FORMAL POWER SERIES FOR ASYMPTOTICALLY HYPERBOLIC
BACH-FLAT METRICS

AGHIL ALAEE AND ERIC WOOLGAR

Abstract. It has been observed by Maldacena that one can extract asymptotically anti-de Sitter Einstein 4-metrics from Bach-flat spacetimes by imposing simple principles and data choices. We cast this problem in a conformally compact Riemannian setting. Following an approach pioneered by Fefferman and Graham for the Einstein equation, we find formal power series for conformally compactifiable, asymptotically hyperbolic Bach-flat 4-metrics expanded about conformal infinity. We also consider Bach-flat metrics in the special case of constant scalar curvature and in the special case of constant $Q$-curvature. This allows us to determine the free data at conformal infinity, and to select those choices that lead to Einstein metrics. The asymptotically hyperbolic mass is part of that free data, in contrast to the pure Einstein case. We then choose a convenient generalization of the Bach tensor to (bulk) dimensions $n > 4$ and consider the higher dimensional problem. We find that the free data for the expansions split into low-order and high-order pairs. The former pair consists of the metric on the conformal boundary and its first radial derivative, while the latter pair consists of the radial derivatives of order $n - 2$ and $n - 1$. Higher dimensional generalizations of the Bach tensor lack some of the geometrical meaning of the 4-dimensional case. This is reflected in the relative complexity of the higher dimensional problem, but we are able to obtain a relatively complete result if conformal infinity is not scalar flat.

1. Introduction

In seminal work, Fefferman and Graham [16, 17] studied formal series solutions of the Einstein equation for asymptotically hyperbolic metrics expanded about conformal infinity. This led to the identification of data for the singular boundary value problem for these metrics, the discovery of obstructions to power series solutions, and ultimately the discovery of new conformal invariants for the conformal boundary. It also laid the groundwork for holography within the AdS/CFT correspondence.

More recently, Gover and Waldron [18] and Graham [19] have performed similar analyses for a scalar geometric PDE problem, a singular boundary value problem for the Yamabe equation. Albin [1] has announced an analysis of asymptotically hyperbolic formal series solutions of the Euler-Lagrange equations of Lovelock actions in arbitrary dimensions.

Here we study the question of formal series expansions for a fourth-order geometric PDE in the asymptotically hyperbolic setting. We focus on the Bach equation in dimension $n = 4$, and on a slightly modified equation amenable to our methods when $n > 4$. The Bach equation is

\[(1.1) \quad 0 = B_{ab} := \frac{1}{(n - 3)} \nabla^b \nabla^d W_{abcd} + \frac{1}{(n - 2)} W_{abcd} R^{bd},\]

where $W_{abcd}$ is the Weyl tensor, $R_{ab}$ is the Ricci tensor, and $B_{ab}$ is called the Bach tensor. On closed 4-manifolds, (1.1) is the Euler-Lagrange equation for the functional

\[(1.2) \quad W(g) = \int_M |W_g|^2 dV_g,\]
though for $n \geq 5$, critical points of this functional are all locally conformally flat and therefore satisfy (1.1) somewhat trivially. There are inequivalent ways to extend the Bach tensor, originally defined only for $n = 4$, to higher dimensions. (The choice (1.1) is an integrability condition for conformally Einstein metrics (see, e.g., [11]).)

We seek solutions of (1.1) with a pole at infinity of order 2, expressible as

$$(1.3)$$

$$g = \frac{1}{x^2} (dx^2 \oplus h_x) ,$$

on a complete $n$-manifold $(M, g)$, or at least on a collar neighbourhood $x < \epsilon$, where $h_x$ extends differentiably to $x = 0$ and induces a Riemannian metric on each constant-$x$ hypersurface. Metrics obeying (1.3) are called conformally compactifiable and asymptotically hyperbolic. Metrics expressed in the form of (1.3) are said to be in (Graham-Lee) normal form. For small $x$, an open region in $(M, dx^2 \oplus h_x)$ may be isometrically embedded as an open, bounded region in a product manifold in which the locus $x = 0$ becomes a boundary. This locus, equipped with the conformal class $[h_0]$, is called conformal infinity (see Section 2 for more terminology). When such a metric is Einstein, it is called Poincaré-Einstein. We will use the term Poincaré-Bach for Bach-flat metrics of the form (1.3). As with the Poincaré-Einstein case [16, 17], we will pursue here the relatively modest goal of finding formal power series for $h_x$ for Poincaré-Bach metrics. We do not consider convergence, not even on a collar of $x = 0$. The question of asymptotics, and in particular the existence of smooth conformal compactifications, for asymptotically hyperbolic solutions of the $n = 4$ Bach equation on a neighbourhood of conformal infinity was taken up by Anderson in [4, 5].

Define

$$(1.4)$$

$$E_g := \text{Rc}_g + (n - 1)g ,$$

$$A_g := \text{tr}_g E_g = \text{Scal}_g + n(n - 1) ,$$

we sometimes omit the subscript $g$) and recall that a conformally compactifiable and asymptotically hyperbolic metric has $E_g \in O(x)$. If $E_g = O(x^2)$, a calculation shows that

$$(1.5)$$

$$h'_x(0) = 0 ,$$

where we denote differentiation with respect to $x$ by a prime. We recall (following terminology in [15]) that a conformally compactifiable metric is asymptotically hyperbolic Einstein to order $k$ if $E_g \in O(x^k)$ for $x$ any special defining function; this is also called asymptotically Poincaré-Einstein (APE) to order $k$. Any metric that is APE to order $2k < n - 1$ is partially even to order $2k$, by which we mean that the odd-order derivatives $h^{(2j-1)}(0)$ vanish for $j \leq k$.

### 1.1. Four bulk dimensions.

A major motivation for the present paper is the assertion of Maldacena [25] that in $n = 4$ bulk dimensions one can replace Einstein gravity by classical conformal gravity, by which is meant the variational theory of the action functional (1.2) with suitable asymptotically anti-de Sitter or asymptotically hyperbolic fall-off conditions and other conditions. Maldacena’s proposal is that the condition $h'_x(0) = 0$, together with certain physical considerations, selects only those critical points of this action which are Einstein. For another approach, based on Anderson’s formula [3] for renormalized volume but ultimately invoking other considerations as well, see [2].

It seems to us more satisfactory (and obviously more in the spirit of holography) instead to search for well-defined asymptotic conditions which alone can select Einstein metrics, at least when considering Riemannian signature metrics. This brings us to our first main result.
Theorem 1.1. Let $h_0$ be a Riemannian metric on $\Sigma^3$ and let $\Phi$, $\Psi$ be smooth symmetric $h_0$-tracefree $(0,2)$-tensors on $\Sigma$ such that $\text{div}_{h_0} \Psi = 0$. Let $T_i$ denote smooth functions on $\Sigma$ for $i \geq 2$. For any such data $h_0$, $\Phi$, $\Psi$, $T_i$ with $i \geq 2$, the equations $B_g = 0$ admit a unique normal form solution (1.1) on $(M^4, g)$ with $h_x \equiv h(x)$ given by a formal power series in $x$, such that $(\Sigma, [h_0]) = \partial_{\infty} M$ is the conformal infinity, with $h(0) = h_0$, $h'(0) = 0$, $\text{tr}_{h_0} h''(0) = \Phi$, $\text{tr}_{h_0} h''''(0) = \Psi$, and $\text{tr}_{h_0} h^{(i)}(0) = T_i$.

Here $\text{tr}_{h_0}$ and $\text{tr}_{h_0}$ denote the tracefree and trace parts of a $(0,2)$-tensor (converted to an endomorphism using $h_0$), respectively. The $T_i$ data are an artifact of conformal freedom (they can be made to vanish by choosing an appropriate conformal representative; see the next subsection).

In [22], the problem of boundary data for Bach-flat metrics in 4-dimensions is studied in harmonic gauge rather than in the Graham-Lee normal form gauge of equation (1.3), with analogous results to ours.

In [22], the variations of the on-shell action (1.2) (i.e., the value of the action at a Bach-flat metric) in 4-dimensions due to variations in $h_0 := h(0)$ and $h'(0)$ are computed. The variation with respect to $h_0$ is complicated but reduces when $h'(0) = 0$ to (a constant times) the third-order (in powers of $x$) piece of the electric components of the Weyl tensor evaluated at conformal infinity [22 Equation (29)]. A simple calculation then yields that this variation is just proportional to $\Psi$. The variation with respect to $h'(0)$ is (a constant times) the second-order piece of the electric Weyl tensor at infinity [22 Equation (24)], which we compute to be $-\frac{1}{2}(\Phi + \text{tr}_{h_0} \text{Rc}_{h_0})$, or simply $-\frac{1}{2}\Phi$ when $h_0$ is Einstein.

1.2. Choosing the conformal representative and the mass aspect. In view of [25], one can try to find the subset of formal power series for Bach-flat metrics which are formal power series for Poincaré-Einstein 4-metrics. Such metrics have $h'(0) = 0$ and $h''(0) = -2P_{h_0}$, where $P_{h_0}$ denotes the Schouten tensor of $h_0$. However, the 4-dimensional Bach tensor is conformally invariant. Its vanishing is an integrability condition for conformally Einstein metrics. To choose Einstein representatives within conformal classes of metrics, one must impose a further condition that will fix the trace data in Theorem 1.1. Now, Einstein metrics obviously have constant scalar curvature $\text{Scal}_g = -12$ and constant Branson $Q$-curvature $Q_g = 6$ where

$$Q_g := \frac{1}{6} \left[ -\Delta_g \text{Scal}_g + \text{Scal}_g^2 - 3|\text{Rc}_g|^2 \right].$$

One can impose one of these conditions (constant $A_g$ or constant $Q_g$) in order to fix the infinitely many trace data $T_i$ (except, it turns out, $T_4$) in Theorem 1.1 leaving finitely many data to be chosen by imposing conditions at infinity.

To see that the condition $A = 0$ fixes a unique representative metric $g$ within its conformal class of Bach-flat metrics, consider that if $\tilde{g} := u^2 g$ and $g$ both have scalar curvature $-n(n-1)$, then $u$ must be a positive solution of the Yamabe equation 

$$-\frac{4}{n(n-2)} \Delta_g u + \left( u \frac{4}{n(n-2)} - 1 \right) u = 0$$

and $u \to 1$ at conformal infinity. But then $u \equiv 1$ by the maximum principle. (We assume here completeness with no “inner” boundary—if one is present, there may sometimes be other solutions for $u$.) Since the condition $Q = 6$ fixes the same free data, it also fixes a unique representative metric $g$ within its conformal class of Bach-flat metrics.

It turns out that neither fixing $A_g$ (and thus $\text{Scal}_g$) nor fixing $Q_g$ will determine $T_4$. Consider the quantity [28, 13, 29]

$$\mu := \frac{1}{3!} \text{tr}_{h_0} h^{(4)}(0) - \left| \frac{1}{2!} h''(0) \right|_{h_0}^2 = \frac{1}{3!} T_4 - \left| \frac{1}{2!} h''(0) \right|_{h_0}^2.$$
When conformal infinity carries a round sphere metric, this quantity is called the *mass aspect function*. In that case, if $g$ is Poincaré-Einstein the mass (the integral of $\mu$ over conformal infinity) must vanish \[7\], and indeed so must the mass aspect (e.g., see the proof of Conjecture 2.7). More generally, to select Poincaré-Einstein metrics, we must choose the correct conformal class, and this was not completely achieved by choosing data as in Theorem 1.1. We must in addition impose the condition $T_4 = \frac{3}{2} h''(0) |h_0'|^2$ so that $\mu = 0$.

**Corollary 1.2.** Let $\Psi$ be a symmetric $(0,2)$-tensor on conformal infinity with $\text{tr}_{h_0} \Psi = 0$, $\text{div}_{h_0} \Psi = 0$. A formal power series for an asymptotically hyperbolic 4-metric in normal form with $h(0) = h_0$, $h'(0) = 0$, $h''(0) = -2P_{h_0}$, $h'''(0) = \Psi$, and $\frac{1}{2} \text{tr}_{h_0} (h^{(4)}(0)) = |P_{h_0}|^2$ is a formal solution of the system $B_g = 0$, $A_g = 0$ if and only if it is a formal solution of the Einstein equations.

**Corollary 1.3.** Let $\Psi$ be a symmetric $(0,2)$-tensor on conformal infinity with $\text{tr}_{h_0} \Psi = 0$, $\text{div}_{h_0} \Psi = 0$. A formal power series for an asymptotically hyperbolic 4-metric in normal form with $h(0) = h_0$, $h'(0) = 0$, $h''(0) = -2P_{h_0}$, $h'''(0) = \Psi$, and $\frac{1}{2} \text{tr}_{h_0} (h^{(4)}(0)) = |P_{h_0}|^2$ is a formal solution of the system $B_g = 0$, $Q_g = 6$ if and only if it is a formal solution of the Einstein equations.

If one does not fix $\frac{1}{2} \text{tr}_{h_0} (h^{(4)}(0)) = |P_{h_0}|^2$ (i.e., $\mu = 0$) but one does fix all the other data as in Corollary 1.2 or 1.3, one obtains for each choice of mass aspect function $\mu$ a formal power series for an asymptotically Poincaré-Bach metric. Such a series represents a conformally Poincaré-Einstein metric of arbitrary mass.

