb{R}_{\geq 0}, Z_{T^\ast\mathbb{R}_{\geq 0}} + \pi^\ast\varphi(s)\partial_s)) \subseteq \partial_{\infty}\bar{X}$; similarly, there is a stop $g \subseteq \partial_{\infty}\bar{Y}$. Observe that the analogously defined stop $h \subseteq \partial_{\infty}(X \times Y)^{sm}$ (namely the core of the first factor in (6.5)) is precisely the product stop appearing in (6.1). More precisely, the product stop lives in $\partial_{\infty}(\bar{X} \times \bar{Y})$, and the deformation from $\bar{X} \times \bar{Y}$ to $(X \times Y)^{sm}$ sends it to $h$. Since this deformation is supported away from these stops, it indeed makes sense to compare them.

Now Corollary 2.11 gives quasi-equivalences
\begin{align}
\mathcal{W}(X) & \sim \mathcal{W}(\bar{X}, f), \quad (6.6) \\
\mathcal{W}(Y) & \sim \mathcal{W}(\bar{Y}, g), \quad (6.7) \\
\mathcal{W}((X \times Y)^{sm}) & \sim \mathcal{W}((X \times Y)^{sm}, h). \quad (6.8)
\end{align}

By the deformation discussed above, this last functor is the same as
\begin{align}
\mathcal{W}((X \times Y)^{sm}) & \sim \mathcal{W}(X \times Y, h) = \mathcal{W}((X, f) \times (Y, g)) \quad (6.9)
\end{align}
and so this functor is also a quasi-equivalence. In particular, it follows that to construct the Künneth functor $\mathcal{W}(X) \otimes \mathcal{W}(Y) \to \mathcal{W}((X \times Y)^{sm})$ for Liouville sectors, it suffices to construct the Künneth functor $\mathcal{W}(X, f) \otimes \mathcal{W}(Y, g) \to \mathcal{W}((X, f) \times (Y, g))$ for stopped Liouville manifolds.

### 6.2 Making product Lagrangians cylindrical

A well known complication in proving Künneth formulae for wrapped Fukaya categories is that the property of being cylindrical at infinity is not preserved under products: if $L \subseteq X$ and $K \subseteq Y$ are cylindrical at infinity, the product Lagrangian $L \times K \subseteq X \times Y$ inside the product Liouville manifold $(X \times Y, \lambda_X + \lambda_Y)$ need not be, and typically is not.
The goal of this subsection is to describe a deformation of the product \( L \times K \subseteq X \times Y \) (called the cylindrization of \( L \times K \)) which is cylindrical at infinity, for any pair \( L \) and \( K \) satisfying the (mild) assumption that both primitives \( f_L \) and \( f_K \) (of \( \lambda_X|_L \) and \( \lambda_Y|_K \), respectively) are compactly supported. That this assumption does not result in any loss of generality is guaranteed by:

**Lemma 6.1.** For any exact cylindrical Lagrangian \( L \subseteq X \), there exists a compactly supported exact Lagrangian isotopy \( L \sim L' \) such that \( \lambda_X|_{L'} \) has a compactly supported primitive \( f_{L'} \).

**Proof.** Fix a primitive \( f_L \) of \( \lambda_X|_L \). Let \( H : X \to \mathbb{R} \) be a compactly supported Hamiltonian which equals 1 over a large compact subset of \( X \). For any \( a \in \mathbb{R} \) with \(|a| \) sufficiently small, applying the (forwards or backwards) Hamiltonian flow of \( H \) to \( L \) for small time defines a compactly supported isotopy \( L \sim L' \) and a primitive \( f_{L'} = f_L + a \) near infinity. By conjugating such an isotopy by the Liouville flow (pushing it towards infinity), we may in fact achieve \( f_{L'} = f_L + a \) for arbitrary \( a \in \mathbb{R} \). Finally, perform such an isotopy separately in each of the non-compact ends of \( L \).

Let \( L \subseteq X \) and \( K \subseteq Y \) be two exact cylindrical Lagrangians inside Liouville sectors \((X, \lambda_X)\) and \((Y, \lambda_Y)\) (whose Liouville vector fields are tangent to their respective boundaries). Since \( L \) and \( K \) are exact, there exist primitives \( f_L : L \to \mathbb{R} \) and \( f_K : K \to \mathbb{R} \) satisfying \( df_L = \lambda_X|_L \) and \( df_K = \lambda_Y|_K \). We say \( L \) (resp. \( K \)) is strongly exact iff \( \lambda_X|_L \equiv 0 \) (resp. \( \lambda_Y|_K \equiv 0 \)), equivalently, iff \( Z_X \) (resp. \( Z_Y \)) is everywhere tangent to \( L \) (resp. \( K \)). If both \( L \) and \( K \) are strongly exact, then the product Lagrangian \( L \times K \subseteq X \times Y \) inside the product Liouville manifold \((X \times Y, \lambda_X + \lambda_Y)\) is also strongly exact, hence, in particular, cylindrical at infinity.

We now define the cylindrization \( \tilde{L} \times \tilde{K} \subseteq X \times Y \), assuming only that \( f_L \) and \( f_K \) are both compactly supported. Fix extensions \( \tilde{f}_L : X \to \mathbb{R} \) and \( \tilde{f}_K : Y \to \mathbb{R} \) which vanish near the boundary and are supported inside subdomains \( X_0 \subseteq X \) and \( Y_0 \subseteq Y \) (respectively) whose completions are \( X \) and \( Y \). We now consider the Liouville form

\[
\lambda_X + \lambda_Y - d(f_L \phi_K) - d(\phi_L f_K), \tag{6.10}
\]

where \( \phi_L : X \to [0, 1] \) and \( \phi_K : Y \to [0, 1] \) are smooth functions which vanish over \( X_0 \) and \( Y_0 \) (and near \( \partial X \) and \( \partial Y \)), are \( Z \)-invariant near infinity, and equal 1 over a neighborhood of \( \partial \infty L \) and \( \partial \infty K \), respectively. Note that the restriction of \((6.10)\) to \( L \times K \) is compactly supported, and hence the associated Liouville vector field is tangent to \( L \times K \) outside a compact set.

We now claim that for suitable choices of \( \phi_L \) and \( \phi_K \), this deformed Liouville form \((6.10)\) remains convex outside \( X_0 \times Y_0 \). More precisely, the associated Liouville vector field is outward pointing along \( \partial(X_0 \times Y_0) \) and exhibits its exterior as the positive half of a symplectization. To see this, we may calculate the Liouville vector field corresponding to \((6.10)\) to be

\[
[Z_X + \phi_K X_{f_L} + X_{\phi_L f_K}] + [Z_Y + \phi_L X_{f_K} + X_{\phi_K f_L}]. \tag{6.11}
\]

Consider now the positive flow of this vector field starting at a point of \((X \setminus X_0) \times Y \), so the \( X \)-component of the vector field is given by \( Z_X + X_{\phi_L f_K} \) (note that \( \phi_K X_{f_L} \) vanishes over this locus since \( f_L \) is supported inside \( X_0 \)). Now we note that \( X_{(e^{Nz_X}) \phi_L} = e^{-N}(e^{NZ_X})_* X_{\phi_L} \), so

\(52\)
replacing $\phi_L$ with $(\epsilon^{NZ_X})_*\phi_L$ and taking $N \to \infty$, the term $X_{\phi_L}^*f_K$ becomes negligible. Thus for $N < \infty$ sufficiently large, starting at any point outside $X_0 \times Y$, this flow is complete and escapes to infinity. A symmetric argument implies applies to the case where one starts at a point outside $X \times Y_0$ (after replacing $\phi_K$ with $(\epsilon^{NZ_Y})_*\phi_K$ for $N$ sufficiently large). Hence, implicitly fixing such a sufficiently large $N$ and replacing $\phi_L$ and $\phi_K$ as above, we see that outside $X_0 \times Y_0$ the flow is complete and escapes to infinity. Moreover, the same holds at every point of the linear interpolation between the product Liouville vector field $Z_X + Z_Y$ and (6.11).

Since the linear deformation of Liouville forms between $\lambda_X + \lambda_Y$ and (6.10) (where we have replaced $\phi_L$ and $\phi_K$ with their pushforwards under $\epsilon^{NZ_X}$ and $\epsilon^{NZ_Y}$ for a fixed large $N$) maintains convexity outside $X_0 \times Y_0 \subseteq X \times Y$, it is necessarily induced by a Hamiltonian symplectomorphism $\Phi : X \times Y \to X \times Y$, fixed over $X_0 \times Y_0$, so that $\Phi^*(\lambda_X + \lambda_Y) = (6.10)$. Concretely, $\Phi$ is characterized uniquely by the properties that $\Phi = \text{id}$ over $X_0 \times Y_0$ and $\Phi_*(6.11) = Z_X + Z_Y$. Since $L \times K$ is cylindrical at infinity with respect to (6.10), it follows that its image
\[ L \times K := \Phi(L \times K) \subseteq (X \times Y, \lambda_X + \lambda_Y) \tag{6.12} \]
is cylindrical at infinity. Note that by taking $\phi_L$ and $\phi_K$ to be supported in small neighborhoods of $\partial_\infty L$ and $\partial_\infty K$ (in particular, vanishing over large compact subsets of $X$ and $Y$), we can ensure that $\Phi$ is supported in an arbitrarily small neighborhood of $((L \cap X_0) \times \partial_\infty K) \cup (\partial_\infty L \times (K \cap Y_0))$ (in particular, $\Phi = \text{id}$ and $L \times K = L \times K$ over arbitrarily large compact subsets of $X \times Y$). Note also that the choices going into the definition of the cylindrization $L \times K$ form a contractible space. Although we will suppress the dependence of $L \times K$ on all of these choices, it will be important to study the dependence of this construction on $N$ (which measures the proximity to infinity of the cylindrization) in order to control holomorphic disks and positivity of wrappings.

### 6.3 Wrapping product Lagrangians

We will need to know that formation of the cylindrized product $L \times K$ respects positivity of isotopies near infinity. More precisely, given two Lagrangian isotopies $\{L_t\}_{t \in [0,1]}$ and $\{K_t\}_{t \in [0,1]}$ which are positive near infinity (meaning $\partial_t \partial_\infty L_t$ and $\partial_t \partial_\infty K_t$ are positively transverse to the respective contact distributions), we would like to know that the isotopy $\{L_t \times K_t\}_{t \in [0,1]}$ is positive near infinity (at least for controlled choice of cylindrization $L_t \times K_t$ of the product $L_t \times K_t$).

Fix functions $f^L_t : X \to \mathbb{R}$ and $f^K_t : Y \to \mathbb{R}$ satisfying $df_t^L|_{L_t} = \lambda_X|_{L_t}$ and $df_t^K|_{K_t} = \lambda_Y|_{K_t},$ supported inside $X_0$ and $Y_0$ (and away from $\partial X$ and $\partial Y$), respectively. Also fix $\tilde{\phi}_L^t : X \to \mathbb{R}$ and $\tilde{\phi}_K^t : Y \to \mathbb{R}$ as before. We define the cylindrized isotopy $L_t \times K_t$ as before, using the Liouville form (6.10) with $\phi_L$ and $\phi_K$ replaced with their pushforwards under $\epsilon^{NZ_X}$ and $\epsilon^{NZ_Y}$; we emphasize that this cylindrized isotopy depends on a choice of sufficiently large $N$.

**Lemma 6.2.** If $\{L_t\}_{t \in [0,1]}$ and $\{K_t\}_{t \in [0,1]}$ are each positive isotopies, then for $N < \infty$ sufficiently large (depending on the entire isotopy $\{L_t \times K_t\}_{t \in [0,1]}$), the cylindrized isotopy $L_t \times K_t := \Phi_t(L_t \times K_t)$ is positive at infinity.

**Proof.** By symmetry, it suffices to make a calculation in the chart $X \times (Y \setminus Y_0)$, in which the product Liouville form is given by $\lambda_X + \lambda_Y$ and the deformed Liouville form is given by
\[ \lambda_X + \lambda_Y - d(f_t^L(e^{NZY})_*, \phi_{K}^t). \] The corresponding Liouville vector fields are given, respectively, by

\begin{align}
Z_X + Z_Y, \\
Z_X + Z_Y + X_{f_t^L(e^{NZY})_*, \phi_{K}^t} + e^{-N} f_t^L(e^{NZY})_* X_{\phi_{K}^t}.
\end{align}

(6.13)  \hspace{2cm} (6.14)

To understand what happens in the limit \( N \to \infty \), we pull back under \( e^{NZY} \), to obtain, respectively,

\begin{align}
Z_X + Z_Y, \\
Z_X + Z_Y + X_{f_t^L(\phi_{K}^t)} + e^{-N} f_t^L X_{\phi_{K}^t}.
\end{align}

(6.15)  \hspace{2cm} (6.16)

In these coordinates, the term with the factor \( e^{-N} \) evidently becomes negligible as \( N \to \infty \), and hence the defining relations \( \Phi_t = \text{id} \) over a large compact subset and \( (\Phi_t)_*(6.16) = (6.15) \) show that as \( N \to \infty \), the limit of \( \Phi_t \) exists (converging smoothly) and is the identity on the \( Y \)-coordinate. The limit of \( (e^{-NZY})_*(L_t \times K_t) \) therefore also exists. The pulled back Liouville form \( \lambda_X + e^N \lambda_Y \) converges (after rescaling by \( e^{-N} \)) in the limit to \( \lambda_Y \). We thus conclude that evaluating this limiting form on the limiting deformed isotopy \( (e^{-NZY})_*(L_t \times K_t) \) only sees the \( \partial_{\infty} K_t \) factor (since the limiting \( \Phi_t \) is the identity on the \( Y \)-coordinate), which by assumption moves positively. We conclude that for sufficiently large \( N < \infty \), the isotopy \( L_t \times K_t \) is positive at infinity.

\[ \square \]

Note that the size of \( N < \infty \) needed to ensure positivity of the cylindrized isotopy \( L_t \times K_t \) depends on the entire isotopies \( \{L_t\}_{t \in [0,1]} \) and \( \{K_t\}_{t \in [0,1]} \), and in particular cannot be made to coincide with a given previously chosen \( N \) for \( L_0 \times K_0 \) or \( L_1 \times K_1 \). This means that arguments involving cylindred product isotopies require some care (though no serious issues will arise). It also means that the above is not sufficient for ensuring positivity of cylindred product isotopies over noncompact parameter spaces (as are needed, for example, to describe cofinal wrappings); this will be resolved in §6.5 by taking \( N \) to be a function of \( t \) and refining the above analysis.

### 6.4 Cohomological Küneth functor

In fact, due to the fact that passing from a chain complex to its cohomology does not commute with tensor product, it is convenient to define not just a cohomological Küneth functor but rather a homotopical Küneth functor (which, in particular, induces the former). That is, instead of passing from Floer cochains \( CF^\bullet \in \text{Ch} \) all the way to Floer cohomology \( HF^\bullet \), we pass only to the homotopy category \( H^0 \text{Ch} \) (which solves the aforementioned issue as \( \text{Ch} \to H^0 \text{Ch} \) does commute with tensor product).

To justify writing \( CF^\bullet(L, K) \in H^0 \text{Ch} \), note that the usual proof of invariance of Floer cohomology by constructing continuation maps does in fact show that \( CF^\bullet(L, K) \in H^0 \text{Ch} \) is a well-defined object in the homotopy category (independent of choice of Floer data up to canonical isomorphism). Similarly, the multiplication operation \( \mu^2 \) defines a well-defined associative map \( CF^\bullet(L_0, L_1) \otimes CF^\bullet(L_1, L_2) \to CF^\bullet(L_0, L_2) \) in the homotopy category (note that, in the discussion of \( CF^\bullet \in H^0 \text{Ch} \), the higher \( A_\infty \) operations \( \mu^k \) for \( k \geq 3 \) do not make
an appearance beyond using $\mu^3$ to show associativity of $\mu^2$). We may also define wrapped Floer cochains in the homotopy category by the usual direct limit

$$CW^\bullet(L, K) := \lim_{(L \sim L^w)^+} CF^\bullet(L^w, K)$$

(6.17)

now taking place inside $H^0 Ch$ (compare [26, §3.4]). Note that multiplication with the continuation element $c \in HF^\bullet(L^w, L^w)$ is indeed a well-defined map $CF^\bullet(L^w, K) \to CF^\bullet(L^w, K)$ in the homotopy category.

Now let $X$ and $Y$ be Liouville sectors, and let us begin the construction of the “homotopical Künneth functor”. To a pair of exact cylindrical Lagrangians $L \subseteq X$ and $K \subseteq Y$, we associate the deformed product $L \times K \subseteq X \times Y$, which is well-defined up to contractible choice of exact cylindrical Lagrangian isotopy (parametrized by the choices of $\phi_L$, $\phi_K$, and $N$). It follows that Floer cochains between objects such as $L \times K$ is well-defined. To be precise, if the pairs $L_1, L_2 \subseteq X$ and $K_1, K_2 \subseteq Y$ are disjoint at infinity, then so is the pair $(L_1 \times K_1, L_2 \times K_2)$ for sufficiently small choices of cylindrical perturbation, and it follows from this and the contractibility of the space of choices involved, that $CF^\bullet(L_1 \times K_1, L_2 \times K_2)$ is a well-defined object of the homotopy category.

**Lemma 6.3.** There is a canonical isomorphism in the homotopy category

$$CF^\bullet(L_1, L_2) \otimes CF^\bullet(K_1, K_2) = CF^\bullet(L_1 \times K_1, L_2 \times K_2),$$

(6.18)

which is compatible with the isomorphisms [26, Lemma 3.21] induced by deforming the pairs $(L_1, L_2)$ and $(K_1, K_2)$ through pairs which are disjoint at infinity. This isomorphism is also compatible with product, namely the following diagram (in the homotopy category) commutes:

$$CF^\bullet(L_1, L_2) \otimes CF^\bullet(K_1, K_2) \otimes CF^\bullet(L_2, L_3) \otimes CF^\bullet(K_2, K_3) \to CF^\bullet(L_1, L_3) \otimes CF^\bullet(K_1, K_3)$$

$$CF^\bullet(L_1 \times K_1, L_2 \times K_2) \otimes CF^\bullet(L_2 \times K_2, L_3 \times K_3) \to CF^\bullet(L_1 \times K_1, L_3 \times K_3).$$

*Proof.* To establish (6.18), fix almost complex structures $J_X : [0, 1] = \overline{S}_{1,1} \to J(X)$ and $J_Y : [0, 1] = \overline{S}_{1,1} \to J(Y)$ used to define the left hand side. As is well understood, there is a tautological isomorphism of complexes

$$CF^\bullet(L_1, L_2; J_X) \otimes CF^\bullet(K_1, K_2; J_Y) = CF^\bullet(L_1 \times K_1, L_2 \times K_2; J_X \times J_Y).$$

(6.20)

Namely, the intersection points generating both sides are obviously in bijection with each other. To compare the differentials, note that a holomorphic map into the product is simply a pair of holomorphic maps into both factors. Transversality on each of the factors (including for the constant strips at intersection points $L_1 \cap L_2$ and $K_1 \cap K_2$) implies transversality in the product, so we obtain the isomorphism (6.20).

It remains to show that the complex on the right hand side of (6.20) calculates $HF^\bullet(L_1 \times K_1, L_2 \times K_2)$. There are two issues: deforming $L_i \times K_i$ into $L_i \times K_i$ and deforming $J_X \times J_Y$ to become cylindrical at infinity. We argue that as long as both of these modifications are made sufficiently far out near infinity (the former of which can be ensured by using sufficiently large
$N$), the holomorphic curves contributing to the differential remain inside a fixed compact subset of $X \times Y$ disjoint from the neighborhood of infinity where the modifications took place. To see this, we follow the proof of [26, Proposition 3.19]. This proof produces an $R < \infty$ and a compact subset $C$ of $X \times Y$ such that for any holomorphic map $u : \mathbb{R} \times [0, 1] \to X \times Y$ contributing to the differential of either complex and any interval $I \subseteq \mathbb{R}$ of length $\geq R$, there exists a point in $I \times [0, 1]$ which is mapped by $u$ to the union of $C$ with the small neighborhood of infinity where we (possibly) modify $L_i \times K_i$ and $J_X \times J_Y$ (the point is that over the complement of this union, there is a lower bound on the distance between the two Lagrangians boundary conditions with respect to the metric induced by the almost complex structures). Now the bounded geometry and monotonicity arguments from [26, Proposition 3.19] show that, as long as the modification region is far enough out near infinity, such a holomorphic curve does not have enough energy to travel between this modification locus and the compact set $C$. Since all the intersections between $L_1 \times K_1$ and $L_2 \times K_2$ lie inside $C$, we conclude that in fact for every interval $I \subseteq \mathbb{R}$ of length $\geq R$, there exists a point in $I \times [0, 1]$ which is mapped by $u$ to $C$. The monotonicity and bounded geometry arguments now bound the entire image of $u$ inside a fixed larger compact set $C'$ (as long as the modification region is far enough out near infinity). This defines a homotopy equivalence (6.18). To show that the homotopy equivalence (6.18) is independent of the choices made in the above definition, simply execute the same argument above with families of almost complex structures $\mathbb{R} \times [0, 1] \to J(X)$ and $\mathbb{R} \times [0, 1] \to J(Y)$.

One similarly checks that (6.18) is compatible with the isomorphisms [26, Lemma 3.21] induced by deforming the pairs $(L_1, L_2)$ and $(K_1, K_2)$ through pairs which are disjoint at infinity.

Finally, we claim that (6.18) is compatible with product, namely that (6.19) commutes. The argument is the same. Namely, first choose Floer data for the $A_\infty$ operations (that is, the differentials and the product) for the ordered tuples of Lagrangians $(L_1, L_2, L_3)$ and $(K_1, K_2, K_3)$, and use the product Floer data on $X \times Y$, arguing that disks contributing to $\mu^2$ in the product are products of disks in each factor (and thus are transverse). Then perturb at infinity to make things cylindrical, and argue that the disks remain the same as long as the perturbation happens sufficiently far out near infinity.

We now argue that the homotopy equivalence (6.18) respects continuation elements. To begin, let us define precisely what we mean by continuation elements on the right hand side of (6.18). Given two positive isotopies $L \rightsquigarrow L^w$ and $K \rightsquigarrow K^w$, the resulting isotopy $L \times K \rightsquigarrow L^w \times K^w$ is, for suitable choice of cylindrization data, also positive by Lemma 6.2. Since the space of such data is contractible, we conclude that the continuation element associated to the cylindrized product isotopy is a well-defined element in the homology $HF^\bullet(L^w \times K^w, L \times K)$.

Having defined what we mean by continuation elements on the right hand side of (6.18), we now begin the comparison of continuation elements by considering the case of small positive pushoffs. Recall that if $L^+$ denotes an (unspecified) small positive pushoff of $L$, the homology group $HF^\bullet(L^+, L)$ has an algebra structure, and moreover this algebra structure has a unit [26, Proposition 3.23]. Now using the fact that cylindrized products of positive isotopies are again positive (proved in §6.3), we conclude that $(L \times K)^+ = (L^+ \times K^+)$, and
so (6.18) gives a homotopy equivalence
\[
CF^*(L^+, L) \otimes CF^*(K^+, K) = CF^*((L \times K)^+, L \times K).
\]  
(6.21)

Since (6.18) is compatible with the isomorphisms of [26, Lemma 3.21], it follows that this is in fact an equivalence of algebras (i.e. algebra objects in the homotopy category of complexes).

The unit \(1_L \in HF^*(L^+, L)\) is defined by the property that multiplication with it induces the identity map on \(HF^*(L^+, L)\), and this in fact automatically implies that multiplication with it is the identity map on \(CF^*(L^+, L)\) up to homotopy. Indeed, since \(1_L \cdot 1_L = 1_L\), multiplication by the unit is idempotent as an endomorphism of \(CF^*(L^+, L)\) up to homotopy, and multiplication by the unit is also a homotopy equivalence by cofibrancy [26, Lemma 3.6]. Together, these imply that multiplication by \(1_L\) is homotopic to the identity map on \(CF^*(L^+, L)\). It now follows that under the algebra isomorphism (6.21), multiplication with the cycle \(1_L \otimes 1_K\) acts as the identity on the right (up to homotopy). It follows that the map of algebras \(HF^*(L^+, L) \otimes HF^*(K^+, K) \to HF^*((L \times K)^+, L \times K)\) (which may not be an isomorphism over the integers due to torsion issues) sends the unit to the unit. It now follows directly from the definition of continuation elements in terms of these units [26, Definition 3.25] that (6.18) also respects continuation elements, namely that for any pair of positive isotopies \(L \rightsquigarrow L^w\) and \(K \rightsquigarrow K^w\), the map
\[
HF^*(L^w, L) \otimes HF^*(K^w, K) \to HF^*(L^w \times K^w, L \times K)
\]  
(6.22)
sends the product of continuation elements to the continuation element.

Having shown that the homotopical Künneth isomorphism (6.18) respects continuation elements, let us now derive from this a canonical map on wrapped Floer cochains
\[
CW^*(L_1, L_2) \otimes CW^*(K_1, K_2) \to CW^*(L_1 \times K_1, L_2 \times K_2)
\]  
(6.23)
in the homotopy category. Note that the right hand side above is indeed a well-defined object of \(H^0 Ch\), for the same reason we used above to argue that \(CF^*(L_1 \times K_1, L_2 \times K_2)\) was well-defined, together with the fact that isotopies of exact Lagrangians induce equivalences on wrapping categories and thus also on \(CW^*\).

**Remark 6.4.** The map (6.23) should be thought of as being defined via a “cylindrized product” functor on wrapping categories \((L_1 \rightsquigarrow -)^+_{X} \times (K_1 \rightsquigarrow -)^+_{Y} \to (L_1 \times K_1 \rightsquigarrow -)^+_{X \times Y}\) covered by a map on directed systems induced by Lemma 6.3 and the compatibility of continuation elements. We do not quite define such a functor between wrapping categories, however, due to the ambiguity in choosing cylindrization data. (Note, in particular, that \(L \times K\) need not move via positive/negative isotopies as the cylindrization data is varied.)

To define the map (6.23), we should define a map
\[
CF^*(L_1^w, L_2) \otimes CF^*(K_1^w, K_2) \to CW^*(L_1 \times K_1, L_2 \times K_2)
\]  
(6.24)
for every pair \((L_1 \rightsquigarrow L_1^w)^+\) and \((K_1 \rightsquigarrow K_1^w)^+\) in the wrapping categories of \(L_1\) and \(K_1\), and we should verify that these maps are compatible with the maps in the directed systems defining \(CW^*(L_1, L_2)\) and \(CW^*(K_1, K_2)\).
The isotopies $L_1 \rightsquigarrow L^w_1$ and $K_1 \rightsquigarrow K^w_1$ induce an isotopy $L_1 \times K_1 \rightsquigarrow L^w_1 \times K^w_1$ (up to contractible choice of cylindrization data). Lemma 6.3 defines a map

$$CF^\bullet(L^w_1, L_2) \otimes CF^\bullet(K^w_1, K_2) \to CF^\bullet(L^w_1 \times K^w_1, L_2 \times K_2).$$

A choice of cylindrization data for the isotopies $L_1 \rightsquigarrow L^w_1$ and $K_1 \rightsquigarrow K^w_1$ induces a map

$$CF^\bullet(L^w_1 \times K^w_1, L_2 \times K_2) \to CW^\bullet(L_1 \times K_1, L_2 \times K_2),$$

and using the last property from [26, Lemma 3.26] (at the homotopy level), it follows that this map is independent of the choice of cylindrization data. Composing (6.25) and (6.26) defines our map (6.24).

Now suppose we have a pair of positive isotopies $L^w_1 \rightsquigarrow L^{w'}_1$ and $K^w_1 \rightsquigarrow K^{w'}_1$. By Lemmas 6.2, 6.3, and the discussion above about compatibility of continuation elements, we can choose cylindrization data to show that the induced diagram

$$CF^\bullet(L^w_1, L_2) \otimes CF^\bullet(K^w_1, K_2) \xrightarrow{(6.25)} CF^\bullet(L^w_1 \times K^w_1, L_2 \times K_2)$$

commutes. The maps (6.26) from the complexes on the right to $CW^\bullet(L_1 \times K_1, L_2 \times K_2)$ tautologically commute with the right vertical continuation map, and hence with the entire diagram. The compositions of the horizontal arrows with these maps to $CW^\bullet(L_1 \times K_1, L_2 \times K_2)$ are, by definition, the specified maps (6.24). It follows that (6.24) is compatible with the continuation maps associated to $L^w_1 \rightsquigarrow L^{w'}_1$ and $K^w_1 \rightsquigarrow K^{w'}_1$ as desired, thus completing the definition of (6.23).