### 1.3. Higher bulk dimensions.

The Bach tensor is most naturally defined in 4 dimensions, where it has vanishing divergence and trace, is a local conformal invariant, and obstructs conformally Einstein metrics, while nontrivially generalizing the Einstein condition (i.e., there are Bach-flat metrics that are not Einstein, but Einstein metrics are Bach-flat). There are many inequivalent generalizations of the Bach tensor for $n > 4$ [41], each preserving some desirable properties of the 4-dimensional Bach tensor but none preserving them all. Despite this, the $n > 4$ case provides an opportunity to gain insight into higher-order geometric equations.\[2\] We will observe an interesting “splitting” of the free data, which may be common in higher order geometric equations, as well as a delicate mechanism for fixing the conformal gauge.

The Bach tensor as defined by (1.1) is not conformally invariant for $n \geq 5$ (see \[41\] equation 4.16). More importantly for present purposes, the divergence of the tensor defined by (1.1) is not identically zero when $n \geq 5$. Instead, it is given by

$$
\nabla^b B_{ab} = \frac{(n-4)}{(n-2)^2} \left[ \nabla_a E_{bc} - \nabla_b E_{ac} - \frac{1}{2(n-1)} (g_{bc} \nabla_a A - g_{ac} \nabla_b A) \right] E^{bc}.
$$

The quantity in square brackets is the Cotton tensor, written in terms of $E_{ab}$. The vanishing of the right-hand side of (1.8) is a necessary integrability condition for solutions of $B = 0$. This imposes constraints on the otherwise-free data. This may be an advantage in other contexts, but it complicates the power series analysis and diverts attention from some of our main points.

\[1\]There is debate over whether complete metrics can have vanishing mass but nontrivial mass aspect when $n = 4$ and $A \geq 0$ (see \[12\] for further details).

\[2\]It is possible to preserve the desirable properties of the Bach tensor in higher (even bulk) dimensions, at the expense of working with a tensor of higher differential order, specifically the *ambient obstruction tensor*. Helliwell \[23\] has studied asymptotically hyperbolic metrics with vanishing obstruction tensor as a generalization of Anderson’s boundary regularity studies \[41, 5\] to higher (even) dimensions.
To apply the Fefferman-Graham procedure in the same manner as when \( n = 4 \), it is useful to preserve the vanishing of the divergence of the (generalized) Bach tensor. To this end, we note that by simple manipulations the right-hand side of (1.8) can be written as a divergence of a symmetric \((0, 2)\)-tensor \( X_{ab} \) which vanishes when \( n = 4 \). Then \( \hat{B} := B - X \) is divergence-free, as desired (it is not in general tracefree, however), and reduces to \( B \) when \( n = 4 \).

**Proposition 1.4.** Define

\[
(1.9) \quad \hat{B}_{ab} := B_{ab} - \frac{(n - 4)}{2(n - 2)^2} \left\{ \frac{n}{(n - 1)} A E_{ab} - 2 E_{ac} E_b^c + \left[ |E|_g^2 - \frac{(n + 2)}{4(n - 1)^2} A^2 \right] g_{ab} \right\}.
\]

Then \( \nabla^b \hat{B}_{ab} = 0 \).

**Proof.** Take the divergence of (1.9) and use (1.8). \( \square \)

It is easy to check that \( \hat{B} = 0 \) derives as the Euler-Lagrange equation of the action

\[
(1.10) \quad S = \int_M \left[ |E|^2 - \frac{n A^2}{4(n - 1)} + (n - 2) A - 2(n - 1)(n - 2) \right] dV
\]

\[
= \int_M \left[ |\text{Rc}|^2 - \frac{n \text{Scal}^2}{4(n - 1)} - \frac{1}{2} (n - 2)(n - 4) \text{Scal} - \frac{1}{4} (n - 1)(n - 2)^2(n - 4) \right] dV
\]

on compact manifolds. On asymptotically hyperbolic manifolds, the integral obviously diverges. One can add boundary-at-infinity surface terms, or on APE manifolds and more generally on manifolds of volume renormalizable type one can instead replace the ordinary integral by its Riesz finite part \( R S \) (see [9]) and obtain the same Euler-Lagrange equations. Momentarily reverting to 4 dimensions, one can combine (1.10) with Anderson’s formula [3] for renormalized volume of 4-dimensional APE metrics to obtain

\[
(1.11) \quad R S = -16 \pi^2 \chi(M) + \frac{1}{2} \int_M |W|^2 dV.
\]

Using the techniques of [9, Section 4], in 4 dimensions the variation of \( R S \) produces the same Euler-Lagrange equation as the variation of \( \int_M |W|^2 dV \). This is already clear since \( B = \hat{B} \) when \( n = 4 \).

Amongst higher dimensional generalizations of the Bach equations, the equations \( \hat{B}_g = 0 \) yield to the Fefferman-Graham technique because \( \hat{B} \) is divergence-free, which follows from the fact that it is derived from an action. Furthermore, \( \hat{B} \) has the same principal part on a fixed background (in particular, standard hyperbolic \( n \)-space) as \( B \). Amongst actions that are quadratic in \( W, E, \) and \( A \), these conditions fix the action up to addition of the integral of \( c|W|^2 \), which would add terms of the form \( W_{ijkl} E^{ij} \) to \( \hat{B} \). As will become evident, terms of this form modify our series expansions only at order \( x^n \) and beyond, and will not affect our conclusions. In this sense, our results are in fact general. We did not investigate the case of so-called Gauss-Bonnet gravity in which we also add terms \( \int_M (c_1 A + c_2) dV \) to the action (for constants \( c_1 \) and \( c_2 \)) since that action may need renormalization, except that standard computations (basically borrowed from the Einstein case) show that for \( c_1 \neq 0 \) then the condition \( h'(0) = 0 \) derives now from the formalism and is no longer an assumption.

The free data split into low order and high order pairs. The former pair consists of \( h(0) \) and \( h'(0) \) (for simplicity, we will set \( h'(0) = 0 \)), while the latter pair consists of \( h^{(n-2)}(0) \) and

\[\text{Footnote: For APE metrics, } \int_M |W|^2 dV \text{ is classically defined, while the only term in } S \text{ requiring renormalization is the volume term } \int_M -2(n-1)(n-2) dV \text{ in the top line of (1.10).}\]
Note that the trace of $\hat{B}$ does not vanish identically; rather, the vanishing of the trace imposes the nontrivial condition

\begin{equation}
|E_g|^2 = \frac{1}{4} A_g^2
\end{equation}

when $n > 4$. If we were to further impose $A = 0$ as we did when $n = 4$, the only solutions would be Einstein metrics.

**Theorem 1.5.** Let $(M, g)$ be asymptotically hyperbolic and either even-dimensional, or odd-dimensional with conformal infinity whose Fefferman-Graham obstruction tensor \[16\] (see also \[15, section 3.1\]) vanishes. Let \( g = \frac{1}{2^\nu} (dx^2 \oplus h_0) \) be Poincaré-Bach with $-(n - 2) \text{tr}_{h_0} h''(0) = \text{Scal}_{h_0} \neq 0$ and $h'(0) := h'_{x} |_{x=0} = 0$. Let $\Phi$ and $\Psi$ be tracefree symmetric $(0,2)$-tensors on conformal infinity such that $\Psi$ is $h_0$-divergenceless. Then for each such $\Phi$ and $\Psi$ there is a unique formal power series solution of the equations $B_g = 0$ such that $\text{tr}_{h_0} h^{(n-2)}(0) = \Phi$, $\text{tr}_{h_0} h^{(n-1)}(0) = \Psi$.

We assume three restrictions on the data, which we now discuss.

The condition $h'(0) = 0$ is imposed mainly for tractability and focus. Without it, some of our expressions become quite complicated without compensating gains in insight. We see from the theorem that the remaining data split in a manner reminiscent to that of the Poincaré-Einstein case, with “Neumann data” now consisting of $\Phi$ and $\Psi$ (obviously the condition $h'(0) = 0$ is also of Neumann type, but were $h'(0)$ not fixed it would be natural to think of it as low-order data and pair it with the Dirichlet data $h_0$). The gap between the orders of these types of data disappears when $n = 4$.

The condition on $\text{Scal}_{h_0}$ is related to the part of the $\hat{B} = 0$ equation that fixes the conformal gauge. This equation is merely quasi-linear, and the Frobenius-type technique used in Fefferman-Graham type analyses can fail. It happens not to fail when this condition is met.

Finally, if $n$ is odd but the Fefferman-Graham obstruction tensor of the conformal boundary does not vanish, there exist families of formal polyhomogeneous series solutions of the equations $B_g = 0$ with the same free data as above (such series contain terms consisting of powers, logarithms, and their products). But there are no new, further obstructions to formal power series solutions beyond the obstruction in odd bulk dimension already known from the Poincaré-Einstein case \[16, 17\] (at least when $\text{Scal}_{h_0} \neq 0$). Intuitively one can see this by noting that $\hat{B}$ is homogeneous in $E := \text{Rc} + (n - 1)g$. We are essentially expanding the Bach tensor about $E = 0$, while expanding $E$ about a background hyperbolic metric. The recurrence relation for the coefficients of a linear homogeneous equation, here the equation (or, rather, system of equations) relating $\hat{B}$ to $E$, can always be solved (though the equation for $\hat{B}$ is only quasi-linear in $E$, so issues arise as discussed above). In contrast, the usual Fefferman-Graham obstruction arises because the recurrence relation for the Einstein tensor expansion is about a background metric determined by $h_0$, not about zero, and so the Poincaré-Einstein problem is not homogeneous. While we also expand about a background metric determined by $h_0$, we introduce no new source of nonhomogeneity and, concomitantly, no new obstructions.

In \[6\], the Bach-flat condition is studied for constant-scalar-curvature asymptotically de Sitter spacetimes in arbitrary dimension, but using harmonic gauge. The series expansion is in terms of a timelike defining function. This work focuses on extracting Einstein metrics, so the expansion is assumed to agree with the usual Fefferman-Graham expansion to order $n - 2$ inclusive, so $h'(0) = 0$ and $h^{(n-2)}(0)$ is fixed. Modulo this difference, the results are commensurate with ours.
Finally, questions arise from our work, some of which we have considered but are unable to answer. We pose two of the more important ones here, in the hope that others will be able to take them up.

One important question concerns the Lorentzian formulation. What are the free data if the metric is Lorentzian, and how do these data relate to the particle content? Similar questions were studied in physics several years ago. For example, Stelle [27] studied an action for Lorentzian signature metrics in 4 spacetime dimensions. His action differed from ours in several ways. He had an Einstein-Hilbert term (i.e., a term linear in scalar curvature; compare the second line of (1.10) with $n = 4$) as well as terms quadratic in curvatures. He did not include a $|W|^2$ term, citing the Gauss-Bonnet theorem in asymptotically flat spacetime, and he linearized about Minkowski spacetime (thus foregoing a renormalized volume term). He found the following particle content: a graviton, a massive scalar field, and a massive spin-2 particle with negative linearized energy.

Another interesting question was raised by Anderson, who asked for a characterization of data at infinity for conformally Poincaré-Einstein metrics in arbitrary coordinate gauges [5, p 463]. Since we work in a fixed gauge, and study formal expansions only, our work seems not to shed light on this issue.

1.4. Preview. This paper is organized as follows. In Section 2 we state our conventions and briefly recall the basic theory of asymptotically hyperbolic metrics and Poincaré-Einstein metrics. In Section 3 we expand $B_g$ and $\hat{B}_g$ in terms of the tensor $E_g := R g + (n - 1) g$. Section 4 is dedicated to the case of $n = 4$. In Section 4.1 we discuss the equation $B^\perp = 0$ in $n = 4$ dimensions, while in Section 4.2 we apply the Bianchi identity and obtain a condition on the divergence of the free data $h^{(3)}(0)$. The equation $A = 0$ is discussed in Section 4.3. An alternative to fixing the conformal gauge by setting $A = 0$ is instead to fix the $Q$-curvature. This is discussed in Section 4.4. The proofs of Theorem 1.1 and Corollary 1.2 then follow quickly from the earlier subsections and are given in Section 4.5.

We discuss the $n \geq 5$ case in Section 5. Section 5.1 is dedicated to the $\hat{B}^\perp = 0$ equation, Section 5.2 to the $\hat{B}^\diamond = 0$ equation (i.e., the mixed components of $\hat{B}$), and Section 5.3 to the $\hat{B}_{00} = 0$ equation where the issue of the conformal gauge arises. With this background, the proof of Theorem 1.5 is then quite brief and comprises Section 5.4.

1.5. Acknowledgements. AA was supported by a post-doctoral fellowship from the Natural Sciences and Engineering Research Council (NSERC). The work of EW was supported by an NSERC Discovery Grant RGPIN 203614. Both authors are grateful to the Fields Institute for Research in Mathematical Sciences, where much of this work was carried out, and to the organizers of its 2017 Thematic Programme on Geometric Analysis for a stimulating environment. We are also grateful to the Banff International Research Station for hosting us at its workshop 18W5108 and to C Robin Graham for discussions and helpful comments on an earlier draft.