The discussion above applies more generally to any configuration of stops on $X$ and $Y$. Namely, we obtain a morphism

$$CW^\bullet(L_1, L_2)_{f} \otimes CW^\bullet(K_1, K_2)_{g} \to CW^\bullet(L_1 \times K_1, L_2 \times K_2)_{h}.$$  

if $f \subseteq \partial_{\infty}X$, $g \subseteq \partial_{\infty}Y$, and $h \subseteq \partial_{\infty}(X \times Y)$ are closed and $h$ is contained inside $(f \times Y) \cup (X \times g)$ (note that this is not a closed subset of $\partial_{\infty}(X \times Y)$). We have thus defined the cohomological Künneth functor

$$H^\bullet W(X, f) \otimes H^\bullet W(Y, g) \to H^\bullet W(X \times Y, h).$$

In fact, we have done slightly better, in that ours is a functor between categories enriched over the homotopy category of chain complexes (rather than simply their homology groups).

### 6.5 Cofinality of product wrappings

We now study when the Künneth maps on wrapped Floer cohomology (6.23) and (6.28) are quasi-isomorphisms. More precisely, we study when product wrappings are cofinal (which obviously implies that (6.23) and (6.28) are quasi-isomorphisms). To do this, the cofinality criterion Lemma 2.1 will be essential.
We argue that (6.23) is a quasi-isomorphism for $X$ and $Y$ Liouville manifolds. It is enough to show that for cofinal wrappings $\{L^t\}_{t \geq 0}$ and $\{K^t\}_{t \geq 0}$ of $L^0$ and $K^0$, the product $\{L^t \times K^t\}_{t \geq 0}$ is a cofinal wrapping of $L \times K$ (in fact, it is enough to exhibit a single pair of cofinal wrappings $\{L^t\}_{t \geq 0}$ and $\{K^t\}_{t \geq 0}$ for which this is true). Fix contact forms $\beta_X$ and $\beta_Y$ on $\partial_{\infty} X$ and $\partial_{\infty} Y$, respectively, and choose wrappings $\{L^t\}_{t \geq 0}$ and $\{K^t\}_{t \geq 0}$ which simply follow the Reeb vector fields $\mathbf{R}_{\beta_X}$ and $\mathbf{R}_{\beta_Y}$ at infinity. We will show that the product wrapping $\{L^t \times K^t\}_{t \geq 0}$ satisfies the cofinality criterion (Lemma 2.1) with respect to the “product contact form”

$$\beta_{X \times Y} := \min(\beta_X + \lambda_Y, \lambda_X + \beta_Y).$$  \hfill (6.30)

(Recall that $\partial_{\infty}(X \times Y)$ is covered by two charts $\partial_{\infty}X \times Y$ and $X \times \partial_{\infty}Y$, and interpret $\beta_X + \lambda_Y$ and $\lambda_X + \beta_Y$ as contact forms on each of these charts, respectively; concretely $\beta_{X \times Y}$ is the contact form on $\partial_{\infty}(X \times Y)$ which corresponds to the Liouville subdomain $X_0 \times Y_0 \subseteq X \times Y$, where $X_0 \subseteq X$ and $Y_0 \subseteq Y$ are the Liouville subdomains corresponding to $\beta_X$ and $\beta_Y$, respectively.)

We saw in §6.3 that the wrapping $\{L^t \times K^t\}_{t \geq 0}$ is at least positive. For our present purpose of finding a lower bound on $\beta_{X \times Y}(\partial_t \partial_{\infty}(L^t \times K^t))$, we just need a quantitative refinement of the same argument. Over the unperturbed locus $\partial_{\infty} L_t \times \partial_{\infty} K_t \times \mathbb{R} \subseteq \partial_{\infty}X \times \partial_{\infty}Y \times \mathbb{R}$ (rather, the unperturbed locus is an arbitrarily large compact subset of this), the product contact form $\beta_{X \times Y}$ is given by $e^{\min(0,-s)} \beta_X + e^{\min(0,s)} \beta_Y$, and its evaluation on $\partial_t(\partial_{\infty} L_t \times \partial_{\infty} K_t \times \mathbb{R})$ is thus given by

$$e^{\min(0,-s)} \beta_X(\partial_t \partial_{\infty} L_t) + e^{\min(0,s)} \beta_Y(\partial_t \partial_{\infty} K_t) \geq \begin{cases} \beta_X(\partial_t \partial_{\infty} L_t) & s \leq 0, \\ \beta_Y(\partial_t \partial_{\infty} K_t) & s \geq 0. \end{cases}$$  \hfill (6.31)

In fact, both terms on the right are simply 1, since by definition $\partial_{\infty} L_t$ and $\partial_{\infty} K_t$ follow the Reeb flows of $\beta_X$ and $\beta_Y$, respectively.

We now consider the perturbed locus where $L^t \times K^t$ differs from $L^t \times K^t$. To specify this perturbation, we specify now a function $N(t)$ (fixing $f_L^t$, $f_K^t$ and $\phi_L^t$, $\phi_K^t$). Following the reasoning from §6.3 surrounding (6.15)–(6.16), we may observe that

$$\beta_{X \times Y}(\partial_t \partial_{\infty}(L^t \times K_t)) = \beta_Y(\partial_t \partial_{\infty} K_t) + O(e^{-N(t)}(1 + |N'(t)|)),$$  \hfill (6.32)

where the constant in the $O(\cdot)$ depends on $t$. The first term again equals 1, and a function $N : \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}$ makes the second term negligible iff it solves the differential inequality

$$|N'(t)| + 1 \leq \varepsilon(t)e^{N(t)},$$  \hfill (6.33)

where $\varepsilon : \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}_{>0}$ is a continuous function depending on the isotopies $L^t$, $K^t$, the primitives $f_L^t$, $f_K^t$, and the functions $\phi_L^t$, $\phi_K^t$.

To solve the differential inequality (6.33), first note that it makes sense for Lipschitz functions $N$, and within this class of functions, if $N_1$ and $N_2$ are solutions then so is $\min(N_1, N_2)$. Therefore it suffices to find, for arbitrarily large $T < \infty$, solutions $N : [0, T) \rightarrow \mathbb{R}_{>0}$ which go to infinity at $T$ (then just take the minimum of all such). Such solutions may be constructed by taking $N \equiv a$ over $[0, t_0]$ and then continuing for $t > t_0$ by taking $N'(t)$ as large as possible subject to (6.33) (for sufficiently large $a < \infty$, this solves (6.33) and diverges to
infinity in finite time). This produces the desired cylindrized isotopy \( \{L^t_1 \times K^t_1\}_{t \geq 0} \) for which \( \beta_{X \times Y}(\partial_t \partial_{\infty}(L^t_1 \times K^t_1)) \) is bounded below, and hence by Lemma 2.1 is cofinal.

Let us now show how to adapt the above argument to show that (6.28) is a quasi-isomorphism for the product stop

\[
\mathfrak{h} := (\mathfrak{c}_X \times \mathfrak{g}) \cup (f \times \mathfrak{g} \times \mathbb{R}) \cup (f \times \mathfrak{c}_Y) \subseteq (X \times \partial_{\infty} Y) \cup (\partial_{\infty} X \times Y) = \partial_{\infty} (X \times Y)
\]

for stopped Liouville manifolds \((X, f)\) and \((Y, g)\). Choose smooth contact Hamiltonians on \(\partial_{\infty} X\) and \(\partial_{\infty} Y\) vanishing precisely along \(f\) and \(g\), and let \(\beta_X\) and \(\beta_Y\) be the corresponding contact forms on \(\partial_{\infty} X \setminus f\) and \(\partial_{\infty} Y \setminus g\), respectively (so the Reeb vector fields of \(\beta_X\) and \(\beta_Y\) are complete). Let \(\{L^t_1\}_{t \geq 0}\) and \(\{K^t_1\}_{t \geq 0}\) be positive isotopies which, outside fixed compact subsets of \(X\) and \(Y\), coincide with the flow by (the linear Hamiltonian corresponding to) the chosen contact vector fields on \(\partial_{\infty} X\) and \(\partial_{\infty} Y\). We now consider again the product contact form (6.30). As before, this product contact form \(\beta_{X \times Y}\) corresponds to the contact type hypersurface \(\partial(X_0 \times Y_0)\), where \(X_0 \subseteq X\) and \(Y_0 \subseteq Y\) are the subsets corresponding to \(\beta_X\) and \(\beta_Y\), respectively. Note that now \(X_0\) and \(Y_0\) are not compact, rather they approach \(\partial_{\infty} X\) and \(\partial_{\infty} Y\) along \(f\) and \(g\), respectively. Their product \(X_0 \times Y_0\) approaches \(\partial_{\infty} (X \times Y)\) along the product stop \(\mathfrak{h}\) from (6.34), so the product contact form \(\beta_{X \times Y}\) from (6.30) is a contact form on \(\partial_{\infty} (X \times Y) \setminus \mathfrak{h}\). Now the same reasoning as before shows that there is a lower bound on the evaluation of \(\beta_{X \times Y}\) on the \(t\)-derivative of the product isotopy \(\partial_t \partial_{\infty}(L^t_1 \times K^t_1)\), and hence the product isotopy \(\{L^t_1 \times K^t_1\}_{t \geq 0}\) is cofinal. We conclude that (6.28) is an isomorphism for the product stop (6.34).

### 6.6 Construction of the Künneth functor

**Proof of Theorem 1.5.** Fix stopped Liouville manifolds \((X, f)\) and \((Y, g)\). We construct a bilinear \(A_{\infty}\)-functor

\[
\mathcal{W}(X, f) \otimes \mathcal{W}(Y, g) \hookrightarrow \mathcal{W}((X, f) \times (Y, g))
\]

lifting the cohomology level functor constructed in §6.4. This also provides a bilinear \(A_{\infty}\)-functor \(\mathcal{W}(X) \otimes \mathcal{W}(Y) \to \mathcal{W}(X \times Y)\) for Liouville sectors \(X\) and \(Y\) in view of the comparison of products in §6.1, specifically the quasi-equivalences (6.6)–(6.7) and (6.9).

Fix data for defining \(\mathcal{W}_X = \mathcal{W}(X, f)\) as in §2.3, namely a poset of Lagrangians \(\mathcal{O}_X\) and compatible families of cylindrical at infinity almost complex structures

\[
J_{L_0, \ldots, L_k} : \mathfrak{S}_{k, 1} \to \mathcal{J}(X)
\]

for which the relevant moduli spaces of holomorphic disks are cut out transversally. This defines a strictly unital \(A_{\infty}\)-category \(\mathcal{O}_X\), whose localization at the continuation morphisms we denote by \(\mathcal{W}_X\). Similarly, fix \(\mathcal{O}_Y\) and \(\mathcal{O}_{X \times Y}\) (and cylindrical almost complex structures) for defining \(\mathcal{W}_Y = \mathcal{W}(Y, g)\) and \(\mathcal{W}_{X \times Y} = \mathcal{W}((X, f) \times (Y, g))\).

Our goal is to construct a bilinear \(A_{\infty}\)-functor \(\mathcal{W}_X \otimes \mathcal{W}_Y \to \mathcal{W}_{X \times Y}\) lifting the cohomology level functor constructed in §6.4. We will define this functor as a composition

\[
\mathcal{W}_X \otimes \mathcal{W}_Y \to \mathcal{W}^{\text{prod}}_{X \times Y} \to \mathcal{W}_{X \times Y},
\]
where the intermediate category $\mathcal{W}_{X \times Y}^{\text{prod}}$ is defined as follows.

Fix a countable collection $I_{X \times Y}^{\text{prod}}$ of pairs of Lagrangians $(L \subseteq X, K \subseteq Y)$ (disjoint at infinity from $\mathfrak{f}$ and $\mathfrak{g}$, respectively), representing every pair of isotopy classes. For each such pair $(L, K)$, choose cofinal wrappings $L = L^{(0)} \sim L^{(1)} \sim \ldots$ (away from $\mathfrak{f}$) and $K = K^{(0)} \sim K^{(1)} \sim \ldots$ (away from $\mathfrak{g}$). Furthermore, assume that these $L^{(i)}$ and $K^{(i)}$ are chosen generically so that they are all (over all $(L, K) \in I_{X \times Y}^{\text{prod}}$) mutually transverse (hence disjoint at infinity) and such that the restrictions of $\lambda_X$ to $L^{(i)}$ and $\lambda_Y$ to $K^{(i)}$ have primitives supported inside fixed compact subsets of $X$ and $Y$, respectively. Let $\mathcal{O}_{X \times Y}^{\text{prod}} := \mathbb{Z}_{\geq 0} \times I_{X \times Y}^{\text{prod}}$ denote the set of all pairs $(L^{(i)}, K^{(i)})$, and equip $\mathcal{O}_{X \times Y}^{\text{prod}}$ with a total order isomorphic to $\mathbb{Z}_{\geq 0}$ such that $(L^{(i)}, K^{(i)}) > (L^{(j)}, K^{(j)})$ for $i > j$. To turn $\mathcal{O}_{X \times Y}^{\text{prod}}$ into an $A_\infty$-category, we choose compatible families of almost complex structures

$$J_{(L_0,K_0),\ldots,(L_r,K_r)} : \mathfrak{s}_{r,1} \to \mathcal{J}(X \times Y)$$

(6.39)

for $(L_0, K_0) > \ldots > (L_r, K_r) \in \mathcal{O}_{X \times Y}^{\text{prod}}$, which are products of almost complex structures on $X$ and $Y$ that are separately cylindrical at infinity on each factor. The moduli spaces of holomorphic disks in $X \times Y$ with boundary on $L_0 \times K_0, \ldots, L_r \times K_r$ are compact by the usual monotonicity and uniformly bounded geometry arguments from [26, Proposition 3.19] (uniformly bounded geometry is preserved under taking products, and the distance between $L \times K$ and $L' \times K'$ near infinity is bounded below since the same holds for the pairs $(L, L')$ and $(K, K')$). This defines $\mathcal{O}_{X \times Y}^{\text{prod}}$ as an $A_\infty$-category. The quasi-isomorphism (6.20) defines continuation elements in $HF^0(L^{(i+1)} \times K^{(i+1)}, L^{(i)} \times K^{(i)})$, and the localization of $\mathcal{O}_{X \times Y}^{\text{prod}}$ at these continuation elements is denoted $\mathcal{W}_{X \times Y}^{\text{prod}}$. The usual arguments [26, Lemma 3.37] show that the morphism spaces in $\mathcal{W}_{X \times Y}^{\text{prod}}$ are indeed given by the direct limit of Floer cohomology over wrapping both factors separately in $X$ and $Y$.

It remains to construct functors

$$\mathcal{W}_X \otimes \mathcal{W}_Y \to \mathcal{W}_{X \times Y}^{\text{prod}} \to \mathcal{W}_{X \times Y}$$

(6.40)

which on homotopy/cohomology induce the isomorphisms described in §6.4.

We define the functor $\mathcal{W}_X \otimes \mathcal{W}_Y \to \mathcal{W}_{X \times Y}^{\text{prod}}$ via an $A_\infty$-trimodule defined as follows. We define an $(\mathcal{O}_{X \times Y}^{\text{prod}}, \mathcal{O}_X, \mathcal{O}_Y)$-trimodule $\mathcal{T}$, namely a trilinear $A_\infty$-functor

$$\mathcal{T} : (\mathcal{O}_{X \times Y}^{\text{prod}})^{\text{op}} \otimes \mathcal{O}_X \otimes \mathcal{O}_Y \to \text{Ch},$$

(6.41)

by counting holomorphic strips up to translation as in Figure 19, for $K_0 > \cdots > K_k \in \mathcal{O}_X$, $L_0 > \cdots > L_\ell \in \mathcal{O}_Y$, and $M_0 > \cdots > M_m \in \mathcal{O}_{X \times Y}^{\text{prod}}$. Such a strip can be thought of either as a pair of maps to $X^-$ and $Y$ as on the left of Figure 19 or as a single map to $X \times Y$ as on the right (via folding the strip).

We choose compatible families of almost complex structures on $X$ and $Y$, cylindrical at infinity, over each half of the strip, respectively (s-invariant in the thin parts of the strip, with respect to fixed universal strip-like coordinates). We require that the negative strip-like coordinates (2.11) for $\mathcal{O}_X$, $\mathcal{O}_Y$, and $\mathcal{O}_{X \times Y}^{\text{prod}}$ extend as in [26, Equation (5.7)] and that on the trimodule domain strips, we use the tautological strip-like coordinates at $s = \pm \infty$ (these assumptions ensure that the gluing maps on the bimodule domain strips respect the global
Figure 19: Holomorphic maps used to define the \((\mathcal{O}^{\text{prod}}_{X \times Y}, \mathcal{O}_X, \mathcal{O}_Y)\)-trimodule \(T\).

\((s, t)\)-coordinates. As a map to \(X \times Y\), the folded strip should be holomorphic with respect to the product of these almost complex structures. As a pair of maps to \(X^-\) and \(Y\), the left half (mapping to \(Y\)) should be holomorphic, and the right half (mapping to \(X^-\)) should be antiholomorphic. The usual monotonicity and uniformly bounded geometry arguments from [26, Proposition 3.19] apply to show that such (possibly broken) holomorphic strips map to a fixed compact subset of the target, and hence the (Gromov–Floer compactified) moduli spaces of such strips are indeed compact. Choosing Floer data generically we obtain transversality, and counting the zero-dimensional moduli spaces defines our desired trimodule \(T\) (the fact that \(T\) satisfies the trimodule equations is, as usual, an immediate consequence of the usual analysis of the boundary of the one-dimensional compactified moduli spaces).

To define the functor \(\mathcal{W}_X \otimes \mathcal{W}_Y \to \mathcal{W}^{\text{prod}}_{X \times Y}\) from the trimodule \(\mathcal{T}\), argue as follows. The localization \((\mathcal{C}^{\text{prod}}_{X \times Y})^{-1}\mathcal{T}\) is calculated on cohomology by taking the direct limit over wrappings on \(\mathcal{O}^{\text{prod}}_{X \times Y}\). This yields the tensor product of wrapped Floer complexes in \(X\) and \(Y\), and hence \((\mathcal{C}^{\text{prod}}_{X \times Y})^{-1}\mathcal{T}\) is \(C^*_X\) and \(C^*_Y\)-local on the right. Hence for every pair \(L \in \mathcal{W}_X\) and \(K \in \mathcal{W}_Y\), the natural map of \(\mathcal{W}^{\text{prod}}_{X \times Y}\)-modules \((\mathcal{C}^{\text{prod}}_{X \times Y})^{-1}\mathcal{T}(-, L, K) \xrightarrow{\sim} (\mathcal{C}^{\text{prod}}_{X \times Y})^{-1}\mathcal{C}^{-1}_X, C^{-1}_Y(-, L, K)\) is a quasi-isomorphism, and the former is representable (by any pair \((L', K')\) in \(\mathcal{W}^{\text{prod}}_{X \times Y}\) isotopic to \(L\) and \(K\)). We have thus shown that the image of the \((\mathcal{W}^{\text{prod}}_{X \times Y}, \mathcal{W}_X, \mathcal{W}_Y)\)-trimodule \((\mathcal{C}^{\text{prod}}_{X \times Y})^{-1}\mathcal{C}^{-1}_X, C^{-1}_Y\) viewed as a bilinear functor

\[
\mathcal{W}_X \otimes \mathcal{W}_Y \to \text{Mod}_{\mathcal{W}^{\text{prod}}_{X \times Y}} \tag{6.42}
\]

is contained in the image of the Yoneda embedding of \(\mathcal{W}^{\text{prod}}_{X \times Y}\) (appealing to Lemma A.2). Appealing to the Yoneda Lemma A.1, this trimodule \(\mathcal{T}\) thus defines (up to inverting quasi-equivalences) the desired functor \(\mathcal{W}_X \otimes \mathcal{W}_Y \to \mathcal{W}^{\text{prod}}_{X \times Y}\). Moreover, one can verify in a manner identical to the proof of Theorem 1.4 that the action of this functor on objects and morphisms agrees cohomologically with the tautological isomorphism (6.20) (or rather the
version of (6.20) which exists for wrapped Floer homology of product Lagrangians computed with product wrappings and product almost complex structures); in particular this functor is a quasi-equivalence.

We now turn to the construction of the functor $W_{X \times Y}^{\text{prod}} \rightarrow W_{X \times Y}$. The construction of this functor, and the proof it is a quasi-equivalence, is very similar to construction of the functor in the proof of Theorem 1.4.

We begin by fixing a Hamiltonian symplectomorphism $\Phi : X \times Y \rightarrow X \times Y$ (supported near infinity) such that $\Phi \mathcal{O}_{X \times Y}^{\text{prod}}$ are cylindrical at infinity (realizing the cylindrizations of these product Lagrangians, as defined in §6.2). To define such a $\Phi$ simultaneously cylindrizing all $L \times K$ (for $(L, K) \in \mathcal{O}_{X \times Y}^{\text{prod}}$) at once, we argue as follows. First, we need to make a more careful construction of $\mathcal{O}_{X \times Y}^{\text{prod}}$. The cylindrization operation for $L \times K$ takes place inside a small neighborhood of $(\partial L \times c_Y) \cup (c_X \times \partial K) \subseteq \partial_{\infty} (X \times Y)$. Of course, an arbitrarily small neighborhood of this locus may intersect $L' \times K'$ for other $(L', K') \in \mathcal{O}_{X \times Y}^{\text{prod}}$, which is problematic. To prevent this, we incorporate the choices of such neighborhoods into the inductive construction of $\mathcal{O}_{X \times Y}^{\text{prod}}$, namely we pick small neighborhoods of $\partial_{\infty} L$ and $\partial_{\infty} K$ as we choose $(L, K) \in \mathcal{O}_{X \times Y}^{\text{prod}}$ by induction (over $\mathbb{Z}_{\geq 0}$, not a larger ordinal) and we ensure at each step of the induction that such neighborhoods are mutually disjoint. For this to make sense, we must show that every Lagrangian admits a cofinal sequence of wrappings disjoint at infinity from any fixed finite number of standard neighborhoods of Legendrians, but this follows from Lemma 2.2.

We now define an $(\mathcal{O}_{X \times Y}, \mathcal{O}_{X \times Y}^{\text{prod}})$-bimodule $\mathcal{B}$ by counting holomorphic strips up to translation as in Figure 3, for $K_k > \cdots > K_0 \in \mathcal{O}_{X \times Y}$ and $L_0 > \cdots > L_\ell \in \mathcal{O}_{X \times Y}^{\text{prod}}$. We require that the negative strip-like coordinates (2.11) for $\mathcal{O}_{X \times Y}^{\text{prod}}$ and $\mathcal{O}_{X \times Y}$ extend as in [26, Equation (5.7)] and that on the bimodule domain strips, we use the tautological strip-like coordinates at $s = \pm \infty$ (these assumptions ensure that the gluing maps on the bimodule domain strips respect the global $(s, t)$-coordinates). We use almost complex structures

$$J_{K_k, \ldots, K_0, L_0, \ldots, L_\ell} : \overline{\mathbb{F}}_{k+\ell+1,1} \rightarrow \mathcal{J}(X \times Y)$$

(6.43)
satisfying the following conditions. For any bimodule domain strip $C$ (identified with $\mathbb{R} \times [0, 1]$ up to $\mathbb{R}$-translation), let $N_r \subseteq C$ denote the closed $r$-neighborhood of the marked points on the left of the strip (i.e. those mapping to intersection points $\Phi(L_i \cap L_{i+1})$ for $L_i \in \mathcal{O}_{X \times Y}^{\text{prod}}$) with respect to the Riemannian metric $ds^2 + dt^2$. The almost complex structures are required to satisfy the following conditions:

(i) Over $C \setminus N_{\frac{3}{4}}$, we require the almost complex structures to be cylindrical at infinity on $X \times Y$.

(ii) Over $N_{\frac{3}{4}}$, we require the almost complex structures to be $\Phi_*$ of a product of cylindrical at infinity on $X$ and $Y$ respectively.

(iii) Fix once and for all an exhaustion

$$K_1 \subseteq U_1 \subseteq K_2 \subseteq U_2 \subseteq \cdots \subseteq X \times Y$$

(6.44)

with $U_i$ open and $K_i$ compact, such that

$$\inf_i d_{X \times Y}((X \times Y) \setminus U_{2i}, K_{2i}) > 0,$$

(6.45)

$$\inf_i (d_X \times d_Y)((X \times Y) \setminus \Phi^{-1}(U_{2i+1}), \Phi^{-1}(K_{2i+1})) > 0,$$

(6.46)
where \( d_{X \times Y} \) denotes distance with respect to a cylindrical metric on \( X \times Y \), and \( d_X \times d_Y \) is with respect to a product of cylindrical metrics. Over \((C \setminus N^\circ_2) \times \bigcup_i(U_{2i} \setminus K_{2i})\), we require the almost complex structures to agree (away from a compact subset of \( X \times Y \)) with a family of cylindrical at infinity almost complex structures on \( X \times Y \). Over \( N^\circ_2 \times \bigcup_i(U_{2i+1} \setminus K_{2i+1})\), we require them to agree (away from a compact subset of \( X \times Y \)) with a product of families of cylindrical at infinity almost complex structures on \( X \) and \( Y \) respectively.

By choosing these almost complex structures generically, we can ensure that the moduli spaces of strips are cut out transversally. Compactness of the moduli spaces of such (stable) strips follows from the same argument used in the proof of Theorem 1.4. This defines the spaces of strips along with the composition of the map as a continuation map counting strips

\[
\mathcal{B}(-, L) = CF^*(-, \Phi L).
\]

Indeed, the domains defining the structure maps for \( \mathcal{B}(-, L) \) have no boundary marked points on the left, and hence the almost complex structures \((6.43)\) are everywhere cylindrical at infinity on \( X \times Y \). Next, still following the proof of Theorem 1.4, we construct a homotopy between the two compositions in the diagram of \( \mathcal{O}_{X \times Y} \)-modules

\[
\begin{align*}
CF^*(-, \Phi L) \otimes CF^*(\Phi L, \Phi K) & \xrightarrow{\mu^2} CF^*(-, \Phi K) \\
\mathcal{B}(-, L) \otimes CF^*(L, K) & \xrightarrow{\mu^{11}} \mathcal{B}(-, K).
\end{align*}
\]

Of course, the isomorphism \((6.18)\) was only an isomorphism in the homotopy category, so we should first say what we mean by the map \( CF^*(\Phi L, \Phi K) \to CF^*(L, K) \) above. We define this map as a continuation map counting strips \( \mathbb{R} \times [0, 1] \) which are holomorphic with respect to almost complex structures which (1) are cylindrical at infinity for \( s \geq 2 \), (2) are \( \Phi_s \) of product of cylindrical at infinity for \( s \leq -2 \), (3) agree over \( \{ s \geq -1 \} \cap \bigcup_i(U_{2i} \setminus K_{2i}) \) (minus some compact subset of \( X \times Y \)) with cylindrical at infinity almost complex structures, and (4) agree over \( \{ s \leq 1 \} \cap \bigcup_i(U_{2i+1} \setminus K_{2i+1}) \) (minus some compact subset of \( X \times Y \)) with \( \Phi_s \) of product of cylindrical at infinity almost complex structures. This continuation map agrees on homotopy with the isomorphisms \((6.18)\), since we can just take our family of almost complex structures to be independent of \( s \) over a large enough compact subset of \( X \times Y \) to contain all holomorphic curves (appealing to the proof of the isomorphism \((6.18)\)). We may now define the homotopy between the two compositions in \((2.23)\) by the family of domain curves illustrated in Figure 4. The domain on the left of Figure 4 defines the composition \( \mu^{11} \circ ((6.47) \otimes (6.18)) \), and the domain on the right defines the composition \((6.47) \circ \mu^2 \).

The striped regions indicate the interface between the regions where the almost complex structures are cylindrical at infinity and \( \Phi_s \) of cylindrical at infinity.