2. Preliminaries

2.1. Notation and conventions. As already stated, we use $n = \dim M$ to be the dimension of the bulk manifold $(M, g)$.

We define the rough (or connection) Laplacian to be the trace of the Hessian, i.e., $\Delta_g := \tr_g \text{Hess} = g^{ab} \nabla_a \nabla_b$ for a given Levi-Civita connection $\nabla_g$. 
In index notation, we have

\[ R^{a}_{bcd} = \partial_{c} \Gamma^{a}_{bd} - \partial_{d} \Gamma^{a}_{bc} + \Gamma^{a}_{ce} \Gamma^{e}_{bd} - \Gamma^{a}_{de} \Gamma^{e}_{cd}, \]

\[ W_{abcd} = R_{abcd} - \frac{1}{(n-2)} (g_{ac} R_{bd} - g_{ad} R_{bc} - g_{bc} R_{ad} + g_{bd} R_{ac}) \]

\[ + \frac{1}{(n-1)(n-2)} (g_{ac} g_{bd} - g_{ad} g_{bc}) \]

\[ = R_{abcd} - \frac{1}{(n-2)} (g_{ac} E_{bd} - g_{ad} E_{bc} - g_{bc} E_{ad} + g_{bd} E_{ac}) \]

\[ + \frac{A}{(n-1)(n-2)} (g_{ac} g_{bd} - g_{ad} g_{bc}) + \frac{n}{(n-2)} (g_{ac} g_{bd} - g_{ad} g_{bc}) . \]

where \( R_{abcd} := g_{ac} R^{c}_{bcd} \) and we define

\[ E_{ab} := R_{ab} + (n-1) g_{ab} , \]

\[ A := g^{ab} E_{ab} = R + n(n-1) . \]

We note that \( E \) is not the tracefree Einstein tensor (except of course when \( A = 0 \)). We also define the Schouten tensor

\[ P_{ab} := \frac{1}{(n-2)} \left( R_{ab} - \frac{1}{2(n-1)} R g_{ab} \right) , \]

and the tracefree Einstein tensor

\[ Z_{ab} := R_{ab} - \frac{1}{n} R g_{ab} . \]

Finally, in keeping with standard usage, for a function \( f \) depending on a defining function \( x \) for conformal infinity, we write \( f \in \mathcal{O}(x^{p}) \) if there are constants \( C > 0 \) and \( \epsilon > 0 \) such that \( |f| < C x^{p} \) for all \( x < \epsilon \). Clearly, if \( f \in \mathcal{O}(x^{p}) \) for some \( p > q \), then \( f \in \mathcal{O}(x^{q}) \) as well.

2.2. Asymptotically hyperbolic metrics. Let \( \bar{M} \) be a compact manifold-with-boundary with interior \( M \). A metric \( g \) on \( M \) is called conformally compactifiable if there is a \( C^{\infty} \) metric \( \bar{g} \) on \( \bar{M} \) and a positive function \( \rho : M \to (0, \infty) \), such that

\[ g = \rho^{-2} \bar{g} \]

on \( M \), and such that \( \rho \) extends smoothly to \( \bar{M} \) with \( \rho = 0 \) and \( d \rho \neq 0 \) pointwise on \( \partial M \).

We refer to \( \partial M \) as the boundary-at-infinity of \( M \). It is sometimes denoted by \( \partial_{\infty} M \). The conformal equivalence class \( [h] \) of \( h := \bar{g} |_{\partial M} \) is called the conformal boundary of \( (M, g) \). We call \( \rho \) a defining function for the conformal boundary. We can always arrange that \( |d\rho|^{-2}_{\bar{g}} (\partial M) = 1 \).

If \( \bar{g} \) is \( C^{1} \), we can solve the eikonal differential equation \( |dx|^{2}_{\bar{g}} = 1 \) in a collar neighbourhood of \( \partial \bar{M} \), subject to the boundary condition \( x = 0 \) on \( \partial M \). Then \( x \) is called a special defining function and \( (M, g) \) is called conformally compactifiable and asymptotically hyperbolic, or simply asymptotically hyperbolic. On a neighbourhood of conformal infinity, the metric can then be written in the form of equation (2.3); equivalently, \( dx^{2} + h_{x} \) is a metric in Gaussian normal coordinate form, and \( g \) is then said to be in Graham-Lee normal form. By analyzing the formula for the conformal transformation of the curvature, one then sees that the sectional curvatures of an asymptotically hyperbolic metric approach \(-1\) as \( x \to 0 \).

There is some freedom to choose \( x \), corresponding to the freedom to choose a conformal representative \( h_{0} \) in \([h]\). We will choose a representative \( h_{0} \) below, so that \( x \) will be determined, but the freedom to vary these choices remains. For greater detail, please see [17, 15].
2.3. Poincaré-Einstein metrics. These are asymptotically hyperbolic Einstein metrics. They obey the negative Einstein equation

\[ E_g := Rc_g + (n - 1)g = 0. \]

on the bulk \( n \)-dimensional manifold \((M, g)\).

We briefly review the Fefferman-Graham expansion for these metrics. If we insert (1.3) into (2.6), we obtain

\[
E_{00} = -\frac{1}{2} \text{tr}_{h_x} h''_x + \frac{1}{2x} \text{tr}_{h_x} h'_x + \frac{1}{4} \left| h'_x \right|^2 \\
E^\sigma = \frac{1}{2} \left[ \text{div}_{h_x} h'_x - d \text{tr}_{h_x} h'_x \right] \\
E^\perp = -\frac{1}{2} h''_x + \frac{(n - 2)}{2x} h'_x + \frac{1}{2x} h_x \left( \text{tr}_{h_x} h'_x \right) + \frac{1}{2} h'_x \circ h'_x - \frac{1}{4} h'_x \text{tr}_{h_x} h'_x + \text{Rc}_{h_x}
\]

where \( E^\perp \) is the tensor on the level sets \( x = \text{const} \) obtained by projecting \( E \) onto the tangent spaces of these sets, \( E_{00} = E(\partial_x, \partial_x) \), and \( E^\sigma \) is the covector field on the levels sets of \( x \) defined by \( E^\sigma(\partial_y) = E(\partial_x, \partial_y) \).

If one computes the order-\( l \) derivative of the above expression for \( E^\perp \) with respect to \( x \), the result is

\[ x h_x^{(l+2)} + (l - n + 2) h_x^{(l+1)} - h_x \text{tr}_{h_x} h_x^{(l+1)} = F(h_x, \ldots, h_x^{(l)}) \quad l = 0, 1, 2, \ldots \]

Setting \( x = 0 \) in this equation allows one to compute by iteration the \( x \)-derivatives of order \( 1, \ldots, n - 2 \) of \( h_x \) at \( x = 0 \) in terms of \( h_x^{(0)} \). When \( l = n - 2 \) the coefficient of \( \text{tr}_{h_x} h_x^{(n-1)} \) will vanish. If the tracefree part of \( F \) does not vanish under these circumstances, then there is an obstruction to the existence of the Mclaurin expansion of \( h_x \) about \( x = 0 \). The nonvanishing terms define the ambient obstruction tensor which is of much interest in conformal geometry. The obstruction is avoided by adding logarithmic terms so that we no longer have a Mclaurin expansion for \( h_x \), but instead have a polyhomogeneous expansion. In any case, \( \text{tr}_{h_x} h_x^{(n-1)} \) is free data and can be freely chosen. Once it has been chosen, the iteration can be restarted and continued to all orders, either as a Mclaurin expansion or a polyhomogeneous expansion, as appropriate. The coefficients of the higher order terms in the expansion will in general depend on both \( h_x^{(0)} \) and \( \text{tr}_{h_x} h_x^{(n-1)}(0) \), but are otherwise completely determined. Two important results easily derived from this iteration procedure are that (i) all the odd derivatives \( h_x^{(2l+1)} \) vanish at \( x = 0 \) for \( 2l + 1 < n - 1 \), and (ii) when \( n \) is even, \( \text{tr}_{h_x} h_x^{(n-1)} \) vanishes at \( x = 0 \).

Because of the second Bianchi identity, one usually focuses attention on \( E^\perp \) alone, but the vanishing of \( E^\perp \) imposes conditions on the divergence of \( h_x \) which govern the divergence of certain data. Let \( n \) be even. Differentiating \( E^\perp \) with respect to \( x \) \((n - 2)\)-times using (2.7), we obtain that \( \text{div}_{h_x} h_x^{(n-1)} - d \text{tr}_{h_x} h_x^{(n-1)} \), evaluated at \( x = 0 \), is given by a sum of terms each of which has a factor of the form \( h_x^{(2l+1)} \) evaluated at \( x = 0 \), for some \( l \) such that \( 2l + 1 < n - 1 \). But in the last paragraph we noted that each odd derivative must vanish. Then \( \text{div}_{h_x} h_x^{(n-1)} - d \text{tr}_{h_x} h_x^{(n-1)} \) vanishes at \( x = 0 \), and since \( \text{tr}_{h_x} h_x^{(n-1)} \) itself vanishes at \( x = 0 \), we conclude that for even \( n \) then \( \text{div}_{h_x} \text{tr}_{h_x} h_x^{(n-1)} \) vanishes at \( x = 0 \). In the AdS/CFT correspondence, this allows for the interpretation of \( \text{tr}_{h_x} h_x^{(n-1)} \) as the vacuum expectation value of the CFT stress-energy tensor [24] [14]. The vanishing of \( \text{tr}_{h_x} h_x^{(n-1)} \) means that there is no conformal anomaly (which would break
the conformal invariance of the CFT), while the vanishing of \( \text{div}_{h_x} h_x^{(n-1)}|_{x=0} \) implies that the appropriate Ward identity is also anomaly-free.

For odd \( n \), this analysis determines \( \text{div}_{h_x} t f h_x^{(n-1)}|_{x=0} \) in terms of lower derivatives of \( h_x \) at \( x = 0 \), but it need not vanish. Again, for greater detail, please see [17, 15].

3. The Bach tensor

3.1. Bach tensor in terms of \( E \) and \( W \). In this section, we record the main formulas used to expand the Bach tensor in a series. The formulas are straightforward to derive, but the derivations are often tedious and lengthy calculations, so we include only the main intermediate steps in the derivation. To begin, the Bach tensor can be expanded in terms of derivations. The formulas are straightforward to derive, but the derivations are often tedious and lengthy calculations, so we include only the main intermediate steps in the derivation. To begin, the Bach tensor can be expanded in terms of derivations.

Lemma 3.1.

\[
B_{ac} = \frac{1}{(n-2)} \left\{ \Delta E_{ac} - \frac{(n-2)}{2(n-1)} \nabla_a \nabla_c A - \frac{1}{2(n-1)} g_{ac} \Delta A + 2 W_{abc} E^{bd} \\
- \frac{n}{(n-2)} \left[ E_{a}{}_{b} E_{bc} - \frac{A}{(n-1)} E_{ac} \right] + \frac{1}{(n-2)} \left[ E^2 - \frac{A^2}{(n-1)} \right] g_{ac} \\
+ n E_{ac} - g_{ac} A \right\},
\]

where, furthermore, writing

\[
g = \frac{1}{x^2} \bar{g}, \quad \bar{g} = dx^2 \oplus h_x,
\]

and using the coordinate notation \( x^a = (x^0, x^i), \ i \in \{1, \ldots, n-1\} \) so that \( x^0 \equiv x \), then

\[
\Delta E_{ac} = \Delta^g E_{ac}
\]

\[
x^2 \Delta^g E_{ac} + x \left[ 6 \nabla_0 E_{ac} + 2 g_{a}^{bc} \nabla^{b} E_{bc} + 2 \delta^{c}_{a} \nabla^{b} E_{ab} - 2 \nabla_{a} E_{0c} - 2 \nabla_{c} E_{0a} - n \nabla_{0} E_{ac} \right] \\
- 2(n-2) E_{ac} + 2 \bar{g}_{ac} E_{00} - n \delta_{a}^{c} E_{0c} - n \delta_{c}^{a} E_{0a} + 2 g_{a}^{b} \delta_{b}^{c} \left( E_{00} + h^{ij} E_{ij} \right).
\]

Proof. First, we remark on notation. Here \( \bar{\nabla} \) is the Levi-Civita connection compatible with \( \bar{g} \). By \( \nabla_a E_{bc} \), we mean \( (\nabla_{\partial_a} E) (\partial_b, \partial_c) \), and \( \bar{\nabla}^{b} E_{ab} : = \bar{g}^{bc} \bar{\nabla}_b E_{ac} \).

These results are by direct and simple, if tedious, computation. To obtain (3.1), simply plug (2.6) into (1.1) and compute using the second Bianchi identity. To obtain (3.3), note that the connection coefficients \( \Gamma^a_{bc} \) of \( \bar{g}_{ab} \) are related to those of \( g_{ab} \) (denoted \( \Gamma^{a}_{bc} \)) by

\[
\Gamma^a_{bc} = \tilde{\Gamma}^a_{bc} - \frac{1}{x} (\delta^a_b \delta^c_d + \delta^a_c \delta^c_b - \delta^a_0 \bar{g}_{bc})
\]

The usual expansion for a connection in terms of its coefficients yields

\[
\nabla_a E_{bc} = \nabla_a E_{bc} + \frac{1}{x} \left( 2 \delta^{a}_{c} E_{bc} + \delta^{b}_{a} E_{ac} + \delta^{0}_{a} E_{ab} \right) - \bar{g}_{ab} E_{0c} - \bar{g}_{ac} E_{0b}
\]

Now differentiate once more by applying \( \nabla_a \) to (3.5) and use that \( \Delta^g E_{ac} = g^{bd} (\nabla_b \nabla_a E_{bc}) \). This is lengthy but simple and we omit the details.

□
It will be useful to expand equation (3.1) componentwise. The non-vanishing Christoffel symbols of the Levi-Civita connection of $\tilde{g}_{ij}$ in the coordinates $x^a = (x^0 = x, x^i)$ are

$$\tilde{\Gamma}^0_{ij} = -\frac{1}{2} h'_i h'_j =: K_{ij},$$

$$\tilde{\Gamma}^i_{0j} = \tilde{\Gamma}^i_{0j} = \frac{1}{2} h^{ik} h'_k = -h^{ik} K_{jk} =: K^i_j,$$

$$\tilde{\Gamma}^i_{jk} = \Xi^i_{jk},$$

where the $\Xi^i_{jk}$ are the Christoffel symbols of the Levi-Civita connection $D = D_x$ compatible with $h_x$ on each constant-$x$ slice. Then we easily compute that

$$\tilde{\nabla}_0 E_{00} = E'_0,$$

$$\tilde{\nabla}_i E_{00} = D_i E_{00} + 2 K^i_k E_{0k},$$

$$\tilde{\nabla}_0 E_{0i} = E'_0 + K^i_k E_{0k},$$

$$\tilde{\nabla}_i E_{0j} = D_i E_{0j} + K^i_k E_{jk} - K_{ij} E_{00},$$

$$\tilde{\nabla}_0 E_{ij} = E'_i + K^i_k E_{jk} + K^j_k E_{ik},$$

$$\tilde{\nabla}_i E_{jk} = D_i E_{jk} - K_{ij} E_{0k} - K_{ik} E_{0j}.$$

Differentiating these expressions once more and summing, one obtains the expressions

$$(\Delta_g E)_{00} = x^2 \left\{ E'_{00} + \Delta_h E_{00} - H E'_{00} - 2|K|^2_h E_{00} + 2D^i (K^j_i E_{0j}) + 2K^{ij} D_j E_{0j} + 2K^j_k K^{jk} E_{ik} \right\}$$

$$- x \left\{ (n-6) E'_{00} - 4D^i E_{0i} - 4K^{ij} E_{ij} + 4H E_{00} \right\} - 4(n-2) E_{00} + 2h^{ij} E_{ij},$$

$$(\Delta_g E)_{0i} = x^2 \left\{ E'_{0i} + \Delta_h E_{0i} - H E'_{0i} + 2K^i_j E_{0j} + (K^i_j) E_{ij} - 2K^i_j K^j_k E_{0k} - |K|^2_h E_{0i} 
-H K^j_i E_{0j} + 2K^j_k K^j_i E_{ik} + (D_j K^j_k) E_{ik} - 2K^j_k D_j E_{00} - (D^j E_{ij}) E_{00} \right\}$$

$$- x \left\{ (n-6) E'_{0i} + nK^j_i E_{0j} - 2D^j E_{ij} + 2H E_{0i} + 2D_j E_{00} \right\} - (3n-4) E_{0i},$$

$$(\Delta_g E)_{ij} = x^2 \left\{ E'_{ij} + \Delta_h E_{ij} - H E'_{ab} + 2K^i_k E'_{jk} + 2K^j_k E'_{ik} - H K^k_j E_{jk} - H K^k_j E_{ik} + (K^i_k) E_{jk} + (K^j_k) E_{ik} + 2K^i_k K^j_l E_{kl} - 2K_{ik} D^j E_{0j} - 2K_{jk} D^k E_{0i} \right\}$$

$$- (D^k K^i_k) E_{0j} - (D^k K^j_k) E_{0i} + 2K^i_k K^j_k E_{00} \right\}$$

$$- x \left\{ (n-6) E'_{ij} + (n-8) \left\{ K^k_j E_{jk} + K^j_k E_{ik} \right\} - 2 \left\{ D_i E_{0j} + D_j E_{0i} \right\} - 4K_{ij} E_{00} \right\}$$

$$- 2(n-2) E_{ij} + 2h_{ij} E_{00}.$$  

In the above, indices are raised with $h^{-1}$, denoted as usual by $h^{ij}$. We need also that

$$(\text{Hess } A)_{00} = A'' + \frac{1}{x} A',$$

$$(\text{Hess } A)_{0i} = D_i (A') + K^i_k D_k A + \frac{1}{x} D_i A,$$

$$(\text{Hess } A)_{ij} = D_i D_j A - K_{ij} A' - \frac{1}{h_{ij}} A',$$

$$\implies \Delta_g A = x^2 \left[ A'' - H A' + \Delta_h A \right] - (n-2)x A' ,$$
where (2.7) yields

\[
A = -x^2 \text{tr}_h h'' + (n-1)x \text{tr}_h h'_x + \frac{3}{4} x^2 |h'_x|_h^2 - \frac{x^2}{4} (\text{tr}_h h'_x)^2 + x^2 \text{Scal}_h
\]

\[
= x^2 (2H' - |K|^2_h - H^2 + \text{Scal}_h) - 2(n-1)x H .
\]

Putting this all together, we have

\[
B_{00} = \frac{x^2}{(n-2)} \left\{ \frac{1}{2} E_{00}'' - \frac{1}{2} \text{tr}_h (E^{1''}) - \frac{(2n-3)}{2(n-1)} H E_{00}' - \frac{1}{2(n-1)} H \text{tr}_h (E^{1'})
\right.
\]

\[+ 2K^{ij} E'_{ij} - (K^{ij})' E_{ij} + \Delta_h E_{00} - \frac{1}{2(n-1)} \Delta_h \hat{A} + 2D_i (K^{ij} E_{0j}) + 2K^{ij} D_i E_{0j}
\]

\[+ 2K^{ij} K_i^k E_{jk} + \frac{1}{(n-1)} H K^{ij} E_{ij} - 2|K|^2_h E_{00} - E_{00}^2 - |E_{00}|_h^2
\]

\[+ \frac{1}{(n-2)} E_{00} \text{tr}_h E^+ + \frac{1}{(n-2)} \left[ |E^+|_h^2 - \frac{1}{(n-1)} \left( \text{tr}_h E^+ \right)^2 \right]
\]

\[+ \frac{x}{(n-2)} \left\{ -(n-4) E_{00}' - 2 \text{tr}_h (E^{1'}) + 4D^j E_{0j} - \frac{(6n-7)}{(n-1)} H E_{00}
\right.
\]

\[+ \frac{1}{(n-1)} H \text{tr}_h E^+ \right\}
\]

\[-3E_{00} + \frac{2x^4}{(n-2)} W_{0i0j} h^{ik} h^{jl} E_{kl} ,
\]

where we write $\hat{A} := \text{tr}_g E \in \mathcal{O}(1/x)$. Continuing, we have

\[
B_{0i} = \frac{x^2}{(n-2)} \left\{ E_{0i}'' + 2K_i^j E_{0j} - H E_{0i}' - \frac{(n-2)}{2(n-1)} D_i \left[ E_{00}' + \text{tr}_h (E^{1'}) \right] + \Delta_h E_{0i}
\right.
\]

\[+ D^k (K_i^j E_{ij} - K_{ik} E_{00}) + K^{jk} D_j E_{ik} - K_i^j D_j E_{00} - \frac{(n-2)}{2(n-1)} \left[ 2D_i (K^{jk} E_{jk})
\right.
\]

\[+ K_i^j D_j E_{00} + K_i^j D_j (\text{tr}_h E^+) \right] + K''_{ij} h^{jk} E_{0k} - H K_i^j E_{0j} - |K|^2_h E_{0i}
\]

\[+ \frac{n}{(n-2)} \left[ E_{00} E_{0i} + E_{0j} h^{jk} E_{ki} \right] + \frac{n}{(n-1)(n-2)} \left( E_{00} + \text{tr}_h E^+ \right) E_{0i}
\]

\[+ \frac{x}{(n-2)} \left\{ -(n-6) E_{0i}' - 2D_i E_{00} + 2D^j E_{ij} - \frac{3(n-2)}{2(n-1)} D_i \left( E_{00} + \text{tr}_h E^+ \right)
\right.
\]

\[-nK_i^j E_{0j} - 4H E_{0i}
\]

\[-2E_{0i} + \frac{2x^4}{(n-2)} \left( W_{0ijk} h^{il} h^{kp} E_{lp} - W_{00} h^{jk} E_{0k} \right) ,
\]
and finally

\[
B_{ij} = \frac{x^2}{(n-2)} \left\{ E''_{ij} - \frac{1}{2(n-1)} \left[ E''_{00} + \text{tr}_{h_x}(E^{'1}''') \right] h_{ij} - HE_{ij} + 2K^i_k E'_{jk} + 2K^j_k E'_{ik} \\
+ \frac{1}{2(n-1)} \left[ (n-2)K_{ij} + Hh_{ij} \right] E'_{00} + \frac{1}{2(n-1)} \left[ (n-2)K_{ij} + Hh_{ij} \right] \text{tr}_{h_x}(E^{1'}) \\
- \frac{2}{(n-1)} \left[ (n-2)K_{ij} + Hh_{ij} \right] E_{ij} - \frac{n}{(n-2)} \left[ E_{ij}h^k_{kl}E_{ij} - \frac{1}{n} \left( E^2_{00} + |E^{1'}|_h^2 \right) h_{ij} \right] \right.
\]

\[
\left. + \frac{n}{(n-1)(n-2)} \left[ E_{00} + \text{tr}_{h_x} E^1 \right] \left[ E_{ij} - \frac{1}{n} E_{00}h_{ij} - \frac{1}{n} \left( \text{tr}_{h_x} E^1 \right) h_{ij} \right] \right) \right] \right]
\]

(3.13)

\[
+ \frac{x}{(n-2)} \left\{ -(n-6)E_{ij} - (n-4) \left( K^i_k E_{jk} + K^j_k E_{ik} \right) + 4K^i_k E_{00} - 2HE_{ij} \\
+ \frac{(n-4)}{(n-1)} \left[ E_{00}h_{ij} + \text{tr}_{h_x}(E^{1'})h_{ij} \right] + \frac{2(n-4)}{(n-1)} K^k_lE_{kl}h_{ij} \\
- \frac{1}{(n-1)} \left[ (n-2)K_{ij} + Hh_{ij} \right] E_{00} + \text{tr}_{h_x} E^1 \right] \\
- \frac{(n-4)}{(n-2)} \left[ E_{ij} - \frac{1}{(n-1)} \left( \text{tr}_{h_x} E^1 \right) h_{ij} \right] + \frac{3}{(n-1)} E_{00}h_{ij} \\
+ \frac{x^4}{(n-2)} \left[ W_{ijkl}h^{kp}h^{lq}E_{pq} + 2W_{ikj0}h^{kl}E_{0l} + W_{i0j0}E_{00} \right].
\]

Despite their lengths, the above expressions have a simple structure, owing at least in part to the quasilinearity of the Bach tensor as a function of the metric. For example, the tensor $E$ of an asymptotically hyperbolic metric is $O(x)$ in all dimensions, while its normal form components can diverge as $O(1/x)$. For the Bach tensor we can now read off from the above expressions the comparable result.

**Lemma 3.2.** The normal-form components of the Bach tensor of an asymptotically hyperbolic $n$-manifold admit a $C^0$ extension to conformal infinity, and vanish at conformal infinity when $n = 4$. We have

\[
|\hat{B}|_g \in \left\{ \begin{array}{ll}
O(x^2), & n > 4 \\
O(x^3), & n = 4
\end{array} \right.
\]

**Proof.** In deriving equations (3.11), (3.12), and (3.13), we have not expanded the Weyl tensor contribution to the Bach tensor. To establish the lemma, such an expansion is not necessary. To see this, observe first that the conformal properties of the Weyl tensor are such that $W^g_{abcd} = \frac{1}{x^4} W^g_{abcd}$. Now $\left( W^g \right)^a_{bcd} \in O(1)$, so the components of $W^g$ with respect to a normal-form basis $\{ \partial_0, \partial_i \}$ obey $W^g_{abcd} \in O(1)$ as well (lowering the index with $\hat{g}$). Hence $W^g_{abcd} \in O(x^{-2})$. Further, $h^{ij} \in O(1)$ and, by equations (2.7), $E_{ab} \in O(1/x)$. Thus, any product of the form $W^g \ast h^{-1} \ast E^g$ or $W^g \ast h^{-1} \ast h^{-1} \ast E^g$ (with all indices lowered in $W$) has components that lie in (at worst) $O(x^{-3})$. But each time such a term appears in equations (3.11), (3.12), and (3.13), it appears with coefficient $x^4$, and hence the components of these terms in the normal-form basis vanish at least as $O(x)$.

We simply substitute equations (2.7) into equations (3.11) + (3.13). Together with the fact that the Weyl tensor term $W_{dabc}E^{bd}$ in (3.1), expressed in a normal form basis, is in $O(x)$,
straightforward cancellation of terms now leads directly to
\[ B_{00} \in \mathcal{O}(x) , \]
\[ B_{0i} \in \mathcal{O}(x) , \]
\[ B_{ij} = \frac{(n - 4)}{(n - 2)} \left\{ (n - 3) \left[ K'_{ij} - \frac{1}{(n - 1)} \bar{H}' h_{ij} + \frac{2}{(n - 1)} |K|^2 h_{ij} \right] \\
+ (n - 4) \left[ K^k K_{jk} - \frac{1}{(n - 1)} |K|^2 h_{ij} \right] - Z^h_{ij} + \bar{H} K_{ij} - \frac{1}{(n - 1)} H^2 h_{ij} \right\} + \mathcal{O}(x) , \]
where we write \( h \) for the boundary metric \( h := h_x |_{x=0} \) and write \( Z^h := tf_{h_x} R_c h \).