We may now define the functor

\[
\mathcal{W}^{\text{prod}}_{X \times Y} = \mathcal{O}^{\text{prod}}_{X \times Y}[(C^{\text{prod}}_{X \times Y})^{-1}] \to \mathcal{O}_{X \times Y}[C^{-1}_{X \times Y}] = \mathcal{W}_{X \times Y}
\]

\[ (6.49) \]
using the \((\mathcal{W}_{X \times Y}, \mathcal{W}_{X \times Y}^{\text{prod}})\)-bimodule \(C^{-1}_{X \times Y} \mathcal{B}_{(C_{X \times Y}^{\text{prod}})^{-1}}\). For \(L \in \mathcal{O}_{X \times Y}^{\text{prod}}\), we have quasi-isomorphisms 
\[ C^{-1}_{X \times Y} \mathcal{B}_{(C_{X \times Y}^{\text{prod}})^{-1}}(-, L) \xleftarrow{\sim} C^{-1}_{X \times Y} \mathcal{B}(-, L) = \sim C^{-1}_{X \times Y} CF^*(-, \Phi L) =: \mathcal{W}_{X \times Y}(-, \Phi L). \]
Hence the functor
\[
\mathcal{W}_{X \times Y}^{\text{prod}} \to \text{Mod}_{\mathcal{W}_{X \times Y}} \quad (6.50)
L \mapsto C^{-1}_{X \times Y} \mathcal{B}_{(C_{X \times Y}^{\text{prod}})^{-1}}(-, L) \quad (6.51)
\]
lands in the essential image of the Yoneda embedding \(\mathcal{W}_{X \times Y} \hookrightarrow \text{Mod}_{\mathcal{W}_{X \times Y}}\), thus defining (by Lemma A.1) our functor \(6.49\) (as usual up to inverting quasi-equivalences). Tracing through the definitions and using \(6.48\) shows that the action of this functor on cohomology agrees with the natural maps from \(6.4\) and hence agrees with the isomorphisms on wrapped Floer cohomology they induce; this portion of the argument is identical to that given at the end of the proof of Theorem 1.4.

\[\square\]

### 6.7 Stabilization by \(T^*[0,1]\) or \((\mathbb{C}, \{\pm \infty\})\)

The Künneth functor in the form of Theorem 1.5 proved in the previous subsection gives rise, as a special case, to functors
\[
\mathcal{W}(X) \hookrightarrow \mathcal{W}(X \times T^*[0,1]), \quad (6.52)
\mathcal{W}(X, f) \hookrightarrow \mathcal{W}((X, f) \times (\mathbb{C}, \{\pm \infty\})), \quad (6.53)
\]
(the former for Liouville sectors, the latter for stopped Liouville manifolds). To define these functors from the Künneth bilinear functors
\[
\mathcal{W}(X) \otimes \mathcal{W}(T^*[0,1]) \hookrightarrow \mathcal{W}(X \times T^*[0,1]), \quad (6.54)
\mathcal{W}(X, f) \otimes \mathcal{W}(\mathbb{C}, \{\pm \infty\}) \hookrightarrow \mathcal{W}((X, f) \times (\mathbb{C}, \{\pm \infty\})), \quad (6.55)
\]
it suffices to fix functors
\[
\mathbb{Z} \to \mathcal{W}(T^*[0,1]), \quad (6.56)
\mathbb{Z} \to \mathcal{W}(\mathbb{C}, \{\pm \infty\}), \quad (6.57)
\]
where \(\mathbb{Z}\) denotes the \(A_{\infty}\)-category with a single object \(*\) with endomorphism algebra \(\mathbb{Z}\), sending this object to \([\text{fiber}] \in \mathcal{W}(T^*[0,1])\) and \(i\mathbb{R} \in \mathcal{W}(\mathbb{C}, \{\pm \infty\})\), respectively. The construction of such functors \((6.56)-(6.57)\) can be obtained by sending \(*\) to a fixed representative \(K\) of \([\text{fiber}] \in \mathcal{W}(T^*[0,1])\) (respectively of \(i\mathbb{R} \in \mathcal{W}(\mathbb{C}, \{\pm \infty\})\), and the generator \(1 \in \mathbb{Z}\) to the strict unit in \(\text{Hom}(K,K)\) (note that our construction of partially wrapped Fukaya categories produces categories which are strictly unital).

### 7 Generation by cocores and linking disks

#### 7.1 A vanishing result

**Lemma 7.1.** For any Liouville sector \(X\), we have \(\mathcal{W}(X \times \mathbb{C}_{\text{Re} \geq 0}) = 0\).  

...
Proof. The Hamiltonian function \((\text{Re})^2\) is positive and linear at infinity (for the radial Liouville structure on \(\mathbb{C}\)), and for any two Lagrangians \(L,K \subseteq X \times \mathbb{C}_{\text{Re} \geq 0}\), we have \(e^{N_{X}((\text{Re})^2 \leq N} L \cap K = \emptyset\) for sufficiently large \(N < \infty\). 

\[\square\]

Corollary 7.2. If \(L \subseteq X\) is in the image of any inclusion \(Y \times \mathbb{C}_{\text{Re} \geq 0} \hookrightarrow X\), then \(L\) is a zero object in \(\mathcal{W}(X)\) (and in fact in \(\mathcal{W}(X,f)\) provided \(f \cap \partial_{\infty}(Y \times \mathbb{C}_{\text{Re} \geq 0}) = \emptyset\)).

Proof. If \(L\) is contained in the interior of the image of \(Y \times \mathbb{C}_{\text{Re} \geq 0}\), then the conclusion holds since \(\mathcal{W}(Y \times \mathbb{C}_{\text{Re} \geq 0}) = 0\) by Lemma 7.1 and any \(A_{\infty}\)-functor (in particular \(\mathcal{W}(Y \times \mathbb{C}_{\text{Re} \geq 0}) \to \mathcal{W}(X)\)) sends zero objects to zero objects. In general, simply isotope \(L\) into the interior of \(Y \times \mathbb{C}_{\text{Re} \geq 0}\) (e.g. using the Hamiltonian flow of a defining function \(I\) for \(Y \times \mathbb{C}_{\text{Re} \geq 0}\) and recall that isotopies of exact Lagrangians induce quasi-isomorphisms of objects in the wrapped Fukaya category. 

\[\square\]

7.2 Products of cocores and linking disks

For the purpose of proving Theorem 1.10, we require an understanding of how cocores and linking disks are transformed under taking products.

Obviously, for Weinstein manifolds \(X\) and \(Y\), the product \(X \times Y\) is again Weinstein, and the product of a cocore in \(X\) and a cocore in \(Y\) is a cocore in \(X \times Y\). Moreover, every cocore in \(X \times Y\) is of this form. Note that cocores are strongly exact (the Liouville form vanishes identically on them) and hence cylindrization need not be discussed. We now wish to generalize this discussion to stopped Weinstein manifolds.

Let \((X,f)\) and \((Y,g)\) be stopped Weinstein manifolds satisfying the hypothesis of Theorem 1.10, fixing decompositions \(f = f_{\text{subcrit}} \cup f_{\text{crit}}\) and \(g = g_{\text{subcrit}} \cup g_{\text{crit}}\). The product \(X \times Y\) is a Weinstein manifold, and the product stop
\[
\mathfrak{h} := (c_{X} \times g) \cup (f \times g \times \mathbb{R}) \cup (f \times c_{Y})
\]
(7.1)
is mostly Legendrian, admitting a natural decomposition \(\mathfrak{h} = h_{\text{subcrit}} \cup h_{\text{crit}}\). To see this, first write \(c_{X} = c_{X}^{\text{subcrit}} \cup c_{X}^{\text{crit}}\), where \(c_{X}^{\text{subcrit}}\) (resp. \(c_{X}^{\text{crit}}\)) is the union of the cores of the subcritical (resp. critical) handles (and similarly for \(c_{Y}\)). We may thus define
\[
h_{\text{crit}} := (c_{X}^{\text{crit}} \times g^{\text{crit}}) \cup (f^{\text{crit}} \times g^{\text{crit}} \times \mathbb{R}) \cup (f^{\text{crit}} \times c_{Y}^{\text{crit}}),
\]
(7.2)
which is an open subset of \(\mathfrak{h}\). Clearly \(h_{\text{crit}}\) is a (locally closed) Legendrian submanifold (using the fact that the cocores of the critical handles of \(X\) and \(Y\) are disjoint at infinity from \(f\) and \(g\), respectively), and one may also check that \(h_{\text{subcrit}} := h \setminus h_{\text{crit}}\) is closed and is a countable union of locally closed isotropic submanifolds. Note also that cocores of \(X \times Y\), being cocores of \(X\) times cocores of \(Y\), are disjoint from the product stop \(\mathfrak{h}\).

Let us now compare products of cocores/linking disks of \((X,f)\) and \((Y,g)\) with the cocores/linking disks of \((X \times Y, h)\). Obviously, products of cocores are cocores, and this accounts for all cocores in the product, just as in the case without stops.

Let us now consider products of cocores and linking disks. Consider the linking disk inside \(X\) at a given point of \(f_{\text{crit}}\). Recall from §3.3 that this linking disk admits the following description in terms of Weinstein handles. On the Lagrangian cylinder \(\mathbb{R} \times f_{\text{crit}} \subseteq X\), we introduce a pair of cancelling Weinstein handles of indices 0 and 1 (more precisely,
coupled \((0, 0)\)- and \((1, 1)\)-handles), and the linking disk is a Lagrangian plane invariant under the Liouville flow intersecting \(\mathbb{R} \times f_{\text{crit}}\) precisely at the critical point of index zero. The introduction of these handles increases the core \(c_X\), however note that the new points of \(c_X\) are entirely contained in \(\mathbb{R} \times f\), so in particular the product stop \(\mathfrak{h}\) remains the same. We now take this deformation of Liouville forms on \(X\) and multiply with \(Y\), noting that by the previous sentence, the product stop \(\mathfrak{h}\) remains the same. The result is a deformation of the Liouville form on \(X \times Y\) which introduces a pair of cancelling critical points of index \(k\) and \(k + 1\) for every Weinstein \(k\)-handle of \(Y\). When \(k\) is the critical index for \(Y\), these critical points lie on \(\mathbb{R} \times f_{\text{crit}} \times c_{\text{crit}}^Y\). It follows that the product of a linking disk of \(f_{\text{crit}}\) and a cocore of \(Y\) is the linking disk of the corresponding component of \(f_{\text{crit}} \times c_{\text{crit}}^Y\).

Finally, let us consider products of linking disks and linking disks. We consider the same description of the linking disks as before, namely in terms of a deformation of the Liouville forms on \(X\) and \(Y\) to introduce cancelling Weinstein handles of indices 0 and 1 on \(\mathbb{R} \times f_{\text{crit}}\) and \(\mathbb{R} \times g_{\text{crit}}\). Now the result on the product is that the Liouville form is deformed near \(\mathbb{R} \times f_{\text{crit}} \times g_{\text{crit}} \times \mathbb{R}\) to introduce four cancelling Weinstein handles of indices 0, 1, 1, and 2. The product of the linking disks is now a Lagrangian plane invariant under the Liouville flow intersecting \(\mathbb{R} \times f_{\text{crit}} \times g_{\text{crit}} \times \mathbb{R}\) precisely at the critical point of index 0, and this is exactly the linking disk at the corresponding point of \(f_{\text{crit}} \times g_{\text{crit}} \times \mathbb{R}\).

### 7.3 Proof of generation

**Proof of Theorem 1.10.** Fix a stopped Weinstein manifold \((X, f)\), and consider the Künneth embedding

\[
W(X, f) \hookrightarrow W(X \times \mathbb{C}, h) \quad \text{(7.3)}
\]
\[
L \mapsto L \times i\mathbb{R} \quad \text{(7.4)}
\]

where

\[
\mathfrak{h} = (c_X \times \{\pm \infty\}) \cup (f \times \mathbb{R}) \subseteq \partial_{\infty}(X \times \mathbb{C}) = X \times \partial_{\infty}\mathbb{C} \cup \partial_{\infty}X \times \partial_{\infty}\mathbb{C} \times \mathbb{R} \partial_{\infty}X \times \mathbb{C}. \quad \text{(7.5)}
\]

It is enough to show that the image under Künneth of any \(L \in W(X, f)\) is generated by the images of the linking disks and cocores (see Lemma A.3). By the discussion in §7.2, these images are precisely the linking disks of the product stop \(\mathfrak{h}\). Hence by the wrapping exact triangle Theorem 1.9 and general position (Lemma 2.3), it suffices to show that \(L \times i\mathbb{R}\) can be isotoped through \(\mathfrak{h}\) to a zero object. For such an isotopy, we can simply take (the cylindrization of) \(L\) times an isotopy of \(i\mathbb{R}\) through the stop at \(+\infty \in \partial_{\infty}\mathbb{C}\) to an arc contained in the lower half-plane \(\mathbb{C}_{\text{Im} \leq 0}\), which is a zero object (and hence whose cylindrized product with \(L\) is also a zero object by virtue of the Künneth functor).

**Proof of Theorem 1.13.** Given any \(L \subseteq F \times \mathbb{C}_{\text{Re} \geq 0}\) missing \(\Lambda\) at infinity, the isotopy from the proof of Proposition 7.1 eventually pushes \(L\) to a zero object in \(W(F \times \mathbb{C}_{\text{Re} \geq 0}, \Lambda)\). Perturbing this isotopy to intersect \(\Lambda\) only by passing through \(\Lambda_{\text{crit}}\) transversally via Lemma 2.3 and appealing to the wrapping exact triangle Theorem 1.9 proves the claim.
Proof of Corollary 1.14. The Fukaya–Seidel category of our Lefschetz fibration $\pi : \tilde{X} \to \mathbb{C}$ can be described as the wrapped Fukaya category of the Liouville sector obtained from $F \times \mathbb{C}_{\Re \geq 0}$ by attaching critical Weinstein handles along the vanishing cycles inside (or, rather, their lifts to) $F \times \partial_\infty \mathbb{C}_{\Re \geq 0}$. Denoting by $\Lambda$ the union of these attaching loci, there is a functor

$$\mathcal{W}(F \times \mathbb{C}_{\Re \geq 0}, \Lambda) \to \mathcal{W}((F \times \mathbb{C}_{\Re \geq 0}) \cup \Lambda (\text{handles})).$$

(7.6)

The image of this functor generates the target by Theorem 1.10, since the linking disks to $\Lambda$ are sent to the cocores of the added handles. On the other hand, the domain category is generated by these linking disks by Theorem 1.13, and the cocores of the added handles are precisely the Lefschetz thimbles.

Proof of Theorem 1.11. We follow the proof of Theorem 1.10. To see that the product stop $\mathfrak{h}$ remains mostly Legendrian, write it as $\mathfrak{h} = (\mathfrak{c}_{X, f} \times \{\pm \infty\}) \cup (\mathfrak{f} \times \{0\})$, use the given decompositions of the two copies of $\mathfrak{c}_{X, f}$ into critical and subcritical parts (note that the Liouville vector field must be tangent to $\mathfrak{c}_{X, f}^{\text{crit}}$, hence the Liouville form vanishes identically on it, so it is indeed Legendrian inside $\partial_\infty (X \times \mathbb{C})$), and declare $\mathfrak{f} \times \{0\}$ to be subcritical (it follows from the fact that $\mathfrak{f} \times \mathbb{R}$ is mostly Lagrangian that $\mathfrak{f}$ can be covered by the smooth image of a second countable manifold of dimension less than Legendrian). It thus suffices to show that for each generalized cocore $L \subseteq X$ intersecting $\mathfrak{c}_{X, f}^{\text{crit}}$ transversally at $p$, the cylindrized product $L \times i\mathbb{R}$ is isomorphic in $\mathcal{W}(X \times \mathbb{C}, \mathfrak{h})$ to the linking disk at $p \times \infty$.

We discuss first the case that the generalized cocore in question $L$ is invariant under the Liouville flow. Consider isotoping the linking disk $i\mathbb{R}$ of $(\mathbb{C}, \{\pm \infty\})$ to make it (transversally) pass through $\infty$ (and thus become a zero object). The (cylindrized) product of this isotopy with $L$ passes through the product stop $\mathfrak{h}$ once, transversally, at $p \times \infty$ (note that this intersection occurs far away from where the product Lagrangian needs to be cylindrized, since $L$ is Liouville invariant). In view of the wrapping exact triangle and the fact (which follows from Künneth) that the product of anything with a zero object is again a zero object, we conclude that $L \times i\mathbb{R}$ is isomorphic in $\mathcal{W}(X \times \mathbb{C}, \mathfrak{h})$ to the linking disk of the product stop at $p \times \infty$, as desired.

For case of general (i.e. not necessarily globally Liouville invariant) $L$, fix a primitive $f : L \to \mathbb{R}$ of $\lambda_X|_L$. Using the argument from the proof of Lemma 6.1, we may assume that $f$ is compactly supported and that $\tilde{f}$ vanishes at the transverse intersection point $L \cap \mathfrak{c}_{X, f} = \{p\}$. We may thus extend $f$ to all of $X$ so as to be compactly supported and to vanish on a neighborhood of $\mathfrak{c}_{X, f}$, except possibly in a small neighborhood of $p$, where we may only demand that it vanish on $\mathfrak{c}_{X, f}$ itself. We now consider the family of stopped Liouville manifolds

$$(X \times \mathbb{C}, \lambda_X - t df + \lambda_\mathbb{C}, \partial_\infty (\mathfrak{c}_{X, f} \times \mathbb{R}))$$

(7.7)

for $t \in [0, 1]$. Note that, by definition, $X_f$ vanishes over $\mathfrak{c}_{X, f}$ except in a neighborhood of $q$ where it can be nonzero but tangent to $\mathfrak{c}_{X, f}$; hence $(\mathfrak{c}_{X, f} \times \mathbb{R})$ is indeed cylindrical at infinity, so the definition of the stop above makes sense (note that we make no claims about the core of $(X, \lambda_X - df)$). Moreover, this family of stopped Liouville manifolds is nice at infinity: the only changes at infinity occurs where the stop is just a smooth Legendrian, so the picture at infinity simply undergoes a global contact isotopy. In particular, the wrapped Fukaya categories are canonically identified, so to show agreement of $L \times i\mathbb{R}$ with the linking disk
in the category at $t = 0$, it suffices to show agreement in the category at $t = 1$. Now $L$ is invariant under the Liouville flow of the Liouville form $\lambda_X - df$, and hence the argument from the previous paragraph applies. 

8 Stopped inclusions

We now explore geometric conditions under which the pushforward functor on wrapped Fukaya categories $\mathcal{W}(X) \to \mathcal{W}(X')$ induced by an inclusion of Liouville sectors $X \hookrightarrow X'$ is fully faithful. A simple example of such a situation, namely when the wrapping in $X'$ was literally the same as the wrapping in $X$, was explored in Lemma 2.9. More generally, since wrapped Floer homology can be computed by wrapping only one factor, it is enough to assume that when Lagrangians inside $X$ are wrapped inside $X'$, they never re-enter $X$ after leaving. We introduce notions of forward stopped and tautologically forward stopped (and dually backward stopped) inclusions of Liouville sectors which are geometric conditions sufficient to ensure this, and hence to ensure full faithfulness of the pushforward functor on wrapped Fukaya categories. This notion depends only on the contact geometry of the boundary at infinity.

8.1 Review of convex hypersurfaces in contact manifolds

Recall that a compact cooriented hypersurface $H$ inside a cooriented contact manifold $Y$ is called convex iff there exists a contact vector field defined near $H$ which is positively transverse to $H$. Such a contact vector field determines a partition

$$H = H_+ \cup \Gamma H_-$$

where $\Gamma \subseteq H$ (called the dividing set) is a hypersurface transverse to the characteristic foliation (in particular, avoiding its singularities) and all of the positive (resp. negative) tangencies of $\xi$ to $H$ are contained in $H_+$ (resp. $H_-$. Namely, $H_\pm \subseteq H$ are the loci where the contact vector field $V$ is positively/negatively transverse to $\xi$, and they meet along the locus $\Gamma \subseteq H$ where $V \in \xi$. The dividing set $\Gamma$ is a transversely cut out hypersurface inside $H$ for every transverse contact vector field $V$, and is a contact submanifold of $Y$. The unique contact forms $\lambda_\pm$ on $Y$ defined near $H_\pm$ by $\lambda_\pm(V) = \pm 1$ restrict to Liouville forms on $H_\pm$ whose Liouville vector fields are tangent to the characteristic foliation. With these Liouville forms, $H_\pm$ are Liouville manifolds, whose contact boundaries are naturally identified with $\Gamma$.

The partition (8.1) depends on a choice of transverse contact vector field $V$. For a more invariant notion, we may pass to the cores $\epsilon_\pm H$ of $H_\pm$, which do not depend on the choice of $V$. The complement $H \setminus (\epsilon_+ H \cup \epsilon_- H)$ equipped with its characteristic foliation is (non-canonically) diffeomorphic to $\mathbb{R} \times \Gamma$ equipped with the foliation by $\mathbb{R} \times \{p\}$. We thus obtain the following canonical intrinsically defined structure:

$$\epsilon_+ H, \epsilon_- H \subseteq H \quad H \setminus (\epsilon_+ H \cup \epsilon_- H) \to \Gamma,$$

where the second map is projection along the characteristic foliation (i.e. the “contact reduction” of the ‘even contact manifold’ $H \setminus (\epsilon_+ H \cup \epsilon_- H)$. In particular, the contact manifold $\Gamma$ is defined intrinsically in terms of $H$. The image of any section of the projection
$H \setminus (c_{H_+} \cup c_{H_-}) \to \Gamma$ is the dividing set for some transverse contact vector field $V$. The characteristic foliation of $H$ is cooriented (by the coorientations on $H$ and $\xi$), and let us fix conventions so that this coorientation is outward pointing along $\partial H_+$. In particular, we have the following useful result:

**Lemma 8.1.** A subdomain $A \subseteq H$ is the “positive part” of some partition (8.1) associated to a transverse contact vector field iff $c_{H_+} \subseteq A \subseteq H \setminus c_{H_-}$ and the characteristic foliation is outwardly transverse to $\partial A$. More generally, a subdomain $A \subseteq H$ is a Liouville subdomain of the positive part of some partition (8.1) iff $A \subseteq H \setminus c_{H_-}$ and the characteristic foliation is outwardly transverse to $\partial A$. □

**Example 8.2.** Consider a Liouville pair $(\bar{X}, F)$. Choose a contact form near $F_0$ whose restriction to $F_0$ makes it a Liouville domain; this determines coordinates $\mathbb{R}_t \times F_0 \hookrightarrow \partial_\infty \bar{X}$ near $t = 0$ in which the contact form is given by $dt + \lambda F_0$. As in [26, Definition 2.14], removing $(\mathbb{R}_{t>0} \times \mathbb{R}_{|t|<\varepsilon} \times F_0^0, e^{\ast}(dt + \lambda F_0))$ from $\bar{X}$ yields a Liouville sector $X$. The boundary of $\partial_\infty X$ is thus $\partial(\mathbb{R}_{|t|\leq \varepsilon} \times F_0)$, which admits the transverse contact vector field $\frac{d}{dt} + Z_{F_0}$. The dividing set is thus $\{t = 0\}$, and the positive/negative cores are $\{t = \pm \varepsilon\} \times F_0$. Any Liouville subdomain of $F_0$, embedded inside either side $\{t = \pm \varepsilon\} \times F_0$, is a Liouville subdomain of the positive/negative parts of $\partial(\mathbb{R}_{|t|\leq \varepsilon} \times F_0)$.

### 8.2 Forward/backward stopped cobordisms and inclusions

We now define ‘forward stopped’ and ‘tautologically forward stopped’ inclusions of (stopped) Liouville sectors. Being (tautologically) forward stopped depends only on the contact boundary, and so we first define the corresponding notions for contact cobordisms. The dual notions of being (tautologically) backward stopped simply mean (tautologically) forward stopped after negating the Liouville form / the coorientation of the contact structure.

A **contact cobordism** shall mean a contact manifold-with-boundary $M$ whose boundary $\partial M$ is compact, convex, and has a specified decomposition into open pieces $\partial M = \partial_{in} M \sqcup \partial_{out} M$, with $\partial_{out} M$ cooriented in the outward direction and $\partial_{in} M$ in the inward direction. Note that $\partial M$ is required to be compact, but $M$ itself is not. Both $\partial_{in} M$ and $\partial_{out} M$ have positive and negative cores $c(\partial_{in} M)_{\pm}$ and $c(\partial_{out} M)_{\pm}$, respectively. Wrapping in $M$ will tend to push towards $c(\partial_{out} M)_{\pm}$ and away from $c(\partial_{in} M)_{\pm}$ (a convenient class of positive contact vector fields which does precisely this is constructed in [26, §2.9]).

![Figure 20: Deformation of $M$ so that $\partial_{in} M$ and $\partial_{out} M$ touch over $c(\partial_{in} M)_{+}$](image)

**Definition 8.3.** A contact cobordism $M$ is called **tautologically forward stopped** iff it admits a compactly supported deformation (through contact cobordisms) which makes $\partial_{in} M$ touch
\( \partial_{\text{out}} M \) over a neighborhood of the incoming positive core \( \mathcal{C}(\partial_{\text{in}} M)_{+} \) so that it is disjoint from the outgoing negative core \( \mathcal{C}(\partial_{\text{out}} M)_{-} \) (see Figure 20). (This final “pinched” object is not strictly speaking a manifold-with-boundary, so to make this discussion precise, one may work with contact cobordisms equipped with a germ of codimension zero embedding into a contact manifold.)

The contact cobordisms which we are interested in arise from inclusions of (possibly stopped) Liouville sectors. Recall that the contact boundary \( \partial_{\infty} X \) of a Liouville sector \( X \) is a compact cooriented contact manifold with convex boundary \( \partial \partial_{\infty} X \). We coorient this boundary in the outward direction, so positive wrapping inside \( X \) will tend to push Lagrangians towards the positive core \( \mathcal{C}(\partial_{\infty} X)_{+} \). In the presence of a stop \( f \subseteq (\partial_{\infty} X)^{\circ} \) which does not approach the boundary \( \partial \partial_{\infty} X \), the relevant cooriented contact manifold with convex boundary is \( \partial_{\infty} X \setminus f \). For an inclusion of Liouville sectors \( X \hookrightarrow X' \), the difference of their boundaries \( M = \partial_{\infty}(X' \setminus X^{\circ}) \) is a contact cobordism, with \( \partial_{\text{in}} M = \partial \partial_{\infty} X \) and \( \partial_{\text{out}} M = \partial \partial_{\infty} X' \). More generally, for an inclusion of stopped Liouville sectors \( (X, f) \hookrightarrow (X', f') \) satisfying the (rather strong) condition that \( f = f' \cap (\partial_{\infty} X)^{\circ} \) and \( f' \) does not approach \( \partial_{\infty} X \) or \( \partial_{\infty} X' \), we may consider the contact cobordism \( M = \partial_{\infty}(X' \setminus X^{\circ}) \setminus f' \).

**Definition 8.4.** An inclusion of stopped Liouville sectors \( (X, f) \hookrightarrow (X', f') \) (satisfying \( f = f' \cap (\partial_{\infty} X)^{\circ} \) and that \( f' \) does not approach \( \partial_{\infty} X \) or \( \partial_{\infty} X' \)) is called tautologically forward stopped iff the associated contact cobordism is.

**Example 8.5.** Consider a Liouville sector \( X \) including into a slight enlargement \( X^{+} \) of itself, defined by flowing out by the Hamiltonian flow of a defining function for unit time. Then \( M = \partial_{\infty}(X^{+} \setminus X^{\circ}) \) is a contact cylinder, and shrinking \( X^{+} \) back down to \( X \) defines a pinching of \( M \) which shows that \( X \hookrightarrow X^{+} \) is tautologically forward stopped. Hence every trivial inclusion of Liouville sectors \( X \hookrightarrow X' \) is tautologically forward stopped (a trivial inclusion may, by definition, be deformed to \( X \hookrightarrow X^{+} \)).

**Example 8.6.** Let \( X \hookrightarrow X' \) be an arbitrary inclusion of Liouville sectors (which may or may not be tautologically forward stopped); we will show how to modify \( X' \) to make this inclusion tautologically forward stopped. We consider the Liouville hypersurface in \( \partial_{\infty} X' \) defined as a small outward pushoff of some choice of positive part \( (\partial \partial_{\infty} X)_{+} \subseteq \partial \partial_{\infty} X \) (in the sense of (8.1)). Removing from \( X' \) a neighborhood of this Liouville hypersurface as in Example 8.2 defines a Liouville sector \( \tilde{X}' \). Translating this excised neighborhood of the Liouville hypersurface back towards \( \partial \partial_{\infty} X \) shows that the inclusion \( X \hookrightarrow \tilde{X}' \) is tautologically forward stopped. The arbitrary inclusion \( X \hookrightarrow X' \) is thus factored into the tautologically forward stopped inclusion \( X \hookrightarrow \tilde{X}' \) (fully faithful on wrapped Fukaya categories by Corollary (8.13)) and the stop removal inclusion \( \tilde{X}' \hookrightarrow X' \) (a localization on wrapped Fukaya categories if \( (\partial \partial_{\infty} X)_{+} \) is Weinstein by Theorem 1.16).

**Example 8.7.** Consider a Liouville sector \( X \) with \( F \) (a component of) its symplectic boundary. There is an inclusion of Liouville sectors \( F \times T^{*}[0,1] \to X \), giving coordinates on a neighborhood of (a component of) the boundary of \( X \). This inclusion is not usually tautologically forward stopped: \( \partial(F \times T^{*}[0,1]) = F \times (T_{0}^{*}[0,1] \cup T_{1}^{*}[0,1]) \), and only one of these components is tautologically forward stopped using \( \partial X \). We can stop the other component by adding a stop to \( X \) as in the previous Example 8.6. Equivalently, we could apply Example 8.6 directly to the inclusion \( F \times T^{*}[0,1] \to X \) where \( X \) is the convex completion of \( X \).
along the boundary component $F$. The result is a tautologically forward stopped inclusion from $F \times T^*[0,1]$ into $\tilde{X}$ stopped at $F_0$ and a small positive pushoff $F_0^+$ thereof. Combining this with the K"unneth stabilization functor, we obtain (using Corollary 8.13 below) a fully faithful embedding $\mathcal{W}(F) \hookrightarrow \mathcal{W}(\tilde{X}, F \cup F^+)$. The properties of tautologically forward stopped inclusions which are relevant to controlling wrapping are in fact shared by a more general class we term simply forward stopped inclusions. In addition to being more general, the notion of forward stopped inclusions will be more immediately connected to the geometry of wrapping. However, in applications, we have found that the forward stopped inclusions of interest are in fact tautologically forward stopped.