Thus when \( n = 4 \), the normal-form components of \( \hat{B} \) are of order \( x \). If the components of a \( (0,2) \)-tensor in the normal-form basis are in \( \mathcal{O}(x^k) \), obviously the tensor norm of that tensor is in \( \mathcal{O}(x^{p+2}) \), so \( |\hat{B}|_g = |\hat{B}|_g \in \mathcal{O}(x^3) \).

For \( n > 4 \), we must compute the additional terms on the right-hand side of (1.9). Using (2.7), (3.10), and (3.15) we find that
\[ \hat{B}_{00} = B_{00} - \frac{1}{2} (n - 4) \left[ |K|^2 h - H^2 + \mathcal{O}(x) \right] \\
= - \frac{1}{2} (n - 4) \left[ |K|^2 h - H^2 \right] + \mathcal{O}(x) , \]
\[ \hat{B}_{0i} = \mathcal{O}(x) , \]
\[ \hat{B}_{ij} = B_{ij} + (n - 4) \left[ K^k K_{jk} - \bar{H} K_{ij} - \frac{1}{2} \left( |K|^2 h - H^2 \right) h_{ij} \right] \\
= (n - 4) \left[ (n - 3) \left( K'_{ij} - \frac{1}{(n - 1)} \bar{H}' h_{ij} + \frac{2}{(n - 1)} K^k K_{jk} - \bar{H} K_{ij} \right) \right. \\
\left. - \frac{1}{2} |K|^2 h_{ij} + \frac{n}{2(n - 1)} H^2 h_{ij} \right] + \mathcal{O}(x) . \]

Hence \( \hat{B}_{00} \) and \( \hat{B}_{ij} \) are of order 1, and so \( |\hat{B}|_g \in \mathcal{O}(x^2) \) as claimed.

\( \square \)

3.2. The Bianchi identity. In the sequel we will not make direct use of the expansions of \( \hat{B}^\omega \) (i.e., \( \hat{B}_{0i} \)) and \( \hat{B}_{00} \), except somewhat in section 5.3. Instead, we will solve the equation \( \hat{B}^\perp = 0 \) and use the vanishing of the divergence of \( \hat{B} \) to show that the remaining components vanish. Indeed, when \( n = 4 \) (so \( \bar{B} = \hat{B} \)), \( B_{00} \) will vanish simply because then the Bach tensor is traceless.

The vanishing of the divergence (Proposition 1.14) yields the equations
\[ \hat{B}'_{00} - \left[ H + \frac{(n - 2)}{x} \right] \hat{B}_{00} + D^j \hat{B}_{0j} = K^{jk} \hat{B}_{jk} , \]
\[ \hat{B}'_{0i} - \left[ H + \frac{(n - 2)}{x} \right] \hat{B}_{0i} = -D^j \hat{B}_{ij} . \]

Obviously when \( \hat{B}_{ij} = 0 \) this becomes a homogeneous linear system for \( (\hat{B}_{00}, \hat{B}_{0i}) \), admitting the trivial solution.

**Proposition 3.3.** Assume that \( \hat{B}_{ij}^{(\alpha)}(0) = 0 \) for all \( 0 \leq \alpha \leq \beta \). If \( \beta \geq n - 2 \) assume further that \( \hat{B}_{0i}^{(n - 2)}(0) = 0 \). Then \( \hat{B}_{0i}^{(\beta + 1)}(0) = 0 \). In addition, under these conditions we also have \( \hat{B}_{00}^{(\beta + 1)}(0) = 0 \) provided that, for \( \beta \geq n - 2 \), we assume as well that \( \hat{B}_{00}^{(n - 2)}(0) = 0 \).
Proof. We have from Lemma \[3.2\] that \( \hat{B}_{0i} \in \mathcal{O}(x) \) and \( \hat{B}_{ij} \in \mathcal{O}(1) \). Then expand \( B_{0i} = \sum_{\beta=1}^{\infty} b_{i(\beta)} x^\beta \), \( H = \sum_{\beta=0}^{\infty} h_{i(\beta)} x^\beta \), and \( D^j B_{ij} = \sum_{\beta=2}^{\infty} c_{i(\beta)} x^\beta \). Note that \( \hat{B}^{(n-2)}_{0i}(0) = 0 \iff b_{i(n-2)} = 0 \). Then it is an easy exercise to expand (3.18) and obtain

\[
\sum_{\beta=1}^{\infty} [\beta - (n - 2)] x^{\beta-1} - \sum_{\beta=1}^{\infty} \left( \sum_{\alpha=1}^{\beta} b_{i(\alpha)} h_{i(\beta-\alpha)} \right) x^\beta - \sum_{\beta=0}^{\infty} c_{i(\beta)} x^\beta = 0
\]

(3.19)

Equating coefficients of powers of \( x \), we have

\[
b_{i(1)} = -\frac{1}{(n-3)} c_{i(0)},
\]

(3.20)

\[
[\beta - (n - 3)] b_{i(\beta+1)} = c_{i(\beta)} + \sum_{\alpha} b_{i(\alpha)} h_{i(\beta-\alpha)}.
\]

It follows by induction that \( b_{i(\beta+1)} = 0 \) and so \( \hat{B}^{(\beta+1)}_{0i}(0) = 0 \). One sees from the left-hand side of (3.20) that the induction pauses when \( \beta = n - 3 \), but then the assumption \( \hat{B}^{(n-2)}_{0i}(0) = 0 \) fulfills the inductive hypothesis and the induction can be restarted and continued arbitrarily. The proof for \( B^{(\beta+1)}_{00} \) now follows similarly.

We recall that for \( n = 4 \), we have that \( \text{tr}_g \hat{B} \equiv \text{tr}_g B = 0 \). From this, we see that \( B_{00} \) vanishes order-by-order whenever \( B_{ij} \) does. We do not need to appeal to the above proposition.

4. Four dimensions

4.1. The equation for \( B_{ij} \). We set \( n = 4 \) and drop the \( \hat{B} \) notation in this section since \( B \equiv \hat{B} \) for \( n = 4 \). Then equation (3.13) becomes

\[
B_{ij} = \frac{1}{2} x^2 \left\{ E''_{ij} - \frac{1}{6} \left[ E''_{00} + \text{tr}_{h} (E^\perp)^2 \right] h_{ij} - H E'_{ij} + 2K^i_k E'_{jk} + 2K^j_k E'_{ik} \\
+ \frac{1}{3} \left[ K_{ij} + \frac{1}{2} H h_{ij} \right] E_{00} + \frac{1}{3} \left[ K_{ij} + \frac{1}{2} H h_{ij} \right] \text{tr}_{h} (E^\perp) \right\} \\
- \frac{2}{3} K^k_l E'_{kl} h_{ij} - 2E_{ik} h_{kl} E_{jl} + \frac{1}{2} \left( E_{00}^2 + |E^\perp|^2 \right) h_{ij} \\
+ \frac{1}{2} \left[ E_{00} + \text{tr}_{h} E^\perp \right] \left[ E_{ij} - \frac{1}{4} E_{00} h_{ij} - \frac{1}{4} (\text{tr}_{h} E^\perp) h_{ij} \right] \right\} \\
+ \frac{1}{2} x \left\{ 2E'_{ij} + 4K_{ij} E_{00} - 2H E_{ij} + \frac{2}{3} \left[ K_{ij} + \frac{1}{2} H h_{ij} \right] \left[ E_{00} + \text{tr}_{h} E^\perp \right] \right\} \\
+ E_{00} h_{ij} + \frac{1}{2} x^4 \left[ W_{ikjl} h^k p^l q^j E_{pq} + 2W_{ikjl} h^k p^l E_{0l} + W_{000} E_{00} \right].
\]

In view of Lemma \([3.2]\) the above expression can be expanded as a power series in \( x \). If one substitutes (2.7) into (4.1), one obtains an expression that is perfectly regular at \( x = 0 \)—indeed, with vanishing constant term—despite the fact that the expression for \( E \) in (2.7) has some divisions by \( x \). In particular, let LWT denote a sum of low weight terms. These are terms that are regular at \( x = 0 \) and have the form of a (possibly) derivative-dependent coefficient
$C(h_x, h'_x, \ldots, h^{(p)}_x)$ multiplying a nonnegative power of $x$, say $x^q$. The weight is defined to be the order of the highest $x$-derivative of $h_x$ appearing in $C$ minus the power of $x$ multiplying the term; i.e., the weight is $p - q$. For example, the weight of the term $-\frac{1}{4}x^2 \text{tf}_{h_x} h^{(4)}_{ij}(x)$ is $4 - 2 = 2$, while a term such as $x^2 (\text{tr}_{h_x} h') \text{tf}_{h_x} h'_{ij}$ would have weight $1 - 2 = -1$. Then we have the following.

Lemma 4.1.

\begin{equation}
B_{ij}(x) = -\frac{1}{4}x^2 \text{tf}_{h_x} h^{(4)}_{ij}(x) + \text{LWT}.
\end{equation}

Proof. Simply plug (2.7) into (4.1). While the resulting expression is very lengthy, one can eliminate most terms immediately by observing that the highest weight contributions must arise from the linear terms $-\frac{1}{4}x^2 E''_{ij}, x E'_{ij}$, and $E_{00}h_{ij}$. Expanding these terms using (2.7) yields the result.

Lemma 4.2. Let $B_{ij}(x) = 0$ and $n = 4$. Then for some $h_0$-tracefree tensor $F$ on $\partial_{\infty} M$ and any $s \geq 4$ we may write

\begin{equation}
\text{tf}_{h_0} h^{(s)}_{ij}(0) = F_{ij}(h_0, h'(0), \ldots, h^{(s-1)}(0)).
\end{equation}

Proof. Equation (4.2) with $B_{ij}(x) = 0$ implies that

\begin{equation}
\frac{1}{4}x^2 \text{tf}_{h_x} h^{(4)}_{ij}(x) = \text{LWT}.
\end{equation}

If one differentiates the left-hand side $r$-times, with $r \geq 2$, and sets $x = 0$, one obtains $\frac{1}{4^r}r(r - 1) \text{tf}_{h_0} h^{(r+2)}(0)$ plus terms of lower differential order.

On the right-hand side, consider a term of weight $w := p - q$ for $p$ and $q$ as described immediately before Lemma 4.1. If $r < q$, a factor of $x$ remains after differentiation, so the term vanishes when we set $x = 0$. Hence take $r \geq q$. Then the term contributes as

$$\frac{1}{4^r}r^{r-q} \frac{\partial^{r-q}}{\partial x^{r-q}} |_{x=0} C(h_x, h'_x, \ldots, h^{(p)}_x).$$

Thus, the highest derivative that can arise from this term is $h^{(r-q+p)}(0)$. Now $r - q + p = r + w < r + 2$ since $w < 2$.

Combining both sides, we have that $\text{tf}_{h_0} h^{(r+2)}(0)$ equals a sum of terms that depend on no derivative higher than $h^{(r+1)}(0)$. Now set $s = r + 2$.

This lemma does not determine the trace of $h^{(r)}(0)$ for any order $r$. It does, however, show that one can determine all the coefficients in a formal power series solution of $B_{ij} = 0$ in the case of an asymptotically hyperbolic 4-dimensional bulk manifold in terms of given data $h_0 \equiv h(0), h'(0), h''(0)$, and $h'''(0)$ at the conformal boundary, if one is also given as data the traces $\text{tr}_{h_0} h^{(r)}(0)$ for all $r$. There are no obstructions, so it is not necessary to augment the power series with logarithmic terms.

Corollary 4.3. If $B_{ij}(x) = 0$ then there is an $h_0$-tracefree tensor $G$ on $\partial_{\infty} M$ such that

\begin{equation}
\text{tf}_{h_0} h^{(s)}_{ij}(0) = G(h_0, h'(0), h''(0), h'''(0), \text{tr}_{h_0} h^{(4)}(0), \ldots, \text{tr}_{h_0} h^{(s-1)}(0)), \; s \geq 4.
\end{equation}

Proof. Immediate from Lemma 4.2 by induction on $s$.

4.2. The equation for $B_{0i}$. We know from Proposition 4.3 that, in the presence of the condition $B_{ij}(x) = 0$, then the series expansion $B_{0i}(x)$ is determined by the divergence identity except for the coefficient of the order $x^{n-2}$ term. Here we have $n = 4$. Then the only additional information to be learned from solving the $B_{0i}(x) = 0$ equation directly is the condition(s) under which $B_{0i}^{(n)}(0)$
will vanish. The next result shows that the condition $B''_0(0) = 0$ imposes a condition on the data $h^{(3)}(0)$ which, in the Poincaré-Einstein setting, has an important interpretation in the AdS/CFT correspondence.

**Proposition 4.4.** Let $n = 4$ and choose $h'_{ij}(0) = 0$. Then $B''_0(0) = 0 \iff \text{div}_{h_0} \text{tr}_{h_0} h^{(3)}(0) = 0$.

**Proof.** Explicit computation beginning with (3.12) and using (2.7) yields

\begin{equation}
B_0 = \left[ \frac{1}{2} x^2 \text{div}_{h_x} \left( \text{tr}_{h_x} h^{(3)}_x \right) - \frac{1}{2} (n - 4) x \text{div}_{h_x} \left( \text{tr}_{h_x} h''_{x} \right) + LWT \right].
\end{equation}

Now set $n = 4$, differentiate twice with respect to $x$, and set $x = 0$. Upon taking two $x$-derivatives of (3.12), one can see by inspection (using as well (2.7)) that each term arising from twice differentiating the terms denoted LWT either contains a factor of $K_{ij}$ or has a coefficient of $x$ or $x^2$. Hence these terms vanish upon setting $x = 0$ and then $K_{ij} := -\frac{1}{2} h'_{ij}(0) = 0$. Thus we obtain

\begin{equation}
0 = B''_0(0) = D^k \left( \text{tr}_{h_x} h^{(3)}_{ik}(0) \right).
\end{equation}

\[\Box\]

The same result in the Poincaré-Einstein case is essential for the AdS/CFT correspondence, because it allows for the interpretation of $h^{(3)}(0)$ (or, for a $2n$-dimensional bulk, $h^{(2n-1)}(0)$) as the vacuum expectation value of the stress-energy for a conformal field theory defined on $\partial_{\infty}M$.

### 4.3. The condition $A = 0$.

This condition is imposed in Corollary [1.2] and in Theorem [1.5]. Its role is to choose a unique conformal representative within a conformal class $[g]$ of solutions of $B = 0$.

We may compute from (2.7) that

\begin{equation}
A := \text{tr}_g E = -x^2 \text{tr}_{h_x} h''_x + (n - 1) x \text{tr}_{h_x} h'_x + \frac{3}{4} x^2 |h'_x|^2_{h_x} - \frac{x^2}{4} (\text{tr}_{h_x} h'_x)^2 + x^2 \text{Scal}_{h_x}.
\end{equation}

It is convenient to write the condition $A(x) = 0$ as

\begin{equation}
0 = -x \text{tr}_{h_x} h''_x + (n - 1) \text{tr}_{h_x} h'_x + \frac{3}{4} x |h'_x|^2_{h_x} - \frac{x}{4} (\text{tr}_{h_x} h'_x)^2 + x \text{Scal}_{h_x},
\end{equation}

from which it follows immediately that

\begin{equation}
\text{tr}_{h_0} h'(0) = 0.
\end{equation}

If we further assume that $h'(0) = 0$, then we can differentiate (4.9) once and set $x = 0$ to obtain

\begin{equation}
\text{tr}_{h_0} h''(0) = -\frac{1}{(n - 2)} \text{Scal}_{h_0} = -2 \text{tr}_{h_0} P_{h_0}.
\end{equation}

If one differentiates (4.9) twice, sets $x = 0$, and uses $h'(0) = 0$, then one obtains

\begin{equation}
\text{tr}_{h_0} h'''(0) = 0.
\end{equation}

In general, if one differentiates (4.9) $r \geq 1$ times with respect to $x$ and sets $x = 0$, one obtains

\begin{equation}
0 = (n - 1 - r) \text{tr}_{h_0} h^{(r+1)}(0) + F_{n}(h_{0}, h'(0), \ldots, h^{(r)}(0))
\end{equation}

for some function $F_{n}$ that depends on the dimension $n$. When $r = n - 1$, one see from this that $\text{tr}_{h_0} h^{(n)}(0)$ is undetermined, and that there are no solutions unless $F_{n}(h_{0}, h'(0), \ldots, h^{(n-1)}(0)) = 0$ as well.
Proposition 4.5. For \( n = 4 \), choose \( tf_{h_0} h'(0) = 0 \), \( tf_{h_0} h''(0) = -2Z_{h_0} \), \( tf_{h_0} h'''(0) = \Psi \) for \( \Psi \) as in Theorem 1.1 and \( \text{tr}_{h_0} h^{(4)}(0) = T_4 \) for some arbitrary function \( T_4 \). If \( B_g = 0 \) and \( A_g = 0 \), then \( \text{tr}_{h_0} h^{(k)}(0) \) is uniquely determined for all \( k \).

Proof. This is obvious from the above expressions (4.10)–(4.13) and Theorem 1.1 provided equation (4.13) has a solution; i.e., provided \( F_4 = 0 \). With the chosen data, we have from (4.10)–(4.12) that

\[
(4.14) \quad h'(0) = 0, \quad h''(0) = -2P_{h_0}, \quad tf_{h_0} h'''(0) = \Psi.
\]

Then we obtain

\[
(4.15) \quad F_4 = -6 |P_{h_0}|^2 - 6 (\text{tr}_{h_0} P_{h_0})^2 + 6 \left[ R^{ij}_{h_0} (P_{h_0})_{ij} - D^i D^j (P_{h_0})_{ij} + \Delta_{h_0} (\text{tr}_{h_0} P_{h_0}) \right].
\]

The Bianchi identity ensures that \(-D^i D^j (P_{h_0})_{ij} + \Delta_{h_0} (\text{tr}_{h_0} P_{h_0}) = 0\), and it is a simple matter to check that the first three terms on the right of (4.15) sum to zero as well, so \( F_4 \) vanishes as claimed.

This is, of course, not an accident. The conditions \( h'(0) = 0, \ h''(0) = -2P_{h_0}, \ \text{tr}_{h_0} h'''(0) = 0 \), imply that \( g \) is a 4-dimensional APE (asymptotically Poincaré-Einstein) metric. There is no obstruction to power series in \( x \) for such metrics when the bulk dimension \( n \) is even, meaning that for this data the Einstein equations can be solved to order \( n \) inclusive (and indeed to any order in \( x \)). Therefore, we can always solve the equation \( A = 0 \) to order \( n \) inclusive (for \( n \) even), given data for an APE metric. Beyond order \( n \) the coefficient on the left-hand side of equation (4.13) never vanishes, so no obstruction to a recursive solution arises.

4.4. The condition \( Q - 6 = 0 \). Rather than fixing \( A = 0 \), we can fix the \( Q \)-curvature. We recall that the 4-dimensional \( Q \)-curvature is

\[
Q := \frac{1}{6} \left[ -\Delta_g \text{Scal}_g + \text{Scal}_g^2 - 3 |Rc_g|^2_g \right]
\]

\[
(4.16) \quad = -\frac{1}{6} \Delta_g A_g + \frac{1}{6} (A_g - 12)^2 - \frac{1}{2} |E_g - 3g|^2_g
\]

\[
= -\frac{1}{6} \Delta_g A_g - A_g - \frac{1}{2} |E_g|^2_g + \frac{1}{6} A_g^2 + 6,
\]

so Einstein 4-metrics have \( Q = 6 \). This motivates us to consider replacing the condition \( A = 0 \) by the condition \( Q - 6 = 0 \).

Using (3.10) and the last line of (3.9) (and using (2.7) to observe that the \(|E|^2\) term is of lower weight), we may rewrite the condition \( Q - 6 = 0 \) as

\[
(4.17) \quad \frac{1}{6} x^4 \text{tr}_{h_2} h^{(4)}_{x} - \frac{1}{6} x^3 \text{tr}_{h_2} h^{(3)}_{x} + \frac{2}{3} x^2 \text{tr}_{h_2} h''_{x} - 2x \text{tr}_{h_2} h'_{x} = \text{LWT} = \frac{2}{3} x^2 \text{Scal}_{h_0} + O(x^3).
\]

Differentiating once and setting \( x = 0 \), we immediately see that \( \text{tr}_{h_0} h'(0) = 0 \), which is the same result as we obtained by setting \( A = 0 \). As before, set the free data \( tf_{h_0} h'(0) \) to vanish as well, so that \( h'(0) = 0 \). Then we can differentiate (4.17) twice and set \( x = 0 \) to obtain \( \text{tr}_{h_0} h''(0) = -\frac{1}{2} \text{Scal}_{h_0} \), which is the same condition as arises from setting \( A = 0 \), see (4.11).

Since \( tf_{h_0} h''(0) \) is free data for the equation \( B = 0 \) as well as for the equation \( Q - 6 = 0 \), let us now choose \( tf_{h_0} h''(0) = Z_{h_0} \), so that \( h''(0) = -2P_{h_0} \) where \( P_{h_0} \) is the Schouten tensor of \( h_0 \). That is, we choose data that correspond to Poincaré-Einstein metrics to order \( x^2 \) inclusive. One can now compute the coefficients of the higher-order terms in (4.17). The coefficient of the \( x^3 \) term vanishes, hence \( \text{tr}_{h_0} h'''(0) = 0 \). (Again, the tracefree part is free data for \( B = 0 \) as well as for \( Q - 6 = 0 \).)
To go to order $x^4$ and beyond, differentiate (4.17) $k \geq 4$ times, setting $k = 0$, and using the choices and results listed in the last paragraph, we now find

$$
(4.18) \quad \frac{1}{6} k(k - 4) (k^2 - 3k + 6) \operatorname{tr}_{h_0} h^{(k)}(0) = \begin{cases} F(h_0), & k = 4, \\ F(h_0, h^{(5)}(0), \ldots, h^{(k-1)}(0)), & k \geq 5. \end{cases}
$$

From the left-hand side of (4.18), we see that $\operatorname{tr}_{h_0} h^{(4)}(0)$ is not determined by the condition $Q - 6 = 0$. But given $h_0$ and the above choices $\operatorname{tr}_{h_0} h'(0) = 0$ and $\operatorname{tr}_{h_0} h''(0) = \operatorname{tr}_{h_0} P_{h_0} \equiv Z_{h_0}$, if we also choose values for $\operatorname{tr}_{h_0} h^{(3)}(0)$ and $\operatorname{tr}_{h_0} h^{(4)}(0)$ then all higher-order traces are determined by recursive application of (4.18). Now since the left-hand side of (4.18) vanishes when $k = 4$, we observe that we must have $F(h_0)$ = 0 on the right-hand side. But $F(h_0)$ can be separately computed explicitly. We have done so and find that $F(h_0) = 0$. This can also be seen without the explicit calculation, by the following argument. The chosen data and the datum $\operatorname{tr}_{h_0} h^{(3)}(0) = 0$ together imply that $g$ is asymptotically Poincaré-Einstein (APE). Any APE 4-metric has $|E| \in O(x^4)$ [8] and $A \in O(x^5)$ [29], or simply refer to the preceding subsection. Hence these data alone guarantee that $Q - 6 \in O(x^5)$ so the fourth-order Taylor coefficient in the expansion of $Q$ vanishes. But this coefficient is $F(h_0)$ (times a non-zero constant).

Thus we have shown the following.

**Proposition 4.6.** For $n = 4$, choose $\operatorname{tr}_{h_0} h'(0) = 0$, $\operatorname{tr}_{h_0} h''(0) = -2Z_{h_0}$, and $\operatorname{tr}_{h_0} h'''(0) = \Psi$, and $\operatorname{tr}_{h_0} h^{(4)}(0) = T_4$ for some arbitrary function $T_4$. If $B_g = 0$ and $Q_g - 6 = 0$, then $\operatorname{tr}_{h_0} h^{(k)}$ is uniquely determined for all $k$.

### 4.5. The main theorems for $n = 4$

We now have assembled everything we need to prove the $n = 4$ results quoted in the Introduction.

**Proof of Theorem 1.1** Corollary 4.3 allows us to compute iteratively and uniquely the tracefree parts of $h^{(k)}(0)$ for $k \geq 4$ in terms of a boundary metric $h(0) = h_0$, arbitrary data $h'(0)$, $h''(0)$, $h'''(0)$, and the traces $T_i := \operatorname{tr}_{h_0} h^{(i)}(0)$ for $4 \leq i < k$. Proposition 4.4 imposes one restriction on the data, namely that $\operatorname{div}_{h_0} \operatorname{tr}_{h_0} h^{(3)}(0) = 0$. \rule{0.5em}{0.5em}

**Proof of Corollary 1.2** By [16], given $h_0$ there is a unique (formal series expansion for a) Poincaré-Einstein metric in normal form (1.7), with $h(0) = h_0$, such that $h'(0) = 0$, $h''(0) = -2P_{h_0}$, $h'''(0) = \Psi$, and $\operatorname{tr}_{h_0} h^{(4)}(0) = (3!) |P_{h_0}|^2$. But every Poincaré-Einstein metric is Poincaré-Bach, so this formal series represents a Poincaré-Bach metric.

Now Proposition 4.5 and Corollary 4.3 allow us to compute iteratively and uniquely both the trace and tracefree parts of $h^{(k)}(0)$ for $k \geq 4$ in terms of a boundary metric $h(0) = h_0$ and arbitrary data $\operatorname{tr}_{h_0} h'(0)$, $\operatorname{tr}_{h_0} h''(0)$, $\operatorname{tr}_{h_0} h'''(0)$, and $T_4 := \operatorname{tr}_{h_0} h^{(4)}(0)$, yielding a unique formal power series for $h_x$ in (1.1). Choose the data so that $\operatorname{tr}_{h_0} h'(0) = 0$, $\operatorname{tr}_{h_0} h''(0) = -2Z_{h_0}$, $\operatorname{tr}_{h_0} h^{(3)}(0) = \Psi$, and $\operatorname{tr}_{h_0} h^{(4)}(0) = (3!) |P_{h_0}|^2$. In particular, this series will have $h'(0) = 0$, $h''(0) = -2P_{h_0}$, and $h'''(0) = \Psi$.