![Figure 21: Schematic diagram of the codimension zero submanifold-with-boundary $W$ and the contact vector field $V$ certifying that a contact cobordism $M$ is forward stopped.](image)

**Definition 8.8.** A contact cobordism $M$ is called *forward stopped* iff there exists a closed subset $W \subseteq M$ and a positive contact vector field $V$ defined over $\text{Nbd} \partial W$ (where $\partial W \subseteq M$ denotes the boundary in the point set topological sense) satisfying the following conditions (in which case we say $M$ is *forward stopped by* $W$ or $(W, V)$ or that $W$ or $(W, V)$ is a *forward stopping witness for* $M$):

(i) $\partial W$ is compact.

(ii) $W$ is sent into itself by the forward flow of $V$, namely for every trajectory $\gamma : [0, \varepsilon) \rightarrow M$ of $V$ with $\gamma(0) \in W$, we have $\gamma(t) \in W$ for all $t \in [0, \varepsilon)$.

(iii) $V$ is inward pointing along $\partial_{in} M$.

(iv) $V$ is outward pointing along $\partial_{out} M$.

(v) $W \cap \partial_{in} M \subseteq \partial_{in} M$ is the "positive piece" $(\partial_{in} M)_+$ in some partition (8.1) of $\partial_{in} M$.

(vi) $W \cap \partial_{out} M \subseteq \partial_{out} M$ is a Liouville subdomain of the "positive piece" $(\partial_{out} M)_+$ in some partition (8.1) of $\partial_{out} M$. 

72
(Recall Lemma 8.1 for equivalent formulations of (v)–(vi).) The adjective ‘forward stopped’ may also be applied to inclusions of stopped Liouville sectors as in Definition 8.4.

The point of Definition 8.8 is that nothing escapes from $W$ under the flow of suitably chosen positive contact vector fields (a precise such statement is given in Proposition 8.12 and its proof).

**Lemma 8.9.** Given a contact cobordism $M$ and a forward stopping witness $(W, V)$, there exist contact vector fields $T_{\text{in}}$ and $T_{\text{out}}$ inwardly/outwardly transverse to $\partial_{\text{in}}M$ and $\partial_{\text{out}}M$ which coincide with $V$ over $\text{Nbd}(\partial_{\text{in}}M \cap \partial W)$ and $\text{Nbd}(\partial_{\text{out}}M \cap \partial W)$, respectively.

**Proof.** This follows from conditions (iii)–(vi) and the discussion in §8.1. □

**Proposition 8.10.** The property of being forward stopped is invariant under compactly supported deformation of contact cobordisms.

Despite its aesthetic appeal, from a logical standpoint this result is unnecessary in view of [26, Lemmas 2.9 and 3.41].

**Proof.** A deformation of $M$ is smoothly trivial, so we may regard $M$ as fixed and only the contact structure $\xi$ as varying. Fix a forward stopping witness $(W^0, V^0)$ for $(M, \xi^0)$. Let $T_{\text{in}}$ and $T_{\text{out}}$ be a family of inward/outward pointing contact (with respect to $\xi^t$) vector fields defined over $\text{Nbd}(\partial_{\text{in}}M, \xi)$ and $\text{Nbd}(\partial_{\text{out}}M, \xi)$, respectively, so that at time $t = 0$ they agree with $V^0$ as in Lemma 8.9. By modifying our smooth trivialization, we may assume that $T_{\text{in}}^t$ and $T_{\text{out}}^t$ are independent of $t$, so let us just denote them by $\frac{\partial}{\partial r}$.

Let $\hat{M}$ denote the completion of $M$ obtained by gluing on cylindrical ends $\mathbb{R}_{\leq 0} \times \partial_{\text{in}}M$ and $\mathbb{R}_{\geq 0} \times \partial_{\text{out}}M$ via $\frac{\partial}{\partial r}$; we may extend $\xi_t$ to be $\frac{\partial}{\partial r}$-invariant in these ends. We may also extend $W^0 \subseteq M$ to $\hat{W}^0 \subseteq \hat{M}$ by gluing on $\mathbb{R}_{\leq 0} \times (W \cap \partial_{\text{in}}M)$ and $\mathbb{R}_{\geq 0} \times (W \cap \partial_{\text{out}}M)$. Note that the family $(M, \xi^t)$ is contactomorphic to $M_R := M \cup ([-N, 0] \times \partial_{\text{in}}M) \cup ([0, N] \times \partial_{\text{out}}M)$ equipped with $\xi^t$ (to see this, it is enough to cut off the contact vector field $\frac{\partial}{\partial r}$ to make it supported in a small neighborhood of $\partial M$ and then use its flow). Hence it is enough to show that $(M_R, \xi^1)$ is forward stopped. Note that $(M_R, \xi^0)$ is forward stopped, as witnessed by $\hat{W}^0$ and the splicing of $V^0$ with $\frac{\partial}{\partial r}$.

By Gray’s theorem, there is a unique family of vector fields $X_t \in \xi_t$ satisfying $\mathcal{L}_{X_t} \xi_t = \frac{\partial}{\partial r} \xi_t$; uniqueness shows that $X_t$ commutes with $\frac{\partial}{\partial r}$ in the cylindrical ends. If $M$ is non-compact, then note that $X_t$ are supported away from this non-compactness, since by assumption our given deformation is compactly supported. We may now simply flow the stopping witness for $(M_R, \xi^0)$ under $X_t$ to obtain one for $(M_R, \xi^1)$ (we should take $R$ large enough so that the flowed witness remains cylindrical outside $M_R$). □

**Proposition 8.11.** A tautologically forward stopped contact cobordism may be deformed (away from infinity) to be forward stopped.

**Proof.** We will show that (a small deformation of) the limiting pinched cobordism $M$ from Definition 8.3 is forward stopped. By translating $\partial_{\text{in}}M$ outward by its transverse contact vector field $V$, we obtain a genuine contact cobordism $M'$. Let $W \subseteq M'$ be the cylinder over (i.e. the sweepout under $V$ of) a small Liouville domain neighborhood of $\xi(\partial_{\text{in}}M) \subseteq \partial_{\text{in}}M$. 73
Using Lemma 8.1, we see that $W \cap \partial_n M'$ is indeed the positive piece $(\partial_n M')_+$ in some partition (8.1) and that $W \cap \partial_{\text{out}} M'$ is a Liouville subdomain of $(\partial_{\text{out}} M')_+$ in some partition. The vector field $V$ is tangent to $\partial W$ and thus $W$ is a stopping witness for $M$. \hfill \Box

We now argue that being forward stopped tells us something about wrapping, namely, that if $Y \hookrightarrow Y'$ is forward stopped, then if we wrap a given Legendrian submanifold of $Y$ inside $Y'$, once it exits $Y$ it stays within $W$ and never returns to $Y$. More precisely, such wrappings (those which stay inside $W$ and never return to $Y$) are cofinal in all wrappings (wrapping which exit $W$ can of course exist; the claim is simply that they can be ignored for the purposes of calculating wrapped Floer cohomology).

Proposition 8.12. Suppose $Y \hookrightarrow Y'$ is forward stopped by $W$, and let $\Lambda \subseteq Y^{\circ}$ be a compact Legendrian submanifold. Consider wrappings $\Lambda \hookrightarrow \Lambda^{w}$ inside $Y^{\circ}$ followed by wrappings $\Lambda^{w} \hookrightarrow \Lambda^{ww}$ inside $(Y')^{\circ}$ supported inside (i.e. fixed outside) $W$ union any fixed small neighborhood of $W \cap \partial Y$ inside $Y$ and of $W \cap \partial Y'$. The collection of all such compositions $\Lambda \hookrightarrow \Lambda^{ww}$ is cofinal in the wrapping category of $\Lambda$ inside $Y$.

Proof. Fix a positive contact vector field $V$ defined over $\text{Nbd} \partial W$ satisfying the conditions of Definition 8.8. Fix contact vector fields $T$ and $T'$ outwardly transverse to $\partial Y$ and $\partial Y'$ as in Lemma 8.9. We use these transverse contact vector fields to fix coordinates near $\partial Y$ and $\partial Y'$ as in [26, §2.9]. We also fix contact forms near $\partial Y$ and $\partial Y'$ as in [26, §2.9 Equations (2.22) and (2.26)] which evaluate to 1 on $T$ and $T'$ over $\text{Nbd}(W \cap \partial Y)$ and $\text{Nbd}(W \cap \partial Y')$. In particular, over $\text{Nbd}(W \cap \partial Y)$ and $\text{Nbd}(W \cap \partial Y')$, we have coordinates $\mathbb{R}_{t \geq 0} \times (W \cap \partial Y)$ and $\mathbb{R}_{t \geq 0} \times (W \cap \partial Y')$ (respectively) in which $T$ and $T'$ equal $-\frac{\partial}{\partial t}$ and the contact form equals $\lambda - dt$ and $\lambda' - dt$ for Liouville forms $\lambda$ and $\lambda'$ on $W \cap \partial Y$ and $W \cap \partial Y'$.

Figure 22: The positive contact vector fields $V_1$ (left) and $V_2$ (right).

We define a positive contact vector field $V_1$ on $Y$ as follows. Near $\partial Y$, we define $V_1$ by a contact Hamiltonian of the form $M(t)$ satisfying $M(0) = M'(0) = 0$ and $M(t), M'(t) > 0$ for $t > 0$, thus of the form [26, §2.9 Equations (2.23) and (2.29)] with the resulting excellent dynamics near $\partial Y$. In particular, in the coordinates $\mathbb{R}_{t \geq 0} \times (W \cap \partial Y)$ over $\text{Nbd}(W \cap \partial Y)$, we have

$$V_1 = -M'(t)Z_{\lambda} - M(t) \frac{\partial}{\partial t}. \quad (8.3)$$
We extend $V_1$ to all of $Y$ to be complete (this is possible since $\partial W$ is compact: use the argument in the proof of [26, Lemma 3.29]). The vector field $V_1$ is illustrated on the left of Figure 22.

We now define a positive contact vector field $V_2$ on $Y'$. The contact vector field $V_2$ is obtained from $V_1$ by modifying $M(t)$ in a very small neighborhood of $\partial Y$ to not decay to zero but rather to a very small constant $\varepsilon > 0$. Thus $V_2$ equals $-\varepsilon \frac{\partial}{\partial t} = \varepsilon T = \varepsilon V$ over $\text{Nbd}(\partial Y \cap \partial W)$, and we extend $V_2$ to all of $\text{Nbd} \partial W$ as $\varepsilon \cdot V$. Near $\partial Y'$ we declare $V_2$ to again be given by a contact Hamiltonian of the form $N(t)$ satisfying $N(0) = N'(0) = 0$ and $N(t), N'(t) > 0$ for $t > 0$ and equalling $\varepsilon$ outside a very small neighborhood of $t = 0$. Examining the resulting form

$$V_2 = -N'(t)Z_M - N(t)\frac{\partial}{\partial t}$$  \hspace{1cm} (8.4)

over $\text{Nbd}(W \cap \partial Y')$, we see that the flow of $V_2$ attracts towards $W \cap \partial Y'$ in a neighborhood. We extend $V_2$ to the rest of $Y'$ to be complete. The vector field $V_2$ is illustrated on the right of Figure 22.

We now analyze the effect of flowing a given compact Legendrian $\Lambda \subseteq Y'$ under $V_1$ and/or $V_2$. The image of $\Lambda$ under the forward flow of $V_1$ is bounded away from $\partial Y$ except for a neighborhood of $e^{(\partial Y)_+} \subseteq (W \cap \partial Y)$ (this follows from the explicit form of $V_1$ near $\partial Y$, see [26, §2.9 Equations (2.23) and (2.29) and Proposition 2.35]). Hence, fixing such a $\Lambda$, we may choose the modification $V_2$ of $V_1$ to take place in a sufficiently small neighborhood of $\partial Y$ so as to ensure that the forward flow of $\Lambda$ under $V_2$ exits $Y'$ only along (the interior of) $W \cap \partial Y$.

Now $V_2$ is weakly inward pointing along $\partial W$, so the forward flow of $\Lambda$ under $V_2$ either stays entirely within $Y$ or exits $Y$ along $W \cap \partial Y$ and then stays entirely within $W$ (except over a small neighborhood of $W \cap \partial Y'$, where it is not necessarily weakly inward pointing along $\partial W$, but nevertheless attracts towards $W \cap \partial Y'$). Furthermore, the same holds for the flow of $\Lambda$ under $aV_2 + (1 - a)V_1$ for any $a \in [0, 1]$.

With our vector fields $V_1$ and $V_2$ defined and their dynamics understood, we may now conclude the proof. The family of wrappings $\Lambda \rightsquigarrow e^{NV_2} \Lambda$ is cofinal, since $V_2$ is a complete positive contact vector field on $(Y')^\circ$ (use Lemma 2.1). These wrappings may be factorized as $\Lambda \rightsquigarrow e^{NV_1} \Lambda \rightsquigarrow e^{NV_2} \Lambda$, where the second positive isotopy is $e^{N(aV_2 + (1 - a)V_1)} \Lambda$ for $a \in [0, 1]$. The first isotopy $\Lambda \rightsquigarrow e^{NV_1} \Lambda$ clearly takes place entirely inside $Y$. The second isotopy $e^{N(aV_2 + (1 - a)V_1)} \Lambda$ is supported inside $W$ union a small neighborhood of $W \cap \partial Y$ inside $Y$ and of $W \cap \partial Y'$. Indeed, the only points which move during this isotopy are those corresponding to trajectories which have reached a place where $V_1$ and $V_2$ differ, and such trajectories can only end inside $W$ union a small neighborhood of $W \cap \partial Y'$ inside $Y$ and of $W \cap \partial Y'$. $\square$

**Corollary 8.13.** Let $(X, f) \hookrightarrow (X', f')$ be an inclusion of stopped Liouville sectors which is forward stopped by $W$. The pushforward functor $\mathcal{W}(X, f) \rightarrow \mathcal{W}(X', f')$ is fully faithful, and its image is left-orthogonal to every $K \subseteq X'$ (disjoint from $f'$ at infinity) which is disjoint from $X$ and disjoint at infinity from $W$.

**Proof.** For full faithfulness, we just need to argue that $HW^*(L, K)_X, f \rightarrow HW^*(L, K)_{X', f'}$ is a quasi-isomorphism. According to Proposition 8.12, wrapping $L$ inside $X'$ away from $f'$ may be described by first wrapping $L \rightsquigarrow L^w$ inside $X$ away from $f$, and then wrapping
$L^u \sim L^{uw}$ inside $W$ (union a small neighborhood of $\partial W$). The second wrapping is disjoint from $\partial_\infty K \subseteq \partial_\infty X$, and hence the map $HF^\bullet(L^u, K) \xrightarrow{\sim} HF^\bullet(L^{uw}, K)$ is an isomorphism (e.g. by the last property from [26, Lemma 3.26]). Taking the direct limit over pairs of wrappings $L \sim L^u \sim L^{uw}$ yields the map $HF^\bullet(L, K) \xrightarrow{\sim} HF^\bullet(L^w, K)$ which is thus also an isomorphism.

The argument for orthogonality is the same: if $K \cap X = \emptyset$ and $\partial_\infty K \cap W = \emptyset$, then every $L \subseteq X$ has cofinal wrappings away from $K$, and hence the direct limit computing $HW^\bullet(L, K)$ vanishes.

8.3 Viterbo restriction

As an illustration of the use of forward stopped inclusions, we implement a proposal of Sylvan [43] for defining a restriction functor (conjecturally agreeing with Abouzaid–Seidel’s Viterbo restriction functor [6] on the domain of the latter).

Let $X^\text{in}_0 \subseteq X_0$ be an inclusion of Liouville domains, with completions $X^\text{in}$ and $X$. Given any Liouville manifold $W$ and an embedding of $X_0$ as a Liouville hypersurface inside $\partial_\infty W$, we may consider the diagram

\[
\begin{array}{ccc}
W(X) & \longrightarrow & W(W, \mathfrak{c}_X) \\
\downarrow & & \downarrow \\
W(X^\text{in}) & \longrightarrow & W(W, \mathfrak{c}_{X^\text{in}}),
\end{array}
\]  

(8.5)

where the horizontal arrows are given by the composition of the K"unneth stabilization functor $W(X) \rightarrow W(X \times T^*[0,1])$ with pushing forward under the tautological inclusion $X \times T^*[0,1] \hookrightarrow (W, \mathfrak{c}_X)$ near the stop $\mathfrak{c}_X$. Given this diagram, it is natural to ask whether there is a natural functor $W(X) \rightarrow W(X^\text{in})$ making the diagram commute. Sylvan conjectured that Abouzaid–Seidel’s (partially defined) functor $W(X) \rightarrow W(X^\text{in})$ is such a functor. Sylvan also observed that, in the opposite direction, one may, under certain assumptions, use the diagram (8.5) in the special (in fact, universal) case $W = X \times \mathbb{C}_{Re \geq 0}$ to define a priori a restriction functor $T wW(X) \rightarrow TwW(X^\text{in})$, and conjectured that this recovers Abouzaid–Seidel’s restriction functor on the domain of the latter.

To spell this out, observe that the inclusions of Liouville sectors

\[
X \times T^*[0,1] \hookrightarrow (X \times \mathbb{C}_{Re \geq 0}) \setminus \text{Nbd}(X_0 \times \{\infty\}),
\]

(8.6)

\[
X^\text{in} \times T^*[0,1] \hookrightarrow (X \times \mathbb{C}_{Re \geq 0}) \setminus \text{Nbd}(X^\text{in}_0 \times \{\infty\}),
\]

(8.7)

are tautologically forward stopped (by following the trivial open book for the contact boundary of $X \times \mathbb{C}$), and hence induce fully faithful pushforward functors. K"unneth stabilization is always fully faithful, so we have a diagram whose horizontal arrows are fully faithful embeddings:

\[
\begin{array}{ccc}
W(X) & \longrightarrow & W(X \times \mathbb{C}_{Re \geq 0}, \mathfrak{c}_X) \\
\downarrow & & \downarrow \\
W(X^\text{in}) & \longrightarrow & W(X \times \mathbb{C}_{Re \geq 0}, \mathfrak{c}_{X^\text{in}}),
\end{array}
\]  

(8.8)
(where we have used Corollary 2.11 to relate the categories on the right with those on the right of (8.6)–(8.7)). If \( X^{\text{in}} \) is Weinstein, then Theorem 1.13 implies that the bottom horizontal arrow is essentially surjective on twisted complexes, and is thus a pre-triangulated equivalence. Hence inverting it defines a restriction functor
\[
\text{Tw} \mathcal{W}(X) \to \text{Tw} \mathcal{W}(X^{\text{in}})
\]  
(8.9)
making \( \text{Tw} (8.8) \) commute. In fact, by pushing forward under the canonical embedding \( X \times \mathbb{C}_{\mathbb{R}_{\geq 0}} \to W \) near a Liouville hypersurface \( X_0 \hookrightarrow \partial_\infty W \), we see that this restriction functor (8.9) makes \( \text{Tw} (8.5) \) commute as well.

**Remark 8.14.** The assumption that \( X^{\text{in}} \) is Weinstein is used only to ensure essential surjectivity of \( \mathcal{W}(X^{\text{in}}) \to \mathcal{W}(X \times \mathbb{C}_{\mathbb{R}_{\geq 0}}, c_{X^{\text{in}}}) \); the restriction functor (8.9) is defined whenever this holds. More generally, one may define a “Viterbo \( (\mathcal{W}(X), \mathcal{W}(X^{\text{in}})) \)-bimodule” from (8.8) by pulling back the diagonal bimodule from \( \mathcal{W}(X \times \mathbb{C}_{\mathbb{R}_{\geq 0}}, c_{X^{\text{in}}}) \) and ask whether it is representable (possibly by a twisted complex) and thus defines a functor (8.9). It seems plausible that one could use geometric arguments to show this representability for any inclusion of Liouville domains \( X^{\text{in}}_0 \subseteq X_0 \), possibly leading to a favorable comparison with the construction of Abouzaid–Seidel [6].

If we assume that both \( X^{\text{in}}_0 \) and the cobordism \( X_0 \setminus X^{\text{in}}_0 \) are Weinstein (up to deformation), then we can say more about the restriction functor (8.9) and the commutative diagrams (8.5):

**Proposition 8.15.** Suppose both \( X^{\text{in}}_0 \) and \( X_0 \setminus X^{\text{in}}_0 \) are Weinstein. The restriction functor (8.9) is the quotient by the cocores of \( X \) not in \( X^{\text{in}} \), and the diagram
\[
\begin{array}{ccc}
\text{Tw} \mathcal{W}(X) & \longrightarrow & \text{Tw} \mathcal{W}(W, \mathcal{f} \cup c_X) \\
\downarrow \text{(8.9)} & & \downarrow \\
\text{Tw} \mathcal{W}(X^{\text{in}}) & \longrightarrow & \text{Tw} \mathcal{W}(W, \mathcal{f} \cup c_{X^{\text{in}}})
\end{array}
\]
(8.10)
is a homotopy pushout for any stopped Liouville sector \( (W, \mathcal{f}) \) with an embedding \( X_0 \hookrightarrow (\partial_\infty W)^c \setminus \mathcal{f} \) as a Liouville hypersurface.

**Proof.** Since both \( X \) and \( X^{\text{in}} \) are Weinstein, both horizontal functors in (8.8) are essentially surjective on twisted complexes by Theorem 1.13 and are thus pre-triangulated equivalences. The right vertical functor is the quotient by the linking disks of \( c_X \setminus c_{X^{\text{in}}} \) by Theorem 1.16. Since these are precisely the images of the cocores of \( X \) not in \( X^{\text{in}} \), it follows by definition that (8.9) is the quotient by the same.

Now going in the reverse direction, the vertical maps in (8.10) are, respectively, quotienting by the cocores of \( X \) not in \( X^{\text{in}} \) and quotienting by their images the linking disks to \( c_X \setminus c_{X^{\text{in}}} \). We thus conclude that (8.10) is a homotopy pushout by Lemma A.6.

9 Descent formulae

9.1 Homotopy pushout formula

Contrary to the proof sketched in §1.8, the proof of Theorem 1.20 we give here does not depend on having defined homotopy pushouts of \( A_\infty \)-categories in terms of the Grothendieck
construction, rather we will only appeal to Lemma A.6 (compatibility of homotopy colimits with quotients) and Proposition A.9.

Proof of Theorem 1.20. Our first task is simply to setup nice coordinates near the splitting hypersurface \( X_1 \cap X_2 \). To construct these coordinates, we will deform the Liouville form on \( X \) near the splitting hypersurface; this is permitted since such a deformation does not affect the validity of the statement we are trying to prove. The discussion surrounding [26, Proposition 2.25] shows that there exist coordinates near \( X_1 \cap X_2 \) of the form \((F \times T^*[0,1], \lambda_F + \lambda_{T}[0,1] + df)\) where \( f : F \times T^*[0,1] \rightarrow \mathbb{R} \) has proper support over \( T^*[0,1] \) and \( f = f_{\pm} : F \rightarrow \mathbb{R} \) away from a compact subset of \( T^*[0,1] \) and \( X_1 \cap X_2 = F \times N^*[\frac{1}{7}, \frac{1}{7}] \). By assumption, the Liouville manifold \((F, \lambda_F)\) is Weinstein up to deformation, namely there exists a compactly supported function \( g : F \rightarrow \mathbb{R} \) such that \((F, \lambda_F + dg)\) is Weinstein. We may, of course, absorb \( g \) into \( f \) so that \((F, \lambda_F)\) is itself Weinstein. We now consider the obvious linear deformation of Liouville forms between \( \lambda_F + \lambda_{T}[0,1] + df \) and \( \lambda_F + \lambda_{T}[0,1] + d(\varphi(t)f) \) where \( \varphi : [0,1] \rightarrow [0,1] \) is smooth and equals 1 near the boundary and equals 0 near \( t = \frac{1}{2} \). A calculation as in [26, Proposition 2.28] shows that convexity at infinity is preserved under this deformation. Since \( \varphi \) vanishes in a neighborhood of \( t = \frac{1}{2} \), in this deformed Liouville manifold there now exist coordinates \((F \times T^*[0,1], \lambda_F + \lambda_{T}[0,1]) \rightarrow (X, \lambda_X)\) (9.1) strictly respecting the Liouville form, where \((F, \lambda_F)\) is Weinstein, and locally \( X_1 = \{ t \leq \frac{1}{7} \} \) and \( X_2 = \{ t \geq \frac{1}{7} \} \).

Let \( X_1^+ \) denote a small enlargement of \( X_1^+ \), namely locally \( X_1^+ = \{ t \leq \frac{1}{7} \} \) and \( X_2^+ = \{ t \geq \frac{3}{7} \} \), so \( X_1^+ \cap X_2^+ = F \times T^*[\frac{3}{7}, \frac{4}{7}] \) (see Figure 23). There is thus a diagram of \( A_\infty \)-categories, well defined up to quasi-equivalence,

\[
\begin{array}{ccc}
\mathcal{W}(F \times T^*[\frac{3}{7}, \frac{4}{7}]) & \longrightarrow & \mathcal{W}(X_1^+, \mathfrak{r}_1) \\
\downarrow & & \downarrow \\
\mathcal{W}(X_2^+, \mathfrak{r}_2) & \longrightarrow & \mathcal{W}(X, \mathfrak{r}_1 \cup \mathfrak{r}_2)
\end{array}
\] (9.2)
as constructed in §2.3. (Note that the stop \( \mathfrak{r} = \mathfrak{r}_1 \cup \mathfrak{r}_2 \) is disjoint from the chart (9.1) near \( X_1 \cap X_2 \) constructed above.) It is this diagram of \( A_\infty \)-categories which we would like to show is an almost homotopy pushout.

We now introduce more stops into the picture, namely at \( F_0 \times \{ \infty \cdot dt \} \times \{ t = \frac{2}{7} \} \) and \( F_0 \times \{ -\infty \cdot dt \} \times \{ t = \frac{2}{7} \} \), where \( F_0 \subseteq F \) denotes any Liouville domain whose completion is \( F \). We denote the resulting Liouville sectors by \( \tilde{X} \) and \( \tilde{X}_1^+ \); note that we still have \( \tilde{X}_1^+ \cap \tilde{X}_2^+ = X_1^+ \cap X_2^+ = F \times T^*[\frac{3}{7}, \frac{4}{7}] \) since the added stops lie outside the region \([\frac{3}{7}, \frac{4}{7}]\). There is thus a corresponding diagram of \( A_\infty \)-categories

\[
\begin{array}{ccc}
\mathcal{W}(F \times T^*[\frac{3}{7}, \frac{4}{7}]) & \longrightarrow & \mathcal{W}(\tilde{X}_1^+, \mathfrak{r}_1) \\
\downarrow & & \downarrow \\
\mathcal{W}(\tilde{X}_2^+, \mathfrak{r}_2) & \longrightarrow & \mathcal{W}(\tilde{X}, \mathfrak{r}_1 \cup \mathfrak{r}_2).
\end{array}
\] (9.3)

There is a map of diagrams (9.3) \( \rightarrow (9.2) \). By stop removal Theorem 1.16 (after shrinking the stops modelled on \( F_0 \) down to their cores), each of the four maps comprising this map of
diagrams is a quotient by the linking disks of the stops. Thus by Lemma A.6, to show that (9.2) is an almost homotopy pushout, it suffices to show that (9.3) is an almost homotopy pushout.

We now argue that (9.3) is an almost homotopy pushout by appealing to Proposition A.9 (in other words, we wish to show that (9.3) has, up to pre-triangulated equivalence, the same shape as in Example A.10). Let us first argue that the functors comprising (9.3) are all fully faithful. By Corollary 8.13, it is enough to check that each of the corresponding inclusions of Liouville sectors is tautologically backward stopped. We consider the inclusion $(\tilde{X}_1^+, r_1) \hookrightarrow (\tilde{X}, r_1 \cup r_2)$. The incoming core of the boundary of $\partial_\infty \tilde{X}_1^+$ is given by $c_F \times \{-\infty \cdot dt\} \times \{t = \frac{4}{7}\}$, and dragging the stop $F_0 \times \{-\infty \cdot dt\} \times \{t = \frac{5}{7}\}$ from $t = \frac{5}{7}$ to $t = \frac{4}{7}$ shows that this inclusion is tautologically backward stopped (compare Examples 8.6–8.7). Identical considerations show that all the inclusions of Liouville sectors forming the diagram (9.3) are tautologically backward stopped, and so the functors are fully faithful.