Thus the free data for the series that solves $B = 0$ agrees with the corresponding coefficients of a unique Poincaré-Einstein metric. Since the data uniquely determine the full series, and since there exists a formal Poincaré-Einstein metric with these data, the formal solution of $B = 0$ determined by these data must be Poincaré-Einstein. \rule{0.5em}{0.5em}

**Proof of Corollary 1.3** The proof is the same except that it relies Proposition 4.6 rather than Proposition 4.5.
5. Higher dimensions

5.1. Expansion of $\hat{B}^\perp$. We return to equation (3.13). The coefficients of $(n-4)$ in front of several terms no longer cause these terms to vanish, but the highest weight terms are still very simple to extract. We obtain

Lemma 5.1. The components of $B^\perp$ are given by

\[
\hat{B}_{ij} = -\frac{1}{2(n-2)}x^2 tf_{h_x} h_x^{(4)} + \frac{(n-4)}{(n-2)}x tf_{h_x} h_x^{(3)} - \frac{(n-4)(n-3)}{2(n-2)} tf_{h_x} h_x'' + \text{LWT} .
\]

Proof. By inserting equations (2.7) into (3.13) and counting weights, we see that (5.1) holds with $B_{ij}$ on the left rather than $\hat{B}_{ij}$. But from (1.9) we see that the difference between $B$ and $\hat{B}$ consists entirely of lower weight terms.

Then, as with the $n = 4$ case, we set $\hat{B}_{ij} = 0$ on the left of (5.1) and take derivatives with respect to $x$. This yields:

Lemma 5.2. Let $\hat{B}_{ij}(x) = 0$ and $s \geq 2$. Then there is a tracefree symmetric $(0,2)$-tensor $F$ such that

\[
(s - n + 2)(s - n + 1) tf_{h_0} h_0^{(s)}(0) = F_{ij}(h_0'(0), \ldots, h^{(s-1)}(0)) .
\]

Proof. Set $\hat{B}_{ij}(x) = 0$ in (5.1) and multiply the equation by $2(n-2)$ to remove a denominator

\[
0 = -x^2 tf_{h_x} h_x^{(4)} + 2(n-4)x tf_{h_x} h_x^{(3)} - (n-4)(n-3) tf_{h_x} h_x'' + \text{LWT} .
\]

Setting $x = 0$ in (5.3), we obtain $0 = -(n-4)(n-3) tf_{h_0} h_0^{(2)}(0) + \text{LWT} \big|_{x=0}$. But at $x = 0$ the only lower weight terms that can contribute are those that depend only on $h_0$ and $h'(0)$. This yields (5.2) with $s = 2$. Now differentiate (5.3) $s$ times with respect to $x$ and set $x = 0$ (and of course set $B = 0$). Observe that $s$ derivatives of a lower weight term will still be of lower weight than $tf_{h_x} h_x^{(s)}$, and so cannot contain a term with $s$ or more $x$-derivatives of $h_x$ unless multiplied by a positive power of $x$. As a result, the non-zero contributions to the lower weight terms that survive when we set $x = 0$ will have at most $(s - 1)$ $x$-derivatives.

The $F$ in the above lemma is not meant to be the same one as in Lemma 4.2; it changes with dimension. We will also use $F$ to denote distinct functions (more precisely, distinct sections of tensor bundles, with different numbers of functional arguments) below. The analogue of Corollary 4.3 for $n \geq 5$ is tedious to write out but its content is straightforward. It says that the tracefree parts of the coefficients $h^{(k)}(0)$ are either free data or functions of lower order free data.

Corollary 5.3. For $n = \dim M \geq 5$, let $g$ be a solution of $\hat{B}_{ij}(x) = 0$ in normal form (1.3) with $h_x$ given by a formal power series. Then $h_0$, $h'(0)$, $h^{(n-2)}(0)$, and $h^{(n-1)}(0)$ are free data for the series, as are the traces $\text{tr}_{h_0} h^{(r)}$ for all $r$. For those $s$ for which $tf_{h_0} h^{(s)}(0)$ is not free data, we have as follows:
a) For \( n = 5 \),

\[
\text{tf}_{h_0} h^{(s)}(0) = \begin{cases} 
F(h_0, h'(0)), & s = 2 , \\
F(h_0, h'(0), \text{tr}_{h_0} h''(0), h^{(3)}(0), h^{(4)}(0)), & s = 5 , \\
F(h_0, h'(0), \text{tr}_{h_0} h''(0), h^{(3)}(0), h^{(4)}(0), \text{tr}_{h_0} h^{(5)}(0), \ldots, \text{tr}_{h_0} h^{(s-1)}(0)), & s \geq 6 .
\end{cases}
\]

b) For \( n = 6 \),

\[
\text{tf}_{h_0} h^{(s)}(0) = \begin{cases} 
F(h_0, h'(0)), & s = 2 , \\
F(h_0, h'(0), \text{tr}_{h_0} h''(0)), & s = 3 , \\
F(h_0, h'(0), \text{tr}_{h_0} h''(0), \text{tr}_{h_0} h^{(3)}(0), h^{(4)}(0), h^{(5)}(0)), & s = 6 , \\
F(h_0, h'(0), \text{tr}_{h_0} h''(0), \text{tr}_{h_0} h^{(3)}(0), h^{(4)}(0), h^{(5)}(0), \text{tr}_{h_0} h^{(6)}(0), \ldots, \text{tr}_{h_0} h^{(s-1)}(0)), & s \geq 7 .
\end{cases}
\]

c) For \( n \geq 7 \),

\[
\text{tf}_{h_0} h^{(s)}(0) = \begin{cases} 
F(h_0, h'(0)), & s = 2 , \\
F(h_0, h'(0), \text{tr}_{h_0} h^{(2)}(0), \ldots, \text{tr}_{h_0} h^{(s-1)}(0)), & 3 \leq s < n - 2 \\
F(h_0, h'(0), \text{tr}_{h_0} h^{(2)}(0), \ldots, \text{tr}_{h_0} h^{(n-3)}(0), h^{(n-2)}(0), h^{(n-1)}(0), \text{tr}_{h_0} h^{(n)}(0), \ldots, \text{tr}_{h_0} h^{(s-1)}(0)), & s \geq n .
\end{cases}
\]

In all cases, when \( s = 2 \) and \( h'(0) = 0 \) we have \( \text{tf}_{h_0} h''(0) = -\frac{2}{(n-3)} \text{Z}_{h_0} \) where \( \text{Z}_{h_0} := \text{tf}_{h_0} \text{Rc}_{h_0} \).

Proof. The assumption that the series solution exists implies that when \( s = n - 2 \) or \( s = n - 1 \), equation (5.2) still holds; i.e., for those \( x \)-values, the right-hand side \( F_{ij} \) is assumed to vanish (see below).

By way of example, we consider the simplest case, that of \( n = 5 \). For \( s = 2 \), the result is immediate from (5.2). Likewise, we see immediately that the left-hand side of (5.2) vanishes for \( s = 3 \) and \( s = 4 \), so we cannot use this equation to determine \( h^{(3)}(0) \) or \( h^{(4)}(0) \). For \( s = 5 \), the result is again immediate from (5.2) except that we can omit the \( h_0 \)-tracefree part of \( h''(0) \) from the list of arguments because we have already shown that \( \text{tf}_{h_0} h''(0) \) is determined by \( h_0 \) and \( h'(0) \). For \( s = 6 \), we can use the \( s = 5 \) result to omit \( \text{tf}_{h_0} h^{(5)}(0) \) from the list of arguments, but \( \text{tr}_{h_0} h^{(5)}(0) \) has not been determined and so must be included. By a finite induction, we see that we can then omit the tracefree parts of \( h^{(k)} \) for all \( 5 \leq k < s \), but not the trace parts. The arguments for \( n = 6 \) and \( n \geq 7 \) are similar.

The final statement is easily seen by direct calculation from (3.13). Indeed, by inspection one can observe that the only nonvanishing tracefree contributions when \( x = 0 \) and \( h'(0) = 0 \) must be terms proportional to \( \text{tf}_{h_0} h''(0) \) coming from \( E' \) and \( E'' \), and a \( \text{Z}_{h_0} \) term arising from the
tracefree part of $E^\perp$ (see the penultimate line of (3.13)). A detailed calculation establishes the correct proportions of each such term, yielding the coefficient of $tf_{h_0} h^{(k)}(0)$ for each $k$. The free data are those $tf_{h_0} h^{(k)}(0)$ for which this coefficient vanishes.

These results do not discuss the cases $s = n - 1$ and $s = n - 2$. For these cases, the left-hand side of (5.2) vanishes, so the corresponding derivatives cannot be determined. However, it is not clear that the right-hand sides vanish. This is the question of obstructions to formal power series solutions. By answering this question, which we will do in the proof of Theorem 1.5, we can remove the assumption that $h$ be given by a formal power series in Corollary 5.3 since the absence of obstructions means that such a formal series exists.

5.2. Expansion of $\hat{B}^\circ$. The divergence identity $\nabla^b \hat{B}_{ab} = 0$ implies that

$$\hat{B}_{0i}^\prime - \left[ H + \frac{(n-2)}{x} \right] \hat{B}_{0i} = -D^i \hat{B}_{ij},$$

where the right-hand side is the component expression for $\text{div}_{h_0} B^\perp$. This expression admits the zero solution when $B^\perp = 0$. Indeed, expanding in a power series and using from (3.16) that $\hat{B}_{0i} \in O(x)$ so that $\hat{B}_{0i} = \sum_{p=1}^{\infty} b_{i}^{(p)} x^p$, we have

$$\sum_{p=1}^{\infty} \frac{[p - (n - 3)] b_{i}^{(p)} x^{p-1}}{p} - \sum_{p=1}^{\infty} \left( \sum_{q=1}^{p} b_{i}^{(q)} h^{(p-q)} \right) x^p = \sum_{p=1}^{\infty} c_{i}^{(p)} x^{p-1},$$

where $h^{(q)}$ and $c_{i}^{(p)}$ denote the coefficients in the power series expansions of the mean curvature $H$ or constant-$x$ hypersurfaces and the divergence $D^i \hat{B}_{ij}$ of $\hat{B}$, respectively. We obtain

$$b_{i}^{(1)} = - \frac{1}{(n-3)} c_{i}^{(0)} ,$$

$$[p - (n - 3)] b_{i}^{(p+1)} = c_{i}^{(p)} + \sum_{q=1}^{p} b_{i}^{(q)} h^{(p-q)} , \quad p \geq 1 ,$$

and in particular the coefficients $b_{i}^{(p)}$ of $\hat{B}_{0i}$ vanish up to order $n - 3$ inclusive whenever the coefficients $c_{i}^{(p)}$ of $D^i \hat{B}_{ij}$ do. At order $n - 2$, $b_{i}^{(n-2)}$ is free data but if it is chosen to vanish, and if the coefficients $c_{i}^{(p)}$ continue to vanish for higher orders, then the coefficients $b_{i}^{(p)}$ continue to vanish for higher orders as well.

Hence the condition $\hat{B}_{0i} = 0$ is consistent, order-by-order in the power series expansion, with the vanishing of $\hat{B}_{ij}$, provided that the right-hand side of (5.9) vanishes when $p = n - 3$. This imposes one condition on the otherwise-free data. To obtain this condition, we will work directly from (3.12) and (1.9) to write

$$\hat{B}_{0i} = \frac{1}{2(n-2)} \left[ x^2 D^j \left( tf_{h_0} h_{ij}^{(n)} \right) - (n-4)x D^j \left( tf_{h_0} h_{ij}^{(n-2)} \right) \right] + \text{LWT} .$$

Differentiating $k \geq 1$ times and setting $x = 0$ and $\hat{B}_{0i} = 0$, we obtain

$$k[k - (n-3)] D^j \left( tf_{h_0} h^{(k+1)}(0) \right)_{ij} = \text{LWT} , \quad k \geq 1 .$$

We observe that $D^j \left( tf_{h_0} h^{(n-2)}(0) \right)_{ij}$ is therefore undetermined but:
Lemma 5.4. $D^j \left( \operatorname{tf}_{i} h^{(n-1)}(0) \right)_{ij}$ is determined by this equation by terms containing only lower-order $x$-derivatives.

Proof. Set $k = n - 2$ in (5.11) and note that a term of weight lower than $k + 1$ which is non-zero when $x = 0$ cannot contain an $x$-derivative of order greater than $k$.

5.3. The condition $\hat{B}_{00} = 0$. The divergence identity for $\hat{B}$ implies that

$$\hat{B}'_{00} - \frac{(n-2)}{x} \hat{B}_{00} - H \hat{B}_{00} + D^i \hat{B}_{0i} + K^{ij} B_{ij} = 0. \tag{5.12}$$

Using the expansions $\hat{B}_{00} = \sum_{p=0}^{\infty} b^{(p)} x^p$, $H = \sum_{p=0}^{\infty} h^{(p)} x^p$, $D^i \hat{B}_{0i} + K^{ij} B_{ij} = \sum_{p=0}^{\infty} c^{(p)} x^p$, we obtain the recursive relation

$$b^{(0)} = 0, \quad [p - (n-2)]b^{(p)} = c^{(p-1)} + \sum_{q=0}^{\infty} b^{(q)} h^{(p-q-1)}, \quad p \geq 1. \tag{5.13}$$

Thus for $p < n - 2$, the coefficients $b^{(n-2)}$ of $\hat{B}_{00}$ are determined by the low-order data, and vanish when the coefficients of $\hat{B}_{00}$ and $B_{ij}$ vanish to that order. The coefficient $b^{(n-2)}$ is undetermined and is therefore part of the free data but if it vanishes and the higher-order coefficients of $\hat{B}_{0i}$ and $B_{ij}$ vanish up to some given order then the coefficients of $\hat{B}_{00}$ continue to vanish to that order as well.