Let us now ask for the left-orthogonal complements of $\mathcal{W}(F \times T^*[\frac{3}{7}, \frac{4}{7}])$ inside $\mathcal{W}(\tilde{X}_1^+, r_i)$ for $i = 1, 2$. The Lagrangians inside $\{t \leq \frac{5}{7}\}$ (for $i = 1$) or $\{t \geq \frac{6}{7}\}$ (for $i = 2$) are left-orthogonal to $\mathcal{W}(F \times T^*[\frac{3}{7}, \frac{4}{7}])$ by Corollary 8.13. Together with $\mathcal{W}(F \times T^*[\frac{3}{7}, \frac{4}{7}])$, these Lagrangians generate $\mathcal{W}(\tilde{X}_1^+, r_i)$ for $i = 1, 2$ by the wrapping exact triangle (push any Lagrangian until it lies in $\{t \leq \frac{1}{7}\}$ or $\{t \geq \frac{6}{7}\}$; this costs some number of linking disks, but these are generated by the subcategories in question by applying Künneth to $T^*[0, 1]$ with a stop times $F$). The Lagrangians inside $\{t \leq \frac{1}{7}\}$ and $\{t \geq \frac{6}{7}\}$ thus split-generate the “right-new” objects. Their images in $\mathcal{W}(\tilde{X}, r_1 \cup r_2)$ are mutually orthogonal by Corollary 8.13, which finishes off the verification of the hypotheses of Proposition A.9. We have thus shown that (9.3) (and hence (9.2)) is an almost homotopy pushout, as desired.  

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure23.png}
\caption{Liouville sectors $X_i^+$ near the chart (9.1), with two dots indicating the location of the stops imposed to obtain $\tilde{X}_i^+$. The arrows indicate the direction of the Reeb flow.}
\end{figure}
9.2 Effect of Weinstein handle attachment

Proof of Corollary 1.21. Fix a stopped Liouville sector \((X^{\text{in}}, f^{\text{in}})\) of dimension \(2n\), and let \(\Lambda^{k-1} \subseteq (\partial_{\infty}X^{\text{in}})^{\circ} \setminus f^{\text{in}}\) be a parameterized isotropic sphere with a trivialization of its symplectic normal bundle (i.e. the data for attaching a Weinstein \(k\)-handle). Let \(X\) be the result of attaching a Weinstein \(k\)-handle to \(X^{\text{in}}\) along \(\Lambda\). There is an open embedding \(\partial_{\infty}X^{\text{in}} \setminus \Lambda \hookrightarrow \partial_{\infty}X\), and we let \(f\) denote the image of \(f^{\text{in}}\) under this embedding. We may view \(X\) as a gluing or union in the sense of Theorem 1.20 (see also [22, §3.1]) of:

(i) \(X_1 := X^{\text{in}}_\Lambda\), defined as \(X^{\text{in}}\) with an added stop along \(\Lambda\) (or rather the corresponding Liouville sector \(X^{\text{in}} \setminus \text{Nbd } \Lambda\); note that \(\Lambda\) comes with a canonical Weinstein ribbon \(T^*\Lambda \times \mathbb{C}^{n-k}\) since its symplectic normal bundle is trivialized as part of the handle attaching data), and

(ii) \(X_2 := T^*B^k \times \mathbb{C}^{n-k}\), along \(T^*(S^{k-1} \times (-\varepsilon, \varepsilon)) \times \mathbb{C}^{n-k}\).

It follows that there is an almost homotopy pushout

\[
\begin{array}{ccc}
\mathcal{W}(T^*(S^{k-1} \times [0,1]) \times \mathbb{C}^{n-k}) & \longrightarrow & \mathcal{W}(X^{\text{in}}_\Lambda, f^{\text{in}}) \\
\downarrow & & \downarrow \\
\mathcal{W}(T^*B^k \times \mathbb{C}^{n-k}) & \longrightarrow & \mathcal{W}(X, f).
\end{array}
\] (9.4)

We now analyze the critical and subcritical cases separately.

If \(k < n\) (i.e. \(\Lambda\) is subcritical), then \(\mathcal{W}(T^*(S^{k-1} \times [0,1]) \times \mathbb{C}^{n-k}) = 0 = \mathcal{W}(T^*B^k \times \mathbb{C}^{n-k})\) since \(n - k > 0\) (one argument goes via Theorem 1.10, which shows they are generated by the empty set, compare Example 1.12), so (9.4) reduces to a fully faithful embedding \(\mathcal{W}(X^{\text{in}}_\Lambda, f^{\text{in}}) \hookrightarrow \mathcal{W}(X, f)\). On the other hand, stop removal Theorem 1.16 in the subcritical case implies that \(\mathcal{W}(X^{\text{in}}_\Lambda, f^{\text{in}}) \simeq \mathcal{W}(X^{\text{in}}, f^{\text{in}})\) is a quasi-equivalence, and hence, by inverting this latter quasi-equivalence, we obtain a fully faithful embedding

\[
\mathcal{W}(X^{\text{in}}, f^{\text{in}}) \hookrightarrow \mathcal{W}(X, f).
\] (9.5)

Geometrically, this functor first perturbs a Lagrangian in \(X^{\text{in}}\) to avoid \(\Lambda\) and then completes it inside \(X\). If \(X^{\text{in}}\) is a Weinstein manifold and \(f^{\text{in}}\) is mostly Legendrian, then using Theorem 1.10 we see that (9.5) is in fact a quasi-equivalence.

Let us now consider the case \(k = n\) (i.e. \(\Lambda\) is Legendrian), so we may write (9.4) as

\[
\begin{array}{ccc}
\mathcal{W}(T^*(S^{k-1} \times [0,1])) & \longrightarrow & \mathcal{W}(X^{\text{in}}_\Lambda, f^{\text{in}}) \\
\downarrow & & \downarrow \\
\mathcal{W}(T^*B^k) & \longrightarrow & \mathcal{W}(X, f).
\end{array}
\] (9.6)

The categories \(\mathcal{W}(T^*B^k)\) and \(\mathcal{W}(T^*(S^{k-1} \times [0,1]))\) are both generated by a cotangent fiber (see Example 1.12), and the endomorphism algebras of these cotangent fibers are \(\mathbb{Z}\) and \(C_{-\omega}(\Omega S^{n-1})\), respectively, by Abbondandolo–Schwarz [1] and Abouzaid [4] (along with Theorem 1.5). The images of these cotangent fibers inside \(\mathcal{W}(X^{\text{in}}_\Lambda, f^{\text{in}})\) and \(\mathcal{W}(X, f)\) are the
linking disk $D \subseteq X^m_\Lambda$ of $\Lambda$ and the $[\text{cocore}] \subseteq X$, respectively. We thus obtain a diagram of $A_\infty$-algebras

$$
\begin{align*}
C_-(\Omega S^{n-1}) &\longrightarrow CW^*(D, D)_{X^n_{\Lambda, f^n}} \\
\downarrow &\downarrow \\
Z &\longrightarrow CW^*([\text{cocore}, [\text{cocore}])_{X,f},
\end{align*}
$$

(9.7)

which remains a homotopy pushout since the cotangent fiber generates $W(T^*(S^{k-1} \times [0, 1]))$.

\[\square\]

### 9.3 Sectorial hypersurfaces and coverings

We introduce and study sectorial hypersurfaces and sectorial coverings, establishing some basic properties. This section may be regarded as a continuation of [26, §2].

#### 9.3.1 Sectorial hypersurfaces

**Lemma 9.1.** Let $H_1, \ldots, H_n \subseteq X$ be a collection of cleanly intersecting hypersurfaces in a symplectic manifold. The following are equivalent:

(i) All multiple intersections $H_{i_0} \cap \cdots \cap H_{i_k}$ are coisotropic.

(ii) All pairwise intersections $H_i \cap H_j$ are coisotropic.

(iii) We have $C_i \subseteq TH_j$ over $H_i \cap H_j$, where $C_i$ denotes the characteristic foliation of $H_i$.

**Proof.** It is equivalent to prove the corresponding statement for tuples of codimension one subspaces $V_1, \ldots, V_n$ inside a symplectic vector space $W$. Pass to the $\omega$-orthogonal complements $C_1, \ldots, C_n \subseteq W$, which are lines inside $W$. The three conditions in question can now be stated as follows:

(i) All sums $C_{i_0} + \cdots + C_{i_k} \subseteq W$ are isotropic.

(ii) All sums $C_i + C_j$ are isotropic.

(iii) All pairs $C_i$ and $C_j$ are $\omega$-orthogonal.

The equivalence of these is now obvious. \[\square\]

Recall that when working in a Liouville manifold-with-boundary with Liouville vector field $Z$, we write $\text{Nbd}^Z$ to indicate a $Z$-invariant neighborhood.

**Definition 9.2.** Let $X$ be a Liouville manifold-with-boundary. A collection of hypersurfaces $H_1, \ldots, H_n \subseteq X$ (cylindrical at infinity) will be called *sectorial* iff their characteristic foliations are $\omega$-orthogonal (over their intersections) and there exist functions $I_i : \text{Nbd}^Z H_i \to \mathbb{R}$ (linear near infinity) satisfying:

$$
dI_i|_{C_i} \neq 0, \quad dI_i|_{C_j} = 0 \text{ for } i \neq j, \quad \{I_i, I_j\} = 0.
$$

(9.8)

We also allow immersed hypersurfaces $H \rightarrow X$ (cylindrical at infinity), with $I$ now defined on $\text{Nbd}^Z H$ regarded as an immersed codimension zero submanifold of $X$, and the subscripts $i$ in the identities (9.8) now indexing the “local branches” of $H$. 81
Remark 9.3. A word of caution is in order: we do not show that the space of tuples \( \{ I_i : \text{Nbd}^Z H_i \to \mathbb{R} \} \) for a given sectorial collection \( H_1, \ldots, H_n \) is contractible (or even connected). Some care is thus warranted regarding whether certain constructions/results depend on a choice of \( \{ I_i : \text{Nbd}^Z H_i \to \mathbb{R} \} \).

Lemma 9.4. Sectorial hypersurfaces \( H_1, \ldots, H_n \subseteq X \) are mutually transverse, that is 
\[
\text{codim}(TH_i \cap \cdots \cap TH_k) = k \quad \text{over} \quad H_i \cap \cdots \cap H_k, \quad \text{and these multiple intersections are coisotropic.}
\]

Proof. It follows from the conditions \( dI_i|_{C_i} \neq 0 \) and \( dI_i|_{C_j} = 0 \) for \( i \neq j \) that the characteristic lines \( C_i \) are linearly independent, which implies mutual transversality of their symplectic orthogonal complements \( TH_i \). That the intersections are coisotropic follows from Lemma 9.1.

Example 9.5. A Liouville manifold-with-boundary \( X \) is a Liouville sector iff \( \partial X \) is sectorial.

Example 9.6. Let \( Q \) be a manifold, and let \( G_1, \ldots, G_n \subseteq Q \) be a collection of mutually transverse hypersurfaces. Their inverse images inside \( T^*Q \) form a sectorial collection of hypersurfaces. Namely, we may take \( I_t \) to be the Hamiltonian lifts of vector fields \( V_t \) on \( Q \) where \( V_i \) is transverse to \( G_i \) and tangent to \( G_j \) for \( j \neq i \). More generally, the same holds for the inverse image in \( T^*Q \) of any self-transverse immersed hypersurface \( G \hookrightarrow Q \).

Lemma 9.7. Let \( H_1, \ldots, H_n \subseteq X \) be a sectorial collection of hypersurfaces, with a choice of \( I_i : \text{Nbd}^Z H_i \to \mathbb{R} \). There exist unique functions \( t_i : \text{Nbd}^Z H_i \to \mathbb{R} \) satisfying \( Zt_i \equiv 0 \) near infinity, \( H_i = \{ t_i = 0 \}, \{ I_i, t_j \} = \delta_{ij}, \) and \( \{ t_i, t_j \} = 0. \)

Proof. The properties \( H_i = \{ t_i = 0 \} \) and \( X_{t_i}\{ t_i \} \equiv 1 \) define \( t_i : \text{Nbd}^Z H_i \to \mathbb{R} \) uniquely. Differentiating \( X_{t_i}\{ t_i \} \equiv 1 \) by \( Z \) yields \( X_{t_i}(Zt_i) \equiv 0 \), which together with \( Zt_i = 0 \) over \( H_i \) near infinity implies that \( Zt_i = 0 \) near infinity. The remaining properties follow from a standard calculation as we now recall. The Jacobi identity \( \{ I_i, \{ I_j, t_j \} \} + \{ I_j, \{ t_j, I_i \} \} + \{ t_j, \{ I_i, I_j \} \} = 0 \) implies \( \{ I_j, \{ t_j, I_i \} \} = 0. \) Now \( X_{t_j} \) spans the characteristic foliation of \( H_j \), so since \( dI_i|_{C_j} = 0 \) for \( i \neq j \), we have \( \{ t_j, I_i \} = 0 \) over \( H_j \), so \( \{ I_j, \{ t_j, I_i \} \} = 0 \) implies that in fact \( \{ t_j, I_i \} = 0 \) everywhere for \( i \neq j \). Jacobi again \( \{ t_i, \{ t_j, I_j \} \} + \{ t_j, \{ I_j, t_i \} \} + \{ I_j, \{ t_i, t_j \} \} = 0 \) now yields \( X_{t_i}\{ t_i, t_j \} = 0 \), and symmetrically we have \( X_{t_i}\{ t_i, t_j \} = 0 \). Thus it is enough to show that \( \{ t_i, t_j \} = 0 \) over \( H_i \cap H_j \), and here it follows since \( X_{t_i} \in C_i \) which is tangent to \( H_j \).

Lemma 9.8. The map
\[
(I_{t_1}, t_{i_1}, \ldots, I_{t_k}, t_{i_k}) : \text{Nbd}^Z(H_{i_1} \cap \cdots \cap H_{i_k}) \to T^*\mathbb{R}^k
\]

is a symplectic fibration whose symplectic connection is flat, thus giving a symplectic product decomposition
\[
X = F \times T^*\mathbb{R}^k
\]

identifying \( Z \)-invariant neighborhoods of \( H_{i_1} \cap \cdots \cap H_{i_k} \) and \( F \times T^*\mathbb{R}^k \).

Proof. The Hamiltonian vector fields \( X_{I_{t_1}}, \ldots, X_{I_{t_k}} \), \( X_{t_{i_1}}, \ldots, X_{t_{i_k}} \) are linearly independent and span a symplectic subspace of \( TX \), in view of their Poisson brackets. This subspace is symplectically orthogonal to the kernel of the differential of the map \( (I_{t_1}, t_{i_1}, \ldots, I_{t_k}, t_{i_k}) \),
so we conclude that this map is a submersion with symplectic fibers, and that these vector fields span the horizontal distribution of the induced symplectic connection. Moreover, these vector fields are the horizontal lifts of the corresponding vector fields on the target, so since they commute (by their Poisson brackets), we conclude that the connection is flat.

Remark 9.9. In the coordinates (9.10), the sectorial hypersurfaces are simply the inverse images of the coordinate hyperplanes in $\mathbb{R}^k$. This gives a particularly simple way of “smoothing corners” or doing other local modifications to a sectorial collection of hypersurfaces near a given stratum $H_{i_1} \cap \cdots \cap H_{i_k}$: choose some other collection of mutually transverse hypersurfaces in $\mathbb{R}^k$ and pull back. The new collection stays sectorial: we may take the new $X_{i_i}$ to be the Hamiltonian lifts of vector fields on $\mathbb{R}^k$ which are transverse to our new set of hypersurfaces (compare Example 9.6).

9.3.2 Straightening the Liouville form

We now study the interaction of the splitting (9.10) with Liouville forms.

Lemma 9.10. With respect to the coordinates (9.10), we have

$$\lambda_X = \lambda_F + \lambda_{T^*\mathbb{R}^k} + df$$

(9.11)

for a Liouville form $\lambda_F$ on $F$ and a function $f : F \times T^*\mathbb{R}^k \to \mathbb{R}$ supported in $F_0 \times T^*\mathbb{R}^k$ for some compact $F_0 \subseteq F$. This function $f$ locally factors through $F$ wherever $ZI_i = I_i$ and $Zt_i = 0$ (and hence $f$ may be taken to be zero iff $ZI_i = I_i$ and $Zt_i = 0$ everywhere).

Proof. Let $\lambda_F$ be the Liouville form on $F$ obtained as the restriction of $\lambda_X$ to $F \times \{0\} = I_{t_1}^{-1}(0) \cap t_1^{-1}(0) \cap \cdots \cap I_{t_k}^{-1}(0) \cap t_k^{-1}(0)$. Since $\omega_X = \omega_F + \omega_{T^*\mathbb{R}^k}$ from Lemma 9.8, the difference between $\lambda_X$ and $\lambda_F + \lambda_{T^*\mathbb{R}^k}$ is closed. To check that this difference is exact, it is enough to check it on $F \times \{0\}$ (where it a fortiori vanishes) since the inclusion of $F \times \{0\}$ into $F \times T^*\mathbb{R}^k$ is a homotopy equivalence. We fix a choice of $f$ by requiring that $f$ vanish on $F \times \{0\}$.

The identities $ZI_i = I_i$ and $Zt_i = 0$ are equivalent to the assertion that the projection of $Z_X = Z_F + Z_{T^*\mathbb{R}^k} - X_f$ to $T^*\mathbb{R}^k$ equals $Z_{T^*\mathbb{R}^k}$, which is in turn equivalent to $f$ locally factoring through the projection to $F$. Since $ZI_i = I_i$ and $Zt_i = 0$ near infinity, we conclude that $f$ is supported inside $F_0 \times T^*\mathbb{R}^k$ for some compact $F_0 \subseteq F$.

Note that the case $k = 1$ (studied in [26, §2]) and the case $k \geq 2$ of Lemma 9.10 have slightly differing behavior. When $k \geq 2$, the cotangent bundle $T^*(-\varepsilon, \varepsilon)$ is connected at infinity, which means that we have a well-defined compactly supported function $f_\infty : F \to \mathbb{R}$, so we may redefine $\lambda_F$ as $\lambda_F + df_\infty$, so that now in (9.11) we have $f$ having compact support. In contrast, when $k = 1$, there are two compactly supported functions $f_{\pm \infty} : F \to \mathbb{R}$.

We now show how to deform the Liouville form so that it is split $\lambda_X = \lambda_F + \lambda_{T^*\mathbb{R}^k}$ with respect to the coordinates (9.10) (equivalently, so that $ZI_i = I_i$ and $Zt_i = 0$ everywhere). We will do this in two separate steps, corresponding to the two cases $k = 1$ and $k \geq 2$ with differing behavior above.

Lemma 9.11. For any sectorial collection of hypersurfaces $H_1, \ldots, H_n \subseteq X$ and choice of functions $I_i : \text{Nbd}^Z H_i \to \mathbb{R}$, there exists a compactly supported $f : X \to \mathbb{R}$ such that the deformed Liouville vector field $Z = Z_{\lambda + df}$ satisfies $ZI_i = I_i$ and $Zt_i = 0$ in a neighborhood of $H_i \cap H_j$ for every $i \neq j$. 

83
Proof. Work by induction on strata $H_I := \bigcap_{i \in I} H_i$, ordered by reverse inclusion of subsets $I \subseteq \{1, \ldots, n\}$ of cardinality $\geq 2$. Thus we assume the conclusion hold over a neighborhood of $H_j$ for all $J \supseteq I$, and we try to achieve the desired conclusion over a neighborhood of $H_I$. In a neighborhood of $H_I$, we have coordinates $(X, \lambda_X) = (F \times T^*\mathbb{R}^I, \lambda_F + \lambda_{T^*\mathbb{R}^I} + df)$ where $f$ is properly supported over $T^*\mathbb{R}^I$ and independent of the $T^*\mathbb{R}^I$ coordinate near infinity (in the cotangent directions). Since $|I| \geq 2$ so $T^*\mathbb{R}^I$ is connected at infinity, by modifying $\lambda_F$ we may assume that $f$ has compact support. Now since the desired conclusion holds in a neighborhood of $H_I$ for $J \supseteq I$, we conclude that $f$ vanishes identically in a neighborhood of $H_I \cap H_j$ for all $j \notin I$. We may thus simply add $f \prod_{i \in I} \varphi(t_i)$ to the Liouville form of $X$ (for a suitable cutoff function $\varphi : \mathbb{R} \to \mathbb{R}_{\geq 0}$ equalling 1 near zero and of small support) to achieve the desired conclusion over a neighborhood of $H_I$.

**Lemma 9.12.** For any sectorial collection of hypersurfaces $H_1, \ldots, H_n \subseteq X$ and choice of functions $I_i : \text{Nbd}^Z H_i \to \mathbb{R}$, there exists $f : X \to \mathbb{R}$ such that the deformed Liouville vector field $Z = Z_{\lambda + df}$ satisfies $ZI_i = I_i$ and $Zt_i = 0$ (equivalently, the coordinates (9.9)–(9.10) give a splitting of Liouville forms $\lambda_X = \lambda_F + \lambda_{T^*\mathbb{R}^I}$).

The deformation $Z_{\lambda + df}$, while not necessarily compactly supported, is cylindrical at infinity in the sense that there is a diffeomorphism $X = Y \times \mathbb{R}_{\geq 0}$ near infinity such that $Z_{\lambda + rf}$ is outward pointing along $Y \times \{s\}$ for all $r \in [0,1]$.

Proof. Appealing first to Lemma 9.11, we reduce to the case that the desired conclusion already holds in a neighborhood of every pairwise intersection $H_i \cap H_j$ for $i \neq j$. In a neighborhood of $H_i$, we have coordinates $(X, \lambda_X) = (F \times T^*\mathbb{R}, \lambda_F + \lambda_{T^*\mathbb{R}} + df)$ where $f$ is properly supported over $T^*\mathbb{R}$ and independent of the $T^*\mathbb{R}$ coordinate near infinity (in the cotangent directions). In a neighborhood of $H_i \cap H_j$ for any $j \neq i$, we have that $f$ vanishes identically. We now simply consider the deformation $\lambda_F + \lambda_{T^*\mathbb{R}} + d((1 - r\varphi(t_i))f)$ for $r \in [0,1]$ (where $\varphi : \mathbb{R} \to \mathbb{R}_{\geq 0}$ equals 1 near zero and has small support). These deformations associated to the various $H_i$ have disjoint support, so we may perform them simultaneously. The associated family of Liouville vector fields is given by

$$Z_F + Z_{T^*\mathbb{R}} - (1 - r\varphi(t_i))X_F + r f \varphi'(t_i)X_{t_i}. \quad (9.12)$$

Let us show that this vector field is outward pointing along $\partial(F_0 \times \{|I| \leq N\})$ for $F_0 \subseteq F$ a large Liouville domain and sufficiently large $N < \infty$. The vector field $Z_F + Z_{T^*\mathbb{R}}$ is certainly outward pointing along $\partial(F_0 \times \{|I| \leq N\})$. The vector field $X_F$ is tangent to $F$ factor, and vanishes outside a sufficiently large compact subset of $F$, so it is tangent to $\partial(F_0 \times \{|I| \leq N\})$. The vector field $X_{t_i}$ equals $-\partial I_{\mathbb{R}}$ in the $T^*\mathbb{R}$ factor, however the factors $rf\varphi'(t_i)$ are bounded, so this term is negligible compared to $Z_{T^*\mathbb{R}} = I_{\mathbb{R}}$. We conclude that during our prescribed deformation, the Liouville vector field remains outward pointing along $\partial(F_0 \times \{|I| \leq N\})$. Finally, we should show how to patch together these contact type hypersurfaces (defined over each Nbd $H_i$) globally. This is straightforward since $Z$ is not changing near the pairwise intersections $H_i \cap H_j$, so near such and higher intersections, we may take any contact hypersurfaces we like.

**Remark 9.13 (Sectorial hypersurfaces and products).** Given sectorial hypersurfaces $H_1, \ldots, H_n \subseteq X$ and $H_1', \ldots, H_n' \subseteq X'$, we would like to know that their product

$$H_1 \times X', \ldots, H_n \times X', X \times H_1', \ldots, X \times H_n' \subseteq X \times X' \quad (9.13)$$
is again sectorial. So that these product hypersurfaces are cylindrical at infinity, we must, at a minimum, assume that the Liouville vector fields on \(X\) and \(X'\) are everywhere tangent to the \(H_i\) and \(H'_i\). If, in addition, the functions \(I_i\) and \(I'_i\) satisfy \(ZI_i = I_i\) and \(Z'I'_i = I'_i\) everywhere, then their pullbacks to \(X \times X'\) show that the collection of hypersurfaces (9.13) is indeed sectorial. These hypotheses on the input hypersurfaces are precisely the properties ensured by applying Lemma 9.12. Thus whenever we want to consider products of sectorial hypersurfaces, we will first apply Lemma 9.12 to each factor.

**9.3.3 Liouville sectors with corners**

**Definition 9.14.** A *Liouville sector with (sectorial) corners* is a Liouville manifold-with-corners whose boundary, viewed as an immersed hypersurface, is sectorial.

We will usually drop the qualifier ‘sectorial’, except in the following remark.

**Remark 9.15.** A Liouville sector with sectorial corners is, in particular, a *Liouville sector with (naive) corners*, namely a Liouville manifold-with-corners for which there exists an outward pointing Hamiltonian vector field defined near the boundary which is linear at infinity (indeed, a Hamiltonian giving such a vector field on a Liouville sector with sectorial corners is given by \(\sum_i \varphi(t_i)I_i\) for a cutoff function \(\varphi\) supported near zero). Smoothing the corners of a Liouville sector with naive corners \(X\) yields a Liouville sector \(X^{\text{sm}}\) [26, Remark 2.12]. A Liouville sector with sectorial corners is a much stronger notion than a Liouville sector with naive corners (e.g. the corner strata of the latter need not even be coisotropic). Since we will not need the notion of a Liouville sector with naive corners in this paper, we shorten ‘Liouville sector with sectorial corners’ to ‘Liouville sector-with-corners’.

The wrapped Fukaya category of a Liouville sector-with-corners \(X\) may be defined either as that of its smoothing: \(W(X) := W(X^{\text{sm}})\) (which is well-defined in view of Lemma 2.6), or, equivalently, and somewhat more intrinsically, as the wrapped Fukaya category of its interior (which is an *open Liouville sector* in the sense of [26, Remark 2.8]): \(W(X) := W(X^\circ)\) (see [26, §3.8]).

**Example 9.16.** A product of Liouville sectors, each of which has been straightened as in Remark 9.13, is a Liouville sector-with-corners. More generally, the same holds for products of Liouville sectors-with-corners.

Recall that a Liouville sector \(X\) has \(\partial X = F \times \mathbb{R}\) whose symplectic reduction \(F\), termed the symplectic boundary of \(X\), is a Liouville manifold. We extend this terminology to sectors-with-corners: each corner stratum of \(X\) is coisotropic, and its symplectic reduction (namely the \(F\) factor appearing in (9.10)) is called a *symplectic boundary stratum* of \(X\). These symplectic boundary strata are themselves Liouville sectors-with-corners (the \(I_i\) and \(t_i\) descend in view of their Poisson brackets). We will refer to the maximal proper symplectic boundary strata (i.e. those of real codimension two) as *symplectic (boundary) faces*.

We now consider various gluing operations for Liouville sectors-with-corners. Let us first recall the situation for Liouville sectors. Given Liouville sectors \(X\) and \(Y\) with common symplectic boundary \(F\), we may glue them to obtain a Liouville manifold \(X \#_F Y := X \cup_{F \times \mathbb{R}} Y\). The common boundary, now in the interior, is a sectorial hypersurface. The same operation may also be described in terms of the corresponding Liouville pairs \((\hat{X}, F)\) and
We write \( \partial X \), the result being denoted by \((\bar{X}, F) \#_F (\bar{G}, F)\). A direct construction of \# in the language of Liouville pairs may be found in [22, \S 3.1], and reasoning as in [26, \S 2] shows it is equivalent to the connect sum of Liouville sectors.

We now extend this picture to Liouville sectors-with-corners in various ways. We limit our discussion to the case that the boundary consists of exactly two faces meeting precisely along the corner locus.

**Construction 9.17.** Items of the following two kinds can each be used to produce one of the other:

- A Liouville sector-with-corners \( X \), with symplectic faces \( F, G \), which in turn have common symplectic boundary \( P \).
- A Liouville sector \( X^{\text{sm}} \) with symplectic boundary expressed as \( F \#_P G \).

**Construction.** We write \( \partial X = H_1 \cup H_2 \) where \( H_1 = F \times \mathbb{R}, \ H_2 = G \times \mathbb{R}, \) and \( H_1 \cap H_2 = P \times \mathbb{R}^2 \). We apply Lemma 9.12 so that the coordinates (9.10) strictly respect Liouville forms; explicitly, these are a compatible collection of coordinates

\[
\begin{align*}
F \times T^*\mathbb{R}_{\leq 0} &\hookrightarrow X, \tag{9.14} \\
G \times T^*\mathbb{R}_{\leq 0} &\hookrightarrow X, \tag{9.15} \\
P \times T^*\mathbb{R}^2_{\leq 0} &\hookrightarrow X, \tag{9.16} \\
P \times T^*\mathbb{R}_{\leq 0} &\hookrightarrow F, \tag{9.17} \\
P \times T^*\mathbb{R}_{\leq 0} &\hookrightarrow G, \tag{9.18}
\end{align*}
\]

where \( F \) and \( G \) are Liouville sectors and \( P \) is a Liouville manifold (though we write \( T^*\mathbb{R}_{\leq 0} \), we really mean \( T^*(-\varepsilon, 0] \) for small \( \varepsilon > 0 \)). The first three of these are coordinates near \( H_1, H_2, \) and \( H_1 \cap H_2 \), and the last two are coordinates near \( \partial F \) and \( \partial G \), respectively. The coordinates \( P \times T^*\mathbb{R}^2_{\leq 0} \hookrightarrow X \) account for the entire corner locus of \( X \), so we may describe a smoothing of this corner simply by smoothing the corner of \( \mathbb{R}^2_{\leq 0} \).

The smoothing of this corner may be described as follows (a very similar discussion appeared earlier in \( \S 6.1 \), in particular around Figure 18). Let \( X \) denote the result of gluing onto \( X \) (via (9.14)–(9.18)) copies of

\[
\begin{align*}
\left[ \frac{F \cup_{P \times T^*[0,1]} G }{P \times T^*[0,1]} \right] \times (T^*\mathbb{R}_{\geq 0}, Z_{T^*\mathbb{R}_{\geq 0}} + \pi^* \varphi(s) \partial_s), \tag{9.22}
\end{align*}
\]

where \( \pi^* \) denotes the lift from vector fields on a manifold to Hamiltonian vector fields on its cotangent bundle, and \( \varphi : \mathbb{R} \to [0, 1] \) is smooth and satisfies \( \varphi(s) = 0 \) for \( s \leq 2 \) and \( \varphi(s) = 1 \) for \( s \geq 3 \). Now as illustrated in Figure 24, the vector field \( \varphi(s_1) \partial_{s_1} + \varphi(s_2) \partial_{s_2} \) may be deformed over a compact subset of the interior of \( \mathbb{R}^2_{\geq 0} \) to a vector field of the form \( \varphi(s) \partial_s \) for some coordinates \((s, \theta)\) on \( \mathbb{R}^2_{\geq 0} \setminus \{(0, 0)\} \). The locus \( s \leq 1 \) in this deformation is thus a smoothing \( X^{\text{sm}} \) of the corners of \( X \), and its complement can be described as
We will denote this deformation of $\tilde{X}$ by $\overline{X}^{\text{sm}}$, since the above discussion shows it is the convex completion of $X^{\text{sm}}$. Now the smoothed Liouville sector $X^{\text{sm}}$ has boundary neighborhood coordinates

$$\text{(}F \#_p G\text{)} \times T^* \mathbb{R}^{\leq 0} \hookrightarrow X^{\text{sm}}$$

(9.23)

where $F \#_p G$ denotes the Liouville manifold from (9.22), namely obtained by gluing $F$ and $G$ together along $P \times T^*(-\epsilon, \epsilon)$, either side of which is embedded into $F$ and $G$ via (9.17)–(9.18).

Figure 24: Left: The vector field $\varphi(s_1) \partial_{s_1} + \varphi(s_2) \partial_{s_2}$ on $\mathbb{R}^2$ defining the Liouville structure on $P \times T^* \mathbb{R}^2_{ \geq 0}$ (the dotted line indicates the boundary of $X$). Right: The deformed vector field $\varphi(s) \partial_s$ defining the Liouville structure on $P \times T^* \mathbb{R}^2_{ \geq 0}$ which defines what we call $\overline{X}^{\text{sm}}$ (the dotted line indicates a smoothing $X^{\text{sm}}$ of $X$). Note that the deformation is supported in a compact subset of $\mathbb{R}^2_{ \geq 0}$, disjoint from the boundary.

Figure 25: Introducing a corner near the origin to turn $\mathbb{R} \times \mathbb{R}_{ \leq 0}$ (left) into $A$ (right).

This operation works in reverse as well: given a Liouville sector $Y$ with boundary neighborhood coordinates $Q \times T^* \mathbb{R}^{\leq 0} \hookrightarrow Y$ and a splitting of $Q$ as $F \#_p G$, we may introduce a corner into the boundary as follows to producing a Liouville sector-with-corners $X$ with $X^{\text{sm}} = Y$. Concretely, near $P$, there is a neighborhood in $Q$ of the form $P \times T^* \mathbb{R}$ (rather $P \times T^* (-\epsilon, \epsilon)$), and hence a neighborhood in $X$ of the form $P \times T^* (\mathbb{R} \times \mathbb{R}^{\leq 0})$ (rather $P \times T^* ((-\epsilon, \epsilon) \times (-\epsilon, 0])$). We now modify $\mathbb{R} \times \mathbb{R}^{\geq 0}$ near the origin so as to introduce a corner (see Figure 25), and we replace our local chart $P \times T^* (\mathbb{R} \times \mathbb{R}^{\leq 0})$ with $P \times T^* A$ to define our desired $X$. To see that $X$ has sectorial corners, simply note that the Hamiltonian vector field on $Y$ transverse to its boundary is the Hamiltonian lift of $\frac{\partial}{\partial t}$, so the desired vector
fields on $X$ can also be defined on $A$ so that they agree with $\frac{\partial}{\partial t}$ away from a neighborhood of the origin (see Figure 25) and then lifted.

We now discuss a version of the boundary connect sum $\#$ construction for gluing along a shared subsector of the boundary, rather than the whole boundary.

**Construction 9.18.** Items of the following three kinds can each be used to produce one of the other:

- A Liouville sector $X$ with a hypersurface $H \subseteq X$, meeting the boundary transversally, with $\{H, \partial X\}$ sectorial, such that $H$ separates $X$ into two pieces $X_1$ and $X_2$ meeting precisely along $H$.

- A pair of Liouville sectors-with-corners $X_1$ and $X_2$ with two boundary faces each $\partial^j X_i$, $j = 1, 2$, and an identification of the symplectic reductions of $\partial^1 X_1$ and $\partial^1 X_2$.

- A pair of Liouville pairs $(Y_1, Q_1)$ and $(Y_2, Q_2)$ with a common Liouville subsector $Q_1 \leftrightarrow P \leftrightarrow Q_2$.

In this correspondence, $(Y_i, Q_i)$ is the Liouville pair corresponding to the Liouville sector $(X_i)^{sm}$ (the rounding of the sector-with-corners $X_i$).

**Construction.** The passage between the first two inputs in either direction is evident (splitting along $H$ and gluing $\partial^1 X_1$ to $\partial^1 X_2$). Beginning with the second type of input, $X_1$ and $X_2$ with $H = \partial^1 X_1 = \partial^1 X_2$, we apply Lemma 9.12 so as to obtain boundary neighborhood coordinates (9.14)–(9.18) on $X_1$ and $X_2$, say with $F = F_1 = F_2$ corresponding to $H$ and with $G_i$ the remaining the two pieces (i.e. in the context of the first type of input, the symplectic reductions of the two pieces into which $H$ splits $\partial X$). Passing to the equivalent descriptions of $X_i$ in terms of Liouville pairs given by Construction 9.17, we obtain $(Y_i, Q_i)$ together with a common Liouville subsector $Q_1 \leftrightarrow P \leftrightarrow Q_2$.

Now suppose we are given the third type of input, Liouville pairs $(Y_i, Q_i)$ with a common Liouville subsector $Q_1 \leftrightarrow P \leftrightarrow Q_2$. The boundary $\partial P = R \times \mathbb{R}$ separates $Q_i$ into $P \#_R (Q_i \setminus P^o)$. We may thus apply Construction 9.17 to $(Y_i, P \#_R (Q_i \setminus P^o))$ to obtain Liouville sectors-with-corners, each with a boundary face with neighborhood $P \times T^* \mathbb{R}_{\geq 0}$. This yields the second type of input, and gluing along these common faces yields the first.

Going forward, given a pair of Liouville pairs $(Y_1, Q_1)$ and $(Y_2, Q_2)$ along with a common subsector $Q_1 \leftrightarrow P \leftrightarrow Q_2$, we shall call the result of passing to the first item in Construction 9.18 the **gluing of $(Y_1, Q_1)$ and $(Y_2, Q_2)$ along $P$**, denoted

$$(Y_1, Q_1) \#_{P} (Y_2, Q_2). \quad (9.24)$$

We will use the same notation and terminology, the gluing of $X_1$ and $X_2$ along $P$

$$X = X_1 \#_{P} X_2 := X_1 \cup_{P \times \mathbb{R}} X_2 \quad (9.25)$$

for the passage from the second type of input of Construction 9.18 to the first, where $\partial^1 X_1 = \partial^1 X_2 = P \times \mathbb{R}$.

88
9.3.4 Sectorial coverings

**Definition 9.19** (Sectorial covering). Let \((X, \partial X)\) be a Liouville manifold-with-boundary. Suppose \(X = X_1 \cup \cdots \cup X_n\), where each \(X_i\) is a manifold-with-corners with precisely two faces \(\partial^1 X_i := X_i \cap \partial X\) and the point set topological boundary \(\partial^2 X_i\) of \(X_i \subseteq X\), meeting along the corner locus \(\partial X \cap \partial^2 X_i = \partial^1 X_i \cap \partial^2 X_i\). Such a covering \(X = X_1 \cup \cdots \cup X_n\) is called **sectorial** iff the collection of hypersurfaces \(\partial X, \partial^2 X_1, \ldots, \partial^2 X_n\) is sectorial. (Note that this means, in particular, that \(X\) and \(X_1, \ldots, X_n\) are Liouville sectors.)

**Remark 9.20.** There are many possible variations on the above definition which also deserve the name ‘sectorial covering’—the key point is just that the collection of all the boundaries \(\partial X, \partial X_1, \ldots, \partial X_n\) should be sectorial. For example, we could allow \(X\) and the \(X_i\) to have more corners. We could also insist on no corners: require \(X_i \subseteq X\) to be disjoint from \(\partial X\), require \(\partial X, \partial X_1, \ldots, \partial X_n\) to be sectorial, and require \(X_1 \cup \cdots \cup X_n \hookrightarrow X\) to be a trivial inclusion (this comes at the cost of \(X_1, \ldots, X_n\) not literally covering \(X\)). For the purposes of this paper, we work with Definition 9.19 as stated above. The various possible alternative definitions are all related by smoothing of corners, and hence our main results will continue to apply in these more general settings.

**Example 9.21.** Consider two balls \(B_1, B_2 \subseteq \mathbb{R}^n\) whose boundaries are transverse. The cover \(T^*(B_1 \cup B_2) = T^*B_1 \cup T^*B_2\) does not satisfy Definition 9.19, since the boundary of \(T^*(B_1 \cup B_2)\) is not smooth. To make this example conform to Definition 9.19, we should take \(X\) to be the cotangent bundle of a smoothing of \(B_1 \cup B_2\), and we should take \(X_1\) and \(X_2\) to be bounded by disjoint slight perturbations (in \(X\)) of \((\partial B_1) \cap B_2\) and \(B_1 \cap (\partial B_2)\), respectively. In this way, \(X = X_1 \cup X_2\) coincides with \(T^*(B_1 \cup B_2) = T^*B_1 \cup T^*B_2\) except in (the inverse image of) a small neighborhood of \(\partial B_1 \cap \partial B_2\). Similar constructions are often necessary when working with sectorial coverings in the sense of Definition 9.19. (In the ‘no corner’ definition from Remark 9.20, we would just say that \(T^*B_1 \cup T^*B_2\) is a sectorial covering of \(X\).)

**Example 9.22.** The setup of Construction 9.18 gives a sectorial covering \(X = X_1^+ \cup X_2^+\), where \(X_i^+\) is a slight enlargement of \(X_i\), so that \(X_1^+ \cap X_2^+ = H \times (-\varepsilon, \varepsilon)\).

**Example 9.23.** Let \(X\) be a Liouville sector, and let \(\partial X, H_1, \ldots, H_m\) be sectorial. These divide \(X\) into some number of connected components. Suppose that the closure of each such component is embedded, i.e. consists of at most one orthant in every choice of local coordinates (9.10). Defining \(X_1, \ldots, X_n\) to be appropriate slight enlargements of smoothings of corners of these closures, we see that \(X_1, \ldots, X_n\) is a sectorial cover of \(X\).

**Example 9.24.** Let \(X\) be a Liouville sector-with-corners, and smooth its boundary to obtain \(X^{sm}\). The symplectic boundary of \(X^{sm}\) may be described by the natural generalization of Construction 9.17. This symplectic boundary has a sectorial covering by \(F_i\), each of which is (a slight enlargement of) a symplectic boundary face of \(X\) (with smoothed corners).

Recall that given sectorial hypersurfaces \(H_1, \ldots, H_n \subseteq X\), we get Liouville manifolds \(F_{i_1, \ldots, i_k}\) from Lemma 9.8 and 9.10. In fact, we have the following finer structure (which, for convenience, we describe only in the case of sectorial coverings). For any sectorial covering \(X = X_1 \cup \cdots \cup X_n\), stratify \(X\) by strata

\[
X_{I,J,K} = \bigcap_{i \in I} X_i \cap \bigcap_{j \in J} \partial X_j \setminus \bigcup_{k \in K} X_k
\]  

(9.26)
ranging over all decompositions $I \sqcup J \sqcup K = \{1, \ldots, n\}$. The closure of each $X_{I,J,K}$ is a submanifold-with-corners, whose symplectic reduction is a Liouville sector-with-corners. Indeed, this follows since the relevant $I_i$ descend to the symplectic reduction in view of their Poisson brackets.

**Definition 9.25.** A sectorial covering will be called *Weinstein* when the convex completions of all of the symplectic reductions of strata (9.26) are (up to deformation) Weinstein.

**Lemma 9.26.** Given a sectorial covering $X = X_1 \cup \cdots \cup X_n$, the following are also sectorial covers:

\[
X = (X_1 \cup X_2) \cup X_3 \cup \cdots \cup X_n \tag{9.27}
\]

\[
X_1 = (X_1 \cap X_2) \cup \cdots \cup (X_1 \cap X_n) \tag{9.28}
\]

(after smoothing the appropriate corners). Moreover, if the original cover was Weinstein, so are those described above.

**Proof.** The new coverings are sectorial by Remark 9.9. To see that the Weinstein property is preserved, we should note that, following the geometry of Constructions 9.17–9.18, effect on the strata is to perform connect sum along boundary faces, which preserves being Weinstein [22, §3.1].

### 9.4 Boundary cores of sectors with corners

To understand when an inclusion of a Liouville sector $X$ into a larger sector is forward stopped, we use the positive/negative cores $c(\partial_\infty X)_\pm$, which were defined in §8.1. In order to have a similar understanding of the case when $X$ is a sector-with-corners, we will round corners in a particular way and calculate the positive/negative cores of the chosen rounding, as subsets of the original cornered $\partial_\infty X$. We content ourselves with the case when $X$ has exactly two faces as in Construction 9.17.

To begin the discussion, let us recall from §8.1 the situation for Liouville sectors (without corners). So, suppose $X$ is a Liouville sector, with coordinates $F \times T^*\mathbb{R} \leq 0$ given near its boundary, where $F$ is a Liouville manifold. Then we have

\[
\partial \partial_\infty X = F \bigcup_{\mathbb{R} \times \partial_\infty F} F, \tag{9.29}
\]

and $c(\partial_\infty X)_\pm$ are, respectively, the two copies of $c_F$ sitting inside the two copies of $F$ inside $\partial_\infty X$.

Now consider the case that $X$ is a Liouville sector-with-corners, with exactly two faces. Using Lemma 9.12 if necessary, we fix coordinates near its boundary given by $F \times T^*\mathbb{R} \leq 0$ and $G \times T^*\mathbb{R} \leq 0$ overlapping over $P \times T^*\mathbb{R}^2_\leq 0$, where $F$ and $G$ are Liouville sectors both of which have coordinates $P \times T^*\mathbb{R} \leq 0$ near their boundary as in (9.14)–(9.18). The locus $\partial \partial_\infty X$ is the union of $F \bigcup_{\mathbb{R} \times \partial_\infty F} F$ and $G \bigcup_{\mathbb{R} \times \partial_\infty G} G$.

As explained in Construction 9.17, choosing a rounding of the corner of $\mathbb{R}^2_\leq 0$ determines a corresponding rounding $X^{sm}$, a neighborhood of whose boundary is given by $(F \#_p G) \times T^*\mathbb{R} \leq 0$. The cores $c(\partial_\infty X^{sm})_\pm$ are evidently given abstractly by $c_F \cup_{c_F} c_G$, i.e. the relative
cores of $F$ and $G$ attached along their common boundary, $\mathfrak{c}_P$. Let us discuss how they are embedded.

Away from the corner locus, the positive/negative cores $\mathfrak{c}_{(\partial \partial X^m)}^\pm$ are naturally identified, as in §8.1, with two copies of $\mathfrak{c}_F$ and $\mathfrak{c}_G$.

It remains to understand what happens in a neighborhood of the corner locus, where we may work in the local model $P \times T^*\mathbb{R}^2_{\leq 0}$. Before smoothing, the contribution of this local model to $\partial \partial X$ is given by

$$\partial \mathbb{R}^2_{\leq 0} \times \left[ \partial_\infty P \times \mathbb{R}^2 \bigcup_{(\mathbb{R} \times \partial_\infty P) \times S^1} P \times S^1 \right].$$

(9.30)

After rounding the corner of $\partial \mathbb{R}^2_{\leq 0}$, the positive/negative cores lie in the second term $P \times S^1$ and are given by $\mathfrak{c}_P$ times the codirections in $S^1$ which are outward/inward conormal to (the rounded) $\partial \mathbb{R}^2_{\leq 0}$. (Compare the discussion in Construction 9.17 for another look at this geometry.) This completes the description of the $\mathfrak{c}_{(\partial \partial X^m)}^\pm$.

It is natural to ask whether we can describe the limiting behavior of these as we undo the rounding of the corner. It is clear from the above description that this limit has the same description as in the rounded case, so long as by “outward/inward conormal” to a corner, we understand the appropriate quarter cocircle over the corner of $\mathbb{R}^2_{\leq 0}$. We henceforth define the positive/negative cores of $\partial \partial X$ by this limit.

### 9.5 Stopping and the $A_2$ sector

Recall that $A_2$ denotes the Liouville sector associated to the stopped Liouville manifold $(\mathbb{C}, \{e^{2\pi ij/3} \cdot \infty\}_{j=0,1,2})$. As is well known, the Fukaya category of $A_2$ is the category of perfect modules over the $A_2$ quiver $\bullet \rightarrow \bullet$, which evidently has a semi-orthogonal decomposition into two copies of the category of perfect modules over $\bullet$. Geometrically, this semi-orthogonal decomposition can be seen by contemplating the forward stopped-ness and stopping witnesses for the inclusions of $T^*[0,1]$ around any two of the stops.

Here, we will be interested in products $A_2 \times Q$, for a Liouville sector $Q$ with symplectic boundary $F$. By applying Lemma 9.12 to $A_2$ and $Q$, we may ensure that this product $Q \times A_2$ is a Liouville sector-with-corners (see Remark 9.13). In fact for $A_2$, rather than abstractly applying Lemma 9.12, we will simply use the Liouville vector field illustrated on the left of Figure 27. The symplectic faces of this product are $Q \sqcup Q \sqcup Q$ (with a natural cyclic order) and $A_2 \times P$.

Given a Liouville sector $X$ with symplectic boundary $F$, along with a sector embedding $Q \hookrightarrow F$, we may use Construction 9.18 to form $X \#_Q (Q \times A_2)$ (implicitly we are passing $Q \times A_2$ or $(X, F)$ through the first or second bullet point of Construction 9.17 respectively in order for the result can be fed into the second respectively third input of Construction 9.18). As there are three $Q$ faces of $Q \times A_2$, we may glue up to three such (sectors associated to the) pairs $(X, F)$ into $Q \times A_2$ in this way. We will be particularly interested in the following gluing of two such pairs:

**Construction 9.27.** Let $X$ and $Y$ be Liouville sectors, with respective symplectic boundaries $F$ and $G$. Let $Q \hookrightarrow F$ and $Q \hookrightarrow G$ be embeddings of Liouville sectors. Then there is
Figure 26: Gluing Liouville sectors with $Q \times A_2$ in between. The arrows indicate the direction of the Reeb flow.

a Liouville sector-with-corners $X \#_Q (Q \times A_2) \#_Q Y$ with inclusions

$$X \hookrightarrow X \#_Q (Q \times A_2) \#_Q Y \hookrightarrow Y$$

(9.31)

Here we fix the cyclic ordering by Figure 26.

Construction. Perform the gluing operation described below Construction 9.18 twice.

Proposition 9.28. In the setting of Construction 9.27, the inclusion $X \hookrightarrow X \#_Q (Q \times A_2) \#_Q Y$ is tautologically forward stopped, and the stopping witness produced by Proposition 8.11 is disjoint from $Y$.

Proof. To begin let us fix precisely the geometric objects under consideration. We consider $X$ and $Y$ to be their cornered versions from the middle bullet of Construction 9.18, i.e. they each have a boundary face with neighborhood $Q \times T^*\mathbb{R}_{\leq 0}$ where they are glued to $Q \times A_2$ to form $X \#_Q (Q \times A_2) \#_Q Y$ (so $\#_Q$ is $\cup_{Q \times \mathbb{R}}$). The main part of our argument proceeds by deforming $\partial_{\infty} (Q \times A_2)$ to make $\partial \partial_{\infty} X$ and $\partial \partial_{\infty} (X \#_Q (Q \times A_2) \#_Q Y)$ touch (in a way avoiding $\partial \partial_{\infty} Y$). To conclude, we (simultaneously) smooth corners and note that the (smoothed) deformation exhibits the desired tautological forward stopping property (this smoothing step is necessary since the formulation of Definition 8.3 does not allow corners).

We begin with the Liouville vector field on $A_2$ illustrated on the left of Figure 27. This model of $A_2$ has boundary neighborhood coordinates $T^*\mathbb{R}_{\leq 0}$ (times three), and thus we may consider its product with $Q$ (also assumed to have coordinates $T^*\mathbb{R}_{\leq 0} \times P$ near its boundary, for $P$ a Liouville manifold) which is a Liouville sector-with-corners $Q \times A_2$, suitable for gluing to $X$ and $Y$ at the locations indicated on the (right and bottom of the) left half of Figure 27.

Consider now the contact boundary

$$\partial_{\infty} (Q \times A_2) = (\partial_{\infty} Q \times A_2) \bigcup_{\partial_{\infty} Q \times \partial_{\infty} A_2 \times \mathbb{R}} (Q \times \partial_{\infty} A_2).$$

(9.32)

This is a contact manifold with convex corners in the sense that its boundary has two faces, each face has a transverse contact vector field which is tangent to the other face, and these
Figure 27: A deformation of the $A_2$ Liouville sector, starting from the left at $r = 0$, going to the right at $r = 1 - \varepsilon$, and limiting at $r = 1$ to having the upper end pinched. The large arrow indicates the direction of the Reeb flow.

vector fields commute (compare Definition 9.14; the formula from Remark 9.15 implies that the boundary is convex, after smoothing corners).

We would now like to deform $\partial_\infty (Q \times A_2)$ by executing the deformation $\{ A_2^r \}_{r \in [0,1]}$ illustrated in Figure 27. Although $Q \times A_2^r$ is not cylindrical at infinity since the Liouville vector field is not everywhere tangent to $\partial A_2^r$, we will nevertheless make sense of $\partial_\infty (Q \times A_2^r)$ as a deformation at infinity provided we fix a choice of contact form $\alpha_Q$ on $\partial_\infty Q$. Recall that the open inclusion $\partial_\infty Q \times A_2^r \hookrightarrow \partial_\infty (Q \times A_2)$ depends on a choice of contact form on $\partial_\infty Q$.

Fix any such contact form $\alpha_Q$, so $\alpha_Q + \lambda A_2^r$ is a contact form on $\partial_\infty (Q \times A_2^r)$. Now for $A_2^r$, consider the deformation of $\partial_\infty Q \times A_2$ (inside $\partial_\infty (Q \times A_2)$) given by $(\partial_\infty Q \times A_2^r, \alpha_Q + \lambda A_2^r)$. At infinity this deformation simply shrinks one of the ends of $A_2$, and hence this deformation can be extended to all of $\partial_\infty (Q \times A_2)$ by, in the $Q \times \partial_\infty A_2$ portion of $\partial_\infty (Q \times A_2)$, shrinking the end of $A_2$ by $Q \times \partial_\infty A_2^r$. This gives the desired definition of $\partial_\infty (Q \times A_2^r)$, which we can further glue to obtain a deformation $\partial_\infty (X \#_Q (Q \times A_2^r) \#_Q Y)$.

Let us argue that $\partial \partial_\infty (Q \times A_2^r)$ and $\partial \partial_\infty (X \#_Q (Q \times A_2^r) \#_Q Y)$ remain convex during this deformation. These boundaries have corners, so let us instead prove the stronger result that they have convex corners (which implies convexity by the construction of Remark 9.15). Recall that the vector fields demonstrating that $Q \times A_2$ has sectorial corners are simply those lifted from $Q$ and $A_2$, which strictly preserve the Liouville forms. We may assume that our chosen contact form $\alpha_Q$ on $\partial_\infty Q$ is also preserved near the boundary. Now to extend these vector fields to the deformations with parameter $r$, simply observe that over the deformed boundary component of $A_2^r$, the Liouville form is still locally $-s \, dt$ (i.e. the Liouville form on $T^* \mathbb{R}$) and we may take our vector field to be $-\frac{\partial}{\partial t}$, where $t$ is the horizontal coordinate and $s$ is the vertical coordinate in Figure 27. As this vector field strictly preserves the Liouville form, it defines a contact vector field on $(\partial_\infty Q \times A_2^r, \alpha_Q + \lambda A_2^r)$, thus also on $\partial \partial_\infty (Q \times A_2^r)$ and on $\partial \partial_\infty (X \#_Q (Q \times A_2^r) \#_Q Y)$, commuting with the transverse vector fields for the other boundary faces.

Finally, let us argue that this deformation of the inclusion $\partial_\infty X \hookrightarrow \partial_\infty (X \#_Q (Q \times A_2^r) \#_Q Y)$ remains convex during this deformation. These boundaries have corners, so let us instead prove the stronger result that they have convex corners (which implies convexity by the construction of Remark 9.15). Recall that the vector fields demonstrating that $Q \times A_2$ has sectorial corners are simply those lifted from $Q$ and $A_2$, which strictly preserve the Liouville forms. We may assume that our chosen contact form $\alpha_Q$ on $\partial_\infty Q$ is also preserved near the boundary. Now to extend these vector fields to the deformations with parameter $r$, simply observe that over the deformed boundary component of $A_2^r$, the Liouville form is still locally $-s \, dt$ (i.e. the Liouville form on $T^* \mathbb{R}$) and we may take our vector field to be $-\frac{\partial}{\partial t}$, where $t$ is the horizontal coordinate and $s$ is the vertical coordinate in Figure 27. As this vector field strictly preserves the Liouville form, it defines a contact vector field on $(\partial_\infty Q \times A_2^r, \alpha_Q + \lambda A_2^r)$, thus also on $\partial \partial_\infty (Q \times A_2^r)$ and on $\partial \partial_\infty (X \#_Q (Q \times A_2^r) \#_Q Y)$, commuting with the transverse vector fields for the other boundary faces.
A_2)\#_Q Y) into \( \partial_\infty X \leftarrow \partial_\infty (X\#_Q (Q \times A_1^2)\#_Q Y) \) fulfills Definition 8.3 (after smoothing), thus verifying that this inclusion is tautologically forward stopped. First, note that this deformation causes both boundary faces of \( \partial_\infty X \) to touch the boundary of \( \partial_\infty (X\#_Q (Q \times A_1^2)\#_Q Y) \). Smoothing corners, the discussion surrounding (9.30) implies that the outgoing core of \( \partial \partial_\infty X \) meets \( \partial \partial_\infty (\partial T^*\mathbb{R}_{\leq 0} \times F) \) only along the positive conormal at \( 0 \in \mathbb{R}_{\leq 0} \), which implies it is contained in the deformed boundary \( \partial \partial_\infty (X\#_Q (Q \times A_1^2)\#_Q Y) \). It remains to show that it is disjoint from the incoming core of \( \partial \partial_\infty (X\#_Q (Q \times A_1^2)\#_Q Y) \), so is in particular disjoint from its incoming core.

Finally, note that throughout this deformation (and its smoothing), \( \partial_\infty X \) remains separated from \( \partial_\infty Y \), hence the stopping witness produced by Proposition 8.11 is disjoint from \( \partial_\infty Y \) as well.