The left-hand side of the second equation in (5.13) is identically zero when $p = n - 2$. This imposes a condition on the right-hand side. Here the picture is more complicated than in the previous subsection. Effectively, the right-hand side is a form of obstruction to solutions of $\hat{B} = 0$ whose vanishing fixes the conformal gauge of the solution. There are three ways to approach the issue. We can expand the right-hand side of the second equation in (5.13) when $p = n - 2$, we can by-pass this and instead expand the equation $0 = \hat{B}_{00}$ using (3.11) and (3.16), or we can observe that the latter is equivalent to solving $\operatorname{tr}_g \hat{B} = 0$ given a solution of $\hat{B}^\perp = 0$. We choose the latter approach because we see immediately from the definition of $\hat{B}$ that it is equivalent to (5.12), which serves here to replace the conditions $A = 0$ or $Q = 6$ which were used to fix the conformal gauge when $n = 4$.

We expand

$$0 = -\frac{8(n-2)}{(n-4)} \operatorname{tr}_g \hat{B} = 4 |E|_g^2 - A_g^2$$

$$= x^4 \left[ |h'_x|^2_{h_x} - 2 \operatorname{tr}_{h_x} (h'_x \cdot h'_x \cdot h'_x) + (\operatorname{tr}_{h_x} h'_x) \operatorname{tr}_{h_x} (h'_x \cdot h'_x) + \frac{1}{2} |h'_x|^2_{h_x} \operatorname{tr}_{h_x} h''_x \right]$$

$$+ x^3 \left[ -2(n-2) \operatorname{tr}_{h_x} (h''_x \cdot h'_x) + 2(n-3) (\operatorname{tr}_{h_x} h''_x) (\operatorname{tr}_{h_x} h'_x) \right]$$

$$+ x^2 \left[ (n-2)^2 |h'_x|^2_{h_x} - (n^2 - 5n + 5) (\operatorname{tr}_{h_x} h')^2 \right] + \text{LWT}. \tag{5.14}$$

If we twice $x$-differentiate this expression and set $x = 0$, we obtain

$$0 = (n-2)^2 |h'(0)|^2_{h_0} - (n^2 - 5n + 5) (\operatorname{tr}_{h_0} h'(0))^2. \tag{5.15}$$
or in other words
\begin{equation}
(5.16) \quad |\text{tr}_{h_0} h'(0)|_{h_0}^2 = \frac{(n^3 - 7n^2 + 14n - 9)}{(n-1)(n-2)^2} \left(\text{tr}_{h_0} h'(0)\right)^2.
\end{equation}

Since the numerator of the coefficient on the right-hand side has no roots in the positive integers then \(\text{tr}_{h_0} h'(0) = 0\) if and only if \(\text{tr}_{h_0} h'(0) = 0\).

Henceforth, in order to keep the analysis tractable, we choose additional conditions on free data as follows

(i) \(\text{tr}_{h_0} h'(0) = 0\), thus \(\text{tr}_{h_0} h'(0) = 0\) in view of the last paragraph and so \(h'(0) = 0\),

(ii) \(\text{Scal}_{h_0} = -(n-2) \text{tr}_{h_0} h''(0)\),

(iii) \(\text{Scal}_{h_0} \neq 0\).

The first two conditions are satisfied by Poincaré-Einstein metrics. Without the third condition, leading terms in the analysis below would vanish and we would have to compute to higher order.

If we then differentiate (5.14) three times with respect to \(x\), set \(x = 0\), and use condition (i) above, both sides of the resulting equation vanish and we obtain no further information. Now differentiate (5.14) \(k \geq 4\) times and set \(x = 0\). The highest derivative terms are products of \(h'(0)\) with \(h^{(k-1)}(0)\). These products vanish by condition (i) above. The next highest derivatives have the form of products of \(h''(0)\) with \(h^{(k-2)}(0)\). Conditions (ii) and (iii) allow us to use these terms to determine \(\text{tr}_{h_0} h^{(k-2)}(0)\) in terms of lower order data. We obtain
\begin{equation}
(5.17) \quad 0 = - \left(\frac{n^3 - 7n^2 + 14n - 9}{(n-1)(n-2)^2}\right) \left(\text{tr}_{h_0} h''(0)\right) \left(\text{tr}_{h_0} h^{(k-2)}(0)\right) \\
+ (k-2) \left(\frac{n^3 - 7n^2 + 14n - 9}{(n-1)(n-2)^2}\right) \left(\text{tr}_{h_0} h''(0)\right) \left(\text{tr}_{h_0} h^{(k-2)}(0)\right) \\
+ (k-2)(k-3) \left(\frac{n^3 - 7n^2 + 14n - 9}{(n-1)(n-2)^2}\right) \left(\text{tr}_{h_0} h''(0)\right) \left(\text{tr}_{h_0} h^{(k-2)}(0)\right) \\
+ F(h_0, h'(0), \ldots, h^{(k-3)}(0), \text{tr}_{h_0} h^{(k-2)}(0)) \\
= P_n(k-2) \left(\text{tr}_{h_0} h''(0)\right) \left(\text{tr}_{h_0} h^{(k-2)}(0)\right) + F(h_0, h'(0), \ldots, h^{(k-3)}(0), \text{tr}_{h_0} h^{(k-2)}(0))
\end{equation}
for some function \(F\), where \(P_n(t)\) is given by
\begin{equation}
P_n(t) := \frac{(n-2)(n-4)t^2 + (n-3)t - (n^3 - 7n^2 + 14n - 9)}{(n-2)(n-4)^2 + (n-3)t - (n-1)(n-2)(n-4) + 1},
\end{equation}
and in the last line of (5.17) we have used condition (ii). We can use (5.17) to solve for \(\text{tr}_{h_0} h^{(k-2)}(0)\) in terms of lower order data and \(\text{tr}_{h_0} h^{(k-2)}(0)\) provided condition (iii) above holds and provided \(P_n(t)\) has no roots that are integers \(t \geq 2\).

**Lemma 5.5.** Assume conditions (i–iii) above. Then for all \(l \geq 1\), then \(\text{tr}_{h_0} h^{(l)}(0)\) is determined by lower order data and by \((\text{tr}_{h_0} h^{(l)}(0))\).

Unlike the \(n = 4\) case, there is no freedom to choose the “mass aspect”.

**Proof.** The \(l = 1\) case is simply condition (i) while the \(l = 2\) case is condition (ii). For \(l \geq 3\), set \(l = k-2\) in (5.17). We only need to check that \(P_n(l) \neq 0\). Now it is easy to see that for \(n \geq 5\), the quadratic expression \(P_n(t)\) has one root of either sign. To see that the positive root can never be
an integer, observe that $P_n(\sqrt{n-2}) = (n-2)(n-4) + (n-3)\sqrt{n-2} - (n-1)(n-2)(n-4)+1 = -(n-2)(n-4) + (n-3)\sqrt{n-2} + 1 < -(n-2)^2 [n-4 - \sqrt{n-2}] \leq 0$ for $n \geq 6$, while $P_n(\sqrt{n-1}) = (n-3)\sqrt{n-1} + 1 > 0$. Hence, when $n \geq 6$, the square of the positive root $t_*$ lies strictly between adjacent integers $n-2 < t_*^2 < n-1$, so $t_*^2$ cannot be an integer, and so nor can $t_*$. Therefore, for $n \geq 6$, $P_n(l) \neq 0$ for any positive integer $l$. For $n = 5$ we can check explicitly that the discriminant of $P_n$ is 136, which is not a perfect square.\[\square\]

5.4. The proof of Theorem 1.5.

Proof. We begin by choosing $h_0$ such that $\text{Scal}_{h_0} \neq 0$. We set $h'(0) = 0$ and use Corollary 5.3 to obtain $t_{h_0} h''(0) = -\frac{2}{(n-3)} Z_{h_0}$. In accord with condition (ii) and Lemma 5.5 of the previous subsection, we choose $tr_{h_0} h''(0) = -\frac{1}{(n-2)} \text{Scal}_{h_0}$.

Now that we have determined $h''(0)$, we may use this as the first step in an induction. Say for some $2 \leq k < n - 3$, we have determined $h^{(k)}(0)$. We may use Corollary 5.3 to determine $t_{h_0} h^{(k+1)}(0)$. We then use Lemma 5.5 to determine $tr_{h_0} h^{(k+1)}(0)$. When $k$ reaches $n-3$, the induction halts, but we are free to choose $t_{h_0} h^{(n-2)}(0)$. Notice, however, that while the left-hand side of equation (5.2) vanishes for $s = k + 1 = n - 2$, the right-hand side is determined by lower order terms. Therefore one must check that the right-hand side is nevertheless zero, to ensure consistency. We will deal with this momentarily.

At next order, we have from Lemmata 5.3 and 5.4 that the divergence-free part of $t_{h_0} h^{(n-1)}(0)$ is also free data, while the divergence is determined by the lower-order terms already computed. As with the previous order, we again must check a consistency condition, which is that the right-hand side of (5.2) now vanishes when $s = k + 1 = n - 1$. Once this is done, the induction resumes, and all higher order derivatives of $h^{(k)}(0)$, $k \geq n$, are determined iteratively in terms of the free data.

It remains to check that the right-hand side of equation (5.2) vanishes when $s = n - 2$ and when $s = n - 1$. We deal first with $s = n - 2$. With the choices $h(0) = h_0$, $h'(0) = 0$, and $\text{tr}_{h_0} h''(0) = -\frac{1}{(n-2)} \text{Scal}_{h_0}$, we have established that the $h^{(k)}(0)$, $k < n - 2$, are all determined.

But Fefferman and Graham [16, 17] have shown that, given $h(0) = h_0$, there is a metric obeying the Einstein equations up to order $x^{n-2}$ inclusive (and unique to that order), whose $h_2$ obeys $h'(0) = 0$ and $\text{tr}_{h_0} h''(0) = -\frac{1}{(n-2)} \text{Scal}_{h_0}$, agreeing with our data. Moreover, since Poincaré-Einstein metrics obey $\hat{B} = 0$, there must be a choice of data yielding from $\hat{B} = 0$ a metric that is Einstein to order $x^{n-2}$ inclusive. Since the metric we find is uniquely determined by the data up to order $x^{n-3}$ inclusive, our metric and the Fefferman-Graham metric agree to order $x^{n-3}$ inclusive, and there must exist a choice of data $\Phi = t_{h_0} h^{(n-2)}(0)$ in our case so that the metrics agree to order $x^{n-2}$ inclusive. Then for this choice of data, the relevant right-hand side function $F$ from Lemma 5.4 must vanish. But $F = F(h_0, 0, -\frac{1}{(n-2)} \text{Scal}_{h_0})$ does not depend on $\Phi$.

Finally, we deal with $s = n - 1$. In this case, the right-hand side of equation (5.2) must vanish for all $\Phi := t_{h_0} h^{(n-2)}(0)$, not just the value given by the corresponding term in a Poincaré-Einstein metric. But simple counting shows that the total number of $x$-derivatives (i.e., summed over all occurrences of $x$-derivatives of $h_2$) within any single term on the right-hand side of (5.2) cannot exceed $n - 1$, so any $h^{(n-2)}(0)$ appearing in any such term must multiply $h'(0)$ or not multiply any $x$-derivative of $h_2$ at all; e.g., it could possibly multiply $\text{Scal}_{h_0}$, say. But since $h'(0) = 0$ by assumption, the former possibility is excluded, while the latter possibility is ruled out by parity. That is, if one expands (5.13) using (2.7) to obtain $B^\perp$ as a sum of terms, each

---

4We thank DA McNeilly for suggesting the argument used in this proof.
composed of \(x\)-derivatives of \(h_x\) multiplying powers of \(x\), the sum of the number of \(x\)-derivatives and the power of \(x\) is even. This is also true then of the terms in \(\hat{B}^\perp\). Therefore, the sum \(\mod 2\) of the number of \(x\)-derivatives (acting on \(h_x\)) in each term of (5.2) when \(s = n − 1\) should equal \(n − 1\) \(\mod 2\), ruling out terms of the form \(h^{(n−2)}(0) \cdot f(h_0)\) (where by \(f(h_0)\) we of course mean any function of \(h_0\), its intrinsic connection \(D\), etc). Hence the right-hand side \(F\) of (5.2) is independent of \(\Phi\) and so depends only on \((h_0, h'(0), tr h_0 h''(0))\). But, if \(h_0\) yields an unobstructed Poincaré-Einstein metric, then \(F = F(h_0, 0, −\frac{1}{(n−2)}\text{Scal}_{h_0})\) must vanish, and does so independently of \(\Phi\). □

We remark that the condition in the last line of the proof that \(h_0\) should be data for a formal series for a Poincaré-Einstein metric (i.e., that the Fefferman-Graham ambient obstruction tensor for \(h_0\) vanishes) always holds if the bulk dimension \(n\) is even, and holds for odd \(n\) if, for example, \(h_0\) is conformally Einstein. Also, when \(n\) is even, the argument given to rule out obstructions at order \(s = n − 1\) combined a parity argument with an appeal to the Poincaré-Einstein case but this appeal is really just a short-cut. One can use parity alone to complete the argument when the bulk dimension \(n\) is even. If \(n\) is odd, one can similarly show that there is no order \((n−2)\) obstruction purely by parity considerations, without appeal to the existence of a Poincaré-Einstein metric (but of course this would not work at order \((n−1)\) for \(n\) odd).