**Corollary 9.29.** In the setting of Construction 9.27, the functors

\[
W(X), W(Y) \rightarrow W(X\#_Q (Q \times A_2)\#_Q Y)
\]

are fully faithful, and \( W(X) \) is left-orthogonal to \( W(Y) \) inside \( W(X\#_Q (Q \times A_2)\#_Q Y) \). More generally, the same holds if we add stops inside \( (\partial_\infty X)^o \) and \( (\partial_\infty Y)^o \) not approaching the boundary.

**Proof.** According to Proposition 9.28, the inclusion \( X \leftarrow X\#_Q (Q \times A_2)\#_Q Y \) is tautologically forward stopped, and moreover that the resulting stopping witness produced by Proposition 8.11 is disjoint from \( Y \). By symmetry, the corresponding inclusion of \( Y \) is backward stopped. This implies the desired result by Corollary 8.13.

**Example 9.30.** Corollary 9.29 allows us to generalize Example 8.7 from Liouville manifolds to Liouville sectors. Let \( F \) be a Liouville sector with symplectic boundary \( Q \). For an embedding \( \bar{F}_0 \leftarrow \partial_\infty X \) as a Liouville hypersurface, we consider the gluing \( (X, \bar{F})\#_F (F \times A_2) \), which can be equivalently described as \( (X, F\#_Q F) \), for an embedding \( (F\#_Q F)_0 \leftarrow \partial_\infty X \) as a Liouville hypersurface (the “doubling” of \( \bar{F}_0 \leftarrow \partial_\infty X \) along \( F \subseteq \bar{F} \)). Corollary 9.29 shows that the natural embeddings

\[
F \times T^*[0, 1] \leftarrow (X, \bar{F})\#_F (F \times A_2)
\]

coming from the unglued faces of \( F \times A_2 \) both induce fully faithful functors on wrapped Fukaya categories.

### 9.6 Sectorial descent

We begin by discussing how stop removal (Theorem 1.16) and generation (Theorem 1.10) apply in the case of Liouville sectors-with-corners:

**Corollary 9.31.** Let \( X \) be a Liouville sector-with-corners, whose boundary is the union of two faces meeting along the corner locus, fixing notation as in Construction 9.17, so there is a commutative diagram

\[
\begin{array}{ccc}
W(P) & \longrightarrow & W(F) \\
\downarrow & & \downarrow \\
W(G) & \longrightarrow & W(X)
\end{array}
\]

94
If (the convex completions of) $X$, $F$, $G$, and $P$ are all Weinstein up to deformation, then we have:

- $\mathcal{W}(X)$ is generated by the cocores of $X$ and the images of the cocores of $F$, $G$, and $P$.
- For $\bar{X}$ the convex completion of $X$, the functor $\mathcal{W}(X) \to \mathcal{W}(\bar{X})$ is the localization at the union of the images of $\mathcal{W}(F)$, $\mathcal{W}(G)$, and $\mathcal{W}(P)$.
- For $\bar{X}^F$ the convex completion of $X$ along only the face corresponding to $F$, the functor $\mathcal{W}(X) \to \mathcal{W}(\bar{X}^F)$ is the localization at the image of $\mathcal{W}(F)$.

**Proof.** Given coordinates (9.14)–(9.18), we may perform the convex completion operation of gluing on $T^*\mathbb{R}_{\geq 0} \times F$, $T^*\mathbb{R}_{\geq 0} \times G$, and $T^*\mathbb{R}_{\geq 0}^2 \times P$ where $T^*\mathbb{R}_{\geq 0}$ is given the Liouville vector field $Z_{T^*\mathbb{R}_{\geq 0}} + \pi^*(\varphi(s)\partial_s)$ as in Construction 9.17. As explained below (9.22), this operation coincides (up to deformation) with the convex completion of the smoothing of $X$.

The Liouville manifold $\bar{X}$ is equipped with a natural stop given by $c_F \cup (\mathbb{R} \times c_P) \cup c_G$ (two copies of the relative cores of $F$ and $G$, glued along their common copy of $\mathbb{R} \times c_P$), such that the pushforward

$$\mathcal{W}(X) \xrightarrow{\sim} \mathcal{W}(\bar{X}, c_F \cup (\mathbb{R} \times c_P) \cup c_G)$$ (9.36)

is a quasi-equivalence by Corollary 2.11.

Let us now assume $\bar{X}$, $\bar{F}$, $G$, and $P$ are Weinstein up to deformation, and let us choose nice Liouville forms as follows. By assumption, there exists $f$ such that $\lambda_P + df$ is Weinstein, so by adding $d(\varphi(t_1)\varphi(t_2)f)$ to $\lambda_X$ in coordinates (9.16), we may assume that $\lambda_P$ is itself Weinstein. Now $F$ has boundary neighborhood coordinates (9.17), and we modify the Liouville form in these coordinates from $\lambda_P + \lambda_{T^*\mathbb{R}_{\leq 0}}$ by adding $\pi^*(1 - \varphi(t))\frac{df}{dt}$ where $\varphi : \mathbb{R}_{\leq 0} \to \mathbb{R}_{\geq 0}$ equals 1 near zero and is supported near zero. Now the locus $\{t \leq -1\}$ has convex boundary, and the completion along this boundary is $\bar{F}$. There is thus a compactly supported $f$ (supported away from the boundary neighborhood coordinates) such that $\lambda_F + df$ is Weinstein. We may add this to the Liouville form on $X$ (and similarly for $G$). We may now apply Theorem 1.10 to $\mathcal{W}(\bar{X}, c_F \cup (\mathbb{R} \times c_P) \cup c_G)$ and conclude that $\mathcal{W}(X)$ is generated by cocores of $X$ and the stabilizations of the cocores of $F$, $G$, and $P$ (which are the linking disks to the stop).

In view of the equivalence (9.36), stop removal implies that $\mathcal{W}(X) \to \mathcal{W}(\bar{X})$ is the localization at the images of $\mathcal{W}(F)$, $\mathcal{W}(G)$, and $\mathcal{W}(P)$, as these precisely account for all the linking disks to the stop appearing in (9.36). We may also convex complete along only one face, namely we may glue on $T^*\mathbb{R}_{\geq 0} \times F$ (only) to $X$ to obtain what we might write as $\bar{X}^F$. To apply stop removal to the functor $\mathcal{W}(X) \to \mathcal{W}(\bar{X}^F)$, we complete (fully) and add stops. Namely, we consider the diagram

$$
\begin{array}{ccc}
\mathcal{W}(X) & \xrightarrow{\sim} & \mathcal{W}(\bar{X}, c_F \cup (\mathbb{R} \times c_P) \cup c_G) \\
\downarrow & & \downarrow \\
\mathcal{W}(\bar{X}^F) & \xrightarrow{\sim} & \mathcal{W}(\bar{X}, c_G).
\end{array}
$$

(9.37)

The horizontal arrows are quasi-equivalences, and stop removal shows that the right vertical arrow is localization at the image of $\mathcal{W}(F)$, and hence the same applies to $\mathcal{W}(X) \to \mathcal{W}(\bar{X}^F)$. \qed
Proposition 9.32. The case $n = 2$ of Theorem 1.27 implies the general case.

Proof. We argue by induction for $n \geq 3$.

For $I \subseteq \{1, \ldots, n\}$, we use the shorthand $X_I = \cap_{i \in I} X_i$ (so $X_\emptyset = X$). There is a diagram of Liouville sectors $\{X_I\}_I$ over the poset $2^{\{1, \ldots, n\}}$ of subsets of $\{1, \ldots, n\}$ (ordered by reverse inclusion, so $\emptyset$ is maximal). Let $\Sigma_n = \{I \subseteq \{1, \ldots, n\} \mid I \neq \emptyset\}$ be the poset of non-empty subsets of $\{1, \ldots, n\}$, so $2^{\{1, \ldots, n\}} = \Sigma_n$ and hence we get (see (A.14)) a canonical map

$$\text{hocolim}_{I \in \Sigma_n} W(X_I) \to W(X).$$  \hfill (9.38)

Our aim is to show that this map is a pre-triangulated equivalence.

We decompose the poset

$$\Sigma_n = P \cup Q$$  \hfill (9.39)

into $P := \{I \in \Sigma_n \mid n \in I\}$ (those subsets which contain $n$) and $Q := \{I \in \Sigma_n \mid I \neq \{n\}\}$ (those subsets which are not equal to the singleton $\{n\}$), which intersect in $R := P \cap Q = \{J \cup \{n\} \mid J \in \Sigma_{n-1}\}$ (those subsets containing $n$ and at least one other element). In other words, this is the decomposition of $\Sigma_n$ associated to the map $\Sigma_n \to \Sigma_2 = (\bullet \leftarrow \bullet \to \bullet)$ defined by partitioning $\{1, \ldots, n\}$ into $\{1, \ldots, n-1\}$ and $\{n\}$. The hypotheses of Lemma A.14 apply to this decomposition, showing that the natural square

$$\begin{array}{ccc}
\text{hocolim}_{I \in R} W(X_I) & \longrightarrow & \text{hocolim}_{I \in P} W(X_I) \\
\downarrow & & \downarrow \\
\text{hocolim}_{I \in Q} W(X_I) & \longrightarrow & \text{hocolim}_{I \in \Sigma_n} W(X_I)
\end{array}$$  \hfill (9.40)

is a homotopy pushout.

We now relate this homotopy pushout square (9.40) to the square associated to the decomposition

$$X = (X_1 \cup \cdots \cup X_{n-1}) \cup X_n.$$  \hfill (9.41)

Namely, there is a natural (strictly commuting!) map from (9.40) to

$$\begin{array}{ccc}
W((X_1 \cup \cdots \cup X_{n-1}) \cap X_n) & \longrightarrow & W(X_n) \\
\downarrow & & \downarrow \\
W(X_1 \cup \cdots \cup X_{n-1}) & \longrightarrow & W(X)
\end{array}$$  \hfill (9.42)

given on each corner of the square by the map (A.14) (more precisely, (9.40) maps to the localization of (9.40) at the identity morphisms).

Now (9.42) is a homotopy pushout by the case $n = 2$ of Theorem 1.27 (note that the cover $X = (X_1 \cup \cdots \cup X_{n-1}) \cup X_n$ is Weinstein since the cover $X = X_1 \cup \cdots \cup X_n$ is). Hence to show that (9.38) (which is the lower right component of the map (9.40) $\to$ (9.42)) is a pre-triangulated equivalence, it is enough to show that the maps in each of the other three corners of (9.40) $\to$ (9.42) are pre-triangulated equivalences. The map

$$\text{hocolim}_{I \in P} W(X_I) \to W(X_n)$$  \hfill (9.43)
is a quasi-equivalence since \( \{n\} \in P \) is a maximal element. The map
\[
\text{hocolim}_{I \in R} \mathcal{W}(X_I) \to \mathcal{W}((X_1 \cup \cdots \cup X_{n-1}) \cap X_n) \tag{9.44}
\]
is the descent map (note that \( R = \Sigma_{n-1} \)) associated to the cover of \((X_1 \cup \cdots \cup X_{n-1}) \cap X_n\) by \(X_1 \cap X_n, \ldots, X_{n-1} \cap X_n\) (which is Weinstein since \( X = X_1 \cup \cdots \cup X_n \) is), and hence is a pre-triangulated equivalence by the induction hypothesis (Theorem 1.27 in the case \( n - 1 \)). Finally, to analyze
\[
\text{hocolim}_{I \in Q} \mathcal{W}(X_I) \to \mathcal{W}(X_1 \cup \cdots \cup X_{n-1}), \tag{9.45}
\]
note that \( \Sigma_{n-1} \subseteq Q \) is cofinal in the sense of satisfying the hypotheses of Lemma A.7, and hence this is the same as
\[
\text{hocolim}_{I \in \Sigma_{n-1}} \mathcal{W}(X_I) \to \mathcal{W}(X_1 \cup \cdots \cup X_{n-1}), \tag{9.46}
\]
which is again a pre-triangulated equivalence by the induction hypothesis. \( \square \)

**Proposition 9.33.** The case \( n = 2 \) of Theorem 1.27 is implied by the special case of two-element covers obtained by splitting along a sectorial hypersurface (Example 9.22).

![Figure 28: A general two-element sectorial cover of \( X = P \cup Q \cup R \) by \( A = P \cup Q \) and \( B = Q \cup R \).](image)

Proof. Consider the situation in Figure 28, namely \( X = P \cup Q \cup R \) is covered by \( A = P \cup Q \) and \( B = Q \cup R \), which is the structure of a general two-element cover. Note that in a general two-element sectorial cover \( X = A \cup B \), the boundaries \( \partial A \) and \( \partial B \) cannot intersect, since if they did then \( A \) and \( B \) would not cover \( X \) (compare Example 9.21). Let a neighborhood of \( P \cap Q \) be \( F \times T^*[0,1] \) and a neighborhood of \( Q \cap R \) be \( G \times T^*[0,1] \).

Now we have the following diagram of \( A_\infty \)-categories:

\[
\begin{array}{ccc}
\mathcal{W}(F) & \longrightarrow & \mathcal{W}(Q) \longrightarrow \mathcal{W}(B) \\
\downarrow & & \downarrow \\
\mathcal{W}(P) & \longrightarrow & \mathcal{W}(A) \longrightarrow \mathcal{W}(X).
\end{array}
\tag{9.47}
\]
The left square and the composite square are both associated to splitting along a sectorial hypersurface, and the right square is the one associated to our original arbitrary covering \( X = A \cup B \). We are thus done by Proposition A.15.

\[ \square \]

Proof of Theorem 1.27. By Propositions 9.32 and 9.33, it is enough to consider two-element covers obtained by splitting along a sectorial hypersurface (i.e. those from Example 9.22). In other words, we are in the geometric setup of Construction 9.18, namely we have Liouville pairs \((X, F)\) and \((Y, G)\) with a common Liouville subsector \( F \supseteq Q \subseteq G \) (where \( Q \) has boundary neighborhood coordinates \( P \times T^* \mathbb{R} \subseteq 0) \), where (the convexifications of) all of \( X, Y, Q, F \setminus Q, G \setminus Q \), and \( P \) are Weinstein (up to deformation), and we must show that the diagram

\[
\begin{array}{ccc}
W(Q) & \longrightarrow & W(X,F) \\
\downarrow & & \downarrow \\
W(Y,G) & \longrightarrow & W((X,F)\#_Q(Y,G))
\end{array}
\]

(9.48)

is a homotopy pushout.

Figure 29: Auxiliary geometric setup to prove homotopy pushout property. The arrows indicate the direction of the Reeb flow.

To show that (9.48) is a homotopy pushout, we consider a modified geometric setup where \((X, F)\) is replaced with \((X, F)\#_Q(Q \times A_2)\), and similarly for \((Y, G)\). In other words, we consider the square

\[
\begin{array}{ccc}
W(Q) & \longrightarrow & W((X,F)\#_Q(Q \times A_2)) \\
\downarrow & & \downarrow \\
W((Q \times A_2)\#_Q(Y,G)) & \longrightarrow & W((X,F)\#_Q(Q \times A_2)\#_Q(Q \times A_2)\#_Q(Y,G))
\end{array}
\]

(9.49)

associated to the geometry illustrated in Figure 29. Now Corollary 9.29 provides a semi-orthogonal decomposition of \( W((X,F)\#_Q(Q \times A_2)) \) into \( W(X,F) \) and \( W(Q) \) (that these generate follows from Theorem 1.10 and Corollary 9.31), and similarly for \( W((Q \times A_2)\#_Q(Y,G)) \) (into \( W(Y,G) \) and \( W(Q) \)) and \( W((X,F)\#_Q(Q \times A_2)\#_Q(Q \times A_2)\#_Q(Y,G)) \) (into \( W(X,F), W(Y,G), \) and \( W(Q) \)). The square (9.49) is thus of the shape considered in Example A.10, and thus Proposition A.9 applies to show that (9.49) is a homotopy pushout.
We now aim to deduce that (9.48) is a homotopy pushout by constructing a map (9.49) → (9.48) which is a localization and appealing to Lemma A.6. The inclusion $A_2 \hookrightarrow T^*[0,1]$ given by completing/convexifying/capping off the free boundary component of each $A_2$ defines the desired map (9.49) → (9.48). In this inclusion $A_2 \hookrightarrow T^*[0,1]$, there is one linking disk (arc) $\gamma$ in $A_2$ which is sent to a zero object, namely a parallelogram copy of the boundary component which gets capped off. Now in the product $Q \times A_2$, we may consider Lagrangians $L \times \gamma$, where $L \subseteq Q$. We claim that (9.49) → (9.48) quotients at precisely these objects $L \times \gamma$ by stop removal Theorem 1.16 (note that this is a separate statement for each corner of the square). This was shown in Corollary 9.31, so we are done.

A Abstract $A_\infty$-categorical results

In this appendix, we record proofs of some foundational results about $A_\infty$-categories. The first few of these are well-known over a field; we give proofs in the case of coefficients in a general commutative ring (with cofibrancy assumptions as in [26, §3.1]).

A.1 Yoneda lemma

Recall that for left $\mathcal{C}$-modules $M$ and $N$, the mapping complex from $M$ to $N$ in the dg-category $\text{Mod}_\mathcal{C}$ is defined as

$$\text{Hom}_\mathcal{C}(M, N) := \prod_{p \geq 0} \text{Hom}(\mathcal{C}(X_p, X_{p-1})[1] \otimes \cdots \otimes \mathcal{C}(X_1, X_0)[1] \otimes M(X_0), N(X_p)). \quad (A.1)$$

Recall also that there is a functor

$$\mathcal{C} \to \text{Mod}_\mathcal{C}, \quad \mathcal{C}(-, X), \quad (A.2)$$

$$X \mapsto \mathcal{C}(-, X), \quad (A.3)$$

known as the Yoneda functor.

**Lemma A.1.** For any left $\mathcal{C}$-module $M$, the natural map $M(X) \to \text{Hom}_\mathcal{C}(\mathcal{C}(-, X), M(-))$ is a quasi-isomorphism. In particular (taking $M = \mathcal{C}(-, Y)$), the Yoneda functor is fully faithful.

**Proof.** This argument is formally dual to [26, Lemma 3.7]. We consider the mapping cone

$$\prod_{p \geq 0} \text{Hom}(\mathcal{C}(X_p, X_{p-1})[1] \otimes \cdots \otimes \mathcal{C}(X_1, X_0)[1] \otimes M(X_0), N(X_p)) \quad (A.4)$$

(note that the index $p$ above is shifted by one compared to (A.1)). If $\mathcal{C}$ and $M$ are strictly unital, then $f \mapsto f(\otimes 1_X)$ is a contracting homotopy of this complex. In the general cohomologically unital case, the argument is as follows.
Let $f = \prod_{p \geq 0} f_p$ be a cocycle in the complex above. Let $m \geq 0$ be the smallest index such that $f_m \neq 0$. Note that this implies that

$$f_m \in \prod_{X=X_0,...,X_m} \text{Hom}(\mathcal{C}(X_m, X_{m-1}) \otimes \cdots \otimes \mathcal{C}(X_1, X_0), \mathcal{M}(X_m))$$

is a cocycle. Fix a cocycle $1_X \in \mathcal{C}(X, X)$ representing the cohomological unit, and consider $g := f(- \otimes 1_X)$. Using the fact that $f$ is a cocycle, we may calculate that $(dg)_{m-1} = 0$ and

$$(dg)_m = f_m(- \otimes \mu^2(-, 1_X)).$$

(A.6)

Since $\mu^2(-, 1_X)$ is homotopic to the identity map [26, Lemma 3.8], the right hand side is chain homotopic to $f_m$. We thus conclude that $(f - dg)_i = 0$ for $i < m$ and $(f - dg)_m$ represents zero in cohomology. Thus by further adding to $f - dg$ a coboundary, we can find a cocycle $f^+$ cohomologous to $f$ satisfying $(f^+)_i = 0$ for $i \leq m$. Iterating this procedure to take $m$ to infinity, we conclude that $f$ is cohomologous to zero. \qed

### A.2 Quasi-isomorphisms of $A_{\infty}$-modules

There are a priori two different notions of a map $f : \mathcal{M} \to \mathcal{N}$ of $\mathcal{C}$-modules being a quasi-isomorphism. On the one hand, one could work internally to the dg-category $\text{Mod}_\mathcal{C}$ and declare $f$ to be a quasi-isomorphism if it induces an isomorphism in the cohomology category $H^0 \text{Mod}_\mathcal{C}$ (equivalently, it has a inverse up to homotopy). On the other hand, one could work “pointwise on $\mathcal{C}$” and declare $f$ to be a quasi-isomorphism iff $f : \mathcal{M}(X) \to \mathcal{N}(X)$ is a quasi-isomorphism for every $X \in \mathcal{C}$. Fortunately, these two notions turn out to be equivalent:

**Lemma A.2.** A map $f : \mathcal{M} \to \mathcal{N}$ of $\mathcal{C}$-modules has a homotopy inverse iff it is a quasi-isomorphism pointwise on $\mathcal{C}$.

**Proof.** Obviously if $f$ has a homotopy inverse then it is a quasi-isomorphism pointwise. The point is to prove the reverse direction, namely that if $f$ is a quasi-isomorphism pointwise, then it has an inverse up to homotopy.

Let $f : \mathcal{M} \to \mathcal{N}$ be given, and suppose $f : \mathcal{M}(X) \to \mathcal{N}(X)$ is a quasi-isomorphism for every $X \in \mathcal{C}$. We construct $g : \mathcal{N} \to \mathcal{M}$ such that $gf \simeq \text{id}_\mathcal{M}$. This is enough to prove the desired result, since applying the same assertion to $g$, we find $h : \mathcal{M} \to \mathcal{N}$ with $hg \simeq \text{id}_\mathcal{N}$, so $f = \text{id}_\mathcal{N} f \simeq hg f \simeq h \text{id}_\mathcal{M} = h$, and hence $f \simeq h$ and $g$ are inverses up to homotopy.

We are looking for

$$g = \prod_{k \geq 0} g_k \in \prod_{k \geq 0 \atop X_0,...,X_k} \text{Hom}(\mathcal{C}(X_k, X_{k-1})[1] \otimes \cdots \otimes \mathcal{C}(X_1, X_0)[1] \otimes \mathcal{N}(X_0), \mathcal{M}(X_k))$$

(A.7)

$$w = \prod_{k \geq 0} w_k \in \prod_{k \geq 0 \atop X_0,...,X_k} \text{Hom}(\mathcal{C}(X_k, X_{k-1})[1] \otimes \cdots \otimes \mathcal{C}(X_1, X_0)[1] \otimes \mathcal{M}(X_0), \mathcal{M}(X_k))$$

(A.8)

such that $g$ is a cocycle of degree zero and $w$ is of degree $-1$ and satisfies $dw = gf - \text{id}_\mathcal{M}$. We construct $g$ and $w$ by induction on $k$. For the $k = 0$ step, we let $g_0$ be a homotopy inverse to
For the $k \geq 1$ inductive step, we are seeking to find $g_k$ and $w_k$ solving $(dg)_k = 0$ and $(gf - dw)_k = 0$. First observe that (under the induction hypothesis)

$$(dg)_k \in \prod_{X_0, \ldots, X_k \in \mathcal{C}} \text{Hom}(\mathcal{C}(X_k, X_{k-1})[1] \otimes \cdots \otimes \mathcal{C}(X_1, X_0)[1] \otimes N(X_0), \mathcal{M}(X_k)) \quad (A.9)$$

is always a cocycle (for any choice of $g_k$), and moreover its class in cohomology is independent of $g_k$. To find a $g_k$ for which $(dg)_k = 0$, it is thus necessary and sufficient to show that this “obstruction class” $[(dg)_k]$ vanishes. The identity $dw = gf - \text{id}_M$ in degrees $< k$ gives, upon applying $d$, the relation among “obstruction classes” $[(dg)_k]f_0 + g_0[(df)_k] - [(d\text{id}_M)_k] = 0$. The obstruction classes of $\text{id}_M$ and $f$ both vanish since a fortiori they are both cycles. Since $f_0$ is a homotopy equivalence, we conclude that the obstruction class of $g$ vanishes, as desired. This shows that we can choose $g_k$ to satisfy $(dg)_k = 0$.

We now turn to the second equation $(gf - dw)_k = 0$. We have chosen $g$ to satisfy $(dg)_k = 0$, so $gf - dw$ is a cocycle (up to degrees $\leq k$) in the morphism complex (for any choice of $w_k$). Since $gf - dw = \text{id}_M$ in degrees $< k$, we conclude that $(gf - dw)_k$ is a cocycle (for any $w_k$). Since $f_0$ is a homotopy equivalence, we may modify the cohomology class of this cocycle arbitrarily by adding to $g_k$ an appropriate cocycle (note that this operation preserves $(dg)_k = 0$). Performing such a modification of $g_k$ so that $(gf - dw)_k$ becomes null-homologous, we may now choose $w_k$ to ensure that $(gf - dw)_k = 0$ as desired. \qed

### A.3 Generation and quasi-equivalences

For an $A_{\infty}$-category $\mathcal{C}$, denote by $|\mathcal{C}|$ the set of quasi-isomorphism classes of objects (i.e. isomorphism classes of objects in the cohomology category $H^0(\mathcal{C})$). An $A_{\infty}$-functor $F : \mathcal{C} \to \mathcal{D}$ induces a map $|\mathcal{C}| \to |\mathcal{D}|$, which is injective if $F$ is fully faithful and is surjective if $F$ is essentially surjective. In particular, the tautological inclusion $\mathcal{C} \hookrightarrow \text{Tw} \mathcal{C}$ induces an inclusion $|\mathcal{C}| \subseteq |\text{Tw} \mathcal{C}|$.

**Lemma A.3.** Given a collection of objects $\mathcal{A} \subseteq \mathcal{C}$, the subset $|\text{Tw} \mathcal{A}| \subseteq |\text{Tw} \mathcal{C}|$ consisting of objects which are quasi-isomorphic to twisted complexes of objects in $\mathcal{A}$ depends only on $|\mathcal{A}| \subseteq |\mathcal{C}|$. For a quasi-equivalence $F : \mathcal{C} \to \mathcal{D}$, we have $F(|\text{Tw} \mathcal{A}|) = |\text{Tw} F(\mathcal{A})|$.

**Proof.** Given two objects $X, Y \in \mathcal{C}$, we may form $\text{cone}(f) := [X[1] \xrightarrow{f} Y] \in \text{Tw} \mathcal{C}$ for any degree zero cycle $f \in \mathcal{C}(X,Y)$. If $f, f' \in \mathcal{C}(X,Y)$ are cohomologous, then cone$(f)$ and cone$(f')$ are quasi-isomorphic objects of Tw$\mathcal{C}$. More generally, if $X \simeq X'$ and $Y \simeq Y'$ are quasi-isomorphic and $f \in \mathcal{C}(X,Y)$ and $f' \in \mathcal{C}(X',Y')$ are degree zero cycles whose classes coincide under the identification $H^0(\mathcal{C}(X,Y)) = H^0(\mathcal{C}(X',Y'))$, then cone$(f)$ and cone$(f')$ are quasi-isomorphic objects of Tw$\mathcal{C}$. The result now follows by induction. \qed

### A.4 Homotopy colimits of $A_{\infty}$-categories

We provide here an explicit construction of homotopy colimits of $A_{\infty}$-categories (adapting [37, §A.3.5] to the $A_{\infty}$ setting), and we derive some of their basic abstract properties. For
a discussion of how the notion we define here compares with other notions of homotopy colimits, see Remark A.13. As a reminder, all of the $A_\infty$-categories in this paper are small (i.e. they have a set of objects), and by a ‘commuting diagram of $A_\infty$-categories’ we always mean a strictly commuting diagram (rather than only commuting up to specified natural quasi-isomorphism of functors).

We begin by introducing the Grothendieck construction (or ‘lax homotopy colimit’) of a diagram of $A_\infty$-categories $\{\mathcal{C}_\sigma\}_{\sigma \in \Sigma}$ indexed by a poset $\Sigma$ (compare Thomason [44], Lurie [37, Definition A.3.5.11]). To set the stage, recall that the semi-orthogonal gluing $(\mathcal{C}, \mathcal{D})_\Sigma$ of $A_\infty$-categories $\mathcal{C}$ and $\mathcal{D}$ along the $(\mathcal{C}, \mathcal{D})$-bimodule $\mathcal{B}$ is, by definition, the $A_\infty$-category whose objects are $\text{Ob} \mathcal{C} \sqcup \text{Ob} \mathcal{D}$, with $\mathcal{C}$ and $\mathcal{D}$ full subcategories, with $\mathcal{B}$ as the bimodule of morphisms from objects of $\mathcal{C}$ to objects of $\mathcal{D}$, and zero morphism spaces from $\mathcal{D}$ to $\mathcal{C}$. The Grothendieck construction of a diagram of $A_\infty$-categories of the form $\mathcal{C}_0 \to \cdots \to \mathcal{C}_p$ is defined inductively by

$$\text{Groth}(\mathcal{C}) := \mathcal{C}, \quad \text{Groth}(\mathcal{C}_0 \xrightarrow{F_1} \cdots \xrightarrow{F_p} \mathcal{C}_p) := \text{Groth}(\mathcal{C}_0 \xrightarrow{F_1} \cdots \xrightarrow{F_{p-2}} \mathcal{C}_{p-2} \xrightarrow{F_{p-1}} \langle \mathcal{C}_{p-1}, \mathcal{C}_p \rangle_{\mathcal{B}(F_{p-1}, (\mathcal{C}_{p-1}, \mathcal{C}_p)).} \quad (A.11)$$

It is immediate that for any diagram of $A_\infty$-categories $\mathcal{C}_0 \to \cdots \to \mathcal{C}_p$ and any injection of totally ordered sets $i : \{0 < \cdots < q\} \hookrightarrow \{0 < \cdots < p\}$, the full subcategory of $\text{Groth}(\mathcal{C}_0 \to \cdots \to \mathcal{C}_p)$ spanned by $\mathcal{C}_i(j)$ is tautologically identified with $\text{Groth}(\mathcal{C}_{i(0)} \to \cdots \to \mathcal{C}_{i(q)})$. More generally, a map of totally ordered sets $i : \{0 < \cdots < q\} \to \{0 < \cdots < p\}$ covered by a map between diagrams $\mathcal{C}_0 \to \cdots \to \mathcal{C}_q$ and $\mathcal{D}_0 \to \cdots \to \mathcal{D}_p$ induces a functor $\text{Groth}(\mathcal{C}_0 \to \cdots \to \mathcal{C}_q) \to \text{Groth}(\mathcal{D}_0 \to \cdots \to \mathcal{D}_p)$.

Now for any diagram of $A_\infty$-categories $\{\mathcal{C}_\sigma\}_{\sigma \in \Sigma}$ indexed by a poset $\Sigma$, we define $\text{Groth}_{\sigma \in \Sigma} \mathcal{C}_\sigma$ to have objects $\bigsqcup_{\sigma \in \Sigma} \mathcal{C}_\sigma$, with morphism spaces from $\mathcal{C}_\sigma$ to $\mathcal{C}_{\sigma'}$ vanishing unless $\sigma \leq \sigma'$, and so that the full subcategory spanned by $\text{Ob} \mathcal{C}_{\sigma_0} \sqcup \cdots \sqcup \text{Ob} \mathcal{C}_{\sigma_p}$ for any $\sigma_0 < \cdots < \sigma_p$ is given by $\text{Groth}(\mathcal{C}_{\sigma_0} \to \cdots \to \mathcal{C}_{\sigma_p})$. The Grothendieck construction is functorial under maps of posets: a map $\Sigma \to T$ covered by a map of diagrams $\{\mathcal{C}_\sigma\}_{\sigma \in \Sigma} \to \{\mathcal{D}_\tau\}_{\tau \in T}$ induces a functor $\text{Groth}_{\sigma \in \Sigma} \mathcal{C}_\sigma \to \text{Groth}_{\tau \in T} \mathcal{D}_\tau$.

**Lemma A.4.** If each map $\mathcal{C}_\sigma \to \mathcal{D}_\sigma$ is fully faithful (resp. essentially surjective, generating, split-generating), then so is $\text{Groth}_{\sigma \in \Sigma} \mathcal{C}_\sigma \to \text{Groth}_{\sigma \in \Sigma} \mathcal{D}_\sigma$. □

The homotopy colimit of a diagram of $A_\infty$-categories $\{\mathcal{C}_\sigma\}_{\sigma \in \Sigma}$ is defined as the localization of the Grothendieck construction

$$\text{hocolim}_{\sigma \in \Sigma} \mathcal{C}_\sigma := \left(\text{Groth}_{\sigma \in \Sigma} \mathcal{C}_\sigma\right)[A_{\Sigma}^{-1}] \quad (A.12)$$

at the collection $A_\Sigma$ of ‘adjacent’ morphisms $X_\sigma \to F_{\sigma' \sigma}X_\sigma$ corresponding to the identity map in $H^0\text{C}_{\sigma'}(F_{\sigma' \sigma}X_\sigma, F_{\sigma' \sigma}X_\sigma) = H^0(\text{Groth}_{\sigma \in \Sigma} \mathcal{C}_\sigma)(X_\sigma, F_{\sigma' \sigma}X_\sigma)$ for $\sigma \leq \sigma'$ and $X_\sigma \in \mathcal{C}_\sigma$ (compare [37, Lemma A.3.5.13]). Homotopy colimits enjoy the same functoriality as the Grothendieck construction: a map $\Sigma \to T$ covered by a map of diagrams $\{\mathcal{C}_\sigma\}_{\sigma \in \Sigma} \to \{\mathcal{D}_\tau\}_{\tau \in T}$ induces a functor

$$\text{hocolim}_{\sigma \in \Sigma} \mathcal{C}_\sigma \to \text{hocolim}_{\tau \in T} \mathcal{D}_\tau \quad (A.13)$$

since $A_{\Sigma}$ is sent into $A_T$. (Recall the precise definition [26, Definition 3.17] of the localization $\mathcal{C}[W^{-1}]$ as the quotient of $\mathcal{C}$ by the set of all cones $[X \xrightarrow{\alpha} Y]$ where $X, Y \in \mathcal{C}$ and $\alpha \in \mathcal{C}(X, Y)$.
is a cycle representing an element of $W$; this definition is strictly functorial in the sense that for $F : \mathcal{C} \to \mathcal{D}$ with $F(W) \subseteq Z$, there is a canonically induced functor $\mathcal{C}[W^{-1}] \to \mathcal{D}[Z^{-1}]$.

Recall that an $A_{\infty}$-functor is called a quasi-equivalence (resp. pre-triangulated equivalence, Morita equivalence) iff it is fully faithful and essentially surjective (resp. generating, split-generating).

**Lemma A.5.** If each map $\mathcal{C}_\sigma \to \mathcal{D}_\sigma$ is a quasi-equivalence (resp. pre-triangulated equivalence, Morita equivalence), then so is $\text{hocolim}_{\sigma \in \Sigma} \mathcal{C}_\sigma \to \text{hocolim}_{\sigma \in \Sigma} \mathcal{D}_\sigma$.

**Proof.** Combine Lemma A.4 with [26, Corollary 3.14].

As a special case of the functoriality of homotopy colimits under maps of diagrams, note that for any diagram $\{\mathcal{C}_\sigma\}_{\sigma \in \Sigma}$ (where $\Sigma^p = \Sigma \cup \{\ast\}$ denotes the poset formed from $\Sigma$ by adding a maximal element), there is an induced functor

$$\text{hocolim}_{\sigma \in \Sigma} \mathcal{C}_\sigma \to \mathcal{C}_* [1^{-1}] \leftarrow \mathcal{C}_*$$  \hspace{1cm} (A.14)

where $1$ denotes the class of identity morphisms (the homotopy colimit of the diagram $\mathcal{C}_*$ over the one-element poset $\{\ast\}$ is given by this somewhat silly localization $\mathcal{C}_*[1^{-1}]$). This map is functorial in maps of posets $\Sigma \to T$.

A diagram $\{\mathcal{C}_\sigma\}_{\sigma \in \Sigma}$ is called a homotopy colimit diagram iff (A.14) is a pre-triangulated equivalence. A square diagram which is a homotopy colimit diagram is called a homotopy pushout (square). The prefix ‘almost’ in front of ‘homotopy colimit’ or ‘homotopy pushout’ weakens the assertion to (A.14) being fully faithful. It is easy enough to check (using Lemma A.5) that for a map of diagrams $\{\mathcal{C}_\sigma\}_{\sigma \in \Sigma} \to \{\mathcal{D}_\sigma\}_{\sigma \in \Sigma}$ where each $\mathcal{C}_\sigma \to \mathcal{D}_\sigma$ is a pre-triangulated equivalence, each diagram is a(n almost) homotopy colimit diagram iff the other is.

A functor $F : \mathcal{C} \to \mathcal{D}$ is said to quotient by a set of isomorphism classes $Q \subseteq |\text{Tw } \mathcal{C}|$ iff $F(Q)$ are zero objects and the induced functor $\mathcal{C}/Q \to \mathcal{D}/F(Q)$ is a quasi-equivalence (this condition is independent of the choice of set of objects representing the isomorphism classes in $Q$ used to define $\mathcal{C}/Q \to \mathcal{D}/F(Q)$).

**Lemma A.6** (Localization and homotopy colimits commute). If each map $\mathcal{C}_\sigma \to \mathcal{D}_\sigma$ quotients by some set of isomorphism classes $Q_\sigma \subseteq |\text{Tw } \mathcal{C}_\sigma|$, then $\text{hocolim}_{\sigma \in \Sigma} \mathcal{C}_\sigma \to \text{hocolim}_{\sigma \in \Sigma} \mathcal{D}_\sigma$ quotients by the union $\bigcup_\sigma Q_\sigma$.\hfill\Box

A basic property of colimits is that cofinal diagrams of categories have the same colimit (see, e.g., [37, §4.1.1] for rather general homotopy-invariant notions of cofinality and this property). For our purposes, we need only the following very special case of this property:

**Lemma A.7.** Suppose that an inclusion of posets $P \hookrightarrow \Sigma$ satisfies the following properties:

(i) For every $\sigma \in \Sigma$, the subset of elements of $P$ greater than or equal to $\sigma$ has a unique minimal element $p_\sigma$.

(ii) For all $p \in P$ and $p \leq q$, we have $q \in P$.

6It is tempting to write ‘quasi-equivalence’ here instead, but in practice this is too strong a requirement. Writing ‘Morita equivalence’ would weaken our results unnecessarily.
Then, the canonical map \( \text{hocolim}_{\sigma \in P} \mathcal{C}_\sigma \to \text{hocolim}_{\sigma \in \Sigma} \mathcal{C}_\sigma \) is a quasi-equivalence.

**Proof.** Let us denote by \( \mathcal{G}_\Sigma := \text{Groth}_{\sigma \in \Sigma} \mathcal{C}_\sigma \) the Grothendieck construction of the diagram indexed by \( \Sigma \), and similarly \( \mathcal{G}_P \) and \( \mathcal{G}_{\Sigma - P} \). We note first that condition (ii) implies that there is a semi-orthogonal decomposition \( \mathcal{G}_\Sigma = (\mathcal{G}_{\Sigma - P}, \mathcal{G}_P) \). In the formation of the homotopy colimit over \( \Sigma \), the class of morphisms \( A_\Sigma \) we need to invert can be divided into three classes \( A_\Sigma = A_P \sqcup A_{\Sigma - P} \sqcup A_{\Sigma - P \rightarrow P} \), where \( A_P \) and \( A_{\Sigma - P} \) are the morphisms between objects of \( \mathcal{G}_P \) and \( \mathcal{G}_{\Sigma - P} \), respectively, and \( A_{\Sigma - P \rightarrow P} \) are the morphisms from \( \mathcal{G}_{\Sigma - P} \) to \( \mathcal{G}_P \).

Let \( A_{\Sigma - P \rightarrow P}^{\min} \subseteq A_{\Sigma - P \rightarrow P} \) be the subset of morphisms from an object of \( \mathcal{C}_\sigma \) to an object of \( \mathcal{C}_{p_\sigma} \), where \( p_\sigma \) denotes the minimal \( p \in \mathcal{P} \) greater than \( \sigma \) guaranteed by (i). Observe that any morphism in \( A_{\Sigma - P \rightarrow P} \) can be factored as a morphism in \( A_{\Sigma - P \rightarrow P}^{\min} \) followed by a morphism in \( A_P \); it follows that the localization of \( \mathcal{G}_\Sigma \) by \( A_\Sigma \) coincides with the localization by \( A_P \sqcup A_{\Sigma - P}^{\min} \sqcup A_{\Sigma - P \rightarrow P} \). (Note that we may always localize in steps: for classes of morphisms \( W, Z \subseteq H^0 \mathcal{C} \), the natural functors \( \mathcal{C}[W^{-1}][Z^{-1}] \to \mathcal{C}[(W \cup Z)^{-1}] \leftarrow \mathcal{C}[(W \cup Z)^{-1}] \) are both quasi-equivalences.)

Now observe that cones(\( A_{\Sigma - P \rightarrow P}^{\min} \)) is left-orthogonal to \( \mathcal{G}_P \). To see this, consider any morphism \( z \in A_{\Sigma - P \rightarrow P}^{\min}, \) concretely \( z : c_\sigma \to f_{p_\sigma, \sigma} c_\sigma \) for some \( \sigma \in \Sigma - P \), and note that for any object \( d \in \mathcal{C}_{p_\sigma} \subseteq \mathcal{G}_P \) for \( p_\sigma \in \mathcal{P} \), the minimality condition (i) on \( p_\sigma \) implies that \( \sigma \leq p \) if \( p_\sigma \leq p \). If \( \sigma \leq p \) and \( p_\sigma \leq p \) are both false, then there is nothing to show; if they both hold, then the map

\[
\mathcal{C}_p(f_{p_\sigma, \sigma} c_\sigma, d) = \mathcal{G}_\Sigma (f_{p_\sigma, \sigma} c_\sigma, d) \overset{\text{def}}{=} \mathcal{G}_\Sigma (c_\sigma, d) = \mathcal{C}_p(f_{p_\sigma, \sigma} c_\sigma, d)
\]

is a quasi-isomorphism as desired.

Since cones(\( A_{\Sigma - P \rightarrow P}^{\min} \)) is left-orthogonal to \( \mathcal{G}_P \), it follows that \( \mathcal{G}_P \hookrightarrow \mathcal{G}_\Sigma [(A_{\Sigma - P \rightarrow P}^{\min})^{-1}] \) is fully faithful [26, Lemma 3.13]. We may now further localize both sides by \( A_P \) (Lemma 2.4) to obtain a fully faithful embedding

\[
\mathcal{G}_P[A_P^{-1}] \hookrightarrow \mathcal{G}_\Sigma [(A_P \sqcup A_{\Sigma - P \rightarrow P}^{\min})^{-1}].
\]

Now, we claim that (i) implies that the morphisms in \( A_{\Sigma - P} \) are already isomorphisms in this target \( \mathcal{G}_\Sigma [(A_P \sqcup A_{\Sigma - P \rightarrow P}^{\min})^{-1}] \). Indeed, since \( \sigma \leq \sigma' \) implies \( p_\sigma \leq p_{\sigma'} \), any adjacent morphism \( c \to f_{\sigma', \sigma} c \) in \( A_{\Sigma - P} \) differs from the corresponding adjacent morphism \( f_{p_\sigma, \sigma} c \to f_{p_{\sigma'}, \sigma} f_{p_\sigma, \sigma} c \) (which is in \( A_P \)) by morphisms in \( A_{\Sigma - P \rightarrow P}^{\min} \), and hence we conclude by [26, Lemma 3.13] that

\[
\mathcal{G}_P[A_P^{-1}] \hookrightarrow \mathcal{G}_\Sigma [(A_P \sqcup A_{\Sigma - P \rightarrow P}^{\min} \sqcup A_{\Sigma - P})^{-1}]
\]

is fully faithful (and we have already argued above that this functor is the desired map on homotopy colimits \( \text{hocolim}_{\sigma \in P} \mathcal{C}_\sigma \to \text{hocolim}_{\sigma \in \Sigma} \mathcal{C}_\sigma \)). Finally, note that this functor is essentially surjective since every element of \( \Sigma \) is \( \leq \) some element of \( \mathcal{P} \) by (i).

**Corollary A.8.** If \( \Sigma \) has a maximal element \( \tau \in \Sigma \), then the natural functor \( \mathcal{C}_\tau \rightarrows \text{hocolim}_{\sigma \in \Sigma} \mathcal{C}_\sigma \) is a quasi-equivalence.

The quasi-equivalence in Corollary A.8 above is moreover functorial in \( \Sigma \). This is easier to see for its inverse, which may be realized by beginning with the natural map \( \text{Groth}_{\sigma \in \Sigma} \mathcal{C}_\sigma \to \mathcal{C}_\tau \) and localizing so that the domain becomes \( \text{hocolim}_{\sigma \in \Sigma} \mathcal{C}_\sigma \). Now for any map \( \Sigma \to \Sigma' \) of
posets with maximal elements $\tau$ and $\tau'$ (where $\tau$ is not necessarily sent to $\tau'$), covered by a map between diagrams of $A_\infty$-categories $\{C_\sigma\}_{\sigma \in \Sigma} \to \{C_{\sigma'}\}_{\sigma' \in \Sigma'}$, there is a tautologically commutative diagram

$$
\begin{array}{ccc}
\text{Groth } C_\sigma & \longrightarrow & C_\tau \\
\downarrow & & \downarrow \\
\text{Groth } C_{\sigma'} & \longrightarrow & C_{\tau'}
\end{array}
$$

(A.18)

and localizing this diagram to obtain $\text{hocolim}_{\sigma \in \Sigma} C_\sigma \to \text{hocolim}_{\sigma' \in \Sigma'} C_{\sigma'}$ on the left gives the desired result.

**Proposition A.9.** Suppose $\{C_\sigma\}_{\sigma \in \Sigma}$ satisfies the following properties:

(i) Every $\text{Tw}^\pi C_\sigma$ is generated by the images of $C_{\sigma'}$ for $\sigma < \sigma'$ and objects which are left-orthogonal to all these images (call such $X \in \text{Tw}^\pi C_\sigma$ right-new).

(ii) Every $\text{Tw}^\pi C_\sigma$ is generated by the images of $C_{\sigma'}$ for $\sigma < \sigma'$ and objects which are left-orthogonal to all these images (call such $X \in \text{Tw}^\pi C_\sigma$ right-new).

(iii) If $X \in C_\sigma$ and $Y \in C_{\sigma'}$ are right-new and $\sigma$ and $\sigma'$ are incomparable, then $\text{Hom}_{\sigma''}(X, Y)$ is acyclic for every $\sigma'' \geq \sigma, \sigma'$.

Then $\{C_\sigma\}_{\sigma \in \Sigma}$ is an almost homotopy colimit diagram.

*Proof.* We consider $\mathcal{G} := \text{Groth}_{\sigma \in \Sigma} C_\sigma$ and $\mathcal{H} := \text{hocolim}_{\sigma \in \Sigma} C_\sigma$. Since $\text{Tw}^\pi C_\Sigma$ is generated by right-new objects, it is equivalent to localize $\mathcal{G}$ at the adjacent morphisms $Y_\tau \to F_{\tau'} Y_\tau$ for right-new objects $Y_\tau \in \text{Tw}^\pi C_\tau$. We now claim that every right-new object $X_\sigma \in \text{Tw}^\pi C_\sigma$, is, when regarded as an object of $\text{Tw}^\pi \mathcal{G}$, left-orthogonal to the cones on these adjacent morphisms. Indeed, to verify that $\mathcal{G}(X_\sigma, \text{cone}(Y_\tau \to F_{\tau'} Y_\tau))$ is acyclic, there are a few cases to consider: when $\sigma$ and $\tau$ are incomparable, this follows from (iii), when $\sigma \leq \tau$, this follows from full faithfulness of $C_\tau \to C_{\tau'}$, and when $\sigma > \tau$, the only possibility for a nonzero morphism is if $\tau' \geq \sigma$, and then it remains acyclic since $X_\sigma$ is right-new and $C_\sigma \to C_{\tau'}$ is fully faithful. Thus the map $\mathcal{G}(X_\sigma, -) \to \mathcal{H}(X_\sigma, -)$ is a quasi-isomorphism for any right-new object $X_\sigma \in \text{Tw}^\pi C_\sigma$ [26, Lemma 3.13].

Now $\text{Tw}^\pi \mathcal{H}$ is generated by images of right-new objects, so to check that $\mathcal{H} \to \mathcal{G}$ is a quasi-equivalence, it is enough to check that that $\mathcal{G} \to \mathcal{G}$ induces a quasi-isomorphism on morphisms $X_\sigma \to Y_{\sigma'}$ for right-new objects $X_\sigma \in \text{Tw}^\pi C_\sigma$ and $Y_{\sigma'} \in \text{Tw}^\pi C_{\sigma'}$. If $\sigma$ and $\sigma'$ are incomparable, then $\mathcal{G}(X_\sigma, Y_{\sigma'})$ is acyclic by inspection, and $\mathcal{G}(F_{\sigma \sigma'} X_\sigma, F_{\sigma \sigma'} Y_{\sigma'})$ is acyclic by (iii). If $\sigma' < \sigma$, then $\mathcal{G}(X_\sigma, Y_{\sigma'})$ is acyclic by inspection, and $\mathcal{G}(F_{\sigma \sigma'} X_\sigma, F_{\sigma \sigma'} Y_{\sigma'})$ is acyclic since $X_\sigma$ is right-new and $\mathcal{G} \to \mathcal{G}$ is fully faithful. If $\sigma \leq \sigma'$, then $\mathcal{G}(X_\sigma, Y_{\sigma'})$ and $\mathcal{G}(F_{\sigma \sigma'} X_\sigma, F_{\sigma \sigma'} Y_{\sigma'})$ are both quasi-isomorphic to $\mathcal{G}(F_{\sigma' \sigma} X_\sigma, X_{\sigma'})$ since $\mathcal{G} \to \mathcal{G}$ is fully faithful. Thus $\{C_\sigma\}_{\sigma \in \Sigma}$ is an almost homotopy colimit diagram. \qed

**Example A.10.** Let $C, D_1, D_2$ be $A_\infty$-categories, and let $B_i$ be $(C, D_i)$-bimodules. The square of $A_\infty$-categories

$$
\begin{array}{ccc}
C & \longrightarrow & \langle C, D_1 \rangle_{B_1} \\
\downarrow & & \downarrow \\
\langle C, D_2 \rangle_{B_2} & \longrightarrow & \langle C, D_1 \sqcup D_2 \rangle_{B_1 \sqcup B_2}
\end{array}
$$

(A.19)

satisfies the hypotheses of Proposition A.9 and is thus a homotopy pushout square.
Example A.11. Let \( \{ \mathcal{C}_\sigma \}_{\sigma \in \Sigma} \) be any diagram. The diagram \( \{ \text{Groth}_{\tau \leq \sigma} \mathcal{C}_\tau \}_{\sigma \in \Sigma^\triangledown} \) is a homotopy colimit diagram by Proposition A.9. Localizing at \( A_{\Sigma^\triangledown} \) and appealing to Lemma A.6 and Corollary A.8, we conclude that the diagram \( \sigma \mapsto \mathcal{C}_\sigma \) and \( * \mapsto \left( \text{Groth}_{\sigma \in \Sigma} \mathcal{C}_\sigma \right) [A_{\Sigma^\triangledown}^{-1}] \) is a homotopy colimit diagram. We have thus derived what was our original definition of homotopy colimits as a consequence of the formal properties Lemma A.6 and Proposition A.9 they satisfy (note that in this argument, Corollary A.8 was not used as a formal property of homotopy colimits, rather it was applied as a statement about localizations of Grothendieck constructions).

Remark A.12. The hypotheses of Proposition A.9 are not (obviously) preserved under passing to opposite categories. This asymmetry can be traced back to the asymmetry in our definition of homotopy colimits, which is also not obviously preserved under passing to opposite categories. The converse is true as well: by Example A.11, verifying the ‘opposite’ of Proposition A.9 for our definition of homotopy colimits would imply they are compatible with passing to opposite categories.

Remark A.13. A folklore result states that pre-triangulated \( A_\infty \)-categories over a field (or perhaps more generally a commutative ring, with cofibrancy assumptions as in [26, §3.1]) \( k \) are the same as \( k \)-linear stable \( \infty \)-categories. In the latter \( \infty \)-category (of \( k \)-linear stable \( \infty \)-categories), we may consider (homotopy) colimits in the \( \infty \)-categorical sense (i.e. satisfying the relevant universal property). We expect (and closely related results appear in the literature [37, Lemma A.3.5.13]) that this notion of homotopy colimit agrees with what we have defined here, namely that a diagram of pre-triangulated \( A_\infty \)-categories over \( \Sigma^\triangledown \) is a homotopy colimit diagram in the sense we define here iff it is a colimit diagram in the \( \infty \)-categorical sense. To prove this, it would suffice, by Example A.11, to show that the \( \infty \)-categorical colimits commute with localization in the sense of Lemma A.6 and satisfy Proposition A.9 (even just in the special case of \( \{ \text{Groth}_{\tau \leq \sigma} \mathcal{C}_\tau \}_{\sigma \in \Sigma^\triangledown} \)).

It is a well-known fact that, given a “nice decomposition” of a diagram \( \Sigma \), the (homotopy) colimit can be itself decomposed into (a colimit of) smaller colimits (see e.g., [37, §4.2.3] which establishes a general framework for such decomposition formulae). For our purposes, the following special case of this property (discussed as motivation in [37, beginning of §4.2]) will be sufficient:

**Lemma A.14.** Consider a poset \( \Sigma \) with a map to the poset \( \bullet \leftarrow \bullet \rightarrow \bullet \), and denote by \( P \) and \( Q \) the inverse images of \( \bullet \leftarrow \bullet \) and \( \bullet \rightarrow \bullet \), respectively, intersecting along \( R := P \cap Q \). Equivalently, \( P \) and \( Q \) are sub-posets of \( \Sigma \) with \( P \cup Q = \Sigma \), such that no element of \( P \setminus R \) is comparable to any element of \( Q \setminus R \), and no element of \( \Sigma \setminus R \) is less than any element of \( R \). Then the square

\[
\begin{array}{ccc}
\text{hocolim}_{\sigma \in R} \mathcal{C}_\sigma & \longrightarrow & \text{hocolim}_{\sigma \in Q} \mathcal{C}_\sigma \\
\downarrow & & \downarrow \\
\text{hocolim}_{\sigma \in P} \mathcal{C}_\sigma & \longrightarrow & \text{hocolim}_{\sigma \in \Sigma} \mathcal{C}_\sigma
\end{array}
\]  

\( \text{(A.20)} \)

is a homotopy pushout.

**Proof.** Let \( S_\Sigma := \text{Groth}_{\sigma \in \Sigma} \mathcal{C}_\sigma \) and similarly denote by \( S_P, S_Q, \) and \( S_R \) the Grothendieck constructions of the restricted diagrams over \( P, Q, \) and \( R \). By definition, there is a commutative
square of fully faithful embeddings

\[ \begin{array}{ccc}
G_R & \longrightarrow & G_Q \\
\downarrow & & \downarrow \\
G_P & \longrightarrow & G_\Sigma.
\end{array} \quad (A.21) \]

In fact, we claim that (A.21) is a homotopy pushout. To see this, note that the hypotheses on \( P, Q, \) and \( R \) imply that \( G_P = \langle G_R, G_P \setminus R \rangle, \) \( G_Q = \langle G_R, G_Q \setminus R \rangle, \) and in \( G_\Sigma \) there are no morphisms between \( G_P \setminus R \) and \( G_Q \setminus R \) (in either direction); now apply Example A.10.

To obtain (A.20) from (A.21), we localize at morphisms \( A_P, A_Q, A_R, \) and \( A_\Sigma. \) Since \( A_\Sigma = A_P \cup A_Q, \) we may apply Lemma A.6 to the natural map from (A.21) to (A.20) to conclude that (A.20) is a homotopy pushout. \( \square \)

**Lemma A.15.** For any diagram

\[ \begin{array}{ccc}
A & \longrightarrow & B \\
\downarrow & & \downarrow \\
D & \longrightarrow & E \\
\downarrow & & \downarrow \\
\longrightarrow & \longrightarrow & \longrightarrow
\end{array} \quad (A.22) \]

in which the leftmost square a homotopy pushout, the composite square is a homotopy pushout iff the rightmost square is.

**Proof.** By Lemma A.14, the following square is a homotopy pushout

\[ \begin{array}{ccc}
hocolim \left( \begin{array}{c}
A \longrightarrow B \\
\downarrow \\
D
\end{array} \right) & \longrightarrow & \quad \text{hocolim} \left( \begin{array}{c}
A \longrightarrow B \longrightarrow C \\
\downarrow \\
D
\end{array} \right) \\
\downarrow & & \downarrow \end{array} \quad (A.23) \]

Since the left square in (A.22) is a homotopy pushout, the left vertical arrow above is a pre-triangulated equivalence. Thus the right vertical arrow is also a pre-triangulated equivalence. Now consider the following diagram (induced by the natural maps of diagrams):

\[ \begin{array}{ccc}
hocolim \left( \begin{array}{c}
A \longrightarrow B \longrightarrow C \\
\downarrow \\
D
\end{array} \right) & \longrightarrow & \quad \text{hocolim} \left( \begin{array}{c}
A \longrightarrow C \\
\downarrow \\
D
\end{array} \right) \\
\downarrow & & \downarrow \end{array} \quad (A.24) \]
We just saw above that the left vertical arrow is a pre-triangulated equivalence. The bottom horizontal arrow is a pre-triangulated equivalence by applying Lemma A.7 to the natural map in the opposite direction (which is a section), and the top horizontal arrow is a quasi-equivalence by inspection. It follows that the right vertical arrow is a pre-triangulated equivalence, which gives the desired result.
